10.4.2 Three efficiency calibration standards and three background calibration samples should be prepared using both the new lot of cocktail and the old lot. These should be prepared according to the appropriate preparation SOP. The final sample set will, therefore, consist of four sets of three samples each; one spiked set with the old cocktail, one with the new, one blank set with the old cocktail, and another with the new.

10.4.3 In the review of the final counting results, each set of three samples will be reviewed to ensure that the gross count rate for no one sample deviates from the average gross count rate of the three by more than the average 2σ counting uncertainty for that set. Counting uncertainty is described in SOP 708. Subsequent evaluations, described below, will use the combined count rates for the three samples in each set. Luminescence and quench factors will be evaluated for each individual vial in the set.

10.4.3.1 COUNTING EFFICIENCY
The spiked samples should be counted long enough to achieve a 2σ counting uncertainty of 2% or less. This equates to a minimum 10,000 net counts per vial.

10.4.3.2 DER
The Duplicate Error Ratio, described in SOP 715, between the two spiked sample sets will be less than 1.0.

10.4.3.3 RPD
The Relative Percent Difference, described in SOP 715, between the two spiked sample sets will be less than 5.0%.

10.4.3.4 BACKGROUND COUNT RATE
The unspiked samples will counted long enough to achieve a Minimum Detectable Activity, described in SOP 708, that is at least as low as the lowest anticipated client-requested MDA for that analysis. The Duplicate Error Ratio between the blank sets will be less than 1.0.

10.4.3.5 LUMINESCENCE
The luminescence for each blank sample will either be less than 0.5% or within two standard deviations (Excel® formula STDEV()) of the average of the blank luminescence values in the OLD cocktail.

10.4.3.6 QUENCH FACTOR
The quench factor for each sample will be within a margin that is equivalent to a counting efficiency change of less than 5% in the OLD cocktail. If this value is not determined, a margin of ±5 quench factor units may be used.

10.4.3.7 ACCEPTANCE OF RESULTS
Cocktail lot verifications that meet the above criteria may be approved for use by the group supervisor or department manager. Excursions from the above acceptance criteria may be approved by the Department Manager, with appropriate technical justification.

11. CALCULATIONS

Data calculations are found in the preparation SOPs, as well as in SOPs 708 and 715.

12. DEVIATIONS FROM METHOD

This procedure contains no known deviations from the analytical portion of EPA 906.0.

13. SAFETY, HAZARDS AND WASTE DISPOSAL

13.1 SAFETY AND HAZARDS

13.1.1 Normal laboratory safety procedures must be complied with during the conduct of this procedure. No special safety requirements are mandated by this procedure.

13.1.2 High voltage in the range of 1000 volts DC is applied to the photomultiplier tubes in these instruments. This can result in electric shock if the instrument is disassembled with power applied. To minimize the possibility of electric shock, turn off the power and unplug the instrument prior to any disassembly.

13.2 WASTE DISPOSAL

Liquid scintillators contain a solvent and an emulsifying agent to promote mixing with aqueous samples. The solvents used by Paragon are biodegradable, but may not be suitable for sewer disposal. Additionally, the samples may contain concentrations of radioactivity above sewer disposal limits. Contact the Waste Disposal Coordinator and/or Radiological Safety Officer (RSO) for disposal instructions.

DOCUMENT REVISION HISTORY

9/1/06: Wallac LSC procedures incorporated. Various interferences discussed. DOCUMENT REVISION HISTORY section added.

8/31/07: Updated Title. In Section 9, added allowance for interim control limits for Daily QC until sufficient historical data is generated. Added provision to remove outlying data points in a quench calibration curve (Section 9.1.1). Added requirements for monthly gain calibrations, where appropriate (Section 9.3). Updated Table 1 contents.

TABLE 1

SUMMARY OF INTERNAL QUALITY CONTROL (QC) PROCEDURES AND CORRECTIVE ACTION

QC Check	Frequency	Acceptance Criteria	Corrective Action
Efficiency, Background and Quench Factor Checks	Daily	Within derived control limits, as defined in network spreadsheet.	Recount, re-evaluate, service instrument, if necessary or document why condition is acceptable.
Efficiency Calibration	Yearly	For single point efficiency calibrations, the value will be within 5% of the previous calibration value. For quench curves, the fitted values shall be within 5% of the observed value for each point on the curve. Post-calibration method spikes (LSCs) will meet normal LCS acceptance criteria. *	Tag method off-line. Determine and correct problem; verify source activity; recount and/or recalibrate or document why condition is acceptable.
Background Calibration	Continuous	Control limits set from initial calibration run, per details given in SOP Section 9.2.3.	Tag method off-line. Determine and correct problem, re-establish limits; or document why condition is acceptable
Chemical Yield	Each sample, where method allows.	Each sample meets current control limits for analysis. *	Re-prep; or Qualify or narrate why condition is acceptable
Spectral Interferences	Evaluate each result for spectral interferences.	WIND2 count rate within current control limits (SOP Section 4.9) or interfering activity does not compromise quantitation	Re-prep/ recount affected samples; Consult with supervisor or department manager; Determine and correct problem; or qualify or narrate why condition is acceptable

NOTE: This SOP and SOP 715 contain acceptance criteria and corrective action for method blank, laboratory control samples, duplicate samples and matrix spike/matrix spike duplicates.

* as established in the applicable LIMS nickname (e.g., Paragon Standard or as created for a specific client).

HISTORY: Rev0, 2/10/93; Rev1, 4/7/93; Rev2, PCN #387, 2/21/95; Rev3, 5/3/1996; Rev4, 1/12/00; Rev5, 10/2/00; Rev6, 4/24/02; Rev7, 4/7/03; Rev8, 9/23/04; Rev9, 9/11/06; Rev10, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the method to be followed for the determination of radiostrontium (Total Radiostrontium or ^{89}Sr or ^{90}Sr) in environmental, drinking and wastewaters, organic liquids, soils, sediments and solids, air filters, wipes, and vegetation.

2. SUMMARY

2.1 SAMPLE PREPARATION (MINERALIZATION/ CONCENTRATION/ DISSOLUTION)

2.1.1 **Aqueous Samples:** Strontium carrier solution is equilibrated with an aliquot of the sample. A portion of the sample is removed for inductively coupled plasma (ICP) atomic emission spectrometry determination of the pre-separation concentration of strontium in the sample. Aqueous samples are concentrated using cation exchange. The column eluate is taken to dryness and redissolved in 8N nitric acid. Strontium is separated from the concentrated sample as described in Section 2.2 below.

2.1.2 **Soils, Sediments, Vegetation, and Non-organic Solids:** A representative subsample of the sample is dried and ground. The sample may be muffled if significant organic material (e.g., humic soils or oily solids) is present. Strontium carrier solution is equilibrated in 1g of the ground sample. The sample is digested on a steam table in 8N nitric acid. A portion of the sample is removed for ICP determination of the pre-separation concentration of strontium in the sample. The sample is taken to dryness and redissolved in 8N nitric acid. Strontium is separated from the digestate as described in Section 2.2 below.

2.1.3 **Organic Liquids and Hazardous Waste:** Many different challenges may present themselves in this category. In general, the strontium must be liberated from the organic matrix and made soluble in nitric acid. Most frequently, this involves a combination of evaporation and/or ashing followed by digestion steps. Hazardous waste samples are to be run through a cation exchange column. Strontium carrier solution is equilibrated as early in the procedure as practicable, but always prior to the strontium separation step. A portion of the sample is removed for ICP determination of the pre-separation concentration of strontium in the sample. Strontium is separated from the digestate as described in Section 2.2 below. Often other techniques are necessary to ensure thorough solubilization of strontium. These steps should be carried out under direction of the Supervisor or Senior Chemist, and should be carefully documented on a Quality Assurance Summary Sheet (QASS, Form 302) and in the data package case narrative.

2.1.4 **Air Filters:** The preparation of air filters depends upon whether a single filter or a composite is being analyzed and upon how many tests are to be performed on the sample. The digestion of air filters is routinely performed according to SOP 773. The digestate is converted to the nitrate system by evaporation, followed by the addition of nitric acid. Strontium carrier is added to the digestate aliquoted for analysis. A portion of the sample is removed for ICP determination of the pre-separation concentration of strontium in the sample. Strontium is separated from the digestate as described in Section 2.2 below.

2.1.5 **Sample Pretreatment:** Additional preparation steps not defined in this SOP are considered sample pretreatment. These steps should be carried out under direction of the Supervisor or Senior Chemist. All non-routine pretreatment should be carefully documented on a Quality Assurance Summary Sheet (QASS, Form 302) and in the data package case narrative.

2.2 SEPARATION, PURIFICATION, AND MOUNTING

Strontium is separated from the nitric acid digestate/concentrate generated above using Eichrom Sr-Resin. A second aliquot of sample is removed from the eluate following separation for ICP determination of the post-separation concentration of strontium in the sample. The remaining eluate is quantitatively transferred to a stainless steel planchet.

2.3 COUNTING, CALCULATION, AND REPORTING

2.3.1 The planchet is submitted for beta counting on a low background gas flow proportional counter (GFPC), as described in SOP 724. Total Radiostrontium may be determined from one count of the separated Strontium. For the isotopic determination of ^{89}Sr and ^{90}Sr, the planchet should be counted immediately following separation to minimize ingrowth of Yttrium-90. The planchet is then stored and recounted approximately 3-7 half-lives (usually ~14 days) following ^{90}Y ingrowth.

2.3.2 The counting result, immediately ascertained, represents the Total Radiostrontium activity (^{89}Sr + ^{90}Sr plus the fraction of ^{90}Y that has grown in from the separated ^{90}Sr). For samples where only ^{90}Sr is requested and one may safely assume the absence of the short-lived species ^{89}Sr, Total Radiostrontium is routinely reported as ^{90}Sr. This assumption is noted in the narrative.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 The presence of elemental lead, in the sample aliquot in milligram quantities is an interference to this method. The ICP results should be monitored for elevated lead concentrations. The presence of elevated lead concentration in samples necessitates use of reduced aliquots. Initial results for samples showing low chemical yield will be accepted and appropriately qualified in the case narrative, when elevated levels of lead interfere with strontium recovery and re-preparation of the sample is not expected to generate improved results.

4.2 Samples with very elevated native, non-radioactive strontium concentrations will overwhelm the capacity of the Sr-Resin and lead to low chemical yield in the sample. The same is true for elevated levels of native calcium, magnesium, lead and sodium. ICP results should be consulted in cases of anomalously low (or high) chemical yield to determine the possible cause of the occurrence. In such cases, the Supervisor and the Project Manager should be notified as soon as the situation is recognized. The client should be notified of the presence of the matrix interference and be involved in deciding what appropriate course of action should be taken. Generally, re-preparation of such samples will not improve results since the sample quantity that may be processed by the method has effectively been maximized. The sample may be reprocessed with a smaller aliquot, and a matrix spike may be utilized to provide feedback on the quality of data produced in the presence of the matrix interference. Generally, the client would be responsible for the additional cost of ameliorating the effects of the matrix inference in the sample.

4.3 Samples with very elevated dissolved solids interfere with the pre-separation ICP measurement of Sr and will lead to overestimation of the chemical recovery of strontium in the sample. This will result in a low bias in final yield corrected sample activity. The situation is recognized as follows: a) the pre-separation measurement is less than the concentration as calculated from the known quantity of carrier added (Action: narrate interference in pre-separation measurement, low bias in reported result); or b) the pre-separation measurement exceeds the concentration of strontium from the carrier but is less than the post-separation concentration of strontium in the sample (Action: narrate native strontium present in sample, low bias in reported result).

4.4 Elevated levels of ^{85}Sr in the sample may lead to a high bias in the reported sample activity.

4.5 Sr-Resin, with an 8N nitric acid load solution is used to effectively remove Barium-140 and Potassium-40 isotopes as well as other matrix interferences. Tetravalent plutonium, neptunium, cerium and ruthenium, however, are not removed using nitric acid. These isotopes can be effectively removed by including an additional rinse of approximately 5mL of 3N nitric acid-0.05M oxalic acid.

4.6 Solid samples are prepared via nitric acid leaching. Certain forms of Sr, including those bound into the geologic matrix of some soils or rock, may not be effectively addressed by this method. As this method has proven to be sufficient for most forms of surficial contamination, the majority of solid samples analyzed are not likely to be affected by this limitation.

4.7 If the alpha count rate is greater than 10 times background level, there is a potential interference in the analytical method. Consult your Supervisor if this situation occurs.

5. APPARATUS AND MATERIALS

5.1 Disposable ion exchange columns: 15mL resin volume with attachable funnel to receive 2L bottle. Environmental Express #R1010 and #R1030 or equivalents

5.2 Sr-Resin column: Use a Bio-Rad #731-1553 column or equivalent, and transfer the Sr-Resin to the column as a slurry with laboratory water. Add resin up to the ~1.6mL mark on the column. The Sr-Resin is held in place in the column by a layer of clean silica sand on top.

5.3 planchet, flat, cupped, stainless steel, 2" diameter

Prior to use, the planchets are soaked in diluted Radiacwash™ for a minimum of three hours, drained, rinsed with deionized water, transferred to a metal pan, and placed in the drying oven to dry.

5.4 analytical balance, 0.0001g resolution, Mettler® AE 200, or equivalent

5.5 Re-pipettor, Eppendorf® Model 4780 or equivalent, and disposable pipet tips

5.6 filter paper, qualitative, VWR #313, or equivalent

5.7 transfer pipet, 7mL polyethylene, disposable

5.8 graduated cylinder, 1L

5.9 centrifuge, Beckman® GS-6, or equivalent

5.10 centrifuge tubes, polypropylene, 50mL

5.11 plastic bottles, disposable, 2L

5.12 test tubes, disposable, 15mL

5.13 Parafilm™

5.14 watch glass, Pyrex®

5.15 pH paper

5.16 Static Guard™ spray, or equivalent

5.17 specimen cups, polypropylene, 250mL or equivalent

5.18 Radiacwash®

6. REAGENTS

NOTE: TLV and other hazard information may also be given here. Refer to Section 12.1.3 regarding TLVs.

6.1 Deionized (DI) water, from the laboratory DI water system

6.2 Silica sand

6.3 Methanol, reagent grade
TLV = 200ppm

6.4 Strontium carrier, 2.0 mg $^{Sr}/_{mL}$: Dissolve 4.84g reagent grade $Sr(NO_3)_2$ in DI water and dilute to 1L. Record the preparation of this carrier in the Reagent Prep Logbook.

6.5 ^{90}Sr spiking solution, NIST-traceable. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.6 ^{89}Sr spiking solution, NIST-traceable. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.7 Nitric acid, concentrated, 16N, ACS grade.
TLV = 2ppm (TWA) Irritant, corrosive

6.8 Nitric acid, 8N: Cautiously add 500mL of conc. HNO_3 to approximately 400mL DI water and dilute to 1L.
See 6.7 for TLV

6.9 Nitric acid, 1N: Cautiously add 63mL of conc. HNO_3 to approximately 400mL DI water and dilute to 1 L.

See 6.7 for TLV

6.10 Nitric acid, 0.1N: Add 6.3mL conc. HNO_3 to approximately 900mL DI water and dilute to 1 L.
See 6.7 for TLV

6.11 Nitric acid, 0.05N: Add 3.1mL conc. HNO_3 to approximately 900mL DI water and dilute to 1 L.
See 6.7 for TLV

6.12 Nitric acid (3N)-Oxalic acid solution (0.05M): Add 191mL of concentrated nitric acid and add 6.3g of oxalic acid dihydride to 800mL of DI water and dilute to 1L with DI water.
See 6.7 for TLV for Nitric acid
TLV for Oxalic acid = 1 mg/m3 = 0.3ppm

6.13 Cation exchange resin, AG50x8 or AG50x4, Bio-Rad®, Eichrom® or equivalent

6.14 Sr-Resin extraction chromatography resin, particle size 50-100 µm

6.15 ICP Diluting Solution: Carefully add 10mL of conc. Nitric acid and 50mL of conc. Hydrochloric acid to 940mL of DI water.
TLV = 5ppm (ceiling) for HCL Irritant, corrosive
TLV = 2ppm (TWA) for Nitric Acid Irritant, corrosive

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 It is recommended that samples be preserved at the time of collection by adding enough 1N HNO_3 per liter of sample to bring the pH to 2 (15mL 1N HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days, then preserved, and held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.2 The container choice should be plastic (rather than glass) to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 WATER PREPARATION

8.1.1 Verify and record the pH of the sample on a liquid sample condition form (Form 631) according to SOP 733.

8.1.2 Measure the sample volume using an appropriate sized graduated cylinder. The sample is filtered through qualitative filter paper into the graduated cylinder to speed up passage through the column. Transfer the sample into a labeled 2L disposable plastic bottle. Record the volume V_i (in mL) on the benchsheet. Typical sample volume is 1L. If sample is not 1L, note the volume on the benchsheet and dilute to 1L with filtered DI water.

8.1.3 Prepare quality control (QC) samples per Section 10.

8.1.4 Add 0.5mL of Sr carrier. Record the carrier volume and reagent ID in the space provided on the benchsheet.

8.1.5 Mix the sample thoroughly by inverting the disposable bottle 15-20 times and remove a 10.0mL aliquot (or similar known volume using a calibrated pipettor, SOP 321) for ICP determination of Sr. Pipet the aliquot into a 15mL test tube, seal with Parafilm and label with sample ID and "initial-Sr".

8.1.6 In addition, a replicate 0.5mL aliquot (or similar known volume from a calibrated pipettor) of Sr carrier is diluted with 5mL conc. nitric acid and DI water to the default volume used for the water samples. After mixing thoroughly, a 10.0mL aliquot of this dilution is transferred to a test tube labeled ‘reference carrier’ and submitted with the initial samples to provide a reference concentration for the ICP calculations discussed subsequently.

8.1.7 Precondition a disposable ion exchange column with 1-2mL of methanol, just enough to pass filter (the frit at the orifice of the column is hydrophobic). Transfer AG50x8 or AG50x4 resin to the stem of the column as a slurry with DI water to at least the 7cm mark. Place a layer of sand with a spatula (~1cm) on top of the resin bed to hold the resin in place. Attach the funnel to the column (make certain that the column and funnel fit tightly), and precondition with 30mL of 1N HNO_3 to check for leaks.

8.1.8 Pass the sample through the column at a rate of about 1-2mL/min. This is accomplished by inverting the 2L bottle into the funnel that is attached to the top of the cation exchange column. Secure the bottle with a rubber band. The sample will feed automatically through the column.

8.1.9 After the sample has completely passed through the resin, rinse the column with 10mL of 0.1N HNO_3.

8.1.10 Discard the feed and rinse solutions into the Paragon wastewater treatment facility (down the laboratory sink followed by plenty of tap water).

8.1.11 Elute Sr and other cations with 100mL of 8N HNO_3. Collect the solution in a labeled 250mL disposable cup. Place the solution on a steam bath and evaporate to dryness.

8.1.12 The used resin from the column is collected in a wide mouth jar labeled "Used Cation Resin" for disposal. When the container is full, contact the Waste Management Officer for disposal instructions.

8.1.13 The columns are then soaked in Radiacwash®, rinsed with tap water, and disposed of in the sanitary trash.

8.1.14 Dissolve the salts in 5mL of 8N HNO_3 solution. Add the 8N HNO_3 to the specimen cup while the sample is on the steam bath to facilitate complete dissolution of the salt residue.

8.1.15 Proceed to Section 8.5 (isolation of strontium using Sr-resin).

8.2 SOIL PREPARATION

8.2.1 Verify and record the sample condition on a solids sample condition form (Form 631).

8.2.2 Solid samples used in this method should be dried and ground per SOP 721 prior to analysis. If the samples are not conducive to grinding, consult with your Supervisor prior to analysis of samples.

8.2.3 Weigh 1.0g of soil into a labeled 50mL centrifuge tube. Centrifuge tubes may be sprayed with static spray prior to aliquoting samples. Record this initial sample weight on the benchsheet.

8.2.4 Prepare QC samples per Section 10.

8.2.5 Add 0.5mL (or similar known volume using a calibrated pipettor, SOP 321) of carrier solution to the sample in the centrifuge tube.

8.2.6 In addition, a replicate 0.5mL aliquot of Sr carrier is diluted by adding 10mL of 8N nitric acid and bringing up to 50mL with DI water in a labeled centrifuge tube. After vortexing thoroughly, a 0.5mL aliquot of

this solution is transferred to a 15mL test tube labeled with the batch ID and "reference carrier" and diluted with 9.5mL of ICP diluting solution. This tube is submitted to the Metals Lab with the initial and final ICP tubes for analysis.

8.2.7 Add 10mL 8N HNO_3 to each tube from Step 8.2.5. **CAUTION: a vigorous reaction may occur.**

8.2.8 Place the centrifuge tubes on a pre-heated steam bath, with the lids on loosely, for one hour.

8.2.9 Remove from the steam bath and allow to cool.

8.2.10 Centrifuge for 10-15 minutes at 3500rpm. Decant the supernatant into a clean, labeled centrifuge tube.

8.2.11 Add 20mL of DI water to the original tubes containing the soil fraction and vortex thoroughly. Centrifuge and add the supernatant to the tubes from Step 8.2.10 above.

8.2.11.1 Dispose of the soil fraction into the waste container labeled "Contaminated Soils and Solids" (Either LLRW or Non-Rad, depending on the screening data).

8.2.11.2 Soak used centrifuge tubes in Radiacwash®, rinse with tap water, and discard in the sanitary trash.

8.2.12 Dilute the combined solutions from Steps 8.2.10 and 8.2.11 to a final volume of 50mL with DI water.

8.2.13 **Vortex to mix completely.** Using a calibrated pipettor, remove 0.5mL of the solution and transfer to a test tube containing 9.5mL of ICP diluting solution. Seal with parafilm and invert several times to mix thoroughly. Label tubes with sample ID and "initial" Sr.

8.2.14 Transfer the entire solution into a labeled 250mL specimen cup. Rinse the centrifuge tube into cup with DI water to ensure complete transfer. Place on a steam bath and evaporate to dryness.

Soak used centrifuge tubes in Radiacwash®, rinse with tap water, and discard in the sanitary trash.

8.2.15 Dissolve the salts in 5mL of 8N HNO_3 solution. Add the 8N HNO_3 to the specimen cup while the sample is on the steam bath to facilitate complete dissolution of the salt residue.

8.2.16 Proceed to Section 8.5 (isolation of strontium using Sr-resin).

8.3 FILTER PREPARATION

8.3.1 This preparation procedure may begin after a filter has been leached or digested as a common pretreatment step. Frequently, a sub-aliquot of the total volume of digestate is carried through the preparation process. The aliquot volume/total volume ratio represents the fraction of the total activity leached from the filter that is prepared for radiostrontium determination. This fraction, Fi, must be recorded on the benchsheet. If the filter needs to be leached, start at Step 8.3.2. If the filter has been leached and the aliquot size of the leachate is less than 200mL, but the solution is not 8N nitric acid: transfer an appropriate aliquot of digestate to a specimen cup, add carrier as described in Step 8.3.4, and convert to a nitrate system by taking to dryness and redissolving in nitric acid as described in Steps 8.3.9 and 8.3.10. If the aliquot size of the leachate is less than 200mL and the solution is in 8N nitric acid, transfer an appropriate aliquot of digestate to a specimen cup, add carrier as described in Step 8.3.4 and then begin with Step 8.3.9. However, if the aliquot size of the leachate is greater than 200mL, then proceed with Section 8.1 (concentration by cation exchange for waters).

8.3.2 Place the filter sample into a labeled 250mL specimen cup.

8.3.3 Prepare quality control (QC) samples per Section 10.

8.3.4 Add 0.5mL (or similar known volume using a calibrated pipettor, SOP 321) of carrier solution into the specimen cup.

8.3.5 In addition, a replicate 0.5mL aliquot (or similar known volume from a calibrated pipettor) of Sr carrier is diluted in 8N nitric acid to 5mL. A 0.1mL aliquot (or similar known volume from a calibrated pipettor) of this dilution is transferred to a test tube labeled ‘reference carrier’ and submitted with the initial samples to provide a reference concentration for the ICP calculations discussed subsequently.

8.3.6 Add 50mL of 8N HNO_3 to the specimen cup and heat on a steam bath (in a fume hood) for approximately 30 minutes.

8.3.7 Turn the filter over and allow to digest for an additional 30 minutes.

8.3.8 Remove the filter from the liquid and thoroughly rinse both sides into the cup with DI water.

8.3.9 Place the cup on a steam bath and evaporate the solution to dryness.

8.3.10 Dissolve the residue by adding 5mL of 8N HNO_3 to the beaker with a repeater pipette.

8.3.11 After dissolution is complete, pipet a 0.1mL aliquot (or similar known volume using a calibrated pipettor) of the solution into a 15mL test tube. Make certain that the solution is well mixed before pipetting.

8.3.12 Dilute the aliquot in Step 8.3.11 above by adding 9.9 or 10mL of ICP diluting solution. Be sure to record the final diluted volume. Cover the solution with Parafilm and mix thoroughly. This diluted solution will be analyzed by ICP to determine the initial Sr concentration (Ci). Label with the sample ID and "initial Sr".

8.3.13 Proceed to Section 8.5 (isolation of strontium using Sr-resin).

8.4 PREPARATION OF ORGANIC LIQUIDS AND HAZARDOUS WASTE SAMPLES

8.4.1 Organic liquids and hazardous waste samples require muffling in a 600°C (approximately) furnace prior to digestion. The Pyrex® brand glass beaker number (all labware to be used for muffling must have a permanent ID engraved on its surface) is written on the benchsheet in association with the corresponding sample number. For the blank and blank spike a beaker containing a piece of ashless filter paper will be muffled.

8.4.1.1 Weigh 2g up to 10g (to the nearest 0.01g) aliquot of the ground sample into the corresponding labeled Pyrex® beaker. Filters should be cut or folded such that they fit into the bottom of the beaker. Cover the dishes using watch glasses to protect the contents during the muffling.

8.4.1.2 Prepare quality control (QC) samples per Section 10.

8.4.1.3 Add 0.5mL (or similar known volume using a calibrated pipettor) of carrier solution into the specimen cup.

8.4.1.4 In addition, a replicate 0.5mL aliquot (or similar known volume from a calibrated pipettor) of Sr carrier is diluted in 8N nitric acid to 5mL. A 0.1mL aliquot (or similar known volume from a calibrated pipettor) of this dilution is transferred to a test tube, diluted to 10mL, labeled 'reference carrier', and submitted with the initial samples to provide a reference concentration for the ICP calculations discussed subsequently.

8.4.1.5 Place the beaker without the watch glass on a hot plate and take to dryness to prevent splattering in the muffle furnace.

8.4.1.6 Place the beaker with a watch glass in the muffle furnace and heat for at least 4 hours after the temperature reaches the 600ºC preset (approximate temperature). Highly organic materials (or oil matrices) should be muffled overnight.

8.4.1.7 Carefully remove the dishes from the muffle furnace using thick furnace gloves and long tongs. Allow the samples to cool. Alternately, the furnace may be turned off and the samples may cool in the furnace.

8.4.2 The ashed samples are dissolved in hot nitric acid prior to chemical separation.

8.4.2.1 Add 10mL conc. HNO_3 to each beaker and heat on a hot plate at medium setting for approximately one hour, or until a complete dissolution is achieved. If necessary, use a rubber policeman to remove residual material from the surface of the beaker.

8.4.2.2 To a one liter graduated cylinder, add 500mL DI water. Add the dissolved sample and HNO_3. ALWAYS ADD ACID TO WATER. DO NOT ADD WATER TO STRONG ACID.

8.4.2.3 Ensure a quantitative transfer of sample material by rinsing the beaker three times with DI water and adding the rinsate to the graduated cylinder. After transferring the sample digestate, add additional DI water to bring the volume up to one liter.

8.4.3 The diluted sample digestate is then taken through the standard water procedure, beginning at Step 8.1.2.

8.5 ISOLATION OF STRONTIUM USING SR-SPEC COLUMN

8.5.1 Prepare a Sr-Spec column by passing 2mL of 8N HNO_3 through the column. Let the solution drain by gravity flow.

8.5.2 Transfer the sample solution (feed solution) to the Sr-Spec column reservoir using a transfer pipet. Collect the eluate from the column in waste cups.

8.5.3 Rinse the sample cup with 2mL of 8N HNO_3. Add the rinsate to the column after the feed solution has passed through.

8.5.4 Repeat Step 8.5.3 after the first rinse solution has completely passed through.

8.5.5 Repeat Step 8.5.3 again after the second rinse solution has completely passed through.

NOTE: After this Step the column will have been rinsed a total of three times with 2mL volumes of 8N HNO_3. Allow each addition to pass completely through the column before adding the next.

8.5.6 Add 5mL of 3N nitric acid -0.05N oxalic acid into each column and allow to drain.

NOTE: The 3N nitric-0.05N oxalic acid removes Pu(IV), Np(IV) or Ce(IV), which are retained by Sr-resin.

8.5.7 Add 5mL of 8N nitric acid to each column and allow the rinse solution to drain through each column.

NOTE: This additional 8N nitric acid rinse removes any residual oxalic acid and ensures full removal of K^+ and Ba^{2+} that may be present.

8.5.8 Record the end time of the last rinse on the benchsheet, to the nearest 15 minutes. This is the start of ^{90}Y ingrowth. If Sr-89/90 are being determined, proceed through the following steps of this SOP without stopping to minimize the ^{90}Y ingrowth.

8.5.9 The rinse solution collected in the waste cups may be discarded into the laboratory wastewater treatment facility (down the laboratory sink

followed by plenty of cold tap water). The cups may be soaked in Radiacwash®, rinsed with tap water, and reused for waste collection.

8.5.10 Elute Sr from the column by pipetting 5mL of 0.05N HNO_3 into the column with a repeater pipette. Collect the eluate in a labeled 15mL disposable test tube. After this aliquot elutes through the column, pipet another 5mL of 0.05N HNO_3. The final volume in the test tube is 10mL.

8.5.11 After mixing the eluate thoroughly, transfer a 0.1mL (or similar known volume using a calibrated pipettor) aliquot of the solution to a second culture tube labeled with the sample ID and "final-Sr". Dilute to 10mL with ICP diluting solution. The dilution is accomplished by adding the 0.1mL aliquot to 10mL of ICP diluting solution in a 15mL test tube. Be sure to record the final diluted volume. Seal the tube with Parafilm™ and mix well.

8.5.12 Submit both the "initial-Sr" and the "final-Sr" to the Metals Lab for Sr analysis by ICP.

8.5.13 Upon the return of the ICP sample fractions to the lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the laboratory wastewater treatment facility (down the drain in the lab sinks with plenty of cold water). The test tubes may be rinsed with a Radiacwash® solution, followed with tap water and discarded into the sanitary trash.

8.5.14 Place a labeled planchet for each sample on a hot plate (in a hood). Transfer the remaining portion of the Sr eluate to the planchet. As evaporation proceeds, rinse the tube with about 1mL of DI water. Combine the rinsate with the solution in the planchet. Continue heating until the evaporation is complete.

8.5.15 Prepare petri dishes by spraying the inside with static guard, and labeling the cover with the batch ID and sample ID.

8.5.16 Submit planchets to the Instrumentation Group as soon as practical. The counting lab will analyze and ultimately dispose of the planchets in the manner described in SOP 724.

8.6 PREPARATION OF CALIBRATION STANDARDS

NOTE: Calibration standards for this method are prepared annually, or as requested by the Analyst of the Gas Flow Proportional Counter.

8.6.1 Label five flat 2" diameter stainless steel planchets.

8.6.2 Spike each planchet directly with ~500-1000dpm of NIST-traceable ^{90}Sr standard.

8.6.3 Add 0.5mL of Sr carrier.

8.6.4 Dry on a hot plate set at 2 or 3.

8.6.5 Submit to the Instrument Lab with the appropriate documentation.

9. CALCULATIONS

NOTE: Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

9.1 CHEMICAL YIELD CALCULATIONS FOR WATER SAMPLES

NOTE: The ICP data is generally imported directly into the LIMS benchsheet where the chemical yield recovery is automatically calculated. The chemical yield calculations outlined in this Section can also be conveniently and accurately carried out by using an Excel Spreadsheet. To do this, call up the Sr water template from the appropriate subdirectory on the network R:\ drive. The calculations provided by either program mentioned above should be verified periodically by manually calculating the yield.

9.1.1 The following parameters must be recorded on the benchsheet. These values are necessary to calculate chemical recovery and to provide the Instrumentation Group with the sample volume to be used in calculating the final results.

V_i = initial sample volume (mL)

A = volume of acid added to bring sample to 0.1N acidity (mL)

S = volume of carrier solution spiked into sample (mL)

R_i = volume of solution removed for "initial-Sr" ICP analysis (mL)

C_i = concentration of Sr determined in "initial-Sr" aliquot (µg/mL)

C_f = concentration of Sr determined in "final-Sr" solution (µg/mL)

V_f = final volume (mL) of Sr eluate. V_f = 10.0 mL or other calibrated volume as appropriate.

9.1.2 Calculate percent chemical recovery using the following equations:

9.1.2.1 Mi = initial mass of Sr (µg) = (Ci) (Vi + A + S - Ri)

NOTE: The initial mass of strontium added may be underestimated due to matrix interference in the ICP measurement of the pre-separation concentration of strontium. This is the case when the calculated initial Sr (µg) is less than the 'reference carrier' concentration measured parallel to the samples. (The calculation for the reference carrier is the same as the calculation for M_i.) In this case, the reference carrier concentration is substituted for Mi below. If the discrepancy between the measured pre-separation Sr and the carrier reference Sr is greater than 15%, a note about the matrix interference is made in the case narrative.

9.1.2.2 Mf = final mass of Sr (µg) recovered after separation and purification. = (Cf) (Vf) (100)

NOTE: The factor of 100x is due to the dilution made in Step 8.5.11. This may vary according to the actual calibration of the pipettor used to conduct the measurement.

9.1.2.3 % Chemical recovery = Mf/Mi * 100

Chemical recovery results must be submitted to the Instrumentation Lab and recorded on the benchsheet.

9.1.3 Corrected Sample Volume Calculation for Waters, Vc: The sample aliquot volume to be used in calculating the final results must be reduced slightly since two aliquots were removed to determine chemical recovery. If 1L of water is used for analysis, this correction is rather insignificant (approximately 2%). The correction becomes more significant for smaller initial sample volumes.

V_c = sample volume used in calculation of final results (mL):

$$= V_i * \frac{(V_i + A + S - R_i)}{(V_i + A + S)} * \frac{(V_f - 0.1)}{(V_f)}$$

V_c must be submitted to the Instrumentation Group in order to allow calculation of the final results. It is recorded on the benchsheet under the 'Fin Aliq'column in units of mL.

9.2 CHEMICAL YIELD CALCULATIONS FOR SOIL SAMPLES

NOTE: The ICP data is generally imported directly into the LIMS benchsheet where the chemical yield recovery is automatically calculated. The chemical yield calculations outlined in this Section can also be conveniently and accurately carried out by using an Excel Spreadsheet. To do this, call up the Sr soil template from the appropriate subdirectory on the network R: drive. The calculations provided by either program mentioned above should be verified periodically by manually calculating the yield.

9.2.1 The following parameters must be recorded on the benchsheet. These parameters are necessary to calculate chemical recovery and also to provide the instrumentation group with the sample volume to be used in calculating the final results.

W_i = initial mass (g) of sample weighed out in Step 8.2.3

Ci = concentration of Sr determined in "initial-Sr" aliquot (µg/mL)

NOTE: The initial mass of strontium added may be underestimated due to matrix interference in the ICP measurement of the pre-separation concentration of strontium. This is the case when the calculated initial Sr (µg) is less than the 'reference carrier' concentration measured parallel to the samples. In this case, the 'reference carrier' concentration is substituted for Sr_i below. (The calculation for the reference carrier is the same as the calculation for Sr_i.) If the discrepancy between the measured pre-separation Sr and the carrier reference Sr is greater than 15%, a note about the matrix interference is made in the case narrative.

C_e = concentration of Sr determined in "final-Sr" solution (µg/mL)

Sr_i = initial mss (µg) of Sr (after spiking with Sr carrier) in sample aliquot = (C_i) (50) (10)

where: the factor (50) is the leachate volume (in mL), and the factor (10) is the amount the solution was diluted prior to ICP analysis. (Note: dilution volumes may vary according to actual dilutions performed and calibrated volumes for the pipettors used).

Sr_e = mass of Sr in final eluate (µg) = (C_e) (10) (100)

where: the factor (10) is the volume of eluate (in mL) collected during Step 8.5.10, and the factor (100) is the amount the solution was diluted prior to ICP analysis. (Note: Dilution volumes may vary according to actual dilutions performed and calibrated volumes for pipettors used).

V_T = Total volume (in mL) of leachate in Step 8.2.8 (V_T = 50.0 mL)

NOTE: Dilution volumes may vary according to actual dilutions performed and calibrated volumes for pipettors used.

V_A = Aliquot volume (in mL) of leachate purified through Sr-Spec (V_A = 49.5 mL)

NOTE: Dilution volumes may vary according to actual dilutions performed and calibrated volumes for pipettors used).

9.2.2 Calculate the percent chemical recovery using the following equation:

$$\% \text{ Chemical recovery} = \frac{(Sr_e)}{(Sr_i)} \times \frac{(V_A)}{(V_T)} \times (100)$$

9.2.3 Corrected Sample Aliquot Calculation for Soils: The sample weight used in calculating the final results, W_c, should be adjusted according to the following equation:

$$W_c = (W_i) \times \frac{(V_A)}{(V_T)} \times (0.99)$$

W_i = initial sample weight from Step 8.2.3

The factor (V_A / V_T) is used because only a fraction of the total sample digestate solution is aliquotted in Step 8.2.13 for the purification process. The (0.99) factor is included because a 0.1mL aliquot is removed from the 10mL of final eluate in Step 8.5.11, hence the fraction of purified sample evaporated on the planchet = 0.99 (1.00 - 0.1/10 = 0.99).

$$(W_i) x \frac{(V_A)}{(V_T)} x (0.99)$$

9.3 CHEMICAL YIELD CALCULATIONS FOR FILTER SAMPLES
The calculations for filter samples are carried out similar to those for soils above. Aliquot, splits, spiking, and dilution volumes are reflected in the calculations.

9.4 TPU FACTORS (PREPARATION UNCERTAINTY, PU)

9.4.1 As defined in SOP 708, the following preparation uncertainty factors (1σ) should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty. The Prep uncertainty for water and solid samples are statistically equivalent and the greater value should be used in calculations.

9.4.2 Water samples require a preparation uncertainty factor of 0.1033. This is based on one gross aliquotting, two quantitative transfers, one volumetric measurement, and one ICP yield determination.

$$0.1033 = \sqrt{.05^2 + .025^2 + .025^2 + .006^2 + .083^2}$$

9.4.3 Solid samples require a preparation uncertainty factor of 0.1031. This is based on one gross aliquotting, two quantitative transfers, one mass measurement, and one ICP yield determination.

$$0.1031 = \sqrt{.05^2 + .025^2 + .025^2 + .003^2 + .083^2}$$

9.4.4 Filter samples require a preparation uncertainty factor of 0.1033. This is based on one gross aliquotting, two quantitative transfers, one volumetric measurement, and one ICP yield determination.

$$0.1033 = \sqrt{.05^2 + .025^2 + .025^2 + .006^2 + .083^2}$$

10. QUALITY CONTROL

10.1 Method Blank: One method blank is processed per batch of up to 20 samples

(minimum 5% frequency).

10.1.1 Use an appropriate volume of DI water for aqueous samples. Acidify to 0.1N with concentrated HNO_3.

10.1.2 Use an empty centrifuge tube for solid samples.

10.1.3 Use an unused filter (of the same type, if possible) for filter samples.

10.2 Sample Duplicate: One sample duplicate is processed per batch of 10 samples (minimum 10% frequency). A duplicate blank spike may be substituted if the sample size is limited.

10.3 LCS: One Laboratory Control Sample (LCS, blank spike) is processed for each batch of up to 20 samples (minimum 5% frequency). The LCS is prepared as in Section 10.1 and then spiked with ^{90}Sr and/or ^{89}Sr at 10-30 pCi/mL, before processing begins.

11. DEVIATIONS FROM METHOD

There are no known deviations from the referenced methods.

12. SAFETY, HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

12.1.2 Wear gloves, safety goggles, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

12.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). The absence of this information does not imply that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

12.1.4 Care should be taken when diluting acids. Always add the acid *slowly* to the water, not water to acid. Remember acids have a high heat of solution in water and the solution may become hot.

12.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with

compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.2 WASTE DISPOSAL

12.2.1 Corrosive only wastes such as glacial acetic acid and sulfuric acid waste are disposed of by discharging into the laboratory wastewater treatment facility. These materials that are corrosive only (i.e., no hazardous components or characteristics other than corrosivity) may be neutralized in our water treatment facility.

12.2.2 All non-hydrofluoric acid wastes collected from samples loaded on an ion exchange column are collected in awaste tray or cup. The collected non-hydrofluoric acid wastes may be discharged into the laboratory wastewater system for neutralization.

12.2.3 All corrosive used resins (cation exchange and Sr-spec) are extruded from the column into an appropriately labeled carboy. The resin is neutralized with baking soda, allowed to dry, and disposed of as neutralized resin.

12.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

9/7/06: No technical changes. Augmented LIMS program specification language. Added DOCUMENT REVISION HISTORY section. Other minor clerical corrections.

8/31/07: Clarified use of second independent source for spiking (SECTION 6), added comment, 10.3, to add spike before any chemical processing. Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Section 7.1. Removed activity calculations from SECTION 9, and referenced SOP 708 instead.

STANDARD OPERATING PROCEDURE 708 REVISION 8

TITLE: CALCULATIONS FOR RADIOANALYTICAL RESULTS

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7/21/08

QUALITY ASSURANCE MANAGER _____ DATE 7/20/08

LABORATORY MANAGER _____ DATE 7/21/08

HISTORY: Rev0, 10/1/92; Rev1, PCN#11, 10/15/93; Rev2, 10/5/99; Rev3, 9/20/02; Rev4, 3/6/04; Rev5, 7/5/06; Rev6, 4/13/07; Rev7, combined with TPU SOP 743, 8/31/07; Rev8, 7/18/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) provides the basic calculations for Activity Concentration, Total Propagated Uncertainty (TPU), Decision Level (DL), and Minimum Detectable Concentration (MDC). The algorithms provided in this SOP accurately reflect the processes used in the Paragon LIMS system for performing the same calculations.

Deviations from these calculations are special cases, requiring the approval of the Department Manager. These deviations are documented in the individual method SOPs. In addition, method-specific descriptions of uncertainty coefficients and calculational "switches" are also found in the individual method SOPs.

Paragon standard (i.e., default) practices are discussed in this SOP. Client-specified calculations that deviate from Paragon standard practices are defined in the LIMS program specification applicable to the samples being processed.

Where uncertainty calculations are concerned, this SOP describes the principles and practices taken to estimate the TPU in radioanalytical procedures. This procedure incorporates recommendations from the NIST Technical Note 1297, "Guidelines for Evaluating and Expressing the Uncertainty of NIST Measurement Results", which is equivalent to ISO "Guide to the Expression of Uncertainty in Measurements".

DL and MDC calculations provide analytical values that respectively describe the limits of statistical probability for blank sample analyses and for analyses that are distinguishable from a blank sample.

2. SUMMARY

This SOP first describes the calculation of the various correction factors that are applied to all Activity, TPU, DL and MDC calculations.

2.1 CORRECTION FACTORS

Most correction factors are combined and applied as the denominator in the final calculations. The specific correction factors include the following:

- Crosstalk
- External Background
- Base Counting Efficiency
- Efficiency Correction (e.g. Mass Attenuation)
- Progeny Ingrowth
- Progeny Efficiency
- Decay
- Chemical Yield
- Sample Volume
- Emission Abundance
- Units Conversion

After the correction factors have been determined, this SOP describes the appropriate calculations for Activity, TPU, DL and MDC.

Due to the complexity of radioanalytical calculations, Paragon has devised a system that employs a universal calculation format with a series of arithmetic "switches" that allow for the inclusion (or exclusion) of the various correction factors.

2.2 UNCERTAINTY

Radioanalytical data reporting convention includes the estimated analysis uncertainty. This procedure provides estimates of uncertainties throughout the radiochemical preparation and counting process, such that the reported uncertainty includes all known sources of potential error. Individual uncertainty estimates, determined at the one-sigma (1σ) level, are "summed in quadrature" to estimate the one-sigma Total Propagated Uncertainty. Total Propagated Uncertainties (TPU) may subsequently be reported at a multiplier of the sigma value (two- or three-sigma) or at a specific confidence interval (95%, 99%, etc.), as requested by a particular client or procedure. All uncertainties listed in this procedure are given as 1σ values.

Where possible, estimates of uncertainties in various significant steps of radioanalytical procedures are established, either by the collection of empirical data, or by reference to a reliable authority, such as the ANSI N42 standards. These include uncertainty estimates in volume and mass determinations, process reproducibility, instrument calibration and operation, and counting uncertainty.

Estimated uncertainties may be calculated either in activity units (e.g., pCi/g) or as a relative uncertainty (e.g., a percentage of the measured activity). By convention, any uncertainty calculated as a relative value must be multiplied by the sample activity, thereby converting the value to activity units, before using that uncertainty component in the final TPU calculation.

2.3 DLs and MDCs

On a practical basis, the MDC is the level of activity required to be present in a sample to be able to statistically distinguish that sample from one with no activity, at the 2σ confidence interval. More specifically, in a paired observation, in which sample results are background-corrected, the "Decision Level" (or "Critical Level") is the maximum expected result, at the 2σ confidence interval, for a sample with no activity. Therefore, in a sample with an activity concentration equal to the MDC, the minimum expected result at the 2σ confidence interval would be equal to the Decision Level.

Decision Level and MDC determinations are a priori calculations that are generally independent of the actual measured activity concentration in the sample. These calculations can be accurately performed prior to the analysis. Gamma spectroscopy is the exception to this statement, because spectral background is affected by sample activity in a gamma spectroscopy analysis.

As with Activity and TPU, DLs and MDCs for radioanalytical procedures are determined by mathematical formulae that take into account sample volume, chemical recovery, instrument detection efficiency and background, and sample counting duration. This calculation provides for analysis of actual samples to demonstrate the ability to meet desired or required detection limits. This calculation, or an alternative as specified by the client, shall be performed for each type of analysis as a verification of detection limit capabilities.

It is noted that the traditional formulae, described in Section 5.5.1 and 5.5.2 of this SOP, rely on the assumption that the sample count duration and the background calibration count duration are equal. In cases where this assumption does not hold, the refinement in the calculations shown in Section 5.5.3, is appropriate. It is also noted, however, that the use of the traditional formulae is well-entrenched among some clients, despite any differences in count times, and changing this formula may cause unacceptable discontinuity in historical monitoring programs and other scenarios. Consequently, Paragon continues to provide the traditional formulae by default, and offers the revised formula upon request.

The analyst should note that improved detection limits may be obtained through use of larger sample volumes, longer counting times, or improved sample analysis geometries if the *a priori* calculation reveals an inadequate detection limit.

3. RESPONSIBILITIES

3.1 Paragon's Project Managers (PM) serve as the primary interface with the client. To the extent possible, it is the PM's responsibility to understand the client's needs with regard to the manner in which radioanalytical results are calculated, and to inform the client of the option to request client-specified calculations, if necessary. The PM is responsible for creating/maintaining LIMS program specifications that satisfactorily address the clients needs, as applicable.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specifications supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 It is the Department Manager's responsibility to ensure that any material changes to this SOP, which may affect the calculations performed in LIMS, are reflected in the LIMS program. These changes may include correction factors, uncertainty component factors, etc. Updates in LIMS may require the assistance of the IS Department, to make changes to the LIMS program. In all cases, it is also the Department Manager's responsibility to ensure that the calculational changes made in the LIMS program are properly verified.

3.4 It is the analyst's responsibility to be familiar with both the preparation SOP and the analysis SOP for the method results being reported. These SOPs will include calculation coefficients, as well as provide guidance in the fundamental concepts behind the analytical method.

3.5 Analysts must demonstrate the capability to generate acceptable results using the procedures described herein. This demonstration typically comes in the form of supervisory training and review, as well as periodic documentation of the validation of the LIMS program that generally performs these calculations.

3.6 It is the responsibility of all personnel to perform the tasks as described in this SOP. Any anomalies or out-of-control events must be noted, and corrective action taken and documented. For the purpose of this SOP, out-of-control events are defined as those calculations that cannot be validated, by manual calculation, to within 3% of the reported LIMS result. This criteria is defined in SOP 709.

4. APPARATUS AND MATERIALS

There are no apparatus or materials, including reagents and standards, used in this SOP. It is noted, however, that calibration factors and other calculation coefficients may be defined in the individual preparation and analysis SOPs used for a particular method.

5. CALCULATIONS

5.1 GENERAL CORRECTION FACTORS

These general correction factors are applicable to all calculated results for a given sample analysis. The calculation of Activity Concentration, TPU, DL and MDC require identical correction factors, such as chemical yield, etc., to ensure that the final reporting units are comparable, thereby allowing for a valid comparison of results.

5.1.1 Instrument Background (CalBCPM)

The basic instrument background count rate, in counts per minute (cpm), is described in the individual instrument SOPs. This value is subtracted from the gross sample count rate (GCPM) to determine the net sample count rate for the analysis.

This is the background count rate that is subtracted in all analytical methods performed on a given instrument. Additional background correction factors, such as filter contributions or quench curve adjustments, that are applicable to a single method are described below as "External Background (ExtBCPM)".

5.1.2 External Background (ExtBCPM)

External background contributions, such as the additional contribution of paper filters to a beta analysis, which are not accounted for in the basic instrument background calibration, are described in the individual preparation and analysis SOPs.

Additional examples of external background contributions include the batch-specific adjustment of the background quench curve in liquid scintillation analyses, and the yield-dependent beta contribution from the Sm carrier in a Pm-147 analysis.

5.1.3 Crosstalk Count Rate (XTLK)

The Crosstalk Count Rate refers to the additional background contribution, in multi-channel analyses such as gross alpha/beta, in which the analyte results in a region of interest exhibit an interference from other analyte results in a different region of interest. The Crosstalk Count Rate is a function of the Crosstalk Calibration Ratio, which is determined during the base efficiency calibrations.

The primary region of interest is sometimes called the minor region (m) and the interfering region is sometimes called the major region (M). The presence of measurable activity in the major region contributes additional counts to the minor region of interest. These additional counts must be treated as additional background counts since they

interfere with the accurate quantification of activity in the minor region of interest.

For example, in gas-flow proportional counting there are alpha- and beta- regions of interest. The presence of measurable alpha activity primarily shows up in the alpha region. In addition, some alpha activity will also show up in the beta region. These counts are not attributable to beta activity and must be subtracted from the gross beta count rate in order to accurately quantify the true beta activity in the sample. See Figure 1 .

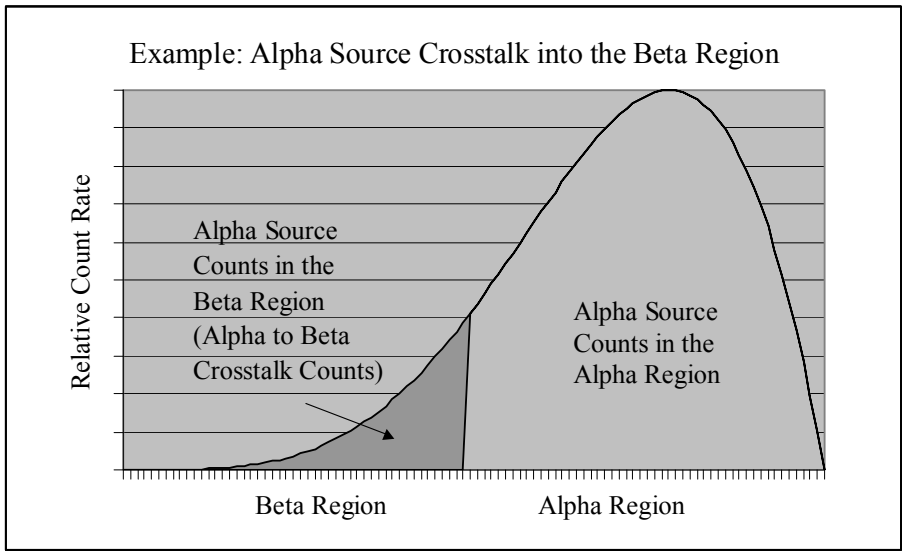

Figure 1

The Crosstalk Calibration Ratio is determined during the base efficiency calibration of the major region and is simply the ratio of net counts in the minor region to net counts in the major region;

$$XTLK_{M>m} = (NetEffCPM_m / NetEffCPM_M)$$

where:

$XTLK_{M>m}$ = Crosstalk Calibration Ratio

$NetEffCPM_m$ = Net count rate in the minor region of interest, during the efficiency calibration of the analyte primarily found in the major region.

$NetEffCPM_M$ = Net count rate in the major region of interest, during the efficiency calibration of the analyte primarily found in the major region.

In alpha/beta example given above, $XTLK_{M>m}$ would be the alpha to beta Crosstalk Calibration Ratio, determined during an alpha efficiency calibration. $NetEffCPM_m$ would be the net beta count rate observed during the alpha efficiency calibration process. $NetEffCPM_M$ would be the net alpha count rate observed during the same alpha efficiency calibration.

The Crosstalk Count Rate in a sample analysis is calculated as the additional count rate in the minor region and is a function of the net sample count rate in the major region;

$$XTLK = (XTLK_{M>m})(NetCPM_M)$$

where:

XTLK = Crosstalk Count Rate in the minor region during a sample analysis, to be treated as additional background.

$NetCPM_M$ = Net count rate in the major region, during a sample analysis.

In alpha/beta example given above, $NetCPM_M$ would be the net alpha count rate. XTLK would be the beta Crosstalk Count Rate, attributable to the sample alpha activity, to be subtracted from the gross beta count rate as additional background.

5.1.4 Base Counting Efficiency (BaseEFF)
The determination of the base counting efficiency is described in the individual preparation and instrument SOPs. The base counting efficiency factor gives the ideal instrument response, in the presence of a particular radionuclide. The units for counting efficiency are "counts per emission".

5.1.5 Efficiency Correction (BaseMassAtt)
The determination of the base efficiency correction factor is described in the individual preparation and instrument SOPs. The correction factor is a unit-less multiplicative correction factor, less than one, that accounts for physical interferences that reduce the sample counting efficiency, such as mass attenuation in a gross alpha/beta analysis or a quench correction in a liquid scintillation analysis.

5.1.6 Progeny Ingrowth (ING)
In cases where the analyte that is isolated in the preparation method decays into a radioactive progeny that is observable in the analysis, the resulting ingrowth of progeny is taken into consideration.

The progeny ingrowth factor describes the relative activity of the ingrown daughter product, as compared to the parent. This special form of the equation assumes that the half-life of the daughter is much shorter than the half-life of the parent;

$$ING = 1 - e^{\lambda * t4}$$

where:

e = the base of the natural logarithm

λ = the decay factor for the progeny;

= ln(0.5) / (progeny half-life)

t4 = the elapsed time the isolation of the parent nuclide to the beginning of the sample count.

Note that in this calculation, as in any decay or ingrowth calculation, the units of time in which the half-life is expressed (e.g. years, days, etc.) must be the same units in which the elapsed time is expressed.

For example, Sr-90 undergoes beta decay, with a half-life of 28.5 years into a radioactive daughter Y-90, which also undergoes beta decay with a half-life of 64 hours. Upon chemical isolation of the Sr-90, the ingrowth of Y-90 immediately resumes. If the sample is held for 72 hours before analysis, the degree of ingrowth of the Y-90 daughter is;

$$1-e^{((ln(0.5)/64h*72h)} = 0.5415$$

Consequently, for a given amount of Sr-90 activity present in the sample, 72 hours after chemical separation there will also be 54.15% of that amount, which will be present as Y-90 activity.

5.1.7 Progeny Efficiency (ProgEFF)

In some cases the progeny emissions are measured and the counting efficiency for the progeny emissions are sufficiently different from the counting efficiency of the parent emissions. In these cases, the counting efficiency of the progeny are determined separately, and are analogous to the base counting efficiency determination. As in any counting efficiency determination, the units are "counts per emission".

5.1.8 Progeny Efficiency Correction (ProgMassAtt)

As with the determination of the base efficiency correction factor, the progeny counting efficiency may need to be corrected for physical interferences, such as mass attenuation in a gross alpha/beta analysis or

a quench correction in a liquid scintillation. This progeny efficiency correction is also a unit-less factor, less than one.

5.1.9 Decay to the Sampling Date (D)

The decay factor is a unit-less correction factor that describes the amount of radioactive parent material remaining after a given period of decay time. By convention, radioanalytical results are generally decay-corrected to the sampling date unless otherwise specified;

$$D = e^{\lambda * t0}$$

where:

λ = the decay factor for the parent;

= ln(0.5) / (parent half-life)

t0 = in the GENERAL CASE, the elapsed time from the field sampling or reference date to the beginning of the sample count (as in H-3).

in the case where INGROWN PROGENY are counted, the elapsed time from the reference date to the isolation/separation of the parent nuclide (as in Sr-90).

5.1.10 Decay During the Count (L)

Since radioactive decay is measured by observation of the radiation emissions over a period of time (usually between 1 and 1,000 minutes), and since the rate of decay changes over time, the change in the decay rate over the duration of the count must be accounted for. This is especially important during the measurement of radionuclides for which the half-life is less than ten times the count duration.

The decay during the count (L) is calculated as follows;

$$L = \left(\left(1 - \exp^{\lambda * t3}\right)/\left(-\lambda * t3\right)\right)$$

where:

λ = the decay factor for the first radionuclide in the chain of radionuclides that are present during the sample count.;

= ln(0.5) / (half-life)

For example, in a Sr-90 analysis in which Sr-90 and its Y-90 daughter are both present, use the half-life of the Sr-90 parent. In a Ra-228 analysis in which the only nuclide present is the Ac-228 daughter, use the half-life of the Ac-228 daughter.

5.1.11 Chemical Yield (yield)

The determination of chemical yield is described in the individual preparation SOPs. Chemical yield is generally determined by pre-separation and post-separation measurement of stable carriers or radioactive tracers added to the sample, and is expressed in decimal format. *For example, a chemical yield of 95.13% is expressed as 0.9513.*

5.1.12 Sample Volume (vol)

The sample volume is the equivalent amount of sample material actually presented for analysis. Described in the individual preparation SOPs, the sample volume for analysis is equal to the original volume of sample aliquotted, less any amounts removed for yield determinations, splits, etc.

5.1.13 Emission Abundance (abund)

Emission abundance values (like half-lives) are derived from published reference tables. These values describe the frequency with which a given emission of radiation occurs for each decay of a parent atom.

For example, the decay of Ba-137m results in a 662 keV gamma photon emission 89.98% of the time. The emission abundance is 0.8998.

In some cases, the analysis of a particular radionuclide may require the measurement of one or more progeny. The creation of these progeny may only occur during a fraction of the parent atom disintegrations. The "branching ratio" for a particular decay scheme describes the frequency of the resulting progeny. As a practical consideration in the Paragon LIMS reporting software, the abundance values and branching ratios are multiplied into a single correction factor.

*For example, in the determination of Cs-137, 94.6% of decays result in the creation of Ba-137m. When measuring the resulting 662 keV gamma emissions, the rate of Cs-137 decay can be inferred by correcting the observation by both the gamma emission abundance and the branching ratio. See Figure 2. The effective correction factor is 0.8998 * 0.9460 = 0.8512.*

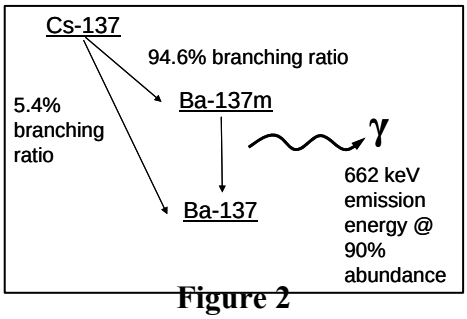

Figure 2

5.1.14 Units Conversion (actconv)
Results are converted into conventional activity reporting units through the application of an appropriate conversion factor. Paragon default reporting units of picoCuries (pCi) are achieved through the application of the conversion factor 2.22 dpm/pCi.

5.2 "SWITCHES" and the STANDARD DENOMINATOR (k)
The application of the various correction factors described above is achieved with a series of arithmetic "switches" that allow for the inclusion (or exclusion) of those factors.

A table of values for the various switches described below, as they are applied to individual methods, is provided in Appendix A. These values may be superseded by subsequent revision of the analytical methods. Consult the individual preparation and analysis SOPs for the latest revisions to the methods.

The combination of selected correction factors and their related arithmetic switches create a standard denominator (k), to be applied in the calculation of Activity, TPU, DL, and MDC;

$$k = (A + B) * C * K * L$$

where:

$$A = \left(BaseEFF * BaseMassAtt^{\mathbf{c}} \right) * \left(1 + \left(1 - \exp^{\lambda * t4} \right) * \mathbf{d} \right)$$

and where:

BaseEFF = Base calibration efficiency (cpm/dpm).

Base MassAtt = Mass attenuation factor for the base efficiency (no units).

switch c = 0, if there is no mass attenuation correction in this method.

1, if there is a mass attenuation correction in this method.

switch d = 0, if there is no ingrowing daughter product present during the count that has the same counting efficiency as the parent (as in gross α/β).

1, if there is an ingrowing daughter product present during the count, and it has the same counting efficiency as the parent (as in Sr/Y-90).

exp = the base e of the natural logarithm (2.718).

λ = the decay constant [ln(.5)/(half-life of the nuclide of interest)].

Similarly,

$$B = \left(ProgEFF * ProgMassAtt^{\mathbf{e}} \right) * \left(1 - \exp^{\lambda * t4}\right) * \mathbf{f}$$

where:

ProgEFF = Progeny calibration efficiency (cpm/dpm), if applicable. See switch f below.

ProgMassAtt = Mass attenuation factor for the progeny efficiency (no units).

switch e = 0, if there is no mass attenuation correction for the progeny in this method.

1, if there is a mass attenuation correction for the progeny in this method.

switch f = 0, if there is no ingrowing daughter products present during the count that have a different counting efficiency from the parent (as in Sr/Y-90 and gross α/β).

1, 2, 3, etc., based on the number of ingrowing progeny present during the count, with a different counting efficiency from the parent (as in Total Radium, where f=3).

$$C = \left(\exp^{\lambda * t2} * \left(1 - \exp^{\lambda * t1}\right)\right)^{\mathbf{g}}$$

where:

switch g = 1, if the analyte to be counted is the ingrown daughter product of the parent target analyte and the parent target analyte is not present in the fraction for analysis (as in Ra-228).

0, Otherwise.

$$K = yield * vol * abund * actconv * \left(\exp^{\lambda * t0}\right)^{\mathbf{h}}$$

where:

yield = chemical yield (no units).

vol = sample size (grams, liters, m3, etc.).

abund = abundance correction, including branching ratios, from published reference data (no units).

actconv = activity units conversion factor, e.g. 2.22 dpm/pCi, to report data in pCi units.

switch h = 0, if the target analyte should not be decay corrected, usually because the specific nuclide is unknown (as in gross αβ, or Total Activity).

1, if the decay factor for the target analyte is known and is to applied (as in Sr-90, Th-228, H-3, etc.).

$$L = \left(\left(1 - \exp^{\lambda * t3}\right)/\left(-\lambda * t3\right)\right)^{\mathbf{h}}$$

where:

switch h = defined above.

IMPORTANT NOTE: In the L factor defined here,

if the g switch defined above is 0, then use the λ of the parent target analyte (as in Sr-90).

if the g switch defined above is 1, then use the λ of the ingrown progeny (as in Ra-228).

5.3 ACTIVITY CONCENTRATION

The determination of the activity concentration in a sample begins with the sample gross count rate measurement on a given instrument, such as a gas-flow proportional counter for gross α/β analyses. Various background count rate contributions, described in Sections 5.1.1 through 5.1.3 above, are subtracted from the gross count rate to yield a net count rate, which is attributable only to the actual sample activity. The standard denominator is then applied to convert the result into conventional reporting units. The final result expresses the radioactive decay rate per volume of sample material, decay corrected to the sampling date;

$$\text{Activity} = \frac{GCPM - \left[CalBCPM + \left(XTLK * a\right) + \left(ExtBCPM * b\right)\right]}{k}$$

where:

GCPM = Gross count rate (cpm)

CalBCPM = Calibrated instrument background count rate (cpm).

XTLK = Crosstalk contribution to the analyte background (cpm).

switch a = 0, if there is no crosstalk contribution in this method.

1, if there is a crosstalk contribution in this method.

ExtBCPM = External background contribution, such as the additional contribution of paper filters to a beta analysis, which is not accounted for in the base background calibration.

switch b = 0, if there is no external background contribution in this method.

1, if there is an external background contribution in this method.

5.4 UNCERTAINTY

In general, uncertainty refers to the estimated lack of accuracy and/or precision in a reported value. The uncertainty is first estimated for each individual process in the analytical method. The component uncertainties are then combined to give a Total Propagated Uncertainty (TPU) for the entire method. When accompanying the reported activity concentration, this TPU describes the range of values in which the laboratory believes that the true value of the sample lies, at the stated confidence interval.

Unless stated otherwise, the values and formulae provided below are stated at the one-sigma (1σ) confidence interval. These values, and the associate TPU, may be expressed at any other confidence interval by multiplying by the equivalent expansion factor, as described in Section 0.

5.4.1 PRIMARY COMPONENTS

Primary components of the TPU calculation are listed below, and are detailed in the Sections shown:

Analyte Count Rate Uncertainty	Section 5.4.2
Chemical Yield Determination Uncertainties:	
Radiometric Tracer Measurements	Section 5.4.3.1
ICP Mass Measurements	Section 5.4.3.2
Gravimetric Mass Measurements	Section 5.4.3.3
Analysis Uncertainties	Section 5.4.4
Preparation and Sample Handling Uncertainties	Section 5.4.5

5.4.2 ANALYTE COUNT RATE UNCERTAINTY (CU)

The analyte count rate uncertainty is the estimated deviation of the observed count rate from the true mean count rate of the analyte of interest. This component of TPU is due solely to the statistically random nature of radioactive decay.

The uncertainty of a single radiometric measurement is estimated as the square root of the total number of counts acquired. It is calculated as a count rate uncertainty, in units of counts per unit of time, as follows:

$$U_R = \sqrt{\frac{R_S}{T_S}}$$

where:

U_R = Count Rate Uncertainty

R_S = Gross Count Rate in the Sample

T_S = Duration of the Sample Count

In practice, however, a single radiometric measurement is rarely used to report activity concentrations. Instead, the gross sample count rate is background corrected by subtracting the background count rate to obtain a sample net count rate. This is known as a "paired observation", and is calculated as a count rate uncertainty, in units of counts per unit of time, as follows:

$$U_R = \sqrt{\frac{R_S}{T_S} + \frac{R_B}{T_B}}$$

where:

R_B = Count Rate in the Instrument Background Determination

T_B = Duration of the Instrument Background Count

In some analytical techniques, multiple background corrections may be made. A routine instrument background correction will be made, based on the periodic background determination ordinarily performed on the instrument. Further background adjustments may be made in cases where the basic background determination is not representative of the specific analytical technique being employed. Some examples include batch-specific adjustments to the quench curve on the liquid scintillation counter, batch-specific adjustments for the filter contribution in I-129 analyses by gas-flow proportional counting, and

sample-specific contributions to the Compton continuum in gamma spectrometry analyses.

In these cases, the contribution of the additional background determination to the overall counting uncertainty is calculated as

$$U_R = \sqrt{\frac{R_S}{T_S} + \frac{R_B}{T_B} + \frac{R_A}{T_A}}$$

where:

R_A = Count Rate in the Additional Background Determination

T_A = Duration of the Additional Background Count

Where multiple, independent measurements contribute to the additional background determination, as in the case of quench curve adjustments or I-129 blank filter counts, conservatively use the count duration of a single measurement, rather than the combined duration of all measurements. The Count Rate should, however, be the average of the individual measurements.

After calculating the Count Rate Uncertainty in units of count per unit time, that number should be converted to activity concentration units, typically pCi/gram or pCi/liter, by dividing by the appropriate conversion factors, for example:

$$\text{Counting Uncertainty (pCi/g,l)} = \frac{\text{Count Rate Uncertainty (cts/min)}}{k}$$

where:

k = the standard denominator defined in section 5.2.

It is important to note that, in potentially zero (or near zero) background counting systems such as alpha spectrometry, the calculation should guard against the erroneous production of a calculated uncertainty that is at or near zero. Reporting a counting uncertainty of zero is unacceptable, since the count is duration is limited (not infinitely long) and the failure to observe an event during the count does not guarantee that an event will never be observed. Reporting zero activity with zero uncertainty (infinite precision) is not possible.

To guard against this possibility, counting uncertainties are re-calculated by substituting the values $(3/T_S)$ for R_S, $(3/T_B)$ for R_B, and $(3/T_A)$ for R_A in the equations above, to calculate a "Zero Uncertainty"

value. If the Zero Uncertainty is greater than the calculated Counting Uncertainty, the value of the Zero Uncertainty replaces the calculated Counting Uncertainty.

The use of the constant 3 in these equations estimates a maximum true value for an observation that resulted in zero events.

5.4.3 CHEMICAL YIELD DETERMINATION UNCERTAINTIES (YU)
These will vary considerably, depending on the method used to quantify the chemical yield of a given separation procedure, as described below.

5.4.3.1 RADIOMETRIC TRACER MEASUREMENTS
Chemical yields may be determined by the analysis of a radioactive tracer added to the sample prior to chemical separation. The method for estimating the uncertainty associated with a radiometric tracer measurement is identical to the analyte count rate uncertainty described in Section 5.4.2 above, except that the tracer counts are used instead of the counts for the analyte of interest.

5.4.3.2 ICP MASS MEASUREMENTS
Chemical yields may be determined by Inductively Coupled Plasma (ICP) analysis of pre-separation vs. post-separation concentrations of a stable carrier element. The uncertainty in this yield determination is assumed to be 8.3% of the measured sample activity.

5.4.3.3 GRAVIMETRIC MASS MEASUREMENTS
Chemical yields may be determined by the measurement of the residual mass of prepared sample deposited onto a planchet or filter. In this case, the error in the yield determination may be significantly affected by interfering chemical constituents native to the sample, which the laboratory has no control over. The uncertainty in a gravimetric yield determination is conservatively estimated at 10% of the measured sample activity.

5.4.4 ESTIMATES OF INSTRUMENT ANALYSIS UNCERTAINTIES (IU)
5.4.4.1 Uncertainties associated with the instrumental analysis of radiochemical samples are assumed to be as follows:

Calibration (In-house prep. of standards): 5.0%

Calibration (Vendor-prepared standards): 2.0%

Counting Reproducibility:	1.0%
Sample Position Reproducibility:	1.5%
Counting Efficiency:	1.5%
Dead Time Estimates:	1.0%

These individual, independent uncertainty components are combined, or propagated, together by calculating the square root of the sum of the squares of the various components. This technique of combining independent uncertainties is also known as "summing in quadrature", and is shown below. This will result in a single uncertainty estimate for a procedure with multiple uncertainty contributions. Note that the same propagation technique is used to combine preparation uncertainty factors in Section 5.4.5.

5.4.4.2 Instrumental Uncertainty (for calibration with a vendor-prepared standard):

Relative Uncertainty =

$$\sqrt{.020^2 + .01^2 + .015^2 + .015^2 + .01^2}$$

$$= 0.0324 = 3.2\%$$

5.4.4.3 Instrumental Uncertainty (for calibration with an in-house prepared standard):

Relative Uncertainty =

$$\sqrt{.05^2 + .01^2 + .015^2 + .015^2 + .01^2}$$

$$= 0.0561 = 5.6\%$$

5.4.5 ESTIMATES OF CHEMICAL PREPARATION UNCERTAINTIES (PU)

5.4.5.1 Uncertainties associated with the various steps in the chemical preparation of samples are estimated to be as follows:

Gross Aliquoting (Sample Homogeneity):	5%	
Quantitative Transfers:	2.5%	#
Spike or Tracer Standard:	2.5%	
Pipetting:	0.4%	*

Volumetric Measurements	
(non-volumetric labware):	0.6% *
Mass Measurements:	0.3% *
Reagent Addition (repipetting/dispensing):	0.6% *
Aliquoting and ICP Yield Determinations	
(Section 3.3):	8.3% *
Gravimetric Yield Determinations (Section 3.3):	10%

* these uncertainty factors have been empirically determined by Paragon.

\# quantitative transfers need not be considered if a tracer or carrier used for yield determinations has already been added to the sample.

5.4.5.2 PROPAGATION OF PREPARATION UNCERTAINTIES

As described above, in Section 5.4.4.1, independent preparation uncertainties are summed in quadrature. Some generalized examples are given below, for clarification. ***Please note that these are examples only.*** Specific preparation uncertainty factors are given in the individual preparation SOPs.

Example 1: Alpha or Beta Analyses by Gas Flow Proportional Counting (GFPC)

minimal preparation, error =

$$\sqrt{(.05^2 + .004^2 + .006^2 + .003^2 + .003^2 + .025^2)} = .0565 = 5.7\%$$

Based on sample homogeneity, a single pipetting, a single volumetric measurement, two mass measurements, and a quantitative transfer.

Example 2: Liquid Scintillation Analyses

minimal preparation, error =

$$\sqrt{(.05^2 + .006^2 + .006^2 + .003^2)} = .0508 = 5.1\%$$

Based on sample homogeneity, two volumetric measurements, and a single mass measurement.

Example 3: Gamma Spectroscopy

minimal preparation, error =

$$\sqrt{(.05^{2} + .003^{2})} = .0501 = 5.0\%$$

Based on sample homogeneity and a single mass measurement.

5.4.6 CALCULATION OF TOTAL PROPAGATED UNCERTAINTY

The individual uncertainties described above are combined, or propagated, together by calculating the square root of the sum of the squares of all the individual uncertainties.

Note that, in order to combine uncertainty factors, those factors must first be in the same units, such as pCi/g or Bq/L. Uncertainty factors that are expressed as a fraction of the sample activity, such as the instrument and preparation uncertainty factors described above, must be multiplied by the sample activity concentration before proceeding with the propagation calculation.

Be sure that all uncertainty factors are in activity concentration units before performing this last step.

$$TPU = \sqrt{\mathrm{CU}^{2} + Yield\mathrm{U}^{2} + \left(I\mathrm{U} * \mathrm{Activity}\right)^{2} + \left(P\mathrm{U} * \mathrm{Activity}\right)^{2}}$$

where:

$YieldU = YU$

in cases where a radioactive tracer is employed and the yield uncertainty has been expressed as a counting uncertainty, in activity concentration units.

And:

$YieldU = \left(YU * Activiy\right)$

in cases where a stable carrier is measured by ICP, gravimetrically, or other non-radioactive yield determinations, and the yield uncertainty is expressed as a relative uncertainty.

5.4.7 EXPANSION OF THE 1σ TOTAL PROPAGATED UNCERTAINTY
As previously mentioned, the TPU calculation above is expressed at the one sigma (1σ, or 68.3%) confidence interval.

The TPU may be expressed at any other confidence interval by multiplying the 1σ TPU by the appropriate expansion factor (z), shown below.

σ value	% confidence interval	Expansion factor (z)
1.00	68.3	1.00
1.96	**95.0**	1.96
2.00	95.4	2.00
2.56	**99.0**	2.56
3.00	99.7	3.00

Additional expansion factors may be determined by calculating the relative coverage area (% confidence interval) of the normal distribution curve.

5.5 Decision Level (DL) and Minimum Detectable Concentration (MDC)
In a background-corrected nuclear measurement, in which the background count rate is expected to randomly vary with a normal distribution, the analysis of a blank sample will naturally show activity that is not necessarily zero, depending on the pairing of these randomly fluctuating count rates. The DL refers to the maximum activity concentration (at the specified confidence interval) that would be expected to be reported in a blank sample analysis.

By extension, the MDC described that level of activity that would have to be in a contaminated sample in order to give a result that is sufficiently higher than the DL, so that the sample is statistically distinguishable from one with no activity.

By convention, the DL and the MDC are expressed at the 95% confidence interval.

As described above, in Section 2.3, Paragon provides default DL and MDC calculations that follow industry convention. These default formulae assume that the background determination for the sample analysis was performed for the same duration as the sample analysis itself.

5.5.1 DL

Unless otherwise specified in documentation of specific analytical methods, instrumentation software, or client requirements, the DL shall be calculated as:

$$DL = \frac{2.33\sqrt{B}}{kT_s}$$

where:

B = the total counts in the background for the sample

T_s = the sample count duration

k = the standard denominator described in Section 5.2

5.5.2 MDC

Unless otherwise specified in documentation of specific analytical methods, instrumentation software, or client requirements, the MDC shall be calculated as:

$$MDC = \frac{4.65\sqrt{B} + 2.71}{kT_s}$$

5.5.3 REVISED DL AND MDC CALCULATIONS IN CASES WHERE THE SAMPLE COUNT DURATION DIFFERS FROM THE BACKGROUND COUNT DURATION

As described above, in Section 2.3, Paragon recognizes that there may be technical refinements to the default DL and MDC calculation, in cases where the sample and background count times differ.

These refinements, while technically sound, are generally provided only at the client's request because many clients view these changes to the calculations as a source of discontinuity to the historical record for some monitoring data. Nonetheless, the analyst should be aware of, and versed in, the revised formulae;

$$MDC = \frac{3.29\sqrt{R_B * T_s * (1 + T_s / T_b)} + 2.71}{k * T_s}$$

$$DL = \frac{2.33\sqrt{R_B * T_s * (1 + T_s / T_b)}}{k * T_s}$$

where:

R_B, k, and T_s are defined as above

T_b = the background calibration count duration

6. QA/QC

All instruments shall be calibrated according to requirements described in SOPs 704, 713, 714, 724, and 783 prior to performing these calculations.

8. DOCUMENT REVISION HISTORY

7/5/06: Augmented LIMS program specification references; updated format; added DOCUMENT REVISION HISTORY.

4/13/07: Added PM involvement under RESPONSIBILITIES, and DOE MDC calculation, per MARLAP, Section 7.

8/31/07: Major Revision, combined with TPU SOP 743 (will be retired). Changed Title. Also added activity calculations from individual method SOPs, and described standardized LIMS calculation.

7/18/08: Corrected the MDC and DL equations where sample and background count times differ by removing the "B" (total background counts) from both equations and replacing with "R_B" defined as the instrument background count rate.

re-released w/o revision 3/13/09 DAS

1.0 SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary to perform validation of radioanalytical calculations and reporting software. This SOP is applicable to all radioanalytical software used at Paragon. This SOP should be used in conjunction with SOP 1400 after installation or modification of any software related to analysis of radiochemical samples. In addition, the procedures described in this SOP shall be performed and documented ***monthly*** to provide ongoing verification of reporting software.

Radioanalytical software uses a combination of complex data reduction techniques and relatively simple data calculation methods to report radioactivity concentrations in samples of various media. This SOP provides methods for independent determination of results that demonstrate correct operation of the analysis software.

2.0 SUMMARY

In order to ensure proper operation of radioanalytical software, it is necessary to perform hand calculations of the results to validate the software. When data are calculated by hand and by the software in question using the same input data, like results should be obtained. This procedure provides guidelines for each of four types of instruments: gas flow proportional counter (GFPC), liquid scintillation counter (LSC), gamma spectrometer, and alpha spectrometer.

Paragon estimates total error (Total Propagated Uncertainty) according to the methods described in SOP 743. See SOP 743 for details of additional error calculations. Calculations may be found in the method-specific SOPs.

3.0 RESPONSIBILITIES

3.1 These procedures shall be performed by personnel trained and authorized by the Department Manager or designee. It is the responsibility of the primary analyst of each instrument (LSC, GFPC, Gamma spec, and alpha spec) to perform and document the monthly verification for each analysis performed in an assigned area.

3.2 It is the responsibility of the Department Manager to ensure that this verification is being performed and documented monthly.

4.0 APPARATUS

This procedure is conducted with the use of a data package containing the benchsheet, the instrument raw data output, Laboratory Information Management System (LIMS) reports, and standard traceability information.

5.0 PROCEDURE

5.1 GAS FLOW PROPORTIONAL COUNTER

5.1.1 ANALYSIS SOFTWARE; GROSS ALPHA/BETA SAMPLES

Choose a sample counted in a batch. From the raw data instrument output, record the sample counts, counting duration, and the values of b and m from the attenuation curve equation. Also record sample ID, sample mass, reported activity in pCi/L, alpha and beta efficiency, and alpha and beta background CPM from the sample's analysis report. ***Note that samples analyzed on LB4100-A and LB4100-B systems will have different values for background, b, m, and efficiency depending on the detector used.***

Calculate the alpha and beta activity in pCi/L,g as per SOP 702. Record the result. The calculated result should match the reported result within 3% (the tolerance is due to rounding of the reported data that is not rounded in the actual calculations). If there is disagreement, notify the Department Manager. Do not use the software until the problem has been resolved and this procedure has been satisfactorily completed.

The calculations shall be performed monthly and documented. If changes are made to the software or problems are detected, then manual calculation verification shall be performed as needed.

5.1.2 ANALYSIS SOFTWARE; Sr-89/90 SAMPLES

From the data reduction sheet, obtain and record sample counts, counting duration, sample mass, reported yield, reported net CPM, beta efficiency, and beta background count rate.

Perform the calculations per SOP 707, record the results. The calculated results should match the reported result within 3% (the tolerance is due to rounding of the reported data which is not rounded in the actual calculations). If there is disagreement, notify the Department Manager. Do not use the software until the problem has been resolved and this procedure has been satisfactorily completed.

The calculations shall be performed monthly and documented. If changes are made to the software or problems are detected, then manual calculation verification shall be performed as needed.

5.1.3 MINIMUM DETECTABLE CONCENTRATION (MDC) CALCULATIONS

As a matter of convention, detection limit estimates for radioanalytical procedures are determined by a mathematical formula that takes into account sample volume, chemical recovery, instrument detection efficiency and background, and sample counting duration. Refer to SOP 708 for calculations. *Note: for purposes of detection limit estimates, minimum detectable activity (MDA) and minimum detectable concentration (MDC) are the same.*

Record the calculated value and the reported value. The calculated result should match the reported result within 3% (the tolerance is due to rounding of the reported data which is not rounded in the actual calculations). If there is disagreement, notify the Department Manager and do not use the software until the problem has been resolved and this procedure has been satisfactorily completed.

The calculations shall be performed monthly and documented. If changes are made to the software or problems are detected, then manual calculation verification shall be performed as needed.

5.2 LIQUID SCINTILLATION COUNTER

5.2.1 ANALYSIS SOFTWARE

From the hardcopy report generated by the liquid scintillation counter, obtain and record the sample CPM and blank CPM.

5.2.2 REPORTING SOFTWARE

Prepare a tritium analysis report using the sample data obtained above. Calculate the final sample activity following the calculations in SOP 704. Record the result. The calculated result should match the reported result within 3% (the allowance is due to rounding corrections). If there is disagreement, notify the Department Manager. Do not use the software until the problem has been resolved and this procedure has been satisfactorily completed.

The calculations shall be performed monthly and documented. If changes are made to the software or problems are detected, then manual calculation verification shall be performed as needed.

5.3 GAMMA SPECTROMETRY SYSTEM

Calculations for gamma spec are performed by vendor-supplied proprietary software, specifically Seeker® gamma spectroscopy software. These calculations shall be verified ***annually*** following the calculations outlined in SOP 713. The manual calculation results should match the reported results within 3%. If there is disagreement, notify the Department Manager. Do not use the software until the problem has been resolved and this procedure has been satisfactorily completed.

In addition, the total propagated uncertainty calculation is performed during data reduction. This calculation shall be verified and documented monthly or following any changes. The calculation for TPU can be found in SOP 743.

5.4 ALPHA SPECTROMETRY SYSTEM

Obtain the raw data sheet and spectrum for a sample. Manually verify the chemical yield, sample activity, uncertainty, MDA, DER, and LCS radiometric recovery. Use calculations found in SOPs 714 and 743. Record the results. The calculated results should match the reported result within 3%. The tolerance is due to rounding of the coefficients listed on the report header. If there is disagreement, notify the Department Manager. Do not use the software until the problem has been resolved and this procedure has been satisfactorily completed.

The calculations shall be performed monthly and documented. If changes are made to the software or problems are detected, then manual calculation verification shall be performed as needed.

STANDARD OPERATING PROCEDURE 711 REVISION 7

TITLE: **PREPARATION OF WATER AND SOLID SAMPLES FOR THE ANALYSIS OF POLONIUM-210 -- EML PROCEDURE Po-01**

FORMS: **302**

APPROVED BY:
TECHNICAL MANAGER _____ DATE 9/10/06
QUALITY ASSURANCE MANAGER _____ DATE 9/8/06
LABORATORY MANAGER _____ DATE 9/10/06

HISTORY: Rev0, 3/6/93; Rev1, PCN #147, 3/1/94; Rev2, 10/6/99; Rev3, 3/27/00; Rev4, 4/26/02; Rev5, 3/28/03; Rev6, 11/29/04; Rev7, 9/11/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedures used to prepare solid and water samples for the analysis of ^{210}Po using EML Procedure Po-01.

2. SUMMARY

Polonium is spontaneously deposited on a nickel disk from a 1N HCl solution. Soil samples are leached with 1N HCl. As soil samples have constituents that may interfere with the Po deposition, a smaller aliquot size for soils is recommended. Waters with high organic content must be evaporated to dryness and wet-ashed with HNO_3 prior to conversion to chloride form. The deposition is specific for Polonium and, therefore, requires no other pre-concentration or separation steps. The recovery in the procedure is monitored with a ^{209}Po tracer. Both tracer and ^{210}Po are counted by alpha spectrometry.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review or precision and accuracy tests.

3.2 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating file information indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample

preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 The presence of excessive precipitate in the final source will lead to degradation of spectral quality due to self-absorption effects.

4.2 The levels of activity taken for analysis should be minimized to prevent contamination of the detection system and overwhelming the tracer. Aliquot size should be judged according to expected activities for the samples (per pre-screening data) and should generally be less than 50pCi.

4.3 The 1N HCl solution used for nickel plating makes the deposition process specific for Polonium. Weaker acid solutions allow deposition of Bismuth and other nuclides, which can be an interference in the analysis.

4.4 The use of nitric acid-preserved samples can be problematic for this method as the mixture of nitric acid with hydrochloric acid forms dilute aqua regia which will attack the disk and can lead to very low plating yields.

4.5 The presence of significant peak activity in the spectrum other than that expected is significant cause for concern. Re-preparation or appropriate sample cleanup may be indicated. Consult a senior analyst or the Radiochemistry Manager for advice in such cases.

5. APPARATUS AND MATERIALS

5.1 steam bath (settings vary with equipment and duration)

5.2 glass hooks and support assembly

5.3 nickel disks, 3/4" diameter with 3mm hole near the edge. Clean by washing in Radiacwash™, followed by DI water. Prior to use, dip disk in conc. HNO_3, followed by conc. HCl for a few seconds, then rinse with DI water. Dip using the glass hook and avoid touching the disk once dipped.

5.4 beakers, 400mL, 600mL, and 1.5L or 2L

5.5 polypropylene cups, 100mL, 250mL

5.6 Infrared (IR) Thermometer, Raynger ST #267249, or equivalent

5.7 hot/stir plates

5.8 graduated cylinders, plastic or glass, 25mL, 100mL, 1000mL

5.9 tongue depressors

5.10 planchets, 1" diameter, stainless steel, cupped

5.11 forceps

5.12 filter paper, qualitative, fluted, Whatman 41™, or equivalent,

5.13 double-sided tape

5.14 pipet, Eppendorf™ or equivalent

5.15 balance, analytical, capable of weighing to 0.0001g

5.16 metal wire, bent into a loop

5.17 pipets, transfer, disposable

5.18 stir bars

5.19 pH paper, capable of testing at pH<2

6. STANDARDS AND REAGENTS

All chemicals and reagents must be reagent grade or better. Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

6.1 Hydrochloric acid (HCl), conc. TLV = 5ppm (ceiling)

6.2 HCL, 1M: Add 83mL conc. HCL to 917mL DI water. See 6.1 for TLV.

6.3 Ascorbic acid

6.4 Nitric acid, conc. TLV = 2ppm

6.5 Amyl acetate

6.6 Thin film solution: Add 1:1 ratio of Amyl acetate and Collodion together. Mix well. Prepare fresh weekly.

6.7 ^{209}Po tracer solution, approximately 20dpm/mL

6.8 ^{210}Po standard solution, approximately 20dpm/mL

6.9 Wash bottle, containing DI water

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Although the client is responsible for conducting the sampling process, it is emphasized that water samples be collected in a manner that addresses the considerations discussed in EPA 900.0 Section Three or Chapter Nine of EPA

SW-846, as appropriate.

7.2 Although the client is responsible for conducting water sampling for compliance purposes, it is recommended that samples be **preserved at the time of collection by adding enough 1N HCl to the sample to bring it to pH 2** (15mL 1N HCl per liter of sample is usually sufficient). If water samples are collected without preservation, they should be brought to the laboratory within 5 days and then preserved and held in the original container for a minimum of ~~14~~ 24 hrs before analysis or transfer of the sample.

7.3 The container should be plastic rather than glass to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 PROCEDURE FOR WATERS

8.1.1 Check that the samples are preserved to pH <2 with HCl and fill out the sample condition form (Form 302).

8.1.2 Using a graduated cylinder, measure 1000mL of the sample into a labeled 1.5 or 2 L beaker. Filter suspended solids, if present, using qualitative filter paper.

8.1.3 Add 50mL conc. HCl.

8.1.4 Add ^{209}Po tracer solution with a calibrated mechanical pipet. Typical activity is 20dpm, or as directed by the primary instrument operator.

8.1.5 Evaporate on a hot plate to near dryness. Transfer to a 250mL polypropylene cup and dry completely.

8.1.6 If the sample was preserved in HNO_3, add 10mL of conc. HCl and dry completely to convert to a HCl system. If the sample was preserved with HCl, proceed directly to following Step.

8.1.7 Redissolve the residue in 100mL of 1N HCl. Heat in a steam bath to aid in dissolution.

8.1.8 Add about 100mg ascorbic acid (estimate on a tongue depressor tip). Swirl to dissolve the ascorbic acid.

8.1.9 Proceed to Section 8.3, nickel deposition.

8.2 PROCEDURE FOR SOILS AND SOLIDS

8.2.1 Weigh out 0.5g of sample in a 250mL polypropylene cup and add appropriate tracers and spiking solution.

8.2.2 Add 25mL of 1N HCl to each sample and place samples in the steam bath using a 100mL polypropylene cup as a lid. Heat the samples for a minimum of four hours, preferably overnight.

8.2.3 After leaching, take the samples from the steam bath and rinse the lids with 1N HCl and allow them to cool.

8.2.4 Using Whatman 41™ filter paper or equivalent, filter samples into a clean, labeled polypropylene cup. Rinse the cup and filter paper with 1N HCl. Bring to 100mL with 1N HCl.

8.2.5 Add ~100mg of ascorbic acid (estimate on tip of tongue depressor), then proceed to Section 8.3, nickel deposition.

8.3 NICKEL DEPOSITION

8.3.1 Clean nickel disk by washing in Radiacwash™. Rinse with DI water. Prior to use, dip disk in conc. HNO_3 followed by conc. HCl for a few seconds, then rinse with DI water. Dip using the glass hook and avoid touching the disk once dipped.

8.3.2 Equilibrate a water bath to ~55°C by placing DI water in a 600mL beaker and placing the beaker on a stirring hot plate to heat.

8.3.3 Put a small, clean (see SOP 720) stir-bar in each sample cup. Place the sample cups in the prepared water bath and allow 10-20 minutes for the temperature to re-stabilize.

8.3.4 Suspend a cleaned nickel disk in each solution using a glass hook.

8.3.5 Note the decay date and time on the benchsheet.

8.3.6 Maintain the water bath at ~55° C and mechanically stir for 4 hours.

8.3.7 After 4 hours, remove the disks and rinse with DI water. Allow disks to air dry. Be careful to hang the disks in the same order as the beakers to avoid confusing their identifications.

8.3.8 Label the back of a 1" stainless steel planchet for each disk with ^{210}Po, the sample ID and batch number. Apply a small piece of double-sided tape to the center of the front of each planchet.

8.3.9 Using forceps, remove each disk from its glass hook and center the planchet on the tape.

8.3.10 Add approximately 250mL of DI water to a 400mL beaker.

8.3.11 Place a metal wire loop into the DI water, making sure the entire loop is covered by the DI water. Bend the arm of the wire loop over the beaker to hold the loop in place.

8.3.12 Place 1 drop of the Thin film solution into the beaker. Allow 30 seconds for the thin film to cure, then remove and allow to dry.

8.3.13 Once dry, place thin film over the planchet.

8.3.14 Repeat Steps 8.3.10 through 8.3.13 above until all samples have thin films placed over them.

8.3.15 Arrange the planchets in a petri dish and label the petri dish with the analyte, sample ID's and batch number. Submit the prepared samples and the updated benchsheet to the Counting Lab. Mark the status sheet "C" for prep complete. The Counting Lab will analyze and ultimately dispose of the planchet and disk in the manner described in SOP 714.

9. CALCULATIONS

9.1 TPU FACTORS. As defined in SOP 743, the following 1 σ preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty:

9.1.1 Water samples require a preparation uncertainty factor of 0.0615. This is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one tracer addition, and one quantitative transfer. See the following equation:

$$0.0615 = \sqrt{0.05^2 + 0.006^2 + 0.025^2 + 0.025^2}$$

9.1.2 Solid samples require a preparation uncertainty factor of 0.0613. This is based on one gross aliquoting (sample homogeneity), one mass measurement, one tracer addition, and one quantitative transfer. See the following equation:

$$0.0613 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2}$$

9.1.3 In practice, these values are substantially equivalent. For simplification in reporting, the first factor of 0.0615 may be used for both matrices.

10. QUALITY ASSURANCE

10.1 A blank and laboratory control sample (blank spike, LCS) is run for each batch. Both are run at a 5% minimum frequency. Each is taken through the entire procedure as specified for the matrix.

10.2 The LCS (blank spike) is spiked with 5-10dpm of ^{210}Po standard solution using a calibrated pipet.

10.3 DI water is used as the matrix for all blanks and blank spikes. Use the same volume as specified for the sample matrix.

10.4 Sample duplicates are run at a 10% minimum frequency. If enough sample is not provided to do duplicates, an LCS duplicate is prepped and analyzed.

11. DEVIATIONS FROM METHOD

This is a Paragon proprietary method. Therefore, there are no deviations from promulgated methods.

12. SAFETY HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.1.3 Gloves, safety glasses and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals. Use care when handling strong acids (e.g. HNO_3, HCl, etc.).

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.3 below.

12.1.5 All non-original containers used to hold reagents (e.g. wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.6 Care should be taken when diluting acids. Unless the method explicitly directs you to do otherwise, **always add acids to water**, not water to acids.

12.2 WASTE DISPOSAL

12.2.1 The analytical process liquid effluent has been determined to not be hazardous in other than corrosivity. This material may be discharged into the Paragon wastewater treatment facility. Here the solution will be neutralized prior to discharge and the activity will be monitored to ensure compliance with Colorado Rules and Regulations pertaining to

Radiation Control Part 4 regarding discharges to sanitary discharges to sanitary sewers.

12.2.2 Solids and filtered residues should be air-dried in a beaker in the fume hood. Solid radchem waste is to be placed in the Radioactive waste/Contact waste bucket in the Actinides Lab.

TITLE: **DETERMINATION OF TOTAL ALPHA-EMITTING RADIUM ISOTOPES IN DRINKING WATER -- EPA METHOD 903.0 AND SW9315**

FORMS: **302, 313, 631**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/4/07

LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, 12/09/92; Rev1, PCN # 160, 3/0/9/94; Rev2, PCN # 233, 6/02/94; Rev3, PCN # 398, 2/25/95; Rev4, 3/15/96; Rev5, 7/17/97; Rev6, 2/14/00; Rev7, 10/12/00; Rev8, 3/01/01; Rev9, 9/24/01; Rev10, 3/02/02; Rev11, 12/04/02; Rev12, 9/22/03; Rev13, 2/27/06; Rev14, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- EPA Method 903.0 and SW-846 Method 9315 -- are applicable to the measurement of total soluble alpha emitting radioisotopes of radium -- namely radium-223, radium-224 and radium-226 -- in drinking water and other environmental waters. It is primarily a screening method for radium-226.

2. SUMMARY

The radium in the drinking water sample is collected by co-precipitation with barium and lead sulfate, and purified by co-precipitation from EDTA solution. Citric acid is added to the drinking water sample to ensure that complete interchange occurs before the first precipitation step. The final $BaSO_4$ precipitate which includes radium-226, radium-224 and radium-223, is alpha counted, per SOP 724, to determine the total disintegration rate of the radium isotopes. The radiometric results are corrected for chemical yield on a sample-by-sample basis using the results of inductively coupled plasma atomic emission spectrometry (ICP-AES) determination of Ba recovery.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 This test will show high bias for radium-226 in the sample results if other alpha emitting isotopes of radium are present in the sample (especially Ra-224 and Ra-223). Reanalysis of the sample following a decay period equal to five half lives of the interfering isotope will provide a more accurate measurement of the Radium-226 concentration of the sample. In cases where radium-224 activity is likely, a decay period of 18 days is appropriate. Where radium-223 is suspected, 57 days is appropriate.

4.2 The presence in the sample matrix of significant natural barium or large quantities of sediment and particulates in the sample may cause interference by elevating the planchet residual mass. The mass on the planchet must be within the efficiency calibration range. Otherwise corrective action, usually re-preparation with a reduced aliquot, must be taken. The matrix interference and corrective actions taken should be clearly documented in a QASS (Form 302), approved by the Department Manger, and disclosed in the case narrative.

4.3 Yield corrections are calculated by ICP measurement of the pre- and post-separation concentrations of barium in the sample. If high barium concentrations are known to be present in the sample matrix, reduced aliquots may be taken without addition of barium to the sample.

4.4 In certain cases it may be advantageous to generate chemical yield data from samples spiked with Ba-133 tracer. The concentration of the tracer is determined by gamma spectroscopy and used in lieu of the chemical yield determined by ICP.

4.5 The presence of sediment or particulate matter in the sample is not accounted for by this method. Failure to remove insoluble particulates from the sample could cause a high bias in activity results, due to alpha emitting radionuclides. Samples

containing significant amounts of sediment will be filtered prior to analysis.

4.6 In cases where "dissolved" analysis of radium is requested, the sample must be filtered in the field and immediately preserved by addition of nitric acid to pH < 2, prior to shipment.

Where the samples have not been filtered and preserved in the field, a non-conformance report (NCR, Form 313) is generated by the analyst and the client is immediately notified. With the client's approval, sediments are removed by filtration, and the sample is subsequently preserved by addition of nitric acid to pH < 2. In this case, the resulting potential low bias in the final analytical results are noted on the NCR and in the case narrative.

4.7 Where drinking water protocols are required by the client, samples will not be filtered prior to analysis. Samples will be run as received through Step 8.1.14 and filtered into a clean centrifuge tube. Proceed directly to Steps 8.1.16 and 8.1.17, then repeat Step 8.1.14 and continue with the procedure.

4.8 Where filtration has been performed, a note must be made on the benchsheet and a narrative comment must inform the client that the sample was filtered and that the final result does not include undissolved particulates that may have been present in the sample.

5. APPARATUS AND MATERIALS

5.1 Counting planchets, stainless steel, 2" diameter

NOTE: Although it is common practice to clean planchets used in the laboratory, cleaning the planchets is not conducive to obtaining an even distribution utilizing this method. Therefore, the planchets used for this method only will be used as received from the manufacturer. Method blank results for each batch will be used to monitor the efficacy of this practice.

5.2 Stir bars, magnetic

5.3 Hot plate, electric, stirring

5.4 Aspiration apparatus

5.5 centrifuge tubes, polypropylene, 50mL

5.6 Analytical balance

5.7 Graduated cylinder, 1L

5.8 Beakers, 1500 or 2000mL

5.9 Hot water bath, 90-100 °C

5.10 Vortex mixer

5.11 Watch glasses

5.12 Cups, Polypropylene, 250mL and 100mL

5.13 Permanently labeled glass beakers, 100mL, or equivalent

5.14 Filter paper, Whatman® #42 (90 mm), or similar

5.15 Parafilm™

5.16 Test tubes, 15mL, disposable, with caps

5.17 Spatulas, plastic

6. REAGENTS

NOTE: TLV and other hazard information may also be given here. As stated in section 12.1.3 of this SOP, any chemical with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Glacial Acetic Acid (CH_3COOH_2), 17.4N, conc.: 99.8 percent, ACS reagent grade. TLV = 10ppm (TWA). Irritant.

6.2 Ammonium Sulfate, 200mg/mL: Dissolve 200g reagent grade $(NH_4)_2SO_4$ in a minimum of water and dilute to 1L.

6.3 Barium carrier, 16mg/mL (approximately 28mg/mL $BaSO_4$ yield, standardized)

6.3.1 Place a 1000mL Class A volumetric flask on a stir plate, add a stir bar and ~500mL of DI water.

6.3.2 Add 28.46g $BaCl_2 \cdot 2H_2O$ and stir until completely dissolved.

6.3.3 Then add 5mL 16N HNO_3.

6.3.4 Remove stir bar, rinsing with DI water, and dilute to 1000mL with DI water.

6.3.5 Transfer to a clean, labeled 1L poly container.

6.3.6 Document the preparation of this carrier in the Reagent Prep Logbook.

6.3.7 Standardization of Ba carrier by ICP analysis

Prepare in triplicate a 1000-fold dilution of the Ba carrier using the ICP solution described in Section 6.14 below. Submit to the metals lab for analysis. Average the results and record in the Reagent Prep Logbook.

TLV = 0.5 mg Ba/m^3 = 0.06ppm (TWA). Irritant.

6.4 Citric acid, 1M: Dissolve 210g reagent grade $C_6H_8O_7 \cdot H_2O$ in water and dilute to 1L.

6.5 Deionized (DI) water, ASTM Type II or better.

6.6 EDTA reagent, basic, 0.25M: Dissolve 20g reagent grade NaOH in 750mL water, heat and slowly add 93g disodium ethylenedinitriloacetate dihydrate ($Na_2C_{10}H_{14}O_8N_2 \cdot 2H_2O$). Heat and stir until dissolved.

6.7 Hydrofluoric acid (HF), 48.0-51.0 %, conc.
TLV = 3ppm (ceiling). Irritant, burns, bone, teeth, fluorosis.

6.8 Lead carrier, 15mg/mL: Dissolve 24g reagent grade $Pb(NO_3)_2$ in water. Add 5mL 16N HNO_3 and dilute to 1L with water.
TLV = 0.05mg/m^3 (= 0.004ppm) as elemental Pb.

6.9 Sodium hydroxide, 6N: Dissolve 240g reagent grade NaOH in 800mL water and dilute to 1L.
TLV of NaOH = 2 mg/m^3 (= 1.22 ppm) (ceiling). Irritant.

6.10 Sulfuric acid, 18N: Cautiously mix one volume reagent grade 36N H_2SO_4 (conc.) with one volume of water.
TLV = 1 mg/m^3 (= 0.25ppm) (TWA). Irritant. Note- A face shield and rubber apron must be worn while handling concentrated sulfuric acid.

6.11 Sulfuric acid, 0.1N: Mix one volume 18N H_2SO_4 with 179 volumes of water.
TLV = 1 mg/m^3 (= 0.25ppm) (TWA). Irritant.

6.12 Non-Ionic Surfactant. Triton X-100® or equivalent.

6.13 Diluted surfactant solution: Dilute 1 drop of non-ionic surfactant in 100mL DI water. Mix thoroughly.

6.14 ICP Diluting Solution, 5% HNO_3 / 2.5% HCl: Carefully add 50mL of concentrated HNO_3 and 25mL of concentrated HCl to 925 mL of DI water. Mix thoroughly.

TLV = 2ppm for conc. HNO_3 (TWA), and 5ppm for conc. HCl (ceiling). Both irritant, corrosive.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 LIQUID SAMPLES

7.1.1 A representative sample must be collected from a free-flowing source of water and sufficient volume be collected so that adequate aliquots may be taken in order to meet the required Minimum Detectable Activity (MDA).

7.1.2 It is recommended that samples be preserved at the time of collection by adding enough 1N HNO_3 to effect a pH of 2 (15mL 1N HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days, then preserved and held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.1.3 The sample should be collected in a plastic container.

7.1.4 A regulatory holding time has not been specified by the EPA.

7.2 SOLID SAMPLES

Preservation is not required. A representative sample of 25-50 grams should be submitted for analysis.

8. PROCEDURE

8.1 PREPARATION OF AQUEOUS SAMPLES

NOTE: See Sections 4.2, 4.5, 4.6, and 4.8 regarding dissolved and suspended solids prior to aliquoting samples.

8.1.1 Verify and record (on Form 631) the pH of the sample according to SOP 733.

8.1.2 Using a graduated cylinder, aliquot the sample into a labeled 1.5L or 2L beaker. A sample aliquot of 1L is typical for this method, but may need to be reduced due to matrix interference. All samples should be brought to a final volume of 1L. Add a stir bar to each beaker and place on a stirring hot plate.

8.1.3 Prepare quality control (QC) samples according to Section 10.

8.1.4 How to take initial ICP aliquot:

8.1.4.1 Prior to adding any reagents, spikes, or carriers to the sample, use a calibrated pipette to remove 1mL of sample and place into a clean test tube filled with 9mL of ICP diluting solution and labeled with the sample ID and “i”, to indicate the initial ICP aliquot. Cover with a test tube cap and invert tube several times to mix thoroughly. Set aside until final ICP aliquot has been taken.

8.1.4.2 A “reference carrier” (RC) must be prepared by adding 1mL Ba carrier to 1L of DI water. Mix thoroughly, remove 1mL of solution and dilute to 10mL as stated above for samples. Submit with samples for ICP analysis to provide a reference

concentration for the yield calculations.

8.1.5 To each sample add 1 to 2 drops non-ionic surfactant, 5mL 1M citric acid, 1mL lead carrier, 1.0 mL barium carrier, and spiking solution per Section 10. Use a Class A pipette or calibrated micropipet to deliver the Barium carrier and spiking solution.

8.1.6 Stir and heat to boiling.

8.1.7 Slowly add 25mL 18N H_2SO_4.

8.1.8 Boil for ten minutes. Remove from heat and retrieve stir bar, rinsing with 0.1N H_2SO_4.

8.1.9 Cover and let stand overnight.

8.1.10 Aspirate the supernatant. The supernatant can be disposed of down the laboratory sink. Refer to Section 12.2.1 of this SOP. Transfer the precipitate to a centrifuge tube, rinsing the beaker with 0.1N H_2SO_4.

8.1.11 Centrifuge at 3500 RPM for 12 - 15 minutes. Discard the supernatant into the laboratory sink and flush with plenty of cold tap water.

8.1.12 Wash the precipitate with 15mL 0.1N H_2SO_4. Centrifuge as above and discard wash into the laboratory sink.

8.1.13 Dissolve the precipitate by adding 25mL basic EDTA reagent. Heat in a hot water bath. Additional basic EDTA can be added in 5mL increments until the precipitate dissolves completely. If necessary, add 6N NaOH dropwise until dissolution is complete.

8.1.14 Once the samples are completely dissolved, remove the tubes from the steam bath and allow the samples to cool.

8.1.15 How to take final ICP aliquot:

8.1.15.1 Vortex the sample to mix thoroughly. Using a calibrated pipette, aliquot 0.1mL of sample into a clean, labeled test tube containing 9.9 or 10mL of DI water (record the volume of water used). Cover with Parafilm™, and invert several times to mix completely. With a calibrated pipette, aliquot 1.0mL of the diluted sample into another clean test tube labeled with the sample ID and "f" and containing 9.0mL of ICP diluting solution. Cover with a test tube cap and mix well. Submit the initial and final test tubes to the metals lab with proper bench sheets for analysis.

8.1.15.2 Upon the return of ICP sample fractions to the radiochemistry lab, and after satisfactory review of the chemical yield data including LIMS validation of the benchsheet, the ICP fractions may be discharged into the PA waste water treatment facility (i.e., down the laboratory sink with plenty of cold tap water). The test tubes may be soaked in a Radiacwash™ solution, rinsed with tap water and discarded into the sanitary trash. The tubes containing the intermediate, DI water diluted, sample may be disposed of in the same manner.

8.1.16 To the remaining sample in the centrifuge tube, add 1 mL ammonium sulfate solution per 50mL of EDTA solution and mix thoroughly by vortexing. Add glacial acetic acid dropwise until precipitation begins. Then add an additional 2mL of glacial acetic acid. **Note the time and date of this precipitation on the benchsheet.** Mix with a vortex mixer or equivalent. Heat in the hot water bath ten minutes.

NOTE: The pH of the precipitation (4-4.5) is absolutely crucial to the success of the separation between lead and barium/ radium. Over-acidification of the solution will cause lead to coprecipitate with barium/radium and may lead to a high planchet mass.

8.1.17 Centrifuge and discard the supernatant into the Pb/Ba waste container.

8.1.18 Wash the precipitate with 15mL water and centrifuge. Discard the wash into the laboratory sink, followed by plenty of cold tap water. Refer to Section 12.2.2 of this SOP.

8.1.19 Label and weigh stainless steel flat-bottomed planchets. Record the weight on the benchsheet. Place planchets on a hot plate.

8.1.20 To transfer the sample to the planchet, add ~4mL of DI water to the centrifuge tubes and vortex until all of the precipitate is suspended. Working quickly to avoid precipitate settling, remove cap, rinse once with DI water, and pour into the planchet. Rinse the centrifuge tube with DI water and add to the planchet. Sample should be evenly distributed on the planchet.

8.1.21 Used centrifuge tubes may be soaked in Radiacwash, rinsed in tap water, then discarded in the sanitary trash.

8.1.22 Dry on a hot plate set at 2 or 3.

8.1.23 It is essential that the (Ba, Ra)SO_4 be evenly distributed on the planchet. Sometimes the sample will separate when it is near dryness.

To correct this, approximately 1mL of diluted surfactant solution is applied to the planchet using a transfer pipet. Carefully swirl the planchet to distribute the precipitate. Repeat as necessary, adding as little of the surfactant solution as possible, as it may add mass to the planchet.

8.1.24 Cool to ambient temperature.

8.1.25 Weigh to the nearest ± 0.1mg on an analytical balance. Record weight on the benchsheet for the calculation of the total weight of the solids on the planchet in mg.

8.1.26 Transfer the planchets to the desiccator in the instrument lab, with the appropriate benchsheets. The planchets will be analyzed and ultimately disposed of as described in SOP 724.

8.2 PREPARATION OF SOLID SAMPLES

8.2.1 Verify and record (on Form 631) the condition of the sample.

8.2.2 Weigh 1 gram of dried, pulverized soil into a permanently labeled 100 mL glass beaker. Typical aliquot size is 1.0 g but may be adjusted due to MDA or matrix interference considerations. Record the sample weight and beaker number on the benchsheet.

8.2.3 Prepare QC samples according to Section 10.

8.2.4 To each sample add 1.0mL barium carrier. Add the appropriate spiking solution amount to any samples that require it, per Section 10. Use a Class A pipette or calibrated micropipet to deliver the barium carrier.

A “reference carrier” must be prepared by adding 1.0 mL Ba carrier to 1L of DI water. A 1mL aliquot is removed from the RC for ICP analysis, as stated in Section 8.1.4.2.

8.2.5 Dry the uncovered beakers on a hotplate set at 2 (samples must be completely dry prior to muffling). Cover the beakers with a watch glass and muffle at 600°C for at least 4 hours.

8.2.6 Transfer the sample to a 250mL polypropylene cup, using at least 20mL conc. HNO_3 to rinse the beaker. Scraping with a plastic spatula may be necessary to remove all of the soil from the beaker.

8.2.7 Add 20mL HF, cover with a 100mL polypropylene cup, and heat for 4 hours on a steam bath.

8.2.8 Remove the 100mL cup and evaporate to dryness. The 100mL cups

may be rinsed off with tap water and discarded into the sanitary trash.

8.2.9 Add 10mL 8N HNO_3 to the samples while they are on the steam bath to facilitate the dissolution.

8.2.10 Transfer the solution to a 1L graduated cylinder, rinsing the polypropylene cup with DI water.

8.2.11 Bring the sample to a volume of 1L with DI water.

8.2.12 Transfer the sample to a labeled 1.5 or 2L beaker, add a stir bar, place on a stirring hotplate, and proceed to Step 8.1.4, without adding barium carrier in Step 8.1.5.

8.3 PREPARATION AND ANALYSIS OF CALIBRATION STANDARDS

8.3.1 Preparation of Efficiency Calibration Standards

8.3.1.1 Spike five 1 liter DI water samples with approximately 1 mL Ba carrier and 2,000 to 5,000 dpm NIST-traceable Ra 226 standard per sample. Follow the same procedure for the preparation of aqueous samples (see Section 8.1).

8.3.1.2 Ingrowth-corrected efficiency calibrations for Total Alpha-Emitting Radium isotopes are performed per SOP 724, with the modifications described below.

8.3.1.3 Ingrowth-corrected efficiency planchets should be relinquished to the instrument lab as soon as possible after separation since the first count of the planchets will be used to extrapolate the base of the efficiency curve as stated in Section 8.3.1.4.2.

8.3.1.4 Newly prepared calibration planchets may be counted repeatedly to obtain total efficiency determinations at various stages of ingrowth.

8.3.1.4.1 Assume that the total efficiency has two distinct components: 1) the base Ra-226 efficiency, that is always used at its full value, and 2) the aggregate efficiency of the three ingrown alpha emitting daughter products, which is used in proportion to the degree of ingrowth.

8.3.1.4.2 By adjusting the estimated base efficiency for Ra-226, the residual efficiency for each calibration count is calculated as the arithmetic difference between the observed total efficiency

and the estimated base efficiency. Theoretically, if the estimated base efficiency is correct, the residual (progeny) efficiency will be the same for all stages of ingrowth. In practice, enter the raw count data into a spreadsheet and allow the Excel "Solver" utility to set the base efficiency such that the variance in the individual residual efficiencies over the ingrowth period is minimized.

8.3.1.4.3 The calculated total efficiency is determined as the base Ra-226 efficiency plus the Ra progeny efficiency, ingrowth corrected. Per Paragon's Laboratory Quality Assurance Plan (LQAP), the calculated total efficiency values are acceptable if they are within 10% of the actual efficiency values observed during the calibration counts.

8.3.2 Preparation of Mass Attenuation Calibration Standards

8.3.2.1 Supply the instrument lab with a series of planchets containing a range of $BaSO_4$ mass from ~10 mg to ~125 mg, including a duplicate for each specified mass. To accomplish this, prepare 14 samples using DI water and spike with approximately 2,000 to 5,000 dpm of Ra-226 standard per sample. Add the proper amount of Ba carrier to each sample to obtain the desired mass on the planchet. The target masses are: 10 mg, 20 mg, 40 mg, 60 mg, 80 mg, 100 mg, and 125 mg. Proceed with the standard aqueous sample preparation method (Section 8.1). Submit planchets to the instrument lab immediately upon completion.

NOTE: Prior to preparing calibration standards, be sure to coordinate with the instrument lab to ensure that detector or time issues can be resolved.

8.3.2.2 Mass attenuation calibrations for Total Alpha-Emitting Radium isotopes are performed using the calibration planchets, prepared as described above, with final masses of barium sulfate ranging from approximately 10mg to 125mg. Every planchet is counted in every detector and the data are composited to create a single yield corrected mass attenuation correction curve.

8.3.2.3 The data is fitted in the traditional method, with the equation taking the form bm^x, where x is the residual mass of the

sample planchet, in mg. This equation would normally provide a mass correction to a zero-mass efficiency calibration. Total radium efficiency calibrations, however, are performed with planchets that have approximately 30mg $BaSO_4$ residual mass. Consequently, the final mass attenuation correction will take the form bm^{x-x°, where x° is the average residual mass of the efficiency calibration planchets.

9. CALCULATIONS

9.1 Calculate the actual volume, V_A, of sample analyzed for samples (accounting for volumes of sample removed) as follows:

$$V_A = V * \frac{V_i - icp_i}{V_i} * \frac{V_f - icp_f}{V_f}$$

where:

V = sample aliquot (L, g)

V_i = sample final dilution volume (mL)

icp_i = initial aliquot taken for ICP (mL)

V_f = sample volume in EDTA (mL)

icp_f = final aliquot taken for ICP (mL)

9.2 Calculate the barium chemical recovery for aqueous samples, Y, as a percentage, as follows:

$$Y_i = V_i * ICP_i * DF$$

$$Y_f = V_f * ICP_f * DF$$

$$Y_{RC} = V_{RC} * ICP_{RC} * DF$$

$$Y = \frac{Y_f}{Y_i + Y_{RC}} * 100\%$$

where:

Y_i = barium recovery from initial ICP aliquot (µg)

ICP_i = initial barium concentration measured by ICP (µg/mL)

DF = dilution factor

Y_f = barium recovery from final ICP aliquot (µg)

ICP_f = final barium concentration measured by ICP (µg/mL)

Y_{RC} = barium recovery from RC aliquot (µg)

V_{RC} = RC final volume (mL)

ICP_{RC} = RC barium concentration measured by ICP (µg/mL)

NOTE: The barium chemical recovery calculations for solid samples are the same as those for aqueous samples, except that Y_i is compared to Y_{RC} to determine which to use in calculating the barium yield, since barium carrier was added prior to taking the initial ICP aliquot. If $Y_i > Y_{RC}$, Y_i is used in the calculation in place of $(Y_i + Y_{RC})$. If $Y_i < Y_{RC}$, Y_{RC} is used in the calculation in place of $(Y_i + Y_{RC})$ and a "low bias" flag is noted on the benchsheet.

9.3 TPU FACTORS

As defined in SOP 708, the following one-sigma (1σ) preparation uncertainty factors should be applied during the final reporting stage of analysis, as a component of the Total Propagated Uncertainty (TPU):

9.3.1 Aqueous Samples require a (1σ) preparation uncertainty factor of 0.107. This is based on one gross aliquot, one volumetric measurement, one ICP determination, one spike/carrier addition, two quantitative transfers, one pipetting and two reagent additions:

$$0.107 = \sqrt{0.05^2 + 0.006^2 + 0.083^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.004^2 + 0.006^2 + 0.006^2}$$

9.3.2 Solid Samples require a (1σ) preparation uncertainty factor of 0.112. This is based on one gross aliquot, one mass measurement, one spike/carrier addition, one volumetric measurement, one ICP determination, one pipetting and two reagent additions, and four quantitative transfers.

$$0.112 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.006^2 + 0.083^2 + 0.004^2 + 0.006^2 + 0.006^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2}$$

In practice, these two preparation uncertainty factors are substantially equivalent. To simplify the data reporting procedure, the greater of the two (0.112) may be used for both matrices.

10. QUALITY CONTROL

Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.1 A blank, prepared with one liter of DI water, acidified to a pH of less than 2 with concentrated nitric acid, for aqueous samples, and a Whatman™ filter paper for solid samples, must be analyzed with each batch of 20 or fewer field samples (i.e.,

at a five percent frequency).

10.2 One blank spike (LCS), prepared with one liter of DI water, acidified to a pH of less than 2 with concentrated nitric acid, for aqueous samples, and a Whatman™ filter paper for solid samples, must be analyzed with each batch of 20 or fewer field samples (i.e., at a 5 percent frequency). The spiking level for LCSs should be at least 4-10 times the requested MDA, or 100 dpm, whichever is larger. The source used to spike the LCS should be a second independent source from the source used for calibration (*required* for DOD samples per LIMS program specification).

10.3 Duplicate sample analyses will be performed at a minimum frequency of ten percent. If there is insufficient sample volume for this frequency of duplicates, LCS duplicates may serve as a measure of batch reproducibility.

11. DEVIATIONS FROM METHOD

11.1 This SOP meets the requirements of and is substantively equivalent to EPA Method 903.0. In addition to describing a procedure for aqueous samples, this SOP describes a procedure for determining total alpha emitting radium in soil, which the laboratory employs at a client's request. Also, this SOP provides procedure for determining the chemical yield by ICP as an addition to EPA Method 903.0. This measurement increases the accuracy of the method.

11.2 In order to completely dissolve the precipitate, 25mL of basic EDTA reagent is added rather than 15 mL stated in EPA Method 903.0 (see Section 8.1.13 of this SOP).

11.3 Only 1.0 mL of barium carrier, instead of 2.0mL, is added to aqueous samples. The lesser amount of carrier facilitates dissolution of the precipitate in EDTA. Since Ba yield is determined by ICP, this amount is more than sufficient for (Ba, Ra)SO_4 precipitation and Ba chemical recovery measurement.

11.4 Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ± 20%, irrespective of the lab's internally derived acceptance criteria.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

12.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals. A face shield and a rubber apron are required when handling

concentrated sulfuric acid.

12.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

12.1.4 Any non original containers be used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.2 WASTE DISPOSAL

12.2.1 The total radium process effluent has been determined to not be hazardous except by corrosivity. This material may be discharged into the laboratory wastewater treatment facility.

12.2.2 The total radium analytical process effluent has been determined to not be hazardous in other than corrosivity, except the Pb containing supernatant. This supernatant must be segregated into the Pb waste container supplied by waste management staff.

12.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

8/31/07: Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Section 7.1. Removed activity calculations from Section 9 and referenced SOP 708 instead. Added comment Section 10 that acceptance limits for quality control parameters may vary per client specifications, consult applicable LIMS program specification. Added use of independent second source for LCS spiking (Section 10.2). Added DOCUMENT REVISION HISTORY and Forms.

STANDARD OPERATING PROCEDURE 713 REVISION 10

TITLE: ANALYSIS OF GAMMA EMITTING RADIONUCLIDES BY GAMMA SPECTROSCOPY -- METHOD EPA 901.1

FORMS: 754 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER Renee Kellogg DATE 7/21/08

QUALITY ASSURANCE MANAGER Deb Schenk DATE 7/20/08

LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: Rev0, 6/1/92; Rev1, 7/27/93; Rev2, 10/15/93; Rev3, 4/26/96; Rev4, 5/16/96; Rev5, 3/20/00; Rev6, 6/15/01; Rev7, 8/24/02; Rev8, 4/7/03; Rev9, 4/10/06; Rev10, 7/20/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary to perform gamma emissions analysis of samples of various media using high purity germanium (HPGe) high-resolution intrinsic gamma spectrometry. This procedure is applicable to all gamma spectrometry analyses performed at Paragon. The procedures outlined in this SOP are based on EPA Method 901.1 and DOE/EML Procedure 4.5.2.3.

2. SUMMARY

Gamma emissions from radionuclides are detected by a semiconductor germanium crystal, which provides a small electronic pulse for each gamma interaction where the pulse height is proportional to the gamma incident energy. This electronic data is converted to digital data by an analog to digital converter (ADC) and stored in a multichannel buffer (MCB). The data collected by the MCB is subsequently interpreted by a complex software program, generating results in units of radioactivity per unit sample volume. The gamma spectroscopy analysis software program that Paragon uses is Seeker®, Version 2.2, a product of Vertechs Software Solution, Inc.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of a proficiency test sample.

3.2 Upon receipt of a new or repaired detector, it is the responsibility of the technician to follow the steps outlined in Appendix D, 'General Gamma Detector Operations', prior to data acquisition.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Manager or designee. Initialing and dating the processed data indicates that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

The physical shape of the source and its proximity to the detector is critical to the efficiency calibration. These factors define the "counting geometry". The calibration geometry and the sample geometry must match within ±0.5cm of the line on the sample container.

5. APPARATUS AND MATERIALS

This procedure is conducted with the use of installed gamma detection and analysis equipment consisting of multiple intrinsic germanium gamma spectrometers mounted in lead shields for the reduction of ambient background radiation, a personal computer analysis system with multichannel analyzer interfaces, three NIM-bin based multichannel buffers, gamma analysis software, and associated nuclear electronics and cabling.

6. REAGENTS

No reagents are used by this procedure. The operator should be aware, however, that water samples are preserved to pH <2 with Nitric Acid (HNO_3).

7. PROCEDURE

7.1 OPERATING CONDITIONS

The gamma spectrometry systems shall be operated with detector bias as specified by the detector manufacturer and amplifier and MCB settings as required to obtain a nominal 0.5keV/channel energy calibration across a range of approximately 40 to 2000keV. The operating conditions shall be verified daily by performance of the daily quality control checks (described in Section 8 below).

7.2 SPECTRUM ACQUISITION

7.2.1 The detector must be calibrated for the geometry of the sample to be analyzed. Efficiency calibration procedures are defined in Section 8 below. A list of current geometries, calibration date and the dates the calibrations expire, as well as standards used for calibration is posted in the instrument lab. This list is maintained by instrument lab personnel

and is exempt from 'Operator Aid' policies, as it is an integral part of gamma operations and is updated on an on-going basis.

Samples shall be placed directly on the detector, inside the lead shield, and in a manner that is level and centered over the detector, unless noted otherwise on a Quality Assurance Summary Sheet (QASS) or other supporting documentation.

7.2.2 After samples have been loaded on the detectors, select the desired detector in the Spectral Display Control menu. Next, select the 'TOOLS' icon, which will then prompt for the ID and the desired live time or count time.

Enter the sample ID as it appears on the sample benchsheet, followed by a space, and then the batch ID (e.g., 0011222-3 GSyymmdd-n). After the ID has been entered, select the 'ID SET' icon to save the sample ID.

Enter the desired count time in seconds in the box labeled 'LIVE TIME' and then select the 'PRE SET' icon to save the count time. Sample count times depend on the sample volume, geometry, and the client's required minimum detectable concentration (MDC). An outline of the geometries and their respective matrix and/or volume can be found in Appendix C of this SOP. LCS samples are typically counted for 1800 seconds (30 minutes) and blank samples will be counted for as long as the longest sample count time.

7.2.3 After the sample ID and count time have been entered and saved, clear the previous spectrum by selecting the 'ERASE' icon.

7.2.4 Begin spectrum acquisition by selecting the 'GO' icon and exit the 'TOOLS' window by selecting 'DONE'.

7.2.5 Enter all samples that are analyzed in the gamma spectroscopy logbook (Form 754). Use the current page with the date that the sample is counted. *Ensure that the detectors being used have passed the Daily QC checks (see Section 8 below).* Necessary information recorded in the gamma spectroscopy logbook includes:

- Paragon sample ID
- detector number
- geometry, including sample orientation and the use of a positioning (puck), if appropriate
- duration of the count
- count start time

- operator's initials
- spectrum file name
- position verification check

7.3 SPECTRUM ANALYSIS

Upon completion of the sample count, the data must be transferred to the workspace and analyzed, using the procedures described below:

7.3.1 Select the appropriate detector, then select the appropriate analysis/application type, based on the sample geometry, from the Application Select menu. Next select 'Read MCA' on the menu bar. By "reading the MCA", the data acquired during the analysis count is transferred to the workspace and default settings and files from the application are applied (i.e., efficiency, library, units, etc.).

When 'Read MCA' is selected, the analysis parameters screen is displayed. At this time the file name is automatically generated. Record this file name in the gamma spectroscopy run log (Form 754).

The analyst will need to verify, enter, or edit the following sample parameters:

Sample ID: This should be automatically transferred in the format described above, but corrections can be made here.

Spec. Code: This field is left blank.

Sample Size: Enter the volume, weight, or number of filters as appropriate.

Units: This will be transferred automatically as a default, but can be changed as needed.

Sampling Start and Stop: This is normally the same date and time for both the start and stop. Enter the collection date of the sample in both boxes. The time of day is generally 12:00:00 for all samples.

Efficiency File: This line should be generated automatically by the computer and is in the form:

$$(D_{xx})(S_{GG}).EFF$$

where:

xx is the detector number

GG is the geometry of the sample.

If changing the efficiency file, make sure the detector of the efficiency file is for the detector the sample was counted on and that the efficiency file has not expired.

After all the parameters and values are satisfactory, select 'OK' to exit the 'Read MCA' window. By selecting 'OK', all of the parameters and values are saved under the file ID and can be retrieved later to further analyze. By selecting 'CANCEL', all of the parameters are lost and the file ID is not saved.

7.3.2 Next, the spectrum must be analyzed to identify peaks at the various energies. To do this, select 'PEAK SEARCH' on the menu bar and the software will apply the resolution calibration to the acquired spectrum to define peaks and peak height. This will prompt the next window, which allows the analyst to see all of the peaks identified, and the counts acquired for each peak.

The analyst shall review the peak search results to identify peak shifts, multiplets, etc. After the peak search results are considered to be satisfactory, select 'DONE' to exit the peak search results window.

7.3.3 To calculate activity concentrations, select the 'CALCULATE' icon under 'ACTIVITY' on the menu tool bar. This will prompt an activity report parameters window. Then perform the following:

Select the desired library to be used in the column labeled 'LIBRARY FILE'. Next select the background file to be used according to the detector and the count date. Background files are named so that the first two numbers correlate to the detector, the next two correlate to the month the background was counted, and the next two correlate to the day of the month. *Background files can be used for one week after counting (i.e. sample counts must be started before the day and time that the background calibrations were completed on the previous week.)*

The LSF File should remain as 'NONE'.

The 'RESULTS FILE' and the 'PRINTOUT FILE' should be the same as the .SPC file, except ending in .RES and .TXT, respectively.

Select 'OK' after the correct library and background have been selected and the Library Search Results window will be shown. This allows the analyst to review peaks that have been matched to specific peaks in the library.

To **finish the calculations**, select 'OK' to prompt the raw data printout. This window allows the analyst to review all of the parameters used in the analysis.

To **save the data**, select the 'SAVE' icon, which calls up the "SAVE" window. For general analyses the fields are automatically populated. The default values (yynnnnD##.RES) are accepted, except where multiple analyses of a spectrum are performed, as described below.

Select "SAVE" again to store the results in the defined .RES file.

Print the raw data by selecting the 'PRINTER' icon.

In some cases, reanalysis of the same spectrum may be required to apply different geometry calibrations or analytical libraries. To perform multiple analyses on the same spectrum, select "SPECTRUM" on the menu bar, then select "EDIT" and return to step 7.3.1, beginning with the "Efficiency File" specification, with the following exception:

> Multiple analyses of a single spectrum require a unique identifier appended to the default file name (yynnnnD##**A**.RES, yynnnnD##**B**.RES, etc.). The unique file name must be defined prior to saving the .RES file, to **prevent overwriting previous files**.

8. QUALITY ASSURANCE/QUALITY CONTROL (QA/QC)

Standards for Daily QC Checks need not be traceable to the National Institute for Standards and Technology (NIST). All Daily QC monitoring shall be recorded in the gamma spectroscopy run log (Form 754). **QC parameters must meet the established limits defined in the instrument software.**

8.1 QC MONITORING

8.1.1 DAILY QC ENERGY CALIBRATION CHECKS

A daily QC check involves performing an energy calibration, as well as monitoring the detector resolution (FWHM) and efficiency. Each detector has a labeled calibration standard. Center the appropriate calibration standard on the corresponding detector. Count each daily check standard as described in the procedure above for 20 minutes using the sample ID "Daily Check".

When the count is complete, select 'DAILY CHECK' under the Application Select menu, then select 'Read MCA' to prompt the edit parameters screen. Select 'OK', as the parameters should be the default.

On the menu bar select 'PEAK SEARCH' as described above, then select 'Q.C.', then 'DETECTOR'. The calibration parameters screen is then prompted. Make sure that the 'ENERGY' bullet is selected.

Select 'OK', choose 'MERGE PSR', then select 'CURVE FIT', then select 'SAVE'. This will save the energy calibration for that day. The program then compares the results of the energy recalibration to the Q.C. parameters (found in the Q.C. editor) established for the specified detector.

8.1.2 CORRECTIVE ACTION FOR DAILY QC FAILURES

If a detector is not within established control limits for any of the bounds tests, corrective action must be taken. The first course of action is to re-run the QC check. If the observed parameter is still outside normal acceptance criteria after the second analysis, the procedure is as follows:

- If one of the centroid exceeds the bounds test (e.g., 662keV), the peak location should be adjusted. This is done by placing a calibration source on the detector (preferably a Laboratory Control Sample, LCS) and starting the detector.

  Clear the current spectrum by typing 'F4' (Clear). The acquisition can then be started by typing 'F2'.

  Move the cursor to the appropriate centroid (e.g., 662keV) and check the actual location. The peak can be moved by adjusting the fine gain, located on the amplifier. *Note that it only requires a minute adjustment (one click) to move the peak three to five keV.* After the peak has been moved to the correct location, re-run the energy calibration.

- If the failure includes one of the other parameters (e.g., FWHM or efficiency), the daily QC can be re-run. If the QC fails for a second time, the detector is taken off-line and the lab Supervisor is contacted.

  NOTE: A pole-zero adjustment can be conducted in the case of a FWHM failure, using the following procedure:

  First, **attach a co-axial cable** from the "1 Meg" port associated with the vertical input on the oscilloscope to the "uni" output on the amplifier.

Next, **set the scope settings** as follows:

Volts/Div(Vertical) = 0.1

Polarity = DC

Trigger Selector = EXT(-)

Mode = DC

Triggering Level = 0

Stability = Preset

Time/Div = 20μs

Variable = Calibrated

Next, **place a source on the detector** and **adjust the signal** so that it is as close to the baseline as possible by using the 'PZ ADJ' dial found on the amplifier.

The energy calibration can now be run again. If any parameter still fails, tag the detector out of service (SOP 317) and notify the lab Supervisor.

All calibration operations must be recorded in the run log, including fine gain adjustments, bounds re-calculations with start and end dates, and calibration re-runs.

8.2 EFFICIENCY CALIBRATION PROCEDURES

Standards for efficiency calibrations shall be traceable to the National Institute for Standards and Technology (NIST). Standards will normally be of the mixed-gamma, multiple-energy type available from several commercial suppliers. The analysis systems shall be calibrated for each physical form of sample to be analyzed (e.g., water, soil, filter, etc.) at least annually. A FWHM calibration shall also be performed at least annually. Note that there is only one FWHM calibration per detector, and it is not geometry specific. Before starting an efficiency calibration, consult with a Senior Instrument Technician. Record all efficiency calibrations in the gamma spectroscopy run log (Form 754).

8.2.1 SPECTRUM ACQUISITION

Place the calibration source for the appropriate geometry on the detector to be calibrated. The efficiency calibration will be initiated like that of a sample count. First, an internal workorder number must be obtained from the current non-client workorder notebook (located in the radium/strontium lab). Use this workorder number and follow the same procedure used to count a sample. Be sure to enter the appropriate dates and time for the calibration standard (2 hours and/or a

duration long enough to acquire 10,000 cts/per energy line that will be used in the calibration). For calibrations where 10,000 cts/per energy line cannot be acquired, Supervisory approval is required.

8.2.2 SPECTRUM ANALYSIS

8.2.2.1 After the acquisition is complete, the MCA of the sample spectrum should be read. In the edit parameters screen, enter the standard calibration origin date, and the appropriate volume/sample size. Select 'PEAK SEARCH', then 'CALIBRATE'. The types of calibrations prompted are: Energy, FWHM and Efficiency. Make sure that the 'EFFICIENCY' bullet is selected. The calibration parameters screen is prompted, at which time the operator must choose the appropriate calibration standard, aliquot size and the appropriate fit formula for the efficiency curve (exponential fit is used in most cases).

Select 'OK' to prompt the calibration workspace. Transfer the peak search results by selecting 'MERGE PSR', then 'CURVE FIT'. View the results of the calibration.

The % difference for the measured efficiency should be less than +/- 5% for all nuclides, but may be up to 10% with specific written approval from the instrument lab Supervisor. If the measured difference exceeds this criterion, the calibration will have to be redone. If efficiency limits are met, select 'OK', then 'SAVE', and then print the calibration.

This calibration should be done annually or when maintenance has been conducted on the detector.

8.2.2.2 If the observed efficiencies need to be adjusted to optimize the fit of the calibration curve, this may be done with the approval of the lab Supervisor. *Do not adjust the Cs-137 efficiency.* If the other efficiencies need to be adjusted, manually calculate the new efficiency, by either increasing or decreasing by a known percentage (usually 5 to 10%).

DO NOT MANUALLY ADJUST EFFICIENCIES WITHOUT FIRST CONFERRING WITH A SENIOR INSTRUMENT TECHNICIAN.

After adjusting a peak, re-start the calibration process (choose the print to screen option until the efficiencies have been accurately adjusted). Manual adjustments are

conducted in the calibration work space.

In all cases, manual adjustments of peak efficiencies will be noted on the calibration output page.

8.2.2.3 After the calibration has been stored, analyze an LCS with the appropriate geometry for 1800 seconds to verify the calibration. This analysis must pass normal LCS acceptance criteria.

8.3 WEEKLY BACKGROUND CALIBRATION

8.3.1 A background calibration is performed weekly. Use the general form, "yymmdd-## Weekly Bkgd", for the sample ID.

8.3.2 Make sure there is no sample in the detector shield. Consult the gamma spec maintenance logbook to see if the detectors have been cleaned within the past month, if not, the detectors need to be cleaned per Section 8.3.5 below.

8.3.3 Start the counts for 1000 minutes (60000 seconds) for each detector in service. Geometry and aliquot are irrelevant.

8.3.4 Record detectors that have been started in the logbook. After the counts are complete, "Read the MCA" and do a 'PEAK SEARCH' as described above. At this point, review the acquired spectral data for evidence of peak-fit errors and/or gain shift. If the spectral quality is acceptable upon review of the 'PEAK SEARCH' results, save the background calibration by selecting 'SAVE AS BKGSUB'. Save each background file as DET##MMDD.BKG, where '##' is the detector number and 'MM' and 'DD' are the month and day the background was started. Then select 'BACKGROUND' under 'QC' on the menu bar. Select 'OK' to analyze the background and see if the count is within control limits. Record any failures in the run log, clean the detector (see 8.3.5 below), and restart the background calibrations.

8.3.5 WEEKLY CALIBRATION FAILURES

The inside of the detector must be thoroughly cleaned with a paper towel dampened with Radiacwash®, or an equivalent EDTA solution. Then wipe the detector with a paper towel dampened with DI water. Record the cleaning date in the gamma spec maintenance logbook.

After this has been done, the background calibration can be run again. If the detector fails after cleaning, the lab Supervisor must be notified and the detector must be tagged out of service (SOP 317) until the problem is resolved.

8.4 QC SAMPLES

One LCS and blank, per geometry, are to be analyzed with every batch of not more than 20 samples.

9. INTERPRETATION OF DATA

The spectrum analysis capabilities of the analytical software are only as good as the software set up. It is essential that appropriate analysis geometries, efficiency files, and library files be used to ensure accurate analyses. Results data must be reviewed as soon as it becomes available to ensure that the calibrations are correct, that the spectral quality is adequate, and that all Q.C. acceptance criteria have been met.

All unknown peaks greater than 5 times the listed critical level must be qualitatively identified in the case narrative. The spectrum must also be reviewed to ensure that characteristic peaks, such as K-40 at 1460keV, and the annihilation peak at 511keV, do not show evidence of a gain shift. A gain shift may show up as a secondary peak slightly offset from all the normal characteristic peaks in the spectrum. A spectrum that shows evidence of a gain shift must be rejected and the sample re-counted. The detector showing the gain shift must have the fine gain on the amplifier adjusted as described previously in Step 8.1.2.

10. PERIODIC MAINTENANCE

Each detector has a Dewar filled with liquid nitrogen to keep the germanium detector cold. Twice per week, the detector Dewars must be filled with liquid nitrogen. Allow 15 minutes after filling before resuming data acquisition.

If a Dewar runs out of liquid nitrogen between fillings, the red bias display, located on the 'BIAS SUPPLY' control board, will be shutdown. If this occurs, tag the detector out of service, and do not operate the detector until the Dewar can be re-filled. The detector may need to be cycled through ambient room temperature before being re-cooled. The lab Supervisor must be notified before proceeding.

To fill the Dewar, follow the steps below:

- After the nitrogen lines have been attached to the 'LIQUID' output of the new tank, flip the 'SOLENOID CONTROL' switches to the 'ON' position. This switch is located on the 'AUTO FILL EXPANSION CONTROL' board. Then depress the red 'MANUAL' fill button on the 'AUTO FILL CONTROLLER'.
- Once the Dewars have been filled, the red LED read-out on the 'AUTO FILL CONTROLLER' should read "168.0", which indicates the number of hours until the next fill should be done.
- If a tank has not been completely filled, an alarm will sound. To silence the alarm, depress the 'ALARM RESET' button on the 'AUTO FILL CONTROLLER'. Once the alarm is shut off, check the 'AUTO FILL EXPANSION CONTROL' board to see which detector LED lights are on

(note that the 'SOLENOID CONTROL' switch will still be in the 'ON' position if a Dewar has not been completely filled).

- To re-fill a partially filled Dewar, depress the two red 'ERROR RESET' buttons on the 'AUTO FILL EXPANSION CONTROL' board and then depress the 'MANUAL' fill button.

- Each detector is equipped with an overflow line. If this line appears to be bleeding an excessive amount of liquid nitrogen, the 'SOLENOID CONTROL' switch should be turned to the 'OFF' position.

- Record all liquid nitrogen fills and re-fills in the gamma LN2 fill logbook.

11. DEVIATIONS FROM THE METHODS

Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of the lab's internally derived acceptance criteria.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Normal laboratory safety procedures (gloves, safety glasses, and lab coats, where necessary) must be complied with during the conduct of this procedure.

12.1.2 Bias applied to detectors is typically in the range of 1000 to 4000 volts DC. This can result in electric shock if bias cables are disconnected while bias is applied. To minimize the possibility of electric shock, bias shall be turned off to any detector before any cabling is disconnected.

12.1.3 The liquid nitrogen used to fill the Dewars is at -196°C. Exposure to the skin can cause severe frostbite. Use insulated gloves when handling frozen lines, valves, etc.

12.1.4 Large liquid nitrogen spills can displace room oxygen and cause asphyxiation. In case of a large liquid nitrogen spill, open the lab doors and allow the liquid nitrogen to dissipate before re-entering the lab.

12.2 WASTE DISPOSAL

12.2.1 The gamma spec instrument technician is responsible for returning the samples to the sample custodian or to the sample storage area after analysis, completing the internal chain of custody (SOP 318).

12.2.2 Some samples will be returned to the client after analysis. Samples or sample wastes containing radioactive materials, which are not being returned to the client, must be disposed of according to Paragon's

procedures for disposal of radioactive materials. Contact the Waste Disposal Coordinator for more information.

DOCUMENT REVISION HISTORY

4/10/06: Made procedural clarifications involving operation of the Seeker® software. Added LIMS Program Specification directive to 'Responsibilities' Section. Added DOCUMENT REVISION HISTORY.

7/20/08: (4/9/07) Minor clerical changes. Added reference in RESPONSIBILITIES to Appendix D and added Appendix D - General Gamma Detector Operations. (6/9/08) Added comment about ingrowth requirement for geometry 17 samples to Appendix B. (7/20/08) Added Operator's Aid exemption text to 7.2.1.

APPENDIX A
COMMON GAMMA ENERGIES AND CHANNEL LOCATIONS

This Section is provided to assist in determining proper channel locations during calibrations and QC checks.

NUCLIDE	ENERGY (keV)	TARGET CHANNEL
Am-241	59.54	120
Cd-109	88.04	176
Co-57	122.06	244
Cs-137	661.65	1324
Y-88	898.04	1796
Co-60	1173.22	2346
Co-60	1332.49	2664
Y-88	1836.06	3672

NOTE: Paragon uses a 2.0keV matching tolerance for nuclide/energy matching; this will allow up to a 4 channel deviation from target channels. In addition, the daily QC checks perform energy versus channel calibrations each time they are run, correcting for small changes in peak channel locations.

APPENDIX B
GEOMETRY/EFFICIENCY LIST

Geometry Number	Geometry Description	Default Count Time (min.)	Efficiency file/Standard file number
01	1 liter H_2O in 2 liter Marinelli	300	01
07	47mm Filter	60	07
08	Five 10 cm filters	1000	08
09	Hi-Q charcoal cartridge	60	09
13	500g Solid	30	13
11	100g Solid	30	11
*17	215g Solid	30	17
18	1350g Solid	120	18
*26	215g Solid (Ra-226)	30	26
27	1332g Solid (Ra-226)	120	27

* Unless otherwise directed, samples packed for Geo17/26 will be ingrown 21 days before analysis to allow Rn222 to approach equilibrium with its progeny.

APPENDIX C

SUMMARY OF INTERNAL QUALITY CONTROL (QC) PROCEDURES AND CORRECTIVE ACTION

QC Check	Frequency	Acceptance Criteria	Corrective Action
Efficiency Check	Daily	Within derived control limits, as established in instrument software.	Recount, re-evaluate, service instrument, if necessary or document why condition is acceptable.
Peak Resolution Check	Daily	Within derived control limits, as established in instrument software.	Recount, re-evaluate, perform pole-zero adjustment, if necessary, and repeat daily performance checks.
Energy Calibration	Daily	Within derived control limits, as established in instrument software.	Recount, re-evaluate, perform fine gain adjustment, if necessary, and repeat daily performance checks.
Peak Background Calibration	Weekly	Within derived control limits, as established in instrument software.	Clean detector, recount, re-evaluate, or document why condition is acceptable.
Efficiency Calibration	Yearly, for each counting geometry.	Each fitted value is within 5% of the observed value. Subsequent LCSs pass within normal acceptance criteria. *	Tag geometry off-line. Determine and correct problem; verify source activity; recount and/or recalibrate. With supervisors written approval, fitted values may be within 10% of observed value.
Peak Resolution (FWHM) Calibration	Yearly	Each fitted value is within 10% of the observed value. Subsequent LCSs pass within normal acceptance criteria. *	Perform pole-zero adjustment, if necessary, and repeat.
Gain shift	Each sample	Review each spectrum to ensure that characteristic peaks @ 511, 1460 KeV are present, not shifted during the count, and properly ID'd by software.	Recount sample after daily performance checks are successfully performed.

NOTE: This SOP and SOP 715 contain acceptance criteria and corrective action for method blank, laboratory control samples, duplicate samples and matrix spike/matrix spike duplicates.

* as established in the applicable LIMS nickname (e.g., Paragon Standard or as created for a specific client

APPENDIX D

GENERAL GAMMA DETECTOR INTALLATION NOTES

Upon receipt of a new or repaired detector the following steps must be taken prior to data acquisition.

1) Inspect the detector for damage during transit.
2) Review accompanying documentation to ensue the following;
    a. Quality Assurance Data Sheet. This documents the detector performance after repair/manufacture.
    b. Spectrum Printout: Supplements the QADS.
    c. Repair Analysis Report (if detector was repaired). This documents the problems identified with the detector and any corrective action/repairs that were undertaken.
3) Cool the detector.

NOTE: The detector must be cooled overnight before applying bias. Do not connect the detector cabling until the assembly has cooled in LN overnight.

a. Inspect the nitrogen dewar to be used, if necessary.

    Note: In all cases, the dewar should not be placed directly on the floor. Insert some vibration absorbing material between the dewar and the floor to minimize microphonic noise (low frequency harmonics) in the detector.

b. Fill the dewar with LN, to within 3-4” of the top of the neck. Do not allow the LN to overflow or to contact the latex collar, though the collar will be cold after filling.
c. Allow the collar to warm for 20-30 minutes to allow enough flexibility to insert the detector cryostat.
d. At this step it is helpful to have a second technician waiting underneath the shield to receive the detector cables and to adjust the position of the dewar, as necessary.
e. Feed the long grey pre-amp cable through the top of the opening in the shield.
f. Carefully insert the cryostat through the shield, into the LN dewar. After inserting the cryostat partway, feed the detector leads through the opening. It may be necessary to move the dewar slightly to one side to accomplish this.
g. After all the cables are clear of the shield and collar, center the dewar and insert the cryostat completely into the LN.
h. The initial cooling of the detector may use a significant volume of LN. After the detector has cooled for 2-3 hours, top off the LN, filling the dewar until the LN spills out of the overflow port.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 714 REVISION 11

TITLE: **ANALYSIS OF ALPHA EMITTING RADIONUCLIDES BY ALPHA SPECTROMETRY**

FORM: **746, 302** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/31/07

QUALITY ASSURANCE MANAGER _____ DATE 8/31/07

LABORATORY MANAGER _____ DATE 8-31-07

HISTORY: Rev0, 9/18/91; Rev1, 7/27/93; Rev 2, 10/21/93; Rev3, 5/20/96; Rev4, 4/7/98; Rev5, 10/24/99; Rev6, 10/18/01; Rev7, 1/4/02; Rev8, 1/2/03; Rev9, 6/18/04; Rev10, 9/11/06; Rev11, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary to perform spectroscopic analysis of alpha emissions on samples of various media using high-resolution ion implanted silicon alpha spectrometry. This procedure is applicable to all alpha spectrometry analyses performed at Paragon. The target analytes are routinely separated from liquids (primarily aqueous) and solid samples (primarily soils, wastes, filters) following equilibration of the sample with a suitable isotopic tracer, and mounted by micro-precipitation onto 25mm, 0.1 micron (µm) pore sized filters, fixed into 31mm stainless steel planchets. Analyte activity is derived from the relative count rates of analyte and tracer isotopes and the known activity of tracer added. When no suitable nuclide is available for use as an isotopic tracer (e.g., ^{237}Np), splits of each sample are prepared following addition of a known quantity of NIST-traceable tracer solution of the target analyte. The chemical yield data generated from split sample analysis is used for the calculation of sample results.

2. SUMMARY

Alpha emissions from radionuclides are detected by an ion-implanted semiconducting silicon wafer, which transfers the energy deposited into a small electronic pulse for each alpha interaction, where the pulse height is proportional to the incident alpha energy. The 600mm^2 ion implanted silicon detectors are mounted in vacuum chambers and operated at or below 500 milliTorr absolute pressure to minimize loss of alpha particle energy during the path from the sample to the detector. The data collection and processing is performed through the AlphaVision32©, v5.3 software package.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. The Alpha Spectroscopist is responsible for day-to-day operations, calibrations, troubleshooting, repair of the instrument, and related details

3.2 It the analyst's responsibility to ensure that the activity of the calibration sources are properly verified at least annually by comparison to an independent source. In addition, it is the analyst's responsibility to ensure that the independent source has been verified by a NIST-traceable laboratory within a year of use. In practice this means that the independent source can be sent off-site for re-verification at an interval of just less than two years.

3.3 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715.

3.4 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.5 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.6 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the report components and review checklists indicate that reviews for precision, accuracy, completeness, and reasonableness are complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.7 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager or designee.

4. INTERFERENCES

4.1 The presence of excessive precipitate in the final source will lead to degradation of spectrum quality due to self-absorption effects. Excessive tailing, poor peak separation or visible evidence of unusual amounts of solids on the final source may necessitate cleanup of the sample (by dissolving LaF_3–analyte precipitate in boric/nitric acid, co-precipitating as a ferric hydroxide, dissolving $FeOH_3$ in HCl and repeating the microprecipitation steps. Additional column separation may be necessary to remove various interfering constituents).

4.2 The levels of activity taken for analysis should be minimized to prevent contamination of the detection system and overwhelming the tracer. Aliquot size should be judged according to expected activities for the samples (refer to pre-screening data available in the work order folder) and should generally be held within the range of less than 30-50pCi.

4.3 For the alpha spectrometry system, a sample with elevated activity is defined as one that has more than 200 total disintegrations per minute (DPM) deposited on the planchet. This includes all requested analytes of interest as well as the tracer analyte. When such a sample is encountered, the Preparation Lab and Instrument Lab Supervisors must be notified so that they can investigate the possibility of equipment contamination. At the instrument, a background check of the detector used to count the sample must be performed before any subsequent samples may be counted by that detector. This is performed to ensure that detector contamination did not occur, which could bias subsequent analyses on that detector. Generally, a 1000-minute background calibration is run in order to fulfill the background check requirement. If the new background calibration passes quality control criteria, this calibration replaces the previous weekly background calibration until the next weekly background calibration is performed. If the new background calibration fails to meet quality control criteria, consult the Department Supervisor for corrective action. Please refer to Section 11 of this SOP for background quality control criteria.

4.4 The Paragon default minimum detectable concentration (MDC) formula referenced in this SOP 708 conservatively assume that background count times equal or exceed sample count times. If extended count times are necessary to meet data quality objectives (DQOs), it is advisable that dedicated background counts be conducted immediately prior to the count to both ensure that count time parity is achieved, and to minimize the potential effect of detector contamination.

4.5 The presence of significant peak activity in a spectrum other than that expected (e.g., thorium peaks in a plutonium spectrum) is significant cause for concern. Re-preparation or appropriate sample cleanup may be indicated. Consult with the Department Manager for advice in such cases.

4.6 Detectors are segregated into U/Th/Np only and Am/Cm/Pu/Np/Po only due to the progeny resulting from U/Th samples. The U/Th progeny will cause an interference in Am/Cm/Pu measurements.

4.7 In some cases, the addition of normal tracer analytes will cause interference in other analytical regions of interest (ROIs). For example, ^{229}Th activity generally "tails" into the ^{230}Th ROI, and ^{243}Am may have measurable ^{241}Am activity present. These potential interferences must be accounted for in the analytical procedure.

4.8 In some cases, two requested analytes may be indistinguishable by alpha

spectrometry (e.g. ^{233}U and ^{234}U). In these cases, the combined ROI is reported as a single result for both analytes (e.g. $^{233/234}$U).

5. APPARATUS, MATERIALS AND REAGENTS

This procedure is conducted with the use of installed alpha detection and analysis equipment consisting of ion implanted silicon detectors mounted in combination vacuum chambers/spectrometers. These spectrometers are controlled by a personal computer based analysis system with multi-channel analyzer interface, integral multi-channel analyzers (MCAs), alpha analysis software, and associated cabling. Currently, the analysis software used to analyze samples is AlphaVision32©, Version 5.3, by EG&G Ortec Corporation. The alpha detectors used to count samples are Ortec "U-024-600-AS" 600mm^2 ULTRA_AS ion-implanted detectors, or equivalent. In addition, the following materials are used for routine maintenance of the detectors.

5.1 KimWipe™ lint-free wipes

5.2 cotton balls

5.3 Methanol, reagent grade
TLV=200ppm

5.4 canned (pressurized) air

6. SAMPLE HANDLING

6.1 All samples received by the radiochemistry Instrument Lab must be checked in within one business day, using the LIMS internal chain of custody (SOP 318).

6.2 Generally, samples with long count times (greater than 360 minutes) are loaded at the end of the day. Samples with shorter count times (less than 360 minutes) may be loaded throughout the day, as time allows

6.3 Generally, samples are prioritized for counting based on the client requested due date.

6.4 Polonium is generally volatile under the vacuum conditions used in this analysis. Samples for polonium analysis are sealed with a thin film covering to prevent detector contamination. The planchets should be carefully handled on the outside of the planchet, with a gloved hand rather than forceps, to prevent puncturing of the thin film.

6.5 In some cases, short-lived analytes or interfering progeny may require samples to be analyzed as quickly as possible. For example, ^{227}Th has an 18.72 day half-life and significant delays in counting will result in elevated detection limits. Also, the ^{232}U- progeny, ^{228}Th ingrows with a half-life of 1.9 years and significant delays in counting will result in ^{228}Th interference in the ^{232}U ROI.

6.6 Uranium and thorium analyses, particularly those in high activity samples, should be removed from the detector as soon as possible after the completion of the count to prevent recoil and progeny contamination of the detector.

6.7 Standard verifications and proficiency demonstrations should be analyzed and processed within 48 hours of receipt from the prep lab due to the pressing production needs of the Department.

6.8 Planchets will be stored in the Instrument Lab for a minimum of three months prior to disposal to allow for reanalysis if necessary.

7. PROCEDURES

Instructions are given for the AlphaVision32© program, Version 5.3. Throughout the text of this document, < > defines a computer keystroke, ___ defines a window header, and [ ] defines a menu option on the AlphaVision software. Basic technician-level access to AlphaVision can be obtained through the user name "user" and the password "user". See the Department Manager for administrator- and supervisory-level access.

7.1 OPERATING CONDITIONS

The alpha spectrometers are operated in a low vacuum system, less than 500milliTorr absolute pressure, at detector bias voltages of typically 30-50 volts DC. The operating conditions shall be verified weekly by running energy/efficiency and background calibrations on each detector. See Section 11 for quality control procedures.

7.2 SAMPLE PREPARATION

Samples are prepared by radiochemical separation applicable to the radionuclide(s) being evaluated. Samples are prepared in the Actinides Preparation laboratories using chemical separation and deposition processes (refer to the radiochemistry preparations procedural SOPs for specific information). The samples are received in the Instrument Lab in the form of a filter mounted on a labeled planchet or as in the case of ^{210}Po, as an electroplated disk to be counted.

7.3 DATA ACQUISITION AND ANALYSIS

7.3.1 Each alpha spec detector is separately contained in a metal housing with an o-ring sealed door hinged at the bottom of the housing. Forceps are used to handle planchets. Planchets are loaded into detectors that are calibrated and have passed all QC checks. Planchets for Uranium or Thorium analysis are loaded only into those detectors that are designated for U/Th. Detector numbers are recorded in the appropriate place on the benchsheet. To load the planchets into the detectors after the vacuum has been properly released from the chamber (see below): Open the door, slide out the tray, place the planchet on the tray, slide the tray back in. Make sure the filter paper on the planchet is centered under the detector. Close the door. *Note that the tray position within the chamber should always be in the position of the current calibration; currently that position is the default (top) position in the chamber.*

7.3.2 Before the analysis can be started, the detector chambers must be evacuated. There is one vacuum line connected to each tower. To evacuate a chamber, turn the knob under the door to the 'PUMP' position. However, once the knob has been turned to apply vacuum to a chamber, all other chambers that are connected to the same vacuum line will temporarily lose vacuum and bias. *If bias to chambers is lost during active counting of samples, the data quality will be compromised!*

On the AlphaVision (AV) grid displayed on the computer, certain colors are set to indicate the status of the chambers:

- **Green** indicates an idle chamber.
- **Red** indicates a detector that is offline.
- **Yellow** indicates a chamber with an active count running.

Therefore, before applying vacuum, chambers where data is being acquired must have the vacuum put on hold by turning the knob under the door to the 'HOLD' position. For example, to start a count in a detector or group of detectors with other samples counting in the same tower (and thus sharing the same vacuum manifold), the vacuum must be put on 'HOLD' for detectors containing the samples that are already counting.

Now it is safe to turn the knobs to the right to 'PUMP' to evacuate all detectors that have been loaded. It is necessary to manually check that all detectors have been properly evacuated. This is done by selecting 'MCA VIEW' by right clicking on that detector with the mouse. Once the spectrum window has opened, select [ACQUIRE] and [ADJUST CONTROLS…]. The vacuum pressure, bias voltage, and current can now be viewed. Once it has been verified that all detectors are pumped down, the detectors that have been placed on 'HOLD' can now be turned to 'PUMP'.

7.3.3 Record the Detector Number, Analytical Run, Sample ID, Analyte Type/Matrix, Count Duration, and Analyst's Initials and in the Alpha Spectroscopy Run Log (Form 746).

7.3.4 After samples have been loaded, and the counting chambers evacuated, start spectrum acquisition as follows:

7.3.4.1 From the AV menu bar select [PROCESS] then [BATCH].

7.3.4.2 Under General, enter the analytical run (i.e., UAS0608100-

2_A) and select the correct template (i.e., iso U or U default) from the drop down menu. Select, [NEXT] which will move to the next screen.

7.3.4.3 In the Batch screen, select the current month and analyte type. Select [NEXT], which will move to the sample screen.

7.3.4.4 In the Sample screen, select [ADD]. A new small screen will open. Enter sample ID of first sample of analytical run only. Select [OK] to close the small screen. Enter the correct sample units (g, L) and sample aliquot size (This may be done in whole numbers instead of entering exact aliquot volumes. In order for LIMS to perform the final calculations, it queries aliquot volumes from the benchsheet, not from the aliquot entry in AV. Therefore, rounding of aliquot sizes in AV does not impact data quality). Select [NEXT], which will move to the Acquisition screen.

7.3.4.5 In the Acquisition screen, enter the run time in minutes. Select [NEXT], which will move to the Analysis Setup screen.

7.3.4.6 In the Analysis Setup screen, select the correct nuclide library, ROI set, and Tracer set from the drop down menus. Enter the Tracer amount from the benchsheet.

7.3.4.7 Select [PREVIOUS] to return to the Sample screen. Enter the remaining sample IDs from the analytical run. Select [FINISH], which will open a screen showing all sample IDs that have been entered.

7.3.4.8 To assign detectors, select a desired detector and drag over to the appropriate sample ID. When all detectors have been assigned, select [START NOW].

7.3.5 When unloading samples, release the vacuum as slowly as possible by turning the knob counterclockwise from ‘Pump’. Turn the knob slowly the rest of the way to vent. *Air should not be heard rushing into the detector to any appreciable extent as air current stirs up particles and potentially contaminates the detector and chamber.*

7.3.6 When removing the samples from the detector chambers, verify the position by checking the sample removed from the detector against the

detector # recorded on the benchsheet. Any discrepancy should be noted on a QASS and/or the benchsheet and the raw data printout. If a discrepancy is found, the sample may need to be re-analyzed.

7.4 SPECTRUM ANALYSIS

Each nuclide emits alpha particles at distinct energies characteristic of the decaying species (see attached Table 1 for a short list of energies). When an alpha particle is incident on the detector, an electrical pulse is generated, the signal produced is analyzed according to pulse height, and is stored as a count in the appropriate channel of the given MCA buffer. As the number of counts stored increases, peaks for each radionuclide begin to form. AV is programmed to conduct an ROI analysis of the spectrum from the data gathered during the count and information that was previously entered (i.e., tracer DPM, target nuclides and relative ROIs, recovery type, etc.). The results of the analysis are then summarized in a raw data results report and a graphical hardcopy printout of the spectrum is produced. The raw data results are also written to the AV database.

7.4.1 After sample acquisition has been started, it is possible to examine the spectrum "live" to make a real-time estimate of chemical yield expected for that sample (note that sufficient time must have elapsed for the spectrum to be discernible, 10-15 minutes is usually sufficient).

7.4.1.1 This may be accomplished by selecting the detector with the mouse, right clicking and choosing [MCA VIEW]. At this point, the chemical yield can be estimated from the net area of the peak. The detector may also be manually analyzed in order to get a printout to determine preliminary chemical yields. See Section 9 for the appropriate calculation.

7.4.1.2 Alternately, select the "spectrum" line in the sample entry in the upper right window, right-click the mouse and select [INTERIM ANALYSIS]. This will perform a normal analysis, as described in Section 7.4.2 below, using the data acquired thus far. The analysis report will show calculated yields, activities, etc. as well as a printout of the interim spectrum.

7.4.2 When the preset live time has elapsed, the detector icon turns solid green to indicate that the full count duration has elapsed. The spectrum and analysis data is then reviewed prior to printing the raw data and saving the .pdf image.

7.4.2.1 In some cases the software fails to recognize the tracer peak in the spectrum and the analysis sequence is stopped

before completion. In this case, at the analyst's discretion, the analytical sequence may be manually taken to completion. Select the analytical parameters by right-clicking the mouse on the spectrum entry in the upper right window. Select [ANALYZE]. In the Analysis window, uncheck the "Shift With Tracer" box, then select [OK]. ROIs may then be evaluated, as described below.

7.4.2.2 Select the "analysis" line in the sample entry in the upper right window. This displays the spectrum and ROIs in the "Spectrum" tab. Specific analytical considerations for evaluating and adjusting ROIs are discussed below. *NOTE – due to limitations in the AlphaVision software, if ROI adjustments need to be made, first select [INTERACTIVE ROI ANALYSIS]*. Adjust ROIs as necessary. ROIs can be adjusted by dragging the ROI boundaries left and right. Finally, select [INTERACTIVE ROI ANALYSIS] again.

7.4.2.3 Select the "Report" tab at the bottom left of the report window to display the raw data report. Select the printer icon at the top left, which will call up the default PDF Factory program. Save the image under the file name designated on the LIMS Instrument Worksheet (e.g., U81925D.PDF), then print a hard copy for further review.

7.4.3 After samples have finished counting, perform a cursory review of the raw data printouts to ensure that chemical yield, duplicate error ratio(s) (DER), minimum detectable activity (MDA), tracer counts, blank activity, and laboratory control sample (LCS) values all satisfy applicable data quality objectives. Check the spectra for peak shifts and peak resolution. Verify that a raw data printout and spectrum is present for all counted samples. Determine if there are samples to be recounted or re-prepared. This will give the Preparation Group adequate time to complete a re-extraction if any of these parameters fail to pass acceptance criteria.

7.4.4 In the absence of client-specific yield requirements, a sample that has between 15-30% yield recovery may be reported in some cases. In such cases, spectral quality must be acceptable in the analyst's judgment and all other QC criteria must be met. The sample is flagged with a "Y2" flag, a narrative comment is made, and the results are reported, with Supervisory oversight.

Samples with chemical yields below 15%, those with yields below client-specific yield requirements, or those that do not meet the spectral

quality requirements listed above require corrective action. An NCR will be initiated (see SOP 928) and sample re-extraction may be necessary. Samples with low yields may still be reported when a sample is of an uncommon matrix, if re-extraction would not be expected to produce improved chemical yield, or if a second extraction of a sample shows repeated poor chemical yield (generally an indication of matrix interference). Low yield is always documented in a case narrative, and an explanation is included if the sample was not re-analyzed. Consult with the Department Manager and the Project Manager before reporting results for a sample that has shown poor yield.

7.4.5 DER values are calculated using the formula found in SOP 715. Compare blank activities to established limits and, if applicable, to client/project-specific data quality objectives. Compare LCS results to the known values for a particular radionuclide for appropriate spikes. The known values are found on the benchsheet; crosscheck this against the standard verification worksheet.

7.4.6 Sample measurements are routinely determined by internal addition of isotopic tracer to each sample prior to separation. Samples are traced with adequate activity and counted for a sufficient period of time such that counting uncertainties of approximately 5% (1 sigma) are obtained for the tracer peak (approximately 400 net tracer counts). Samples that do not achieve approximately 400 tracer counts may be counted longer or are re-prepared to achieve the target uncertainty. However, if tracer counts fall below 400 and all other QC criteria are met and assuming that the additional uncertainty is clearly reflected in the reported TPU or clearly documented in the case narrative, then the samples may be reported, with Supervisory oversight.

7.4.7 ROIs are areas that encompass spectral peaks. Default values have been set based on the expected energies defining the channels between which specific nuclide peaks are expected to fall. Occasionally, slight adjustment of the ROI by a few channels may be necessary to ensure good fit with the acquired data before a final report can be generated. To adjust the ROI, the general guidelines used consist of:

7.4.7.1 For routine Isotopic Uranium, set the boundaries for ^{238}U and ^{234}U so that they are the same distance from the centroid as they are for the tracer, ^{232}U. The ^{235}U ROI will encompass an energy range from approximately 4217keV to 4396keV. The count data for this ROI will be abundance corrected for 85.1% of the total alpha activity measured. This technique minimizes the high bias to the

^{235}U results due to tailing of the ^{234}U peak.

For Isotopic Uranium where $^{235/236}$U is requested, set the boundaries for ^{238}U and ^{234}U so that they are the same distance from the centroid as they are for the tracer, ^{232}U. The area between the right boundary of ^{238}U and the left boundary of ^{234}U represents $^{235/236}$U. The ^{238}U, $^{235/236}$U, and ^{234}U regions should be directly adjacent to each other with no space in between.

7.4.7.2 For Plutonium and Americium, when there are no peaks for the nuclides and the tracer peak resolution is good, ROIs are set to correspond to energies listed in Radioactive Decay Data Tables, David C. Kocher (reference available on Paragon network). Set the ROI for the missing nuclide between the higher and lower energies.

7.4.7.3 Samples analyzed for Isotopic Thorium concentrations have a radioactive tracer, ^{229}Th, added to allow for chemical yield determinations in the separation process. A limitation of this method is that all client and QC samples demonstrate the presence of a small amount of characteristic activity in the ^{230}Th region of interest (ROI) that is attributable to ^{229}Th activity. Peak resolution at this level is inherently limited by methodology and software capabilities.

In order to avoid a high bias to the reported ^{230}Th activity concentrations, an arithmetic correction is made to the count rate in the ^{230}Th ROI. A population of method blank samples, which is assumed to be free of ^{230}Th contamination, is analyzed and the average net contribution to the ^{230}Th ROI is used to make the arithmetic correction. The current blank population (established in April 2006) showed the ^{230}Th correction to be 2.73% of the counts acquired in the ^{229}Th ROI. This value is re-evaluated yearly.

The adjusted number of ^{230}Th background counts is, therefore, calculated as (^{230}Th ROI Calibrated Background Counts) + (0.0273 * ^{229}Th ROI Net Counts). This adjusted background count number is used in all the usual calculations for Net Activity, Counting Uncertainty, and Minimum Detectable Concentration.

This adjustment to the ^{230}Th background counts is made automatically by entering the correction value (2.73%) in the "Contaminated Tracer" box of the "Tracer Information" screen in AlphaVision. This information should only be entered under the supervision of the Department Manager.

For Thorium samples without ^{230}Th activity, set the ROI for the LCS first. This defines the shape of the peaks and gives an idea of the location and the size of the tracer peak. Note the channel for the middle of the tracer peak of the LCS. Additionally, note the channel for the lower energy end of the ROI for the tracer peak of the LCS. The difference in channel number will be used to set the ROI for samples without appreciable ^{230}Th activity. Samples with ^{230}Th activity will have enough peak resolution in order to accurately set ROI boundaries. For a sample without significant ^{230}Th activity, determine the channel number for the middle of the tracer peak, subtract the number of channels determined from the LCS, and set the lower energy ROI at the new channel.

7.4.8 The full width at half maximum (FWHM) is defined as the width of the peak distribution at a level that is half the maximum ordinate of the peak. Except for isotopic thorium analyses, in determining acceptable resolution, the tracer FWHM shall be between 40 and 100keV. Consult the Supervisor for samples that do not meet this criterion. If the deviation is minimal and all other criteria are met, results are reported with a narrative comment and supervisory approval.

7.4.8.1 Due to limitations in the AV software, the FWHM may need to be manually confirmed, if the reported value falls outside the 40–100 keV range.

7.4.8.2 Find the channel inside the peak with the greatest number of counts. Divide this number of counts by 2 to obtain the "half max" value.

7.4.8.3 Find the left-most channel of the peak that has counts less than the "half max" value. Move the cursor to the right, counting the number of channels, until the right-most channel of the peak that has counts less than the "half-max" value is selected. Multiply this number of channels by the slope of the energy calibration (nominally 10.0 kev/CH) to obtain a conservative estimate of the FWHM value, in keV.

7.4.8.4 If greater precision in the FWHM estimation is necessary, calculate the partial channels associated with either side of the spectrum by fitting a straight line between the two channels that bound the "half-max" value, and interpolating the precise point at which the "half-max" value is obtained.

For example, suppose that the half-max value is 80 counts, and left-hand side of the peak includes channel 123 with 70 counts, and channel 124 with 95 counts. The slope of the number of counts per channel is 25 cts/CH (i.e., 95cts-70cts).

Determine the portion of the channel where the peak crosses the 80-count level. This point is calculated as (80 cts –70 cts)/(25 cts/CH) or 0.4 channel. Repeat this process for the right side of the peak.

To calculate the FWHM for this peak begin with an initial value of 0.4 CH, start at channel 124 and count to the right as described above, stopping at the channel that has counts greater than the "half-max" value, and add the fraction of a channel calculated for the right side of the peak. Convert this to keV units by multiplying by the slope of the energy equation.

7.4.9 Isotopic Thorium uses ^{229}Th as a tracer analyte. Because ^{229}Th occurs at emission energies from approximately 4800-5100keV at various branching ratios, this peak is expected to be much broader than other isotopic tracer peaks. Therefore, the calculated FWHM value is expected to be greater than that for other analyses, and spectral quality is still sufficient for accurate quantification. Inspection of thorium spectra from analyzed quality control samples (method blanks and laboratory control samples) indicates that a FWHM value equal to or less than 160keV still provides adequate spectral quality. Therefore, for thorium analyses, 160keV is used as the upper FWHM limit. As with the other analytes, if deviation from 160keV is minimal and all other criteria are met, results are reported with a narrative comment and Supervisory approval.

7.5 MAESTRO (MCA CONTROL OPTION IN ALPHAVISION)

Maestro is used to examine a live spectrum (one that is in the process of being acquired). Maestro can be accessed in AlphaVision by selecting the detector on the grid, right click on the mouse, and select [MCA VIEW]. Data acquisition can be stopped and started, and the buffer cleared with the normal menu options. After viewing the spectrum, exit Maestro to return to AlphaVision.

7.6 DATA REPORTING

7.6.1 For the final data package, individual results forms, QA results forms, and results summaries are generated. These reports are created in LIMS after uploading data from the AV database in the R:\USER directory. The data is uploaded by double-clicking on the "LIMS DATA TRANSFER" icon, located on the desktop of the AV computer.
REVIEWING HARD COPY REPORT FORMS
Review all forms for completeness. Crosscheck raw data to the Raw Data Report form. Check yields, activity values, MDC values, and other data quality control parameters. Note any flags that require an explanation in the narrative.

7.6.2 NARRATIVES
For most clients, a general narrative template may be used.

The narrative template gives a summary of the samples included in the data package, including preparatory information, any anomalous situations encountered, any quality control deviations, or any other applicable information which may affect data quality. .

7.6.3 NARRATIVE COMMENTS

- Any time there is a Non-Conformance Report (NCR), a narrative comment and a copy of the NCR is required. Any time data quality objectives have not been met, but the deviation is not great enough to prohibit reporting (i.e., activity in the blank, but not greater than the requested MDC; $1.42 < DER < 2.13$ (warning versus control limits, see SOP 715); requested MDCs not met as a result of small sample aliquot size), a narrative comment is required.
- Minor anomalous situations that have no effect on results usually do not require a narrative comment, but should have a Quality Assurance Summary Sheet (QASS, Form 302). If in doubt, ask the Department Manager regarding the proper way to narrate an anomalous situation.
- **Gross QC failures cannot be narrated without proper NCR documentation!** If any of these types of situations are discovered at the time of reporting, notify the Department Manager and Project Manager immediately. The following types of situations require an NCR and most likely will require a re-extraction: LCS exceeds control limits; activity in blank greater than requested MDC; DER failure > 2.13; contamination of the sample; chemical yield outside the control

limits.

8. CALCULATIONS

Alpha spectra are interpreted and analyzed by a sophisticated mathematical routine that provides for peak identification, peak area analysis, and peak energy determination. Details of calculations performed by the AlphaVision software can be found in the AlphaVision Software Reference Manual (see References Section below, 15.1). Paragon's routine alpha spectroscopic analysis of samples employs an ROI approach to spectrum analysis.

The following raw data generated by the AV system are used for sample calculations: Analyte and Tracer Net Counts and Count Time; associated Background Counts for each ROI; Background Count Time and Detector Efficiency. Further data (including Sample Aliquot, Split and Dilution Data, Percent Solids Data, Tracer Concentration and Amount Added, and Estimates of Total Uncertainty as described in SOP 708) from the preparation and standards spiking process, is taken from the electronic benchsheet and merged with the count data during the data reduction step during reporting. Total Efficiency calculations assume that the nuclide used for the tracer is not native to the sample.

Total uranium (a modification of EPA 908.0 by alpha isotopic summation) is calculated using the isotopic uranium results. The net counts are summed and the background counts are summed for ^{234}U, ^{235}U and ^{238}U. The equations depicted in Sop 708 are then used, substituting the 'summed net counts' for 'net counts' and 'summed background counts' for 'background counts', to determine the total uranium (TU) results:

where:

$$\mathbf{SmplNtCts_{TOT}} = SmplNtCts_{234} + SmplNtCts_{235} + SmplNtCts_{238}$$

$$\mathbf{BkgCts_{TOT}} = BkgCts_{234} + BkgCts_{235} + BkgCts_{238}$$

9. RESULTS INTERPRETATION

9.1 It is essential that appropriate analysis volume and units, tracer information, efficiency files and library files be used to ensure accurate analyses. Results must be reviewed to ensure that the sample type used was appropriate to the analysis type (e.g., Pu, U, Th, etc.) and the report reflects proper sample volume and units.

9.2 All target analyte peaks in the spectrum must be matched to the appropriate radionuclide, and, where applicable, the presence of a given radionuclide should be supported by the presence of other significant alpha emissions from that radionuclide.

9.3 Although most of the analyses are routine, it is important to note that each radionuclide has a different peak shape. This is especially evident when dealing with high level samples, and radionuclides that do not exhibit clear and defined

peak shapes.

9.4 Peak shape is most often negatively affected by an unusual sample matrix, which may contribute to the attenuation of alpha particles. This attenuation can cause the spectrum to be interspersed with small non-descript peaks, which must be accounted for when adjusting ROI's. If there is any question as to the placement of ROI's see the Alpha Spectoscopist or the Department Manager.

9.5 The radionuclide of interest can also effect the spectrum. For example, thorium spectra usually exhibit more non-descript peak shapes, especially in the ^{229}Th and ^{230}Th ROIs. A typical thorium spectrum is included in Appendix A of this SOP. The other radionuclides analyzed by alpha spectrometry exhibit defined and similarly shaped peaks (i.e., plutonium, uranium, americium, curium, and neptunium). Typical plutonium and uranium spectra are also included.

10. PERIODIC MAINTENANCE

10.1 VACUUM PUMP

The vacuum pump shall be checked weekly. The pressure of both vacuum pumps should be below 100 milliTorr. If the pressure is not below 100milliTorr, see the Department Manager. Note in the Alpha Spec Calibration Log Book, the date and pressure of both vacuum pumps. The pump oil level should be above the "MIN" level mark on the pump. Inform the Primary Alpha Spectroscopist if one or both of the vacuum pumps is above 100milliTorr. Changing the oil in the vacuum pump usually will bring the vacuum pressure down to or below 100milliTorr. The vacuum pump oil should be changed annually to prevent any unusual wear on the vacuum pump. Note the oil change date in the Alpha Spec Maintenance Log.

10.2 AIR FILTERS

Air filters are located at the bottom of the MCA NIMBIN. The air filters need to be cleaned annually or as needed by removing and vacuuming. Note the filter cleaning date in the Alpha Spec Maintenance Log Book.

10.3 DETECTOR AND CHAMBER CLEANING

The detector and chamber should be cleaned annually or as indicated by the results of periodic background measurements. Periodic cleaning to reduce background contamination may be performed at any time. To clean the detectors and chambers, always wear gloves to prevent contamination. Remove the detectors with a 5/16" open-end wrench. *Do not attempt to remove the detectors by hand. This can damage the microdot connection!* Clean the chamber using a clean cotton ball and alcohol. The connection between the detector and the chamber needs to be thoroughly cleaned. Using a clean cotton ball and alcohol, clean the detector window, then the top and sides of the detector. Clean the connection on the top of the detector thoroughly. The detector calibrations (Energy, Efficiency, and Background) must be re-calibrated following cleaning of the chamber, sample tray, or detector.

11. QUALITY CONTROL

11.1 CALIBRATION PROCEDURES

Note that the procedure for acquiring any calibration spectrum is the same as that of a normal sample acquisition. All calibrations must be documented in the Alpha Spec Calibration Log. Calibrations for the alpha spec include energy, efficiency, and background calibrations, and are done each week.

11.1.1 ENERGY AND EFFICIENCY CALIBRATION

Eight electroplated sources are used that consist of ^{241}Am and ^{234}U with a small amount of ^{235}U activity. The sources are counted for approximately 35 minutes. The naming convention for these sources is Paragon source ID 97-19-103-XX, where XX is equal to source 01, 02, etc. The energy/efficiency calibrations are typically done first, before the background checks. When the count is finished, the program will compare the locations of the ^{241}Am, ^{234}U and ^{235}U peaks to the primary emissions energies and perform a linear fit of the energy per channel data. This data will then be stored in the appropriate detector file for reference by the analysis program during sample analyses.

11.1.1.1 Load calibration planchets into an octet

11.1.1.2 Pump down detectors

11.1.1.3 Open AlphaVision

11.1.1.4 Click on the black calibration button to the upper left on the AlphaVision screen

11.1.1.5 Right click on detector you are analyzing and select [MCA VIEW]

11.1.1.6 Click [CLEAR], then [GO] for all detectors you are analyzing in that octet

11.1.1.7 Go back to the first detector and press [CTRL]+[LEFT or RIGHT ARROW] to move the cursor to the ^{241}Am peak at channel 249, make sure the peak is at channel 249 +/- 1

11.1.1.8 If the peak is within range select [STOP], then [CLEAR]

11.1.1.9 If the peak is not within range use the small standard screwdriver to move the “e-cal” potentiometer slightly left or right. Repeat Steps 11.1.1.7 and 11.1.1.8 until the ^{241}Am peak is within range.

11.1.1.10 Exit “MCA view”

11.1.1.11 Click [PROCESS] and then [CALIBRATION]

11.1.1.12 In the General screen enter calibration name (Cymmddxx) and template number (the number on the planchet loaded into the detector)

where:

C = Calibration

y = last digit of the year

mm = month

dd = day

xx = detector number

11.1.1.13 Click on finish

11.1.1.14 After 35 minutes, a small window will appear. Select [CALIBRATION] from drop down menu, then select [CALIBRATE], [SAVE], then [CLOSE]. Repeat for each detector. This saves preliminary calibration data to the database.

11.1.1.15 To analyze the calibration, select detector and click on [SPECTRUM] tab on lower left of report window.

11.1.1.16 Zoom in on each peak by clicking and dragging a box around the peak, then right click and select [ZOOM IN].

11.1.1.17 Move the peak identifier of each peak to the top point of the peak by clicking and dragging the identifier.

11.1.1.18 Due to limitations in the AV software, both the peak identifier and the ROI must be adjusted in order for both the energy and efficiency coefficients to be properly saved. Consequently, move any ROI edge over and then back to its original position.

11.1.1.19 Right click and select [INTERACTIVE ROI ANALYSIS].

11.1.1.20 Repeat Steps 11.1.1.15 through 11.1.1.19 for all detectors in the octet.

11.1.1.21 Go back to first detector in the octet and select the [REPORT] tab at the bottom left of the report window.

11.1.1.22 Select [PRINT] icon in upper left of the report window.

11.1.1.23 In the screen that appears, save under calibration name Cymmddxx in the calibration folder.

11.1.1.24 Repeat Steps 11.1.1.21 through 11.1.1.23 for remaining detectors in the octet.

11.1.2 QA TEST FOR ENERGY/EFFICIENCY CALIBRATIONS
The QA test must be completed before reporting any samples through LIMS, otherwise the calibration report page will not show the correct calibration date.

11.1.2.1 Select [QA/QC] button to the upper left on the AV screen.

11.1.2.2 Select the detector number from list on the upper left and select [CALIBRATION ENERGY].

11.1.2.3 Select [CHART] tab from lower left of the report window.

11.1.2.4 Select [QA] from the menu options, then [CALIBRATION].

11.1.2.5 Select [QA], [DISPLAY], [CUSTOM], then [QUARTER]. Make sure that a dot appears on the chart in correct date.

11.1.2.6 Select [REPORT] tab at bottom left of window, then [PRINT] and minimize PDF factory screen.

11.1.2.7 Select [CALIBRATION EFFICIENCY].

11.1.2.8 Select [CHART] tab from lower left of the report window.

11.1.2.9 Repeat Step 11.1.2.5 and select [REPORT] tab at bottom left of window, then [PRINT]. Save as CCymmddxx. Where the "CC" indicates a calibration control chart and all other factors are as defined above.

11.1.2.10 Repeat Steps 11.1.2.2 through 11.1.2.9 for remaining detectors in octet.

11.1.2.11 Record the results of the calibration in the Alpha Spec Calibration Logbook.

11.1.3 BACKGROUND CALIBRATIONS
A blank filter paper is placed on a numbered planchet, one for every detector. The filter paper is counted for 1000 minutes, typically following the energy/efficiency calibrations. Filter papers and

planchets are replaced at least annually.

11.1.3.1 Place the numbered, detector specific, blank filters into the detector chambers. Close the doors and apply vacuum to the chambers.

11.1.3.2 Open AlphaVision. Using the mouse, select the detector(s) that will be started. From the menu bar, choose [PROCESS] then [BACKGROUND].

11.1.3.3 Under General screen, Enter the batch filename as follows: Bymmddxx

where:
B = Background
y = last digit of the year
mm = month
dd = day
xx = M1, M2, M3, etc...for MCB number

11.1.3.4 Select the proper template from the drop-down menu, depending on whether the Octete is designated for U/Th analysis or Am/Pu analysis.

11.1.3.5 Under General screen, Select [NEXT].

11.1.3.6 Under Sample screen select [ADD] and enter sample ID of samples as Bymmddxx, where xx = detector number.

11.1.3.7 Click on [FINISH].

11.1.3.8 A new window will appear with all samples on it. Click and drag desired detector to sample ID. Select [START NOW].

11.1.3.9 After 1000 minutes, a window will appear for each detector.

11.1.3.10 Select [SAVE]. Save as Bymmddxx in calibration folder, where xx = detector number.

11.1.4 QA TEST FOR BACKGROUND CALIBRATIONS
The QA test must be completed before reporting any samples through LIMS, otherwise the calibration report page will not show the correct calibration date.

11.1.4.1 Select [QA/QC] button to the upper left on the AV screen.

11.1.4.2 Select the detector number from list on the upper left and select [BACKGROUND].

11.1.4.3 Select [CHART] tab from lower left of the report window.

11.1.4.4 Select [QA] from the menu options, then [BACKGROUND].

11.1.4.5 Select [QA], [DISPLAY], [CUSTOM], then [QUARTER]. Make sure that a dot appears on the chart in correct date.

11.1.4.6 Select [REPORT] tab at bottom left of window, then [PRINT]. Save as BCmmddxx, where BC = Background Control Chart.

11.1.4.7 Record the results of the calibration in the Alpha Spec Calibration Logbook.

11.2 CALIBRATION ACCEPTANCE CRITERIA

Because calibrations are performed weekly and the accumulation of 30 data points would be impracticable, acceptance criteria for alpha spec calibrations are based on an initial calibration set rather than a mean and standard deviation of a historical population. Acceptance criteria are updated, at a minimum, when detectors are replaced, or when major service to the Octete is performed.

11.2.1 BACKGROUND ACCEPTANCE CRITERIA

For U/Th detectors, the warning limit is set at 500 counts, and the control limit at 750 counts, over the entire spectrum. Since the background calibration is evaluated over the entire spectrum, elevated counts due to ^{228}Th daughter products (expected progeny) will therefore elevate the entire count. Since these progeny occur at energies higher than most analytes of interest, they do not interfere with data quality, with the exception of ^{228}Th. However, as an additional quality assurance measure, any detectors that exceed the warning limit will be evaluated by the instrument operator to assure that all standard Paragon data quality objectives will still be achieved under normal operating conditions.

For all other detectors, the warning limit is 100 counts and the control limit is 150 counts.

11.2.2 BACKGROUND CALIBRATION CORRECTIVE ACTIONS

If the background determination does not pass acceptance criteria, clean the detectors thoroughly. Most frequently, short-lived decay

products are responsible for the failure. Cleaning a detector will often help expedite the process of returning the backgrounds to normal levels. Repeat the background determination. In some cases, the department manager may OK a detector for use if the background counts are elevated as long as the background peaks do not interfere with the analysis performed on that detector. This decision should be clearly documented in the Instrument Calibration Logbook.

11.2.3 ENERGY CALIBRATION ACCEPTANCE CRITERIA
For energy calibrations, the energy calibration equation is used to calculate the energy in keV of the middle channel of the spectrum (256). The initial calibration is used as baseline and the warning limits are set ±40 keV from the initial value. Control limits are set ±50 keV from the initial value.

11.2.4 CORRECTIVE ACTION FOR ENERGY CALIBRATION
With the calibration source in place, manually adjust the E-cal pot. on the front of the chamber until the ^{241}Am peak centroid lies in channel 249. At this point the energy calibration must be repeated.

11.2.5 EFFICIENCY CALIBRATION ACCEPTANCE CRITERIA
The initial calibration is used as baseline and the warning limits are set at 3.33% of the initial value. Control limits are set 5% of the initial value.

11.2.6 CORRECTIVE ACTION FOR EFFICIENCY CALIBRATION
If it is determined that the instrument response has drifted relative to the point of initial calibration, the weekly operating limits and specific method calibrations will be re-established prior to analysis of further samples.

11.3 QC MONITORING
Please refer to SOP 715 for further details regarding preparation and monitoring of method blanks, laboratory control samples, duplicates, and chemical recoveries in samples.

12. DEVIATIONS FROM METHOD

This SOP describes a confidential, proprietary procedure developed by Paragon Analytics. Therefore, there are no deviations from a promulgated method.

13. SAFETY, HAZARDS AND WASTE DISPOSAL

13.1 SAFETY
Normal laboratory safety procedures must be followed during this procedure. No special safety requirements are mandated by this procedure.

13.2 HAZARDS
There are no special hazards associated with the conduct of this procedure.

13.3 WASTE DISPOSAL
Samples or sample wastes containing radioactive materials that are not being returned to the client must be disposed of according to Paragon's procedures for disposal of radioactive materials. Contact the site Waste Management Officer for more information.

DOCUMENT REVISION HISTORY

9/11/06: Incorporates instructions for the use of AlphaVision32 version 5.3, removed LIMS reporting instructions, added reference to LIMS program specifications, and referred to the re-verification of calibration sources. Added DOCUMENT REVISION HISTORY. Attached Forms.

8/31/07: Removed most actual calculations from Section 8 and referenced SOP 708 instead.

TABLE 1

COMMON ENERGIES AND APPROXIMATE CHANNEL LOCATIONS
(to assist the user during calibrations, QA checks and initial spectral interpretation)

Nuclide	Energy (keV)	Target Channel
Am-241	5485	249
Am-243	5275	228
Cm-242	6112	311
Cm-244	5805	281
Pu-242	4900	190
Pu-238	5499	250
Pu-239	5155	216
Th-228	5423	242
Th-229	4845	184
Th-230	4687	169
Th-232	4010	101
U-232	5320	232
U-234	4775	178
U-235	4396	140
U-238	4196	120

NOTE: Actual Target Channels will vary slightly for each detector; peak energy and channel matching is done weekly with the energy calibration process in AlphaVision.

TABLE 2

SUMMARY OF INTERNAL QUALITY CONTROL (QC) PROCEDURES AND CORRECTIVE ACTION

QC Check	Frequency	Acceptance Criteria	Corrective Action
Energy Calibration	Weekly	The initial calibration is used as baseline Warning limits are set ±40keV from the initial value Control limits are set ±50keV from the initial value	Record failure in the Alpha Spectroscopy Maintenance Log. Check source integrity, detector configuration, recount and reprocess: Tag detector off-line; Determine and correct problem; or Narrate why condition is acceptable
Efficiency Calibration	Weekly	The initial calibration is used as baseline Warning limits are set at 3.33% of the initial value Control limits are set 5% of the initial value	Record failure in the Alpha Spectroscopy Maintenance Log. Check source position and integrity, detector configuration, recount and reprocess; Tag detector off-line; Determine and correct problem; or Narrate why condition is acceptable
Background Calibration	Weekly long background	U/Th detectors - the warning limit is set at 500 counts & the control limit is set at 750 counts, both over the entire spectrum. All other detectors - the warning limit is 100 counts and the control limit is 150 counts.	Clean chamber and detector, repeat check; Tag detector off-line; Determine and correct problem, re-establish limits; or Narrate why condition is acceptable
Vacuum check	Weekly	<100 milliTorr	Check/replace seals; locate and repair leak; or call service
Chemical Yield	Each sample	Each sample meets current control limits for analysis	Re-prep; or Qualify or Narrate why condition is acceptable
Regions of Interest (ROI)	Adjust ROI as needed	ROI is properly set, tailing does not compromise quantitiation	Adjust ROI's to fit identified peaks; For tailing, cleanup or re-prep and recount affected samples, consult with Supervisor; Qualify or Narrate why condition is acceptable
Spectral Interferences	Evaluate each spectrum for spectral interferences	Interfering activity does not compromise quantitation	Recount; Clean-up, re-prep/ recount affected samples; Consult with Supervisor or Department Manager; Determine and correct problem; or Qualify or Narrate why condition is acceptable

NOTE: SOP 715 contains acceptance criteria and corrective action for method blank, laboratory control samples, duplicate samples and matrix spike/matrix spike duplicates.

APPENDIX A

SAMPLE SPECTRA

The following three spectra examples demonstrate a typical uranium, thorium and plutonium spectra. Note that americium, curium, and neptunium spectra are somewhat similar to the plutonium spectrum, in relation to their peak shapes.

The thorium spectrum contains four analytes. The difficulty with the placement of the ROI's for ^{229}Th and ^{230}Th is due to close proximity of the two peaks. The small peaks to the right of the ^{228}Th peak are ^{228}Th daughter products, which are expected progeny.

The plutonium spectrum contains three analytes, with no other obvious peaks present. Note that uranium, americium, curium, and neptunium spectra should also contain no other peaks, other than those accounted for by existing ROIs.

In detectors used for Uranium and Thorium analyses, persistent background peaks are typically seen in the higher energy regions of the spectra. These peaks are associated with natural decay progeny and do not interfere with U and Th analyses except in the case of ^{228}Th, where the increased detector background is unavoidable and typically results in elevated ^{228}Th MDC values.

re-released w/o revision 3/13/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary to perform data review and evaluate the overall quality of results generated by radiochemistry analysis systems, including: gamma spectrometry, alpha spectrometry, alpha scintillation, liquid scintillation and low background alpha/beta analyses. This procedure is applicable to all radiochemistry analytical results generated at Paragon.

2. SUMMARY

Radiochemistry analysis results are generated by the Paragon Laboratory Information Management System (LIMS), from raw data for each of several types of radioactivity measurement devices at the conclusion of the analysis procedure. The data undergo a series of redundant reviews by qualified analysts according to appropriate data review checklists before the final report is released to the client.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to the appropriate SOP and to complete all documentation required for review.

3.2 It is the responsibility of the analyst performing the review to be familiar with the Paragon LIMS Program Specifications, which provide the lab's default acceptance criteria as well as any client-specific requirements.

3.3 At least one of the redundant reviews is to be carried out by a senior analyst who is cognizant of the capabilities and limitations of the procedure under review. All data review is performed by personnel in the laboratory who have demonstrated the familiarity with and the ability to carry out this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the tracking sheet and data review checklist, indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented in either a Quality Assurance Summary Sheet (QASS; Form 302) or Non-Conformance Report (NCR; Form 313), which must then be reviewed and approved by the appropriate Supervisor or Department Manager.

4. APPARATUS AND MATERIALS

This procedure requires access to the Work Order, Project Specific Requirements, any work order change forms, the benchsheet associated with the samples, and any QASSs, NCRs, or Sample Condition Forms (Form 631). Additionally, the instrument raw data, calibrations, report forms, and Data Review Checklists are required (Form 15001, 15002, 15003, 15004 or 15005). A calculator may be needed to perform manual calculations during the review process.

5. REAGENTS

Not applicable.

6. PROCEDURE

6.1 This procedure begins upon completion of the preparation of the samples. This procedure requires the use of the data review checklists, attached to this SOP. Review items on the checklist that are self-explanatory must be completed, but are not discussed further in this SOP. Items that require further explanation or interpretation are discussed below.

6.2 Before proceeding, the analyst must review the LIMS program specifications to ensure compliance with either the Paragon default requirements or the client's project-specific requirements, as appropriate.

6.3 The data review checklist is generally initiated by the preparation technician, prior to delivering samples to the instrument lab. The checklist accompanies the analytical documentation throughout the analysis and reporting process. Before counting, instrument lab personnel should perform a second review of the preparation section of the checklist. Likewise, each section of the review checklist should receive both the first and second reviews before the work described in the next section is initiated.

6.4 Review the benchsheet for completeness and correctness. Generally, this review is done to ensure that the benchsheet accurately reflects the work performed on the samples.

6.4.1 The benchsheet should contain appropriate entries in all necessary fields. Otherwise the value "NA" should be entered, or the field should be "Z'd out".

6.4.2 On the first iteration of the benchsheet where the analyst's initials appear in a given field, the initials must be hand-written to authenticate the LIMS record.

6.4.3 The Quality Assurance Summary Sheets (QASSs), Non-Conformance Reports (NCRs), and Sample Condition Forms should be reviewed to ensure that they are technically and procedurally reasonable, and that they reflect the work that was actually performed on the samples.

6.4.4 Sufficient supporting documentation should accompany the benchsheet so that all entries can be properly verified. These may include "Percent Moisture" determinations, Drying/Grinding Sheets, Distillation Logs, etc.

6.4.5 Any non-routine calculations, such as those done with a common digestion and subsequent splitting of the digestate for multiple analyses, must be verified manually before proceeding.

6.5 Following instrument analysis, a review of the count data is performed.

6.5.1 In addition to the specific questions asked on the data review checklist, the analyst is responsible for ensuring that the calibrations factors used in the analysis appropriately correspond to the presentation of the sample (e.g. ringed planchet calibrations for ringed planchet sample prep, etc.).

6.5.2 All data entered into the instrument, such as collection date for gamma spec, or residual mass for Gas Flow Proportional Counting (GFP), must be verified against the workorder or benchsheet, as appropriate.

6.5.3 The analyst must ensure that all data quality objectives, whether Paragon standard requirements or client-specific requirements, have been met. This may include the evaluation of chemical yields, spike recoveries, blanks activity, negative activity results, duplicate results, etc, as described below. It is important that this verification be performed as soon as possible after analysis, so that any necessary

corrective action can be expedited. Out of control results shall normally be cause for re-extraction and re-analysis of an analytical batch and shall be recorded on a NCR (SOP 928). Where EPA drinking water methodologies are required, LCS and matrix spike recoveries are to be within ±20% of expected values.

6.6 Calculations for Review.

6.6.1 The LCS accuracy:

$$LCS\% = \frac{OBS * 100}{KNV}$$

where: OBS = observed value
KNV = known value.

6.6.2 The Matrix Spike Accuracy:

$$\text{MS\%} = \frac{(MS - SR)}{SAV} * 100$$

where: MS = matrix spike result
SR = native sample result
SAV = spike added value

The above LCS and Matrix Spike values are decay corrected to common reference dates (usually sample collection date for the matrix spike and the count date for LCS) and reported in consistent units for the associated sample or batch.

To avoid confusion with calculated chemical yields, the analyte spike recovery may sometimes be requested to be reported in terms of "Relative Bias". This term is calculated by subtracting 100% from the "% accuracy" results calculated above. The terms "relative bias" and "% accuracy" are equivalent and can be used interchangeably, with equivalent adjustments to established control limits.

6.6.3 Method Blank

6.6.3.1 The sample specific minimum detectable concentration (MDC) will be used to determine the acceptability of blank results. When a batch of samples contains sample volumes that are of comparable size, the blank result will be calculated using the mean aliquot for the batch. On the other hand, the blank volume will be reported as a volume of 1 (one) when a batch of samples contains samples of variable volume (i.e. an order of magnitude difference). A narrative comment will be made directing the client to evaluate the validity of the blank result relative to the individual sample volumes in the case of a wide range of sample volumes. The following is the suggested wording for the narrative comment:

> "Various aliquot sizes were taken for the preparation of these samples. By convention, the results for the batch blank and LCS are determined based on a 1.0g/L aliquot size. Therefore, the blank results are not directly comparable to the sample results. Mathematically dividing the reported blank activity and MDC by a given sample's 'final aliquot' will convert the blank results to a comparable form for that sample."

6.6.3.2 If the blank activity falls above the calculated MDC, the effect on the data will be assessed. An NCR shall be initiated for any samples showing activity less than 5 times the blank activity. These samples shall generally be prepared for reanalysis, except by direction from the department manager. Any samples showing activity less than the client's requested MDC may be reported as acceptable results, with a narrative comment.

6.6.4 Review the precision of results for duplicate(s) in the sample batch and the corresponding sample(s).

The 2σ duplicate error ratio (DER) is calculated as:

$$DER = \frac{/S - D/}{2 * \sqrt{\sigma_S^2 + \sigma_D^2}}$$

where: S = Sample Result
D = Duplicate Result
σ_S = The One-Sigma Sample Total Propagated Uncertainty (TPU)
σ_D = The One-Sigma Duplicate TPU

A 2σ duplicate error ratio in excess of 1.42 shall be noted in the report narrative as being in the warning range. A 2σ duplicate error ratio in excess of 2.13 shall be considered to be out of control and is cause for re-extraction or re-analysis of the sample(s), unless extenuating technical circumstances prevail and are noted in the narrative.

For gamma spectroscopy analyses where several nuclides are reported, 75% of the nuclides must meet the DER requirements.

6.6.5 At the client's request, where the sample result is greater than five times the associated MDC, the duplicates may be analyzed by the Relative Percent Difference (RPD), which is calculated as:

$$RPD = \frac{(|Sampleresult - Duplicateresult|)}{\left(\frac{Sampleresult + Duplicateresult}{2}\right)} * 100$$

An RPD greater than the client's requested acceptance criteria shall be noted in the report narrative. Paragon does not control on RPD. Where the sample activity is less than five times the calculated MDC, the RPD report will be flagged "NC" for "not calculated". This situation should also be narrated.

For gamma spectroscopy analyses where several nuclides are reported, 75% of the nuclides must meet the RPD requirements.

6.6.6 Negative sample results are compared to the associated Total Propagated Uncertainty (TPU).

6.6.6.1 If the magnitude of the negative result is greater than the associated 2σ TPU and less than the 3σ TPU, a narrative comment is made bringing this fact to the client's attention and stating the expected statistical frequency of this event.

6.6.6.2 If the magnitude of the negative result is greater than the associated 3σ TPU the result may be reported, with the approval of the department manager, and with a narrative comment explaining the situation and any limitations to the

usability of the data. At the manager's discretion, an NCR may be initiated and corrective action taken.

6.6.7 A reported zero "0" value for the MDC requires a narrative comment.

Following ANSI N42.23, the TPU is reported to two significant figures. The MDC is rounded to the same decimal place as the TPU. In practice, in samples with significant activity including the LCS, this can result in a reported value of "0" for the MDC.

6.7 Before reporting the data, a complete second review is performed. All steps outlined in Section 6.5 are repeated. The data review checklist is initialed and dated.

6.8 After the data is reported, per the appropriate analytical SOP, the case narrative is written, which summarizes the analytical process. It should address situations requiring a QASS and NCRs. Data qualifiers should be addressed. The narrative should be signed and dated.

6.9 After the data package is complete, the data compiler completes, initials and dates the data review checklist, which is then independently reviewed, initialed and dated by another qualified analyst.

6.10 MANUAL RE-CALCULATION OF REPORTED RESULTS

6.10.1 Once per month, manual calculations are performed on a sample for each method. The results are stored separately from the batch. The exception is where calculations are performed by vendor-supplied, proprietary software that is inaccessible to the analyst. In these cases, such as the SEEKER® gamma spec software, the manual calculation is performed annually.

6.10.2 Non-routine prep situations require a manual calculation to be performed with the analytical batch. This calculation should remain with the batch and should be filed with the work order.

6.11 Upon satisfactory completion of the final review, the final review analyst will sign the narrative and forward the data package to Reports Management.

6.12 REVIEW OF INTERNAL PROFICIENCY DEMONSTRATION DATA
Blank spike trials are performed for the demonstration of method proficiency. A memorandum from the primary operator should accompany the results stating that the results for the specified method meet Paragon standard limits and are acceptable. Upon approval from the Department Technical Manager, the

memorandum and accompanying data are given to the QA Department, with copies to the applicable Supervisor.

7. QUALITY CONTROL

Sample results shall not be considered final until the first and second reviewers have approved the results by initial and dating the data review sheet and the case narrative has been signed. All necessary supporting data shall be forwarded with the results to Reports Management. An electronic copy of the completed data review checklist and in-house documentation, as well as a copy of the final report, will be kept by the laboratory and will be made available internally as needed.

8. REFERENCES

This is a proprietary procedure developed by Paragon. No deviations from a promulgated method are to be noted.

DOCUMENT REVISION HISTORY

7/24/06: Data review checklists now controlled and included as attachments (some items addressed in the checklists are no longer discussed in the body of the SOP). Other clerical editing performed. DOCUMENT REVISION HISTORY section added.

APPENDIX A

TABLE 1

SUMMARY OF INTERNAL QUALITY CONTROL (QC) PROCEDURES AND CORRECTIVE ACTION

QC Check	Frequency	Acceptance Criteria	Corrective Action
Method Blank (MB)	One per batch or 5% frequency	Activity less than MDC, RMDC or 1/5 associated sample activity	Recount; re-prep and/or recount affected batch or samples; determine and correct problem; or qualify or narrate why condition is acceptable
Laboratory Control Sample (LCS)	One per batch or 5% frequency	Meets established control limits	Recount; re-prep and/or recount affected batch or samples; determine and correct problem; or qualify or narrate why condition is acceptable
Duplicate Sample (DUP)	One per batch or 10% frequency	Warning range: 2 sigma DER >1.42 and Control limit: 2 sigma DER >2.13	Narrate 2 sigma warnings; re-prep and/or recount affected samples for 2 sigma failures; determine and correct problem; or qualify or narrate why condition is acceptable
Matrix Spike (MS)	One per batch for analyses which do not otherwise have chemical yield determination	Paragon does not control on matrix spike samples. Matrix spikes are used only as an indication of matrix interference	Narrative comment
Chemical Yield	Each sample	Meets established control limits	Re-prep; notify client; qualify or narrate why condition is acceptable

APPENDIX B

RADIOCHEMISTRY DATA QUALIFIERS (FLAGS)

J – The reported result is an estimated value.
R – The result is rejected by the laboratory, but is included in the report.

U – The reported activity is less than the calculated MDC.
LT –The reported activity is greater that the calculated MDC, but is less than the client's requested MDC.

M – The client's requested MDC was not met, and the sample activity is below the achieved MDC.
M3 – The client's requested MDC was not met, but the sample activity is above the achieved MDC.

B – The activity in the method blank is greater than the calculated MDC.
B3 – The activity in the method blank is greater than the calculated MDC, but less than the client's requested MDC.

H – The LCS recovery is above the upper control limit.
L – The LCS recovery is below the lower control limit.
P – The LCS passes the established control limits.

N – The matrix spike recovery is outside the established acceptance criteria.

W – The Duplicate Error Ratio is above the 1.42 warning level, but below the 2.13 control level.
D – The Duplicate Error Ratio is above the 2.13 control level.
+ – The Relative Percent Difference exceeds the established acceptance criteria.
NC – Not calculated.

Y1 – Chemical yield is in control at 100 – 110%. Quantitative yield is assumed.
Y2 – Chemical yield is outside established control limits.
LB – The initial sample fraction for ICP yield analysis contains less than the amount of carrier known to be added to the sample, between 85% and less than 100% of the known value. To minimize the potential low bias in the final sample results the chemical yield is calculated using the amount of carrier known to be added to the sample.
15% - The initial sample fraction for ICP yield analysis contains less than the amount of carrier known to be added to the sample, less than 85% of the known value. To minimize the potential effect on the data quality the chemical yield is calculated using the amount of carrier known to be added to the sample.

Z – In the initial ICP determination of the carrier analyte, before the carrier is added to the sample, the calculated result is less than zero. To minimize a low bias in the final radioanalytical results, a value of zero is used in the calculations.

* - Aliquot basis “as received”, report basis “dry weight”
# - Aliquot basis “dry weight”, report basis “as received”

Flags specific to Gamma Spectroscopy
SI – Spectral interference.
SQ – Poor spectral quality.
TI – The nuclide is tentatively identified, as it does not meet one or more of the normal identification criteria.
NR – Not reported.
G – The sample density is outside the ±15% comparison to the calibration standard.

_____ Are sample volumes/aliquots cross-checked, correct, and entered in benchsheet? _____
_____ Matrices, units and reporting basis correct? If not, are they documented & QASS included? _____
_____ Is a sample condition form/grinding sheet/drying sheet included with benchsheet? _____
_____ Were the samples relinquished & received properly in the LIMS internal COC? _____
_____ Has the status sheet been updated to C?

Raw Data Review 1st Review _____ Date _____ 2nd Review _____ Date: _____

_____ Position check performed and all samples correctly loaded? _____
_____ Sample ID and Batch ID correct and in the correct format? _____ Yield Summary Sheet Done?_____
_____ Does the ROI Set Name = Program Spec requirements? _____
_____ Does the Nuclide Library = ROI Set Name? _____
_____ Is the FWHM for the tracer 40-100 keV (Thorium = 40-160 keV)? _____
_____ Tracer counts >than 400? If no, has dept mgr. approved? _____
_____ Bkg, Calib file names valid/current ? Calibration equation: offset = 3000 +/- 100 keV; gain = 10 +/- 1? _____ Run Log Date Page
_____ Is the spectrum free of gain shift / other spectral quality issues ("Branching Ratio" = 99.5 - 100.5%)? _____
_____ Is the dead time < 5%? _____
_____ Have the detection limit requirements been met? _____
_____ Chemical yield and QC parameters checked?(Blank,LCS,DER,etc) _____ _____ _____
_____ ROI's correctly fitted to spectral data? _____
_____ Are unknown peaks present? If so, do they compromise qualification/quantification? _____ _____ _____
_____ Is the Th-230 "contaminated tracer" function properly applied? Correction factor = _____. _____
_____ Instrument QASS/NCR's & anomalous situations documented? _____
_____ Were any samples recounted? Notation regarding reason of recount made on benchsheet? _____ _____ _____
_____ Run log present, correct, and complete? _____
_____ Has the data been transferred to LIMS?
_____ Has the status sheet been updated to CC?

Reporting/Packaging 1st Review _____ Date _____ 2nd Review _____ Date: _____

_____ Project Instructions/Specs, Work Orders & WO Changes followed? _____
_____ Narrative proofread and signed? _____
_____ QASS/NCR's & anomalous situations documented in narrative? _____
_____ Client Name, Project Name and Number correct? _____
_____ Is results summary included ? Are sample ID and dates correct? _____
_____ All results for requested samples present? _____
_____ Matrices, units and reporting basis correct? _____
_____ Are there samples with negative activity? Is negative activity > 2σ TPU (NARR) / > 3σ TPU (NCR)? _____
_____ Are there any samples with an MDC of zero caused by ANSI rounding of the TPU? _____
_____ Raw data summary included? Are the count rates, yields, count times correct? _____
_____ Does the raw data match the data summary? _____
_____ Benchsheet completed properly (Z-out, supercede/in-conjunction with, NCR#'s recorded, etc.)? _____
_____ Packaging correct for client report level? _____
_____ Data package inventory sheet prepared, printed, and included with package? _____
_____ For non-routine prep, analysis: is a successful manual calculation provided (within 3%)? _____
_____ Has the status sheet been updated to F ?

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 724 REVISION 10

TITLE: ANALYSIS OF ALPHA AND BETA EMITTING RADIONUCLIDES BY GAS FLOW PROPORTIONAL COUNTER -- METHOD EPA 900.0

FORMS: 780 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/2/07

LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, 5/10/93; Rev3, 7/29/93; Rev4, PCN #149, 3/02/94; Rev5, PCN #466, 4/25/95; Rev6, 3/24/00; Rev7, 1/4/02; Rev8, 4/07/03; Rev9, 8/24/06; Rev10, 8/31/07.

1. SCOPE AND APPLICATION

This procedure describes the steps necessary to perform alpha and beta emissions analysis of samples of various media using the Tennelec LB 4100-W and Tennelec LB5100-W gas flow proportional counting (GFPC) systems. Samples will normally be liquids (primarily water) and solids (primarily soil or sand) evaporated onto planchets or precipitated onto filters. This procedure is applicable to all gross alpha/beta analyses, alpha analyses (such as Total Radium) and certain specific beta analyses (such as ^{90}Sr) performed on the Tennelec LB4100-W and LB5100-W by Paragon.

2. SUMMARY OF METHOD

Alpha and beta particle emissions from the sample produce ionizations in a gas-filled chamber, generating a small electronic pulse for each interaction. The pulse height is dependent upon the incident energy of the particle. Since alpha and beta particles are normally emitted at widely separated energies, the instrument is able to discriminate between the alpha and beta particle interactions. The instrument provides raw counting information to a computer and spreadsheet-based analysis program. This information is then transferred to Paragon's Laboratory Information Management System (LIMS) for further data reduction and reporting. This procedure provides the calibration, data collection, and analysis portions of EPA Method 900.0.

Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of Paragon's internally derived acceptance criteria. In addition, gross alpha analysis of EPA drinking water samples is limited to a residual mass of 100mg on the planchet.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and

interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 It is the responsibility of the instrument operator to coordinate counting activities with preparation lab activities to ensure timely analysis of samples with short-lived radionuclides or other time-sensitive concerns.

3.3 It is the responsibility of the instrument analyst to ensure optimum instrument capacity through the timely performance and documentation of calibrations, daily performance checks, routine maintenance, etc., as described in Table 1.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who work with samples utilizing this method to note any anomalous or out-of-control events associated with the preparation and analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES / DISCUSSION / COMMENTS

4.1 Low background gas proportional counters generally monitor both alpha and beta activity simultaneously. In beta-specific analyses, such as ^{90}Sr, the alpha channel must be monitored for evidence of interfering radionuclides that might cause a bias to the analyte of interest. A count rate in the alpha channel greater than 10 times the crosstalk-corrected background count rate is cause for concern and must be further evaluated by the Department Manager for potential impact on the data quality. Further, these beta-specific analyses should not be performed on detectors that do not meet both the alpha and beta normal performance criteria,

except with the approval of the Department Manager (as in cases where the data quality is not affected).

4.2 Instrument response is greatly affected by the residual mass of the sample on the planchet. This residual mass is generally recorded on the LIMS benchsheet, and must be maintained at a constant weight to allow for the proper mass-attenuation correction. Some samples may absorb moisture from the air (hygroscopicity), making the residual mass unstable. All planchets must be stored in a desiccator to prevent hygroscopicity. The residual mass of planchets that are stored outside a desiccator, awaiting disposal, must be re-verified prior to any requested re-analysis.

4.3 Instrument response is also greatly affected by the distribution of sample residue on the planchet. Planchets must be inspected upon receipt to ensure even deposition of material, generally equivalent to the calibration planchets for that method.

4.4 On gas proportional counters with active guard detectors, the guard detector count rate must be monitored to ensure that that count rate is below established control limits. Elevated guard count rates are potentially indicative of other electronic problems that may bias the final results.

4.5 For samples analyzed by the gas flow proportional counter, an elevated level sample is defined by either a beta count rate of over 5,000 counts per minute (cpm) or an alpha count rate of over 1,000cpm. If a particular sample exceeds either of these parameters, the detector used to count that sample must be evaluated to ensure that no contamination of the detector has occurred. This evaluation is performed by analyzing a blank sample on the detector for a count duration that equals or exceeds the expected count duration for subsequent sample counts. If this blank analysis generates a result that is below the minimum detectable concentration (MDC) for the analysis in question, it may be assumed that no significant contamination of the detector has occurred and samples may be counted on that detector. If the results of the blank analysis are above the calculated MDC, contamination of the detector should be suspected. A Supervisor must then be notified so that proper corrective action procedures may be implemented. The detector in question must be shown to be free of contamination before any sample analysis may proceed.

5. APPARATUS AND MATERIALS

5.1 Gas Flow Proportional Counter; LB5100-W, LB4100-W, or equivalent

5.2 Forceps, stainless steel -- keep separate set for background and source/sample handling

5.3 Stainless steel planchets, 47mm diameter, for background calibration and daily performance checks

5.4 Desiccator

5.5 Kimwipes™

6. REAGENTS

6.1 Methanol, reagent grade

6.2 Color-indicating Dri-Rite™

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 All planchets must be stored in a desiccator to prevent hygroscopicity. The residual mass of planchets that are stored outside a desiccator, awaiting disposal, must be re-verified prior to any requested re-analysis.

7.2 Always handle the sample planchets with forceps or tweezers to minimize sample exposure to the operator and contamination in the laboratory.

8. PROCEDURES

Instructions given below are for the Oxford Systems Unit Manager (OSUM) Version 1.10. Throughout the text of this document, < > defines a computer keystroke, and [ ] defines a menu option in the OSUM software.

8.1 OPERATING CONDITIONS

Each alpha/beta counting system shall be operating with detector bias as determined during the installation and calibration of the system. The proper setting is determined by the generation of a voltage plateau, as described below. The amplifier settings for the instrument shall be determined during instrument installation and calibration to maximize detector efficiency and minimize alpha/beta crosstalk. The operating conditions shall be verified daily by performance of the daily instrument performance checks as described below.

8.2 SAMPLE PREPARATION

Samples to be analyzed by this method will have been prepared by radiochemical procedures applicable to the radionuclide(s) being evaluated. Sample preparation may be limited to quantitative distribution onto a planchet or may be as complex as a complete digestion and chemical separation. See appropriate radiochemical procedure(s).

8.3 SAMPLE ANALYSIS PROCEDURE

The applications software for these instruments is a Windows™ product. It is assumed that the operator of the software is familiar with the basic operation of Windows™.

8.3.1 LOADING SAMPLES

8.3.1.1 To load the LB4100, open one of the four sample drawers in the front of the instrument. Place the sample planchet in one of the four planchet holders. Note the position of the sample on the sample benchsheet and in the instrument run log (Form 780). Close and lock the drawer.

8.3.1.2 To load the LB5100, planchets are placed in individual, numbered carriers in the sample rack. Samples to be counted are identified by one of several group markers, labeled A through L, which must be placed in front of the first numbered planchet holder in a count batch. The count batch is properly ended by placing another group marker or the "END" marker behind the last sample in the count batch. Note the carrier number of the sample on the sample benchsheet and in the instrument run log (Form 780).

8.3.2 SETTING COUNT PARAMETERS

8.3.2.1 Prior to starting the sample analysis, the count parameters must be set properly for each batch. The count parameters may include the α and β counting efficiency files and the required count duration.

8.3.2.2 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Edit Parameters]. Select the [LIMS Data] application. At this point, enter the desired count duration and select the efficiency files that correspond to the analysis to be run. Close this screen when the proper information is entered.

8.3.2.3 The LB5100 uses a typical pull down menu in the main screen. Select [Edit Parameters], choose the appropriate application, and continue as described in the preceding paragraph.

8.3.3 STARTING THE SAMPLE COUNT

8.3.3.1 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Create Batch]. Select the detectors to be started. Type in the proposed file name in the format XXImmdd where XX is the analysis type, I is the instrument used, mm is the month and dd is the day. The following Table specifies the appropriate XX designation:

Analysis Type	XX Designation
Gross α/β	AB
Radiostrontium	SR
Radium-228	RA
Radium-226	RD
Total Radium	TR
Chlorine-36	CL
Iodine-129	IO

Additional count batches on a given day requiring the same file name may be appended with an A, B, C, etc.

Type in the batch ID as shown on the laboratory benchsheet. Select [Run]. The instrument will proceed to prompt for sample IDs for each detector. Enter the sample IDs as they appear on the benchsheet. Select [Done]. For each sample entered, the instrument will now prompt for analysis volume (in grams or liters) and residual mass (in milligrams). Leave the analysis volume blank and enter the residual mass, where appropriate, when it appears on the benchsheet. Select [Next] to proceed to the next sample. Select [Done] when all sample masses have been entered. The detector icons will now turn from green to yellow to indicate that the count is in progress. Enter the file name, detector ID, date and time, type of analysis, etc. as indicated in the instrument run log (Form 780) and on the LIMS benchsheet.

8.3.3.2 On the LB5100, select [Start Count] from the pull down menu. Select the application to be run. Enter the filename in the format listed above and select the group letter that corresponds to the group marker that was placed in front of the samples to be counted. Select [Done]. At this time the instrument will prompt for carrier ID, sample ID, analysis volume, and residual mass. After entering this information for all the samples to be analyzed, select [Done]. Enter the file name, group and carrier ID, date and time, type of analysis, etc. as indicated in the instrument run log (Form 780) and on the LIMS benchsheet.

8.3.4 UNLOADING SAMPLES

8.3.4.1 After the analysis is complete, the samples will be unloaded. In all cases the operator will check the positions of the samples and verify that the position matches the entries in

the run log and on the benchsheet.

8.3.4.2 On the LB4100, the sample analysis must be "freed" before the samples are unloaded. The detector icons on the screen will flash alternately green and yellow to indicate that the desired count time has elapsed and that data acquisition has been completed. Select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Unit Status]. Select the batch ID or file name corresponding to the completed count batch. Select [Free]. At this point the detector icons will stay green. Unlock and open the drawer. Remove the sample planchets, verifying the position against the run log and benchsheet entries. Close and lock the drawer. Initial the "Position Checked" column on the benchsheet.

8.3.4.3 On the LB5100, the sample batch is automatically completed and the carriers are restacked upon completion of the data acquisition. All that remains is to remove the samples, verifying the positions as described in the preceding paragraph.

8.4 DATA OUTPUT

8.4.1 Some tests require a file modification to properly use laboratory-determined base and progeny efficiencies, as well as crosstalk and attenuation factors.

8.4.1.1 Select [File] and [Run Excel].

8.4.1.2 Select [File], [Open…] to open the correct file located in C:\osum\lb4100\aqua\data*.xld, where * is the filename.

8.4.1.3 The library of efficiencies and calibration factors is found starting at cell Q110.

8.4.1.4 Select the appropriate box, including the header line, containing the necessary calibration information.

8.4.1.5 Depress <Ctrl> and <C> to copy the data range.

8.4.1.6 For base efficiencies, paste (<Ctrl> and <V>) the range in the appropriate cells beginning in column A.

8.4.1.7 For progeny efficiency, crosstalk, and attenuation factors, paste the range in the appropriate cells, beginning in column I.

8.4.1.8 Select [File], [Save], then [File], [Exit] to return to the OSUM program.

8.4.2 On both instruments, select [Data Output] from the main instrument menu. Select the correct filename from the displayed list. Data will be output in two forms -- a hard copy will be output from the printer, and a comma-delimited ASCII file will be created on the local drive. It is the ASCII file that will be used in the data reduction and reporting process.

Instrument A automatically creates the ASCII file during data output, but the ASCII file must be manually created on instrument B. To create the ASCII file manually on instrument B:

8.4.2.1 Select [File] and [Run Excel].

8.4.2.2 Select [File], [Open…] to open the correct file located in C:\osum\lb4100\aqua\data*.xld, where * is the filename.

8.4.2.3 Highlight the range from BU16 to CN16 and down to the bottom of the sample data.

8.4.2.4 Depress <Ctrl> and <C> to copy the data range.

8.4.2.5 Open a new Excel spreadsheet and paste the data into the sheet by selecting [Edit], [Paste Special], [Values].

8.4.2.6 Select [File], [Save as…].

8.4.2.7 Save new file under file type "CSV delimited" and name the file "*.ASC", where * is the same as the filename denoted above.

8.4.3 At this time, a preliminary review of the data should be performed to evaluate the quality of the data. Any analytical data quality problems should be identified. Calibration factors, achieved MDCs, Duplicate Error Ratios (DERs), spike recoveries, etc. should be evaluated. These items are formally checked in the data review process, but a preliminary review at this point will give any early warning of potential problems.

NOTE: Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

9. CALIBRATION

The operator is referred to the instrument-specific operation manuals, cited in Section 13,

for specific instructions on performing periodic calibrations. This Section contains those considerations that are specific to Paragon.

9.1 PLATEAU APPLICATION

Plateau measurements are performed to optimize detector operating voltage. A plateau will be run at least on a quarterly basis to verify that the slope at the operating voltage is less than 3.5 % / 100 volts. If the plateau shows a slope at the current operating voltage greater than 3.5%, all other parameters for the instrument will need to be recalibrated, as described below.

9.2 DISCRIMINATOR SETTINGS (CHANNEL CROSSTALK)

Discriminator will be set at the same level for each detector to consistently optimize beta to alpha crosstalk to a maximum of 1%.

Discriminator settings will be verified quarterly, during the plateau verification, by comparing the alpha source efficiency in both the alpha and beta Regions of Interest (ROIs) to those originally observed during the existing plateau calibration count. The observed verification values will be within 5% of the original value. Otherwise, the instrument may be recalibrated or other corrective action taken, with the radiochemistry Manager's approval.

9.3 EFFICIENCY CALIBRATIONS

9.3.1 Standards for calibration shall be traceable to the National Institute for Standards and Technology (NIST) and shall be an independent source from the current spiking standard. Standards for Gross Alpha/Beta analysis will normally be of ^{241}Am for alpha and ^{90}Sr for beta. EPA Drinking Water methodology requires a ^{230}Th alpha source. Project-specific instructions may require a ^{137}Cs beta source. Standards used for efficiency calibrations for analyses counted on the gas flow proportional counter will use standards specific for that analysis, unless other specific instructions are provided, as in the use of ^{89}Sr as a calibration source for ^{228}Ra analysis by EPA 904.0. The analysis systems shall be calibrated for each physical form of sample to be analyzed (e.g., sample evaporated on planchet, filter, etc.) at least annually. All calibration planchets have an expiration date of one year from last verification date.

9.3.2 OUTLIER TEST

9.3.2.1 Calibration standards are generally prepared in sets of at least five, to facilitate the efficient calibration of the instrument. Prior to using a set of calibration standards, a "gross outlier" test will be performed to eliminate the potential use of a calibration planchet that may have been improperly prepared, or suffer from non-uniform deposition of the standard.

9.3.2.2 Count the set of planchets sequentially on the same detector, either on the LB4100 or the LB5100, to achieve a maximum 2% counting uncertainty, at the 1σ confidence interval.

9.3.2.3 Calculate the mean and standard deviation of the set.

9.3.2.4 Any planchets that fall outside a ±2 standard-deviation acceptance limit and fall greater than 5% from the mean value, will be rejected and will not be used for calibrating the instrument.

9.3.3 To initiate efficiency calibrations, fill out a new line in the source table located at C:\OSUM\SOURCES.XLS in excel. Enter in the ID number, emission type (alpha or beta), the half-life (in days), DPM of source, reference date of standard used for source, and new archive filename.

9.3.3.1 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Edit Parameters]. Select the [Efficiency] application. At this point, enter the desired count duration that will ensure that 10,000 counts are acquired. Close this screen when the proper information is entered.

9.3.3.2 On the LB5100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Efficiency]. Select the detectors to be started. Type in the proposed file name in the format EXXmmddY, where XX is the test, mm is the month, dd is the day, and Y is the drawer. Type in the efficiency test name in place of a batch ID. Select [Done]. The instrument will proceed to prompt for sample IDs for each detector. Enter the source ID number in place of the sample ID. Select [Done]. The detector icons will now turn from green to yellow to indicate that the count is in progress. Enter the file name, detector ID, date and time, type of analysis, etc. as indicated in the instrument run log and on the benchsheet. Also make a notation in the instrument maintenance log book.

9.3.3.3 Select [Data Output] from the main instrument menu. Select the correct filename from the displayed list and [Print]. Compare the detector's efficiency with the previously calibrated efficiency. New efficiency should be within 5% of the previous efficiency. If all efficiencies are acceptable, then [Archive] the efficiencies as "Official Values". If the

efficiencies are unacceptable, consult with the Department Manager for instructions.

9.4 MASS ATTENUATION CALIBRATION

9.4.1 Alpha and beta emitting samples that contain any measurable mass deposited on the planchet must be corrected for particle attenuation. This correction is then applied to the sample during the analysis phase. Multiple acquisitions of attenuation data are required. This data is obtained by creating multiple attenuation standards of the same activity and varying masses, normally 0 to 200mg. Each sample is counted in every detector, long enough to acquire approximately 10,000 counts. A fitted curve for the attenuation factor is then generated.

9.4.2 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Edit Parameters]. Select the [LIMS Data] application. At this point, enter the desired count duration that will ensure that 10,000 counts are acquired. Close this screen when the proper information is entered.

9.4.3 On the LB5100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [LIMS Data]. Select the detectors to be started. Type in the proposed file name in the format AXXmmdd where XX is the test, mm is the month, and dd is the day. Additional count batches on a given day requiring the same file name may be appended with an A, B, C, etc. Indicate the type of curve being preformed in place of a batch ID. Select [Done]. The instrument will proceed to prompt for sample IDs for each detector. Select [Done]. The detector icons will now turn from green to yellow to indicate that the count is in progress. Enter the file name, detector ID, date and time, type of analysis, etc. as indicated in the instrument run log and on the benchsheet. Also make a notation in the instrument maintenance log book.

9.4.4 The detector icons on the screen will flash alternately green and yellow to indicate that the desired count time has elapsed and that data acquisition has been completed. Select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Free]. At this point, the detector icons will stay green.

9.4.5 Select [Data Output] from the main instrument menu. Select the correct filename from the displayed list and [Close].

9.4.6 Repeat this process until all the attenuation planchets have been counted in every detector.

9.4.7 Use the data from the files to generate a curve, with the equation taking the general form bmx, where x is the residual mass of the sample planchet, in mg. The estimated target value for the m coefficient is 0.993 for an alpha attenuation curve, and 0.999 for a beta curve. The estimated target value for the b coefficient is 1.00. The template can be found at r:\inst\gfp\calibration\MassAtten_Template.xls.

9.5 INGROWTH CURVE FOR RADIUM-226

9.5.1 Assume that the total efficiency has two distinct components: (1) the base Ra-226 efficiency, that is always used at its full value, and (2) the aggregate efficiency of the three ingrown alpha-emitting daughter products, which is used in proportion to the degree of ingrowth.

9.5.2 Acquisitions of the efficiency at different stages of ingrowth are required in order to determine both the base efficiency and the progeny efficiency. Follow the steps outlined in Section 9.3 and count the efficiency planchets immediately after separation. Then count the planchets again after approximately 1 day, 1.5 days, 2 days, 3 days, 4 days, 5 days, 6 days, 7 days, 9 days, 11 days, 14 days, 17 days, and 20 days.

9.5.3 Use the data from the files to generate a curve, as described below. The template can be found at r:\inst\gfp\calibration\Tot Ra Ingrowth Curve_Template.xls.

9.5.4 By adjusting the estimated base efficiency for Ra-226, the residual (progeny) efficiency for each calibration count is calculated as the arithmetic difference between the observed total efficiency and the estimated base efficiency. Theoretically, if the estimated base efficiency is correct, the residual (progeny) efficiency will be the same for all stages of ingrowth. In practice, set the base efficiency such that the variance in the individual residual efficiencies over the ingrowth period is minimized.

9.5.5 Since the base efficiencies are determined with planchets that have residual mass, it is necessary to adjust the mass attenuation correction curve accordingly. The mass attenuation curve is generated in the manner stated in Section 9.4 with the final mass attenuation equation in the form bmx-x°, where x° is the average residual mass of the base efficiency calibration planchets.

9.6 BACKGROUND CALIBRATIONS

9.6.1 1000-minute background determinations are performed weekly with a clean planchet.

9.6.2 Planchets, pucks, and inserts will be cleaned with RadiacWash™, rinsed with DI water, and dried thoroughly at least monthly. The drawer stage will be cleaned with methanol weekly.

9.6.3 Control limits for weekly background checks are based on historical control limits established from the first 10 data points in the population (+/- 3 sigma). Prior to establishing historical control limits, interim limits are set at <0.50cpm alpha and <3.00cpm beta.

9.6.4 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Background, Weekly]. Select the detectors to be started. Type in the proposed file name in the format BKXmmddW where X is the instrument used, mm is the month and dd is the day. Select [Done]. The instrument will proceed to prompt for sample IDs for each detector -- leave as the detector IDs. Select [Done]. The detector icons will now turn from green to yellow to indicate that the count is in progress. Enter the file name, detector ID, date and time, type of analysis, etc. as indicated in the instrument run log and on the benchsheet. Also complete the appropriate spots on the chart at the top of the instrument run log.

9.6.5 Upon completion, select [Data Output] from the main instrument menu. Select the correct filename from the displayed list and [Archive] as "Official Values". Select [Yes] to replace the existing official values. Close this screen when completed. Open Excel, and print a hard copy of the calibration. If a detector is out of control, the background calibration should be repeated. If it is still out of control, the detector is tagged off-line for the week. If a detector continues to be off-line for the weeks to follow, consult with the Department Manager on how to proceed.

9.6.6 Finally, the weekly calibration values must be copied to the daily background check template to provide weekly control limits for the daily background checks that follow.

9.6.6.1 In the weekly calibration file, copy the range BI7..BJ27 to the clipboard.

9.6.6.2 Open the daily background check template file, BKGAB.XLP, and paste the contents of the clipboard into the same range, BI7..BJ27, by selecting the menu commands [Edit], [Paste Special], [Values], [OK]. See Step 10.2.2 for a more detailed explanation.

9.6.6.3 If weekly background calibrations are recounted on only

selected detectors, paste only those values into the existing BKGAB.XLP file, so as not to overwrite the previous, acceptable values for the other detectors.

9.6.7 On the LB5100, begin the count by selecting the following menu options; [LB5100], [Start Count], [Background_Weekly]. Enter the filename as described above, the group ID, and the analyst's initials. Upon completion of the count, select [LB5100], and [Data Output], enter the file name and print.

10. QUALITY CONTROL

10.1 DAILY INSTRUMENT PERFORMANCE CHECKS

10.1.1 Daily Instrument Performance Checks include both efficiency checks and background checks. Sample analyses must not only be preceeded by acceptable performance checks, but also must be followed by acceptable checks, usually the following day (i.e., all sample analyses will be bracketed with acceptable performance checks).

10.1.2 In the event that the performance checks <u>following</u> the sample analyses do not meet normal acceptance criteria, the impact on the data quality will be evaluated to determine whether the sample analyses should be redone. The sample analysis data may be used, with proper qualification, upon the Department Manager's approval.

10.2 DAILY BACKGROUND CHECKS

10.2.1 Daily background checks consist of a single 60 minute count of a clean planchet.

10.2.2 Control limits for the daily background check are derived from the weekly background calibration. The 1000 minute count rate is scaled to a 60 minute count rate and the Poisson uncertainty is calculated for that result. The final limits for the daily checks are calculated as the mean count rate for that detector ± three times the Poisson uncertainty.

10.2.3 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Background]. Select the detectors to be started. Type in the proposed file name in the format BKXmmdd where X is the instrument used, mm is the month and dd is the day. Additional count batches on a given day requiring the same file name may be appended with an A, B, C, etc. Select [Done]. The instrument will proceed to prompt for sample IDs for each detector -- leave as the detector IDs. Select [Done]. The detector icons will now turn from green to yellow to indicate that the count is in progress. Enter the file name, detector ID, date and time, type of analysis, etc. as indicated in the instrument run log and on the

benchsheet. Also complete the appropriate spots on the chart at the top of the instrument run log.

10.2.4 Select [Data Output] from the main instrument menu. Select the correct filename from the displayed list and [Archive] as "Daily Check". Close this screen when completed. Open Excel, and print a hard copy of the check. If a detector is out of control, the background check should be repeated. If it is still out of control, the detector is tagged off-line for the day and the effect on the samples that were counted on the previous day is evaluated. If a detector continues to be off-line for consecutive days, consult with a primary GFPC operator or the Department Manager on how to proceed.

10.2.5 On the LB5100, begin the count by selecting the following menu options: [LB5100], [Start Count], [Background_Daily]. Enter the filename as described above, the group ID, and the analyst's initials. Upon completion of the count, select [LB5100], and [Data Output], enter the file name and print

10.3 DAILY EFFICIENCY CHECKS

10.3.1 Standards for Daily Efficiency Checks shall be traceable to the National Institute for Standards and Technology (NIST).

10.3.2 Daily Efficiency checks are run for gross alpha and gross beta. Count durations may be automatically terminated after the acquisition of 10,000 counts, if desired. Control limits are established from the first 30 data points in the population (± 3 sigma). Prior to the collection of 30 data points, interim control limits of ±10% of the initial measurement are used.

10.3.3 On the LB4100, select the instrument menu by right-clicking the instrument icon in the upper left corner. Select [Efficiency]. Select the detectors to be started. Type in the proposed file name in the format EFXmmdd where X is the instrument used, mm is the month and dd is the day. Additional count batches on a given day requiring the same file name may be appended with an A, B, C, etc. Select [Done]. The instrument will proceed to prompt for sample IDs for each detector-enter in source ID. Select [Done]. The detector icons will now turn from green to yellow to indicate that the count is in progress. Enter the file name, detector ID, date and time, type of analysis, etc. as indicated in the instrument run log and on the bench sheet. Also complete the appropriate spots on the chart at the top of the instrument run log.

10.3.4 Select [Data Output] from the main instrument menu. Select the correct filename from the displayed list and [Archive] as "Daily

Check". Close this screen when completed. Open Excel, and print a hard copy of the check. If a detector result is outside of normal acceptance criteria, the check should be repeated. If it is still out of control, the detector is tagged off-line for the day and the effect on the samples that were counted on the previous day is evaluated. If a detector continues to be off-line for consecutive days, consult with the Department Manager for corrective action instructions.

10.3.5 On the LB5100, begin the count by selecting the following menu options: [LB5100], [Start Count], [Efficiency_Daily]. Enter the filename as described above, the group ID, and the analyst's initials. Upon completion of the count, select [LB5100], and [Data Output], enter the file name and print.

11. PERIODIC MAINTENANCE

11.1 CONTROL CHARTS

Control charts of the Daily Efficiency checks and the Backgrounds are printed out monthly using the [Control Chart] application from the main instrument menu. Control charts are to be used for trending analysis.

11.2 To facilitate the convenient management of sample data files, the following files can be relocated after the ASCII files are transferred to LIMS. Calibration files can be relocated anytime after the data is output.

11.2.1 Move sample files from:

C:\OSUM\LB4100\Orange (or Aqua)\DATA*.XLD and *.ASC

to

C:\OSUM\LB4100\Orange (or Aqua)\DATA\OLD*.XLD and *.ASC

11.2.2 Move calibration and performance check files from:

C:\OSUM\LB4100\Orange (or Aqua)\CAL*.XLD and *.ASC

to

C:\OSUM\LB4100\Orange (or Aqua)\CAL\OLD*.XLD and *.ASC

11.3 COMPUTER BACK-UP

The computer files are backed-up monthly using an external tape drive. Prior to performing the back-up, scandisk is run and the hard drive is defragmented. No samples can be counted during the back-up procedure, as OSUM needs to be closed.

After a successful backup of the instrument data, individual data files created since the last backup can be deleted from the following locations:

C:\OSUM\LB4100\Orange (or Aqua)\DATA\OLD*.XLD and *.ASC

C:\OSUM\LB4100\Orange (or Aqua)\CAL\OLD*.XLD and *.ASC

11.4 Specific instrument components will be cleaned periodically, as described in Section 9.

12. SAFETY, HAZARDS, AND WASTE DISPOSAL

12.1 SAFETY

Normal laboratory safety procedures must be complied with during the conduct of this procedure.

12.1.1 Laboratory gloves should be worn while handling the lead shielding; wash hands thoroughly afterward.

12.1.2 Laboratory gloves should be worn while using methanol and while cleaning instrument components.

12.2 HAZARDS

Bias applied to detectors is typically in the range of 1500 volts DC. This can result in electric shock if bias cables are disconnected while bias is applied. To minimize the possibility of electric shock, bias will be turned off to any detector before any cabling is disconnected.

12.3 WASTE DISPOSAL

Sample planchets are disposed of, after a minimum 90-day holding period, in a properly labeled steel drum, under the direction of the Waste Management Officer.

DOCUMENT REVISION HISTORY

8/24/06: Discriminator checks and outlier tests for calibration sources incorporated. FoxPro and RadLims instructions removed. Other clerical changes made. Added DOCUMENT REVISION HISTORY section.

8/31/07: Added note (8.4.3) that acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification. Removed data reporting procedures. Added Form.

TABLE 1

SUMMARY OF INTERNAL QUALITY CONTROL (QC) PROCEDURES AND CORRECTIVE ACTION

QC Check	Frequency	Acceptance Criteria	Corrective Action
Efficiency and Background Checks	Daily	Within derived control limits.	Recount, re-evaluate, service instrument, if necessary or document why condition is acceptable.
Background Calibration	Weekly	Within derived control limits.	Tag method off-line. Determine and correct problem, re-establish limits; or document why condition is acceptable
Operating Voltage Plateau Check	Quarterly	Slope <= 3.5% per 100 volts	Recalibrate Plateau.
Discriminator Settings	Yearly, or when operating voltage is changed.	Beta to alpha crosstalk is <= 1%.	Adjust Discriminators.
Efficiency and Mass-Attenuation Calibrations	Yearly, or when operating voltage is changed.	For single point efficiency calibrations, the value will be within 5% of the previous calibration value. For mass attenuation curves, the fitted values shall be within 10% of the observed value for each point on the curve. Fitted values within 15% of the mass attenuation curve will be acceptable, with the department manager's approval. Initial Calibration Verifications (ICVs) will be within 10% of the expected value.	Tag method off-line. Determine and correct problem; verify source activity; recount and/or recalibrate or document why condition is acceptable.
Chemical Yield	Each sample, where method allows.	Each sample meets current control limits for analysis.	Re-prep; or Qualify or narrate why condition is acceptable

Note: This SOP and SOP 715 contain acceptance criteria and corrective action for method blank, laboratory control samples, duplicate samples and matrix spike/matrix spike duplicates.

STANDARD OPERATING PROCEDURE 726 REVISION 6

TITLE: **DETERMINATION OF LEAD-210 IN SOILS, SEDIMENTS, AND WATERS**
Appendix A Amendment Added 11/30/07 DAS

FORMS: **302** **(use current iteration)**

APPROVALS:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/4/07

LABORATORY MANAGER _____ DATE 9/4/07

HISTORY: Rev0, 11/16/93; Rev1, 5/3/96; Rev2, 4/26/02; Rev3, 4/4/03; Rev4, 12/15/04; Rev5, 3/13/07; Rev6, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary for preparation of environmental soils, sediments, and waters for quantitative measurement of ^{210}Pb.

2. SUMMARY

2.1 Pb in soils and sediments is solubilized using nitric, hydrofluoric and hydrochloric acids.

2.2 Pb is pre-concentrated by passing the sample through a cation exchange column. A chromatographic resin with a high affinity for Pb is used to isolate ^{210}Pb from potentially interfering radionuclides. In nitric acid, Pb is retained on the resin while other unwanted sample constituents are not. Pb is stripped from the resin with hydrochloric acid (HCl). The purified solution containing Pb is mixed with liquid scintillation cocktail and counted in a liquid scintillation counter (LSC). Stable Pb, added into the samples at the beginning of the procedure to monitor the chemical recovery, is measured in the sample by ICP-AES before and after chemical separation.

2.3 Air filters may be analyzed by using the soil procedure.

2.4 This procedure may also be used for suspended solids deposited on filters. The dried filter may enter the procedure directly at the grinding stage of sample preparation. The sample aliquot weight, in this case, will have to be adjusted to account for the weight of the filter. The adjusted weight should be calculated on a Quality Assurance Summary Sheet (QASS, Form 302) and recorded on the benchsheet as the sample weight. The remainder of the preparation procedure is identical to that for a soil sample.

2.5 The resin also retains strontium (Sr), and with some slight modifications, this method can be utilized for a sequential preparation of both Pb and Sr. Pb and Sr are both loaded onto the column in nitric acid. Sr is stripped from the column in dilute nitric acid while Pb is retained. Once the Sr has been removed, Pb is stripped from the column with HCl. Refer to SOP 707 for the preparation of Sr samples.

2.6 Actinides are not retained in this procedure, and will pass through when Pb and Sr are loaded onto the column(s). Therefore, the column effluent from the load solutions and subsequent rinses, can be collected and saved for use in actinide separation and purification methods.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the quality control (QC) samples and other quality indicating parameters, as specified in SOP 715, and the LIMS program specifications related to the client, project, and test method being performed.

3.3 It is the responsibility of the analyst performing this method to notify the Instrument Lab of the expected delivery date of the prepared samples, and to coordinate the delivery with instrument capacity and production schedules. This method relies on the analysis of ^{210}Pb directly. The ingrowing ^{210}Bi progeny is a potential interferent, in sufficient amounts, and will cause a high bias in the analytical results. Consequently, the samples should be analyzed within four days of separation to minimize this interference. The laboratory control sample (LCS) results will provide accurate measure of any potential bias.

3.4 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder file information, indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the handling, preparation or analysis of the samples. Any discrepancies must be noted, and corrective action taken and documented.

4. INTERFERENCES

4.1 This SOP is applicable to water and soil samples that do not contain significant concentrations of organically complexed Pb. Organically complexed Pb may not be retained by the cation exchange column. Consequently, samples that are suspected to contain organically complexed Pb should be muffled at 450 °C for at least four hours.

4.2 As described above, significant amounts of ingrowing ^{210}Bi can cause a high bias in the ^{210}Pb results. The samples should be counted within four days of separation (less than one progeny half-life) to minimize this potential interference. In any case, the LCS results provide a measure of any potential bias to the analytical results.

4.3 High concentrations of Group IIA Elements (especially Ca, Mg, Ba), may interfere with the acceptable chemical recovery of ^{210}Pb. If ICP analysis results indicate a low Pb carrier yield, and elevated concentrations of Ca, Mg, etc., it may be necessary to reduce the sample aliquot during reanalysis.

5. APPARATUS AND MATERIALS

5.1 Disposable ion exchange columns: 15mL resin volume with attachable funnel to receive 2 L bottle, Environmental Express #R1010 and #R1030, or equivalents.

5.2 Cation exchange column: Attach the funnel to the column (make certain that the column and funnel fit tightly). Precondition a disposable plastic column with 2-3 mL of methanol (the frit at the orifice of the column is hydrophobic). Transfer AG50x8 (or AG50x4) resin to the stem of the column as a slurry with DI water to the 7 cm mark.

5.3 Sr Resin™ column: Use a Bio-Rad® column (#731-1553) or equivalent, and transfer the Sr Resin to the column as a slurry with DI water. Add resin up to approximately the 1.6mL mark on the column. The Sr Resin is held in place by a layer of clean silica sand on top of the resin bed.

5.4 Eppendorf® pipets, or equivalent, and disposable pipet tips

5.5 Graduated cylinder, 1 L and 25mL sizes

5.6 Plastic bottles, disposable, 2 L

5.7 Specimen cups with lids, polypropylene, 250mL (8oz)

5.8 Analytical balance, 0.0001g sensitivity

5.9 Test tubes, disposable, 15mL

5.10 Graduated cylinder, plastic, 25mL

5.11 Glass cups, disposable

5.12 Liquid scintillation vials, plastic

5.13 Transfer pipets, polyethylene, disposable, 7mL, VWR #14670-103 or equivalent

5.14 Parafilm®

5.15 Hot Block, Environmental Express or equivalent

5.16 Steam bath

5.17 Vortex mixer

5.18 Whatman® filter paper pulp

6. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a Threshold Limit Value (TLV) below 50 ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 ^{210}Pb spiking solution, NIST-traceable. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.2 Pb carrier, 1.0mg Pb/mL: Dissolve 1.60 g Pb $(NO_3)_2$ in 1000 mL of DI water. TLV = 0.05 mg/m^3 = 0.006 ppm (TWA).

The Pb carrier reagent must be analyzed by ICP to accurately determine the Pb concentration. This is accomplished by diluting the Pb carrier reagent 1000-fold with ICP diluting solution. Prepare in triplicate and submit to the Metals Lab for analysis. The preparation and standardization of this reagent must be documented in the Reagent Preparation Logbook.

6.3 Nitric acid 16N, concentrated, reagent grade. TLV = 2 ppm (TWA). Irritant, corrosive.

6.4 Hydrofluoric acid (HF), 48% reagent grade. TLV = 3 ppm.

6.5 Hydrochloric acid 12N, concentrated, reagent grade. TLV = 5 ppm (ceiling). Irritant, corrosive.

6.6 Nitric acid, 8N : Cautiously add 500 mL of conc. HNO_3 to approximately 400mL of DI water and dilute to 1 L. See 6.3 for TLV.

6.7 Nitric acid, 0.1N: Add 6.3 mL conc. HNO_3 to approximately 900mL DI water and dilute to 1 L. See 6.3 for TLV.

6.8 Nitric acid, 0.05N: Add 3.1 mL conc. HNO_3 to approximately 900mL DI water and dilute to 1 L. See 6.3 for TLV.

6.9 Nitric acid, 1N: Add 63 mL conc. HNO_3 to approximately 900mL DI water and dilute to 1 L. See 6.3 for TLV.

6.10 Hydrochloric acid, 6N: Add 500mL of conc. HCL to 400mL of DI water and dilute to 1 L. See 6.5 for TLV.

6.11 Hydrochloric acid, 4N: Cautiously add 330mL conc. HCl to 500mL DI water and dilute to 1 L. See 6.5 for TLV.

6.12 Hydrogen Peroxide (H_2O_2), ACS grade, 30%. TLV = 1 ppm (TWA).

6.13 ICP diluting solution: Carefully add 10 mL of conc. nitric acid and 50mL of hydrochloric acid to 940 mL of DI water. See 6.3 and 6.5 for TLVs.

6.14 Cation exchange resin, AG50x8 or AG50x4, Eichrom® or equivalent.

6.15 Sr Resin™ chromatographic resin (particle size 50-100 μm). Purchased from Eichrom Industries, Inc. (Darien, IL).

6.16 RadiacWash®.

6.17 Methanol, reagent grade. TLV = 200 ppm (TWA).

6.18 Nitromethane, reagent grade. Highly flammable. TLV = 20 ppm (TWA).

6.19 Ultima Gold LLT™ liquid scintillation cocktail.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 It is recommended that water samples be preserved at the time of collection by adding enough nitric acid (HNO_3) per liter of sample to bring the pH to 2 (2mL of conc. HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days, then preserved and held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.2 The container choice should be plastic to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 SOIL PREPARATION

Soils/sediments must be prepared through the grinding stages of SOP 721.

NOTE: The acid dissolution procedure for ^{210}Pb in soil is identical to SOP 773 - Dissolution of Solids for Determination of Actinides, *except for the following*:

- Soils that require muffling will be muffled at a maximum temperature of 450 ^{0}C. Use paper pulp, rather than filter paper, for the method blank and LCS.
- Conc. HCl is added to the sample when re-dissolving the residual salts instead of conc. HNO_3.
- Boric acid is not added to the sample when redissolving the residual salts.

8.1.1 Weigh approximately 2g of soil (dried and finely ground) into a 250mL polypropylene cup. Record weight (W_s) on the benchsheet. Aliquot sizes may be adjusted to meet the client's requested detection limit.

8.1.2 Prepare a blank and blank spike, per Section 10. If other tests are being prepared sequentially with ^{210}Pb, the appropriate tracers, spikes and/or carriers should be added at this time.

8.1.3 Add 1.0mL of 1.0 mg/mL Pb carrier solution.

NOTE: A replicate 1.0mL aliquot (or similar known volume from a calibrated pipettor) of Pb carrier is diluted by adding 5mL of concentrated HCl and diluting to 1 L with DI water. After mixing thoroughly, a 10mL aliquot of this dilution is transferred to a test tube labeled "reference carrier" and submitted with the initial and final tubes for ICP analysis.

See Amendment for this Step, Appendix A. 11/30/07 DAS

8.1.4 Add 25mL conc. HNO_3 to each cup using a volumetric dispenser. Use caution when adding the acid, some soils, especially larger aliquot sizes, may be very reactive, initially.

8.1.5 Using a **plastic** graduated cylinder, add 25mL conc. HF to each cup (do not allow HF to come into contact with any type of laboratory ware made of glass since HF will dissolve glass).

8.1.6 Add 25mL of conc. HCl to each cup. Place a 100mL polypropylene cup as a cover onto the 250 mL cup containing the sample.

8.1.7 Allow the samples to pre-digest at least 1 hour at room temperature to allow any vigorous reaction to subside.

8.1.8 Place the cups on the steam bath and heat for at least 4 hours.

8.1.9 Uncover the cups and take to dryness on the steam bath.

8.1.10 For samples with low organic content, skip to Section 8.1.12. For samples with significant organic content proceed to Section 8.1.11.

8.1.11 Remove from the steam bath and add 10mL conc. HNO_3. An additional 5mL 30% H_2O_2 can be added to assist with dissolution of difficult matrices. Since the addition of H_2O_2 can result in a vigorous reaction, the samples should be allowed to stand at room temperature for a few minutes. After the reaction has subsided, return the cup to the steam bath and take to dryness.

8.1.12 Remove from the steam bath and add 10mL conc. HCL and about 140mL DI water to solubilize the solids. Mix well. Return cups to the steam bath for about 15 min. to warm solution and enhance dissolution of salts.

See Amendment, Appendix A. 11/30/07 DAS

8.1.13 Transfer the sample through a qualitative fluted filter paper into a 1 L graduated cylinder. Rinse the cup two or three times with DI water and transfer the rinsate to the filter.

8.1.14 Dilute to a final volume (V_s) of 1 L with DI water and transfer to a clean, labeled 2 L plastic bottle.

8.1.15 Mix each sample thoroughly by capping and shaking. Pipet a 10mL aliquot (R_i) from each sample into a disposable test tube. Cover with Parafilm® and label with the sample ID and “initial Pb”.

8.1.16 Prepare a cation exchange column per Section 5.2. Condition the column with ~30mL of 1N HNO_3.

8.1.17 Pass the sample through the column at a rate of about 1-2 mL/min. This is accomplished by inverting the 2 L bottle into the funnel that is attached to the top of the cation exchange column. The sample will feed automatically through the column.

8.1.18 After the sample has completely passed through the resin, rinse the column with 10 mL of 0.1N HNO_3.

8.1.19 Discard the feed and rinse solutions into the Paragon wastewater treatment facility.

8.1.20 Elute Pb and other cations with 50mL of 8N HNO_3. Collect the solution in a labeled 250mL cup.

8.1.21 Place on a steam bath and evaporate to dryness.

8.1.22 Extrude the resin from the column and collect in a wide mouth jar labeled "hazardous waste-used acidic resin" in the satellite accumulation area. When the satellite container is full, notify the site Waste Management Officer for further instructions. Soak the empty columns in RadiacWash®, rinse with tap water, and discard into the sanitary trash.

8.1.23 Once dry, dissolve the salts in 5mL of 8N HNO_3 solution. Add the acid to the specimen cup while the sample is still on the steam bath to facilitate complete dissolution of the salt residue.

8.1.24 Proceed to Section 8.3 of this SOP.

8.2 WATER PREPARATION

8.2.1 Using a graduated cylinder, measure the sample to the nearest graduation. Record the sample volume on the bench sheet (V_i). If the sample volume is not 1 L, dilute with deionized water to 1 L. Transfer into a 2 L disposable plastic bottle (usual sample volume = 1 L).

8.2.2 Prepare a blank and blank spike per Section 10. If sample is to be run sequentially for other tests, the appropriate tracers, spikes and/or carriers should be added at this time.

8.2.3 Add 1.00 mL of 1.0 mg Pb/mL carrier (1.0 mg Pb) (S).

NOTE: A replicate 1.0mL aliquot (or similar known volume from a calibrated pipettor) of Pb carrier is diluted by adding 5mL of concentrated HNO_3 and diluting to 1 L with DI water. After mixing thoroughly, a 10mL aliquot of this dilution is transferred to a test tube labeled "reference carrier" and submitted with the initial and final tubes for ICP analysis.

8.2.4 Mix sample thoroughly by inverting capped bottle several times and remove a 10mL aliquot (R_i) for ICP determination of Pb. Place aliquot

in 15mL test tube, seal with Parafilm and label with sample I.D. and "initial-Pb".

8.2.5 Prepare a cation exchange column per Section 5.2. Condition the column with ~30mL of 1N HNO_3. Pass the sample through the column at a rate of about 1-2 mL/min. This is accomplished by inverting the 2 L bottle into the funnel that is attached to the top of the cation exchange column. The sample will feed automatically through the column.

8.2.6 After the sample has completely passed through the resin, rinse the column with 10mL of 0.1N HNO_3.

8.2.7 Discard the feed and rinse solutions down the laboratory sink and into the Paragon wastewater treatment facility.

8.2.8 Elute Pb and other cations with 50mL of 8N HNO_3. Collect the solution in a labeled 250mL polypropylene cup. Place on a steam bath and evaporate to dryness.

8.2.9 See Section 8.1.22 above for column and resin disposal.

8.2.10 Dissolve the salts in 5mL of 8N HNO_3 solution. Add the acid to the specimen cup while the sample is still on the steam bath to facilitate complete dissolution of the salt residue.

8.2.11 Proceed to Section 8.3 of this SOP.

8.3 Pb PURIFICATION WITH Sr Resin™

8.3.1 Place a waste/effluent collection container under the columns.

8.3.2 Precondition a Sr Resin™ column (see Section 5.3 for preparation of Sr Resin™ columns) with 5mL of 8N HNO_3, collecting the rinsate for disposal.

8.3.3 Transfer the sample solution to the column using a disposable transfer pipet.

8.3.4 Using the disposable transfer pipet, rinse the cup with 2mL of 8N HNO_3 and add the rinsate to the column. Repeat twice, allowing the entire rinse volume to pass through the column each time.

8.3.5 Rinse the column with two 5mL aliquots of 0.05N HNO_3. Record the date and time to the nearest 10 minutes of the end of the last rinse on the benchsheet. This is the starting time of the ^{210}Bi ingrowth.

8.3.6 The contents of the waste container can be discarded into the Paragon wastewater treatment facility via the laboratory sink followed by plenty of cold tap water. The waste containers may be rinsed with RadiacWash® solution and tap water and re-used for collecting waste column effluent. If the waste containers are not needed they may be soaked in RadiacWash®, rinsed with tap water, and discarded into the sanitary trash.

8.3.7 Place a labeled disposable glass cup under each column.

8.3.8 Elute Pb from the column with six 5mL rinses of 6N HCl, allowing each rinse to pass through the column before adding the next rinse. Collect the eluate in the labeled disposable glass cups.

8.3.9 Add 5mL of 16N (conc.) nitric acid to the eluate in the glass cup. This will aid in breaking down organic constituents in the column effluent.

8.3.10 Take the samples to dryness by placing the glass cups on a Hot Block set at 100 ^{o}C.

8.3.11 Once dry, remove from Hot Block. While the glass cup is still warm, dissolve the residue by adding 1.0mL of 4N HCl. Immediately cap the glass cups to prevent evaporation and vortex to mix completely. Allow to stand 5 – 10 minutes. Warm the bottom of the capped glass cup briefly in a hot water bath and vortex to be sure all of the Pb is in solution. Allow glass cups to cool. Add 5.0mL of DI water. Record the final volume of 6 mL (V_{Pb}) on the benchsheet. Cap and vortex again.

8.3.12 Add 9.9mL of ICP diluting solution to a test tube that has been labeled with the sample ID and “final-Pb”. Pipet 0.1mL from the thoroughly mixed sample and transfer to the test tube. Cap the test tube and invert several times to mix thoroughly.

8.3.13 Submit the “initial and “final” aliquots to the Metals Lab for ICP determination of Pb concentrations in these solutions. The initial concentration (C_i) and the final concentration (C_f) will be used for the calculation of the chemical yield.

8.3.14 Upon the return of the ICP sample fractions to the lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the Paragon wastewater treatment facility (down the drain in the lab sinks with plenty of cold tap water). The test tubes may

be rinsed with RadiacWash® solution, followed with tap water, and discarded into the sanitary trash.

8.3.15 From the remaining sample in the glass cups, pipet 5.0mL into a plastic liquid scintillation vial. Add 15mL of Ultima Gold LLT™ cocktail to each vial. Cap and shake well to mix. Since the liquid scintillation vial is an optical surface, all labeling should be done on the cap, not on the vial itself. Wipe each vial down using a Kimwipe® moistened with methanol.

8.3.16 Relinquish the samples to the Instrument Lab for counting by liquid scintillation with all appropriate documentation. The LS vials will be analyzed and ultimately disposed of in the manner described in SOP 704.

8.3.17 AFTER THE ICP RESULTS HAVE BEEN REVIEWED AND DETERMINED TO BE ACCEPTABLE, the sample remaining in the glass cup may be disposed into the Pb waste carboy. The glass cups may be rinsed with RadiacWash® solution, followed with tap water, and discarded into the broken glass receptacle.

8.4 PREPARATION OF CALIBRATION STANDARDS

8.4.1 Provide the Instrument Lab with a total of twenty-four liquid scintillation vials consisting of twelve blanks and twelve calibration standards with approximately 1000-2500 dpm of NIST-traceable ^{210}Pb in each. The blanks and calibration sources should be progressively quenched with nitromethane in increments of 15 µL, beginning with 0 µL.

8.4.2 To accomplish this, label twenty-four 2 L disposable plastic bottles. Fill each with 1 L of acidified DI water. Add 1mL of Pb carrier to each. Spike the twelve calibration sources. Process like water samples, following this SOP (starting with Section 8.2.4). Once samples have been transferred to liquid scintillation vials and cocktail has been added, quench with a range of 0-165 µL of nitromethane in 15 µL increments for both the blanks and calibration sources. Shake to mix and wipe the vials with a Kimwipe® moistened with methanol. Relinquish to the Instrument Lab with appropriate documentation.

8.4.3 Each calibration must be verified with a calibration verification set that consists of three method blanks and three LCSs that are processed through the water method and variously quenched at the low, medium, and high ranges of the quench curve. The LCSs should be prepared with an independent second source of NIST-traceable ^{210}Pb, if possible.

The calibration verification set may be prepared either simultaneously with the calibration set or separately, as is most convenient. The verification samples must pass normal Paragon acceptance criteria for method blanks and LCSs.

9. CALCULATIONS

The following parameters must be recorded on the benchsheet. The parameters are necessary to calculate chemical recovery and also to provide the Instrument Lab with the sample aliquot size to be used in calculating the final results.

9.1 PARAMETERS

9.1.1 Soil Samples

W_s = dry weight of soil (g). Refer to Section 8.1.1.

V_s = final volume of digestate (mL). Refer to Section 8.1.14.

C_i = concentration of Pb determined in "initial-Pb" aliquot (µg/mL). Refer to Section 8.3.13.

C_F = concentration of Pb in eluate (µg/mL). Refer to Section 8.3.13.

V_{Pb} = final volume of redissolved sample (mL). Refer to Section 8.3.11.

9.1.2 Water Samples

V_i = initial sample volume (mL). Refer to Section 8.2.1.

S = volume of Pb carrier solution spiked into sample (mL). Refer to Section 8.2.3.

R_i = volume of solution removed for "initial - Pb" ICP analysis (mL). Refer to Section 8.2.4.

C_i = concentration of Pb determined in "initial - Pb" aliquot (µg/mL). Refer to Section 8.3.13.

V_{Pb} = final volume of redissolved sample (mL). Refer to Section 8.3.11.

C_F = concentration of Pb in Pb eluate (µg/mL). Refer to Section 8.3.13.

9.2 CHEMICAL RECOVERY CALCULATIONS

Calculate chemical recovery using the following calculations:

9.2.1 Soil Samples

$$Pb_i = \text{initial mass of Pb } (\mu g) = (C_i)\,(V_s - 10)$$

The factor of 10 accounts for the aliquot removed for ICP analysis. Refer to Section 8.1.15.

$Pb_F = (C_F)(V_{pb})(100)$

The factor of 100 accounts for the dilution made prior to ICP analysis. Refer to Section 8.3.12.

% Pb recovery $= (Pb_F / Pb_i)100$

Chemical recovery results must be submitted to the Instrument Lab.

9.2.2 Water Samples

Pb_i = initial mass of Pb (µg) $= (C_i)(V_i + S - R_i)$

Pb_F = final mass of Pb recovered (µg) $= (C_F)(V_{Pb})100$

% Pb recovery $= (Pb_F / Pb_i)(100)$

Chemical recovery results must be submitted to the Instrument Lab.

9.3 SAMPLE ALIQUOT SIZE TO BE USED IN FINAL RESULTS CALCULATION

9.3.1 For soils, the sample aliquot mass to be used in calculating the final results must be adjusted to account for aliquots that were removed to determine chemical recovery.

W_c = sample mass used in calculation of final results (g).

$= W_s \times [(V_s - R_i) / (V_s)] \times (5/V_{Pb})$

where 5 refers to the volume described in Step 8.3.15.

9.3.2 For waters, the sample aliquot volume to be used in calculating the final results must be adjusted to account for aliquots that were removed to determine chemical recovery.

V_c = sample volume used in calculation of final results (mL).

$= V_i [(V_i + S - R_i) / (V_i + S)]$

9.3.3 W_c and V_c must be submitted to the Instrument Lab in order to allow calculation of the final results.

9.4 TPU FACTORS

As defined in SOP 708, the following preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty.

9.4.1 Water samples require a preparation uncertainty factor of 0.0972 (1σ). This is based on one gross aliquotting, one volumetric measurement, one ICP yield determination, and one pipetting.

$$0.0972 = \sqrt{.05^2 + .006^2 + .083^2 + .004^2}$$

9.4.2 Solid samples require a preparation uncertainty factor of 0.0974 (1σ). This is based on one gross aliquotting, one mass measurement, two volumetric measurements, one pipetting, and one ICP yield determination.

$$0.0974 = \sqrt{.05^2 + .003^2 + .006^2 + .006^2 + .004^2 + .083^2}$$

9.4.3 In practice, these two TPU factors are not significantly different. To facilitate the use of the radiochemistry reporting software, the greater of the two (0.0974) may be used for both matrices.

10. QUALITY CONTROL

Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.1 SOLID SAMPLES

10.1.1 As described above, Whatman® ashless paper pulp is used as the matrix for solid QC. Use enough to absorb the volume of carrier and spike solution added.

10.1.2 One blank is run per batch of 20 samples, or at a 5% frequency.

10.1.3 One sample duplicate is run per 10 samples, or at a 10 % frequency.

10.1.4 One laboratory control sample is run for each batch of 20 samples (5% frequency) with approximately 10-30 pCi ^{210}Pb/gram.

10.2 WATER SAMPLES

10.2.1 One blank using 1 L containing 5mL of concentrated HNO_3 and 995 mL of DI water is run per batch of 20 samples or at a 5% frequency.

10.2.2 One sample duplicate is run per 10 samples or at a 10% frequency.

10.2.3 One laboratory control sample (spiked blank, 1 L, containing 5mL of concentrated HNO_3 and 995mL of DI water) is run for each batch of 20 samples (5% frequency) with approximately 10 to 30 pCi ^{210}Pb/liter.

11. SAFETY, HAZARDS, AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

Care should be taken when diluting acids. Always add acids to water, not water to acid.

11.2 WASTE DISPOSAL

Specific waste disposal instructions are given in the body of the Procedure section.

12. REFERENCES

E.P. Horwitz, R. Chiarizia, and M. Dietz, "A Novel Strontium- Selective Extraction Chromatographic Resin", Solvent Extraction and Ion Exchange, 10 (2), 313-336 (1992).

NOTE: This reference presents data that shows the strong retention of Pb by the Sr•Spec chromatographic resin. Pb retention exceeds Sr retention by more than two orders of magnitude at certain activities.

DOCUMENT REVISION HISTORY

3/13/07: Rev5. Added Form and DOCUMENT REVISION HISTORY. Added scheduling comment and reference to LIMS program specifications to RESPONSIBILITIES. Changed minimum muffling time from 1hr to 4hrs. Added additional comment to INTERFERENCES section. Added Nitromethane to REAGENTS. Revised the calculations. Updated TPU calculations, and changed the preservative used in the QC samples from HCl to HNO_3.

8/31/07: For spiking solution Section 6, added second source statement. Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Section 7.1. Removed activity calculation from Section 9 and referenced SOP 708 instead. Added statement to Section 10 that acceptance limits for quality control parameters may vary per client specifications, consult applicable LIMS program specification.

11/30/07: Appendix A amendment added.

Appendix A

^{210}Pb Soil Modifications

Two modifications have been evaluated to improve the current ^{210}Pb soil procedure. These modifications reduce the required preparation time and remove potassium, which is a potential source of interference for chemical separation on the Sr-Spec column.

Procedures:

Modification to Step 8.1.3:

- A replicate 1.0 mL aliquot (or similar known volume from a calibrated pipet) of Pb carrier is diluted by adding 5mL of concentrated HCl and diluting to 200mL with DI water. After mixing thoroughly, a 1.0mL aliquot of this dilution is transferred to a test tube labeled "reference carrier" with 9.0mL of ICP diluting solution. This is submitted with the initial and final tubes for ICP analysis.

Beginning at Step 8.1.13:

- Transfer the digestate to a labeled 250mL centrifuge bottle. Rinse the cup three times with DI water and dilute to a final volume of 200mL.

- After mixing thoroughly, a 1.0mL aliquot of this solution is transferred to a test tube labeled with the sample ID and "initial Pb" with 9.0mL of ICP diluting solution. Cap and mix thoroughly.

- Add 100 mg of Ca (1.0mL of 100 mg/mL Ca solution)

  Note: Addition of Ca is unnecessary if the sample contains more than 100mg of native Ca. Samples containing high levels of Ca usually can be identified by the effervescence which occurs when the digestion acids are added. If high native Ca is suspected, the "initial Pb" solutions may be analyzed to determine the level of native Ca.

- Add 2g of oxalic acid and dissolve by shaking or vortexing.

- Add 20mL of concentrated NH_4OH. Mix well and allow precipitate to form.

- Centrifuge at approximately 3500 RPM for 10 minutes.

- Decant the supernatant and discard into the Paragon wastewater treatment facility.

- Dissolve the precipitate in 15mL of concentrated HNO_3 by vortexing.

- Bring the solution to 30 mL using DI water. Mix well. This is the 8N HNO_3 load solution to be used in the Pb purification with Sr-Spec resin.

- Centrifuge to separate any undissolved residue which may clog the Sr-Spec resin column.

- Decant the supernatant into a labeled 50mL centrifuge tube.

  Note: If any solids do not centrifuge down it may be necessary to filter the supernatant using a 0.7µm glass fiber syringe filter. If the supertanted is filtered, all rinses from the next Steps are to be filtered through the filter as well.

- Rinse the 250mL centrifuge tube with 5mL of 8N HNO_3 and shake well to rinse the entire tube. Centrifuge and add the rinsate to the 50mL centrifuge tube. Repeat this Step 2 more times.

- Perform Pb purification with Sr-Spec resin (Steps 8.3.1 through 8.3.6)

- Place a labeled 50mL centrifuge tube under each column.

- Elute Pb from the column with six 5mL rinses of 6N HCl, allowing each rinse to pass through the column before adding the next rinse. Collect the eluate in the labeled 50mL centrifuge tube.

- Add 20mg of Ca (0.2mL of 100 mg/ml Ca solution). Mix well.

- Add 15mL of concentrated NH_4OH. This must be done slowly and carefully. Add 5mL, cap and mix tube. Repeat two more times.

- Add 1g of Na_2CO_3. Mix well to dissolve the Na_2CO_3 and allow the Ca(Pb) carbonate to precipitate.

- Centrifuge and discard the supernatant into the Paragon wastewater treatment facility.

- Rinse the precipitate with 10mL of concentrated NH_4OH. Vortex to mix and centrifuge. Discard supernatant into the Paragon wastewater treatment facility.

- Dry the tube and precipitate by placing the uncapped centrifuge tube in a Hot Block set at 100 °C.

- Dissolve the residue by adding 1.0mL of 4N HCl. Add 5.0mL of DI water. Record the final volume of 6 mL (V_{Pb}) on the benchsheet. Cap and mix by vortexing.

- After mixing thoroughly, a 0.05mL aliquot of this solution is transferred to a test tube labeled with the sample ID and “initial Pb” with 10.0mL of ICP diluting solution. Cap and mix thoroughly.

- Continue per SOP 726R6 beginning at Step 8.3.13.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 733 REVISION 7

TITLE: **CHECKING THE pH OF AQUEOUS SAMPLES IN THE RADIOCHEMISTRY DEPARTMENT**

FORMS: **631 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 10/3/07
QUALITY ASSURANCE MANAGER _____ DATE 10/3/07
LABORATORY MANAGER _____ DATE 10/4/07

HISTORY: Rev0, 5/06/93; Rev1, PCN #152, 3/4/94; Rev2, 2/14/00; Rev3, 4/10/02; Rev4, 3/28/03; Rev5, 5/17/04; Rev6, 2/27/06; Rev7, 9/28/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedures used to check and document the pH of aqueous samples being handled by the Radiochemistry Preparation Groups. Only the samples and/or containers actually being analyzed for radionuclides will be checked. Lab personnel will conduct the pH measurement prior to the use of the sample. The pH of the sample will be documented on the Sample Condition Form (Form 631) or on the electronic benchsheet, as applicable. This SOP does not apply to soil, sludge, organic, bioassay or any other non-aqueous samples.

The pH check is important for verifying the preservation status of the sample being analyzed. Presence or absence of acid preservatives can be crucial to analyses such as Tritium and Carbon-14, samples for such analyses should not contain any acid preservative. If the pH measurement on any sample scheduled for these analyses falls below 2, verify that there is no alternate sample container that is unpreserved. If all containers for such a sample were preserved, consult the Department and Project Managers for resolution.

2. SUMMARY

2.1 Aqueous samples that must be preserved by acidification are checked for pH using narrow range indicator paper (pH 0–2.5) at the beginning of any analysis. The sample is applied to the indicator paper using a disposable pipette. The result may be recorded on Sample Condition Form (631).

2.2 If the pH is not less than 2, the analyst may acidify the sample in its original container by adding the proper concentrated acid (generally HNO_3) in increments of 2mL per liter of sample until a pH less than 2 is achieved. At this time the date, time, volume of acid added, pH, and the analyst's initials are recorded on the sample container. The sample should then be stored for at least 24 hours prior to re-checking the pH and removing an aliquot for analysis. Any necessary deviations from this procedure should be reported to the Group Supervisor and the

Project Manager (PM) immediately. Also, samples that are highly basic (>pH 8-9) should be brought to the attention of the Group Supervisor and PM.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Strongly basic samples are not readily amenable to preservation by addition of acid. In addition to potential safety concerns surrounding vigorous reactions upon mixing acid and base, significant dilution may occur. Additionally, acid preservation may alter the chemical makeup of the sample and potentially compromise sample results. Samples that are highly basic (>pH 8-9) should be brought to the attention of the Group Supervisor and PM before proceeding.

4.2 Highly sedimented samples may not be amenable to this method. If significant visible sediments are present, the Group Supervisor and PM should be notified.

4.3 Indicator papers should be read while still wet. Your Supervisor will instruct you on how to read the indicators using the color chart on the box of test strips. Record (Form 631) the pH to the nearest tenth place (e.g., “8.5”).

4.4 Color-blind individuals should ask for assistance if their color blindness may interfere with visual distinction of the color changes in any pH range.

5. APPARATUS AND MATERIALS

5.1 Wide range indicating pH test strips (pH 0-14)

5.2 Narrow range indicating pH test strips (pH 0-2.5)

5.3 Disposable transfer pipets

5.4 Lab marker (e.g., Sharpie or equivalent)

6. REAGENTS

HNO_3, concentrated, Reagent grade. TLV = 2ppm (TWA). Irritant, corrosive.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Although the client is responsible for conducting the sampling process, it is emphasized that water samples should be collected in a manner that addresses the considerations discussed in EPA 900.0, Section Three, or Chapter Nine of EPA SW-846, as appropriate.

7.2 The container should generally be plastic rather than glass to prevent loss due to breakage during transportation and handling, unless specific analytical methods require glass containers.

8. PROCEDURE

8.1 Check out aqueous samples to be analyzed observing internal COC practices (SOP 318).

8.2 Even if the pH of the sample has already been written on the container, indicating that it has been checked by another analyst in an earlier analysis, the pH should still be re-verified prior to aliquotting. Various constituents of the sample may act as buffering agents, allowing the sample pH to increase over time.

8.3 Unless otherwise instructed, the sample should be homogenized or shaken immediately prior to the next step.

8.4 Using a transfer pipette, remove enough sample to wet the indicating area of the pH test strip.

8.5 Transfer the sample to the end of the narrow range (0–2.5) pH paper, being sure to completely wet the indicating area completely. Sample residuals remaining in the pipet shall <u>not</u> be returned to their original containers.

8.5.1 Compare the wet strip to the color chart on the box. Determine the pH to the nearest tenth (e.g., pH = 1.8).

8.5.2 So as not to confuse the pH readings, the individual pH for each sample should be recorded on the Sample Condition Form (631) before proceeding to the next sample. Alternately, the notation “pH<2” may be used.

8.5.3 If the pH reading falls at or above the maximum range of the test strip, repeat the test with a wide range strip (0–14). Refer to Section 2.2 for further instructions.

8.5.4 If the pH is not less than 2, the analyst may acidify the sample in it’s original container by adding the proper concentrated acid (generally

8.5.5 HNO_3) in increments of 2mL per liter of sample until a pH less than 2 is achieved. Mark date, time, volume of acid added, pH, and initials on the sample container. Sample should be held for a minimum of 24hrs before proceeding with analysis.

8.6 Once all markings have been made, the pH strips are set aside to dry then are disposed of in the trashcan. See Section 11.2.2 for disposal of sample residuals.

9. QUALITY ASSURANCE AND CONTROL

None required.

10. DEVIATIONS FROM METHOD

This is a proprietary method developed by Paragon. Therefore, there are no deviations to be noted.

11. SAFETY HAZARDS AND WASTE

11.1 SAFETY AND HAZARDS

11.1.1 Safety glasses, lab coats and gloves should be worn in the laboratory at all times.

11.1.2 Use care when handling strong acids (e.g., HNO_3, HCl, etc.). Work only in a fume hood with adequate ventilation and wear appropriate eye, face, and body protection.

11.2 WASTE DISPOSAL

11.2.1 The process waste from this procedure has been determined not to be hazardous other than the characteristic hazard of corrosivity. After pH determinations, strips are set aside to dry, then disposed of in the sanitary trash.

11.2.2 Sample residuals should be disposed of in the appropriate SAA.

12. REFERENCES

None.

DOCUMENT REVISION HISTORY

9/28/07 Minor editorial corrections throughout. In Summary and Section 8.5.4, updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57). Added DOCUMENT REVISION HISTORY.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 739 REVISION 9

TITLE: **PREPARATION OF SAMPLES FOR ANALYSIS BY GAMMA SPECTROSCOPY**

FORMS: **302** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/15/07

QUALITY ASSURANCE MANAGER _____ DATE 8/12/07

LABORATORY MANAGER _____ DATE 8-16-07

HISTORY: Rev0, 9/20/93; Rev1, PCN #104, 1/24/94; Rev2, PCN #412, 3/21/95; Rev4, 10/12/00; Rev5, 3/11/02; Rev6, 4/07/03; Rev7, 8/27/03; Rev8, 10/3/03 and 1/31/05 (no revisions); Rev9, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps used to prepare soil, water and sludge samples for gamma spectroscopy analysis. Vegetation, air filter and bioassay samples are not addressed in this SOP, and must be handled on a case-by-case basis.

2. SUMMARY

Soils and sludges are prepared (i.e., dried and sieved) per SOP 721, prior to beginning the procedure outlined in this SOP. Some soils and sludges may omit such preparations if approval is given by the Radiochemistry or Project Manager. Waters are either filtered or left unfiltered prior to preparation as per work order or Radiochemistry Manager instructions. Waters are measured volumetrically into an appropriately sized Marinelli beaker. Soils are measured gravimetrically into a Lermer jar or a steel can, as appropriate for the sample size and the analyte. The gamma spec containers are sealed with their lids, and wiped with a damp paper towel to remove potential contamination.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 These procedures are to be performed only by personnel who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specification related to the client, project, and test method being performed.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Gamma spec samples must be produced only in the specific geometry for which the Instrumentation Group has calibrated their spectrometers.

4.2 New containers ordered for gamma spec must be equivalent to those currently in use. The Radiochemistry Manager or designee must approve the use of alternate containers or supplies in advance.

4.3 Gamma spec containers are not reusable due to the possibility of carry-over in the next analysis. Once the analysis is complete, the container is returned to the sample storage area.

4.4 The prep and instrumentation technicians maintain the internal Chain of Custody (COC). When the original client sample container is taken by a prep technician from the sample storage area, he/she logs the sample out as normal. Because gamma spec is a non-destructive test, samples that are designated for other (non-volatile) tests may be used. Check with Group Leaders if there are questions concerning sample availability or if samples are turn-around-time sensitive.

4.5 The prep technician is responsible for creating a gamma fraction for chain of custody. The prep analyst logs out the gamma container on behalf of the counting room analyst and relinquishes the sample along with the benchsheet. After counting, the gamma spec analyst will return the samples to the sample storage area and check them in. If the aliquot taken for gamma spec is needed for other analyses, log in/log out activities are managed by barcode scanning (COC SOP 318).

4.6 The standard filter geometry is a 47mm diameter filter mounted in a 2" stainless steel planchet. For Ra-226 analysis of a solid/soil sample, the packing must be done in a can as a geometry (GEO) 17. Usually the can packing will be done on an “As Received” basis, and the % moisture data will be provided to report on a dry weight basis. If the sample volume is limited, regular Gamma can be packed as a GEO 11 and the “Ra-can” could be packed with the available sample. If the can is not filled to the top, the technician should mark a line on the outside of the container indicating the height of the actual sample and write a Quality Assurance Summary Sheet (QASS), Form 302. This documentation will be included in the final report.

4.7 Filter samples can be digested using SOP 773 or SOP 767, then the digestate is diluted to 1000mL with DI water and packed for Gamma as GEO 1. Samples like vegetation, debris, gloves, wipes, iron bar, lead blocks, ashes, fruits, fish, cloth,

wood chips etc., will be treated with different methods based on the nature of the samples and conditions. The samples may be leached using different acids or digested and packed with different GEO. However, all geometry preparations will be documented on a QASS and a copy will be attached to the benchsheet.

5. APPARATUS AND MATERIALS

5.1 Balance, top loading, 0.01g sensitivity

5.2 Scoops, spatulas, tongue depressors

5.3 Graduated cylinders, type TD (to deliver), 1L

5.4 Marinelli beakers with lids, Ga-ma # 138G, or equivalent *, 2L

5.5 Lermer Jars with 89mm screw lid, plastic, or equivalent *, 16oz

5.6 Large funnel, glass/plastic

5.7 Vinyl tape

5.8 Parafilm™

5.9 Qualitative filter paper, fluted, VWR brand #313 or equivalent

5.10 Cans for Geo 17, House of Cans #3104 or equivalent *

* ***Equivalent containers require approval by the Radiochemistry Manager or designee.***

6. REAGENTS

Deionized (DI) water, obtained from the laboratory's DI water system

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Samples may be collected in any type of glass or plastic container.

7.2 Aqueous samples should be preserved to pH<2 with nitric acid.

7.3 If samples are to be stored for an extended period of time, refrigeration is recommended to prevent biological growth in the sample.

7.4 At the current time, there is no regulatory holding time established for gamma analysis. Many sampling and analysis plans, however, apply a default holding time of 180 days from date of collection. If samples are analyzed more than 180 days after collection, this fact should be noted in the laboratory data package case narrative.

8. PROCEDURE

8.1 PROCEDURE FOR WATER SAMPLES

8.1.1 Samples must be properly preserved before aliquotting. Verify that the pH is less than 2, per SOP 733. If the sample contains visible sediment or other conditions exist that make preservation impractical, notify the

Project Manager (PM) of the lab's intent to proceed with analysis of the unpreserved sample and document the situation on a Quality Assurance Summary Sheet (Form 302).

8.1.2 Do not prepare water samples in the same workspace where soil samples are being prepared. This avoids cross-contamination by dust.

8.1.3 If the sample contains sediment or suspended solids, check the work order for specific instructions as to whether or not the sample should be filtered. If it is not specified, filter per SOP 721. If the project instructions specify "Dissolved" or "Filtered", filter the sample through a fluted filter into a clean 1L graduated cylinder. Pre-filtering may be required for especially turbid samples. If the project instructions specify "Total" or "As Received," shake the sample container to mix thoroughly and aliquot as received.

8.1.4 Liquid samples are prepared in 2L Marinelli beakers. Measure the appropriate volume of water sample in a clean 1L type TD graduated cylinder to the nearest 0.01L (i.e., 10mL). Empty the sample into a clean, labeled Marinelli beaker.

8.1.5 The gravimetric method is adapted for liquid samples other than water. Place an empty Marinelli beaker on the top loading balance and tare the balance to zero. Add the sample slowly into the Marinelli beaker until the final weight is 1000 + 0.01g.

NOTE: If the sample volume provided falls short of the desired geometry, dilute to the appropriate geometry with DI water (e.g., dilute 600mL to 1L). *Make sure to record the original volume on the container and on the benchsheet.*

8.1.6 A method blank is made by adding a representative volume of DI water to an empty, labeled Marinelli beaker. The aliquot size used for the blank is the average volume of the sample volumes involved in the batch. The collection date for the blank is the date the samples are packed.

8.1.7 A Laboratory Control Sample (LCS) needs to be created on the benchsheet for every batch of twenty samples. The prep technician does not physically prepare the LCS, instead, the gamma spec analyst uses a pre-made, independent second source LCS obtained from an outside vendor. The information to be filled in on the benchsheet for the LCS varies depending on the GEO size. For waters, indicate the following:

GEO NUMBER	LCS ALIQ.SIZE
1	1000 mL

8.1.8 Attach the lid of the Marinelli beaker and seal the lid using vinyl tape. Wipe the exterior of the container with a damp paper towel to remove potential contamination. Make sure the container is labeled with the sample ID, aliquot size, date of prep and initials.

8.1.9 Submit the prepared samples to the counting room. The counting room will analyze the samples in the manner described in SOP 713. Upon completion of gamma counting, the sample fraction will be returned to the sample storage area and the gamma spec analyst will check the sample back in to the storage area per COC SOP 318 procedures.

8.2 PROCEDURE FOR SOIL AND SLUDGE SAMPLES

8.2.1 Unless approval to the contrary is given, all soil samples must be dried and sieved through a number 4 sieve prior to preparation for gamma spec analysis. Consult SOP 721 for drying and sieving procedures.

Containers for gamma spec soils are usually prepared when the soil is being prepared for other analyses under SOP 721. The gamma spec prep worksheet for soils should be filled out manually by the prep technician at the time of packing gamma, and the electronic benchsheet will be created later on. The prep worksheet will be attached to the benchsheet when the sample is relinquished to the counting room.

The benchsheet provides information about the prep date, technician, balance number, report basis, etc., as well as all the information about how the sample was packed. Any unusual situation will be documented on a QASS (Form 302).

8.2.2 When using Lermer jars, fill the container to the appropriate level according to the desired geometry. If enough sample is provided, use Geometry 13 (500g). If not, reduce the sample volume to Geometry 11 (100g).

8.2.2.1 Sample volumes should be maintained to within ½ cm of the correct geometry height in the container.

8.2.2.2 Zero out the container weight on the balance prior to weighing out a sample..

8.2.2.3 Soil samples should be well settled into their containers by gentle shaking with the lid on. Do not pack or compress soils into the containers.

8.2.2.4 Consult the Radiochemistry Manager or Group Leader if the sample volume provided is less than a Geometry 11. The analysis will usually still be conducted, but the Project Manager will need to be informed because of the effects on the efficiency calibration and detection limits.

8.2.3 For Ra-226 analysis by gamma spec, the samples will be packed as a GEO 17. Generally, the samples will be packed on a "Dry" basis, however, due to rush turn around times, the sample can be packed "As Received". To accomplish this, transfer the sample to a steel can (appropriate for GEO 17), until it is filled to the top. Tap the can to remove air pockets and to settle the sample. Do not press or "pack" the sample into the can. Add more sample to fill the can to the top. To ensure a tight seal, place a piece of Parafilm over the top of the can then cap the can with the metal lid and seal with the can sealer. Remove any excess Parafilm^{TM} from the outside of the can.

8.2.4 A Laboratory Control Sample (LCS) needs to be created on the benchsheet for every batch of twenty samples. The prep technician does not physically prepare the LCS, instead, the gamma spec analyst uses a pre-made LCS obtained from an outside vendor. The information to be filled in on the benchsheet for the LCS varies depending on the GEO size as follows:

GEO NUMBER	LCS ALIQ.SIZE
11	100g
13	500g
17	215g
26	215g
7	1s
8	1s
9	1s

8.2.5 After the preparation worksheet and the benchsheet are completed, fill out the LIMS tracking sheet. Submit the packet for a peer review.

8.2.6 Submit the samples prepared as above to the counting room. The counting room will analyze the samples in the manner described in SOP 713. Upon completion of gamma counting, the sample fraction will be returned to the sample storage area and the instrument analyst

will check the sample back in to the storage area and fill out the internal COC.

8.3 CALCULATIONS

TPU FACTORS. As defined in SOP 708, the following preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU):

8.3.1 Water samples require a preparation uncertainty factor of 0.0504 at the one-sigma level. This is based on one gross aliquoting (sample homogeneity) and one volumetric measurement. See the following equation:

$$0.0504 = \sqrt{0.05^2 + 0.006^2}$$

8.3.2 Solid samples require a preparation uncertainty factor of 0.0501 at the one-sigma level. This is based on one gross aliquoting (sample homogeneity) and one mass measurement. See the following equation:

$$0.0501 = \sqrt{0.05^2 + 0.003^2}$$

8.3.3 In practice, these two TPU factors are substantially equivalent. To simplify the data reporting procedure, the greater of the two (0.0504) may be used for both matrices.

9. QUALITY CONTROL

9.1 Method blanks will be run at a frequency of five-percent (i.e., one per 20 field samples) with a minimum of one per batch. Method blanks for water consist of deionized (DI) water. Method blanks for solid samples consist of an empty container, appropriate for the geometry (i.e., 13, 11, 17).

9.2 Laboratory Control Samples (LCS) will be run at a frequency of five-percent with a minimum of one per batch. The LCS consists of a pre-made source from an outside vendor.

9.3 Duplicate samples will be run at a frequency of ten-percent with a minimum of one per batch. If insufficient volume is available for a duplicate, a count duplicate may be used.

NOTE:

10. METHOD DEVIATIONS

SOP 739 is a Paragon Analytics procedure and there are therefore no deviations from a reference method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or when handling materials or equipment potentially contaminated with chemicals.

11.1.3 Soil samples should be handled in a hood as much as possible to avoid inhalation and cross contamination with dust. Workspaces should be wiped down with damp paper towels whenever dust is evident and always at the end of the shift.

11.1.4 Any non-original containers that are used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at minimum with: 1) the compound name, 2) NFPA Health, Flammability, and Reactivity ratings, and 3) date.

11.2 WASTE DISPOSAL

11.2.1 All waste materials (e.g., filter papers, paper towels, etc.) shall be surveyed for radioactivity and disposed of accordingly.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

12. REFERENCES

SOP 708, "Calculations for Radioanalytical Results."

DOCUMENT REVISION HISTORY

8/12/07: Updated references and added LIMS program specification language, Section 3.3. Updated COC language to barcode scanning throughout. Correction of Ra226 soil/sludge sample containers from aluminum to steel. Revamped Quality Control requirements, other format, clerical and typographical changes. Added DOCUMENT REVISION HISTORY and Forms.

TITLE: **DETERMINATION OF RADIUM-228 ACCORDING TO EPA METHOD 904.0 OR SW846 METHOD 9320, WITH MODIFICATIONS.**

FORMS: 631 **(use most current iteration)**

APPROVED BY:
TECHNICAL MANAGER _____ DATE 6/27/06
QUALITY ASSURANCE MANAGER _____ DATE 6/24/06
LABORATORY MANAGER _____ DATE 6-27-06

HISTORY: Rev0, 2/1/99; Rev1, 2/8/99; Rev2, 10/7/99; Rev3, 1/26/00; Rev4, 10/19/00; Rev5, 3/13/02; Rev6, 4/7/03; Rev7, 8/27/03; Rev8, 6/26/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- EPA Method 904.0 and SW-846 Method 9320 -- describe the measurement of radium-228 in waters, ground waters, and waste samples. This technique is devised so that the beta activity from actinium-228, which is produced by decay of radium-228, can be determined and related to the activity concentration of radium-228 present in the sample.

This SOP includes instruction for the digestion and separation of soil matrices. However, due to significant potential matrix interference issues, it is STRONGLY recommended that radium-228 analysis in soil and solid matrices be performed by gamma spectrometry, as described in PAR SOP 713. Where the use of this method is required for solid matrices, the default sample size is 0.5 grams, to achieve an MDC of approximately 5pCi/g. This allows for commonly encountered matrix interference issues, including low chemical recoveries.

To quantify actinium-228 and thereby determine radium-228, the efficiency of the beta counter for measuring the very short half-lived actinium-228 (avg. beta energy of 0.404MeV), is to be calibrated with a beta source of comparable average beta energy such as Sr-89 (avg. beta energy of 0.589MeV).

If desired, the determination of radium-226 may be conducted on the purified radium solution prior to barium sulfate precipitation determination of the chemical yield. Methods 903.1, 903.0 or their equivalent methods in SW846, HASL, or Standard Methods, are compatible with this approach.

2. SUMMARY

2.1 The radium isotopes in a water sample are collected by co-precipitation of barium and lead sulfate and purified by re-precipitation out of a basic EDTA solution.

After a 36-hour period to allow for the ingrowth of actinium-228, lead is removed as PbS, actinium is carried on yttrium (Y) as the hydroxide and mounted as the oxalate, and quickly beta counted to minimize decay of the short-lived Ac-228 (~6 hours).

2.2 In solids, radium-228 is liberated from the solid matrix by a total digestion of the solid. The sample is muffled, transferred to a polypropylene specimen cup and digested in the presence of strong acids. After digestion, the sample is brought up to volume with DI water and prepared as a water sample.

2.3 If radium-226 according to EPA Method 903.0 or 903.1 is requested, the supernatant containing radium following separation of the Y/Ac is taken into SOP 712 or 783, as appropriate.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst performing the method to notify the Instrument Lab Gas-Flow Proportional Counter analyst in advance of the number of samples arriving and the expected delivery date and time. This allows the analyst to schedule adequate instrument time to analyze the short-lived Ac-228 analyte.

3.2 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.3 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specifications related to the client, project, and test method being performed.

3.4 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action

taken and documented.

4. INTERFERENCES

4.1 As indicated in EPA method 904.0, performance studies show that the presence of strontium / yttrium-90 in a water sample will lend a positive bias to the measured radium-228 activity.

4.2 Excess barium in the sample may interfere with an accurate chemical yield determination.

4.3 The presence of significant quantities of dissolved constituents that may form insoluble sulfate precipitates interferes with the proper separation of radium and the subsequent quantification of Ra-228. In this case, reduced sample volumes may be required to minimize the matrix interference effects.

4.4 The presence of sediments in the preserved sample is a significant interference to this method. The client should field-filter the samples prior to preserving with HNO_3 and prior to sending them to Paragon. Concerns arise since the 'preservation' recommended by the EPA (adding acid to samples which may also contain barium and or sulfates), will potentially lead to analyte loss due to precipitation. If sediments are removed following 'preservation', significant analyte loss is possible. Likewise, if sediments are left in a sample, which is subsequently nitric acid preserved, radium leaching from the sediments may lead to a very significant high bias in measured radium concentrations.

4.4.1 The presence of significant quantities (>500mg) of suspended solids in a sample will interfere with collection of the barium sulfate precipitate. Any sample having visible sediments will be filtered prior to sample preparation.

5. APPARATUS AND MATERIALS

5.1 Stirring hot plate

5.2 Magnetic stir bars

5.3 Centrifuge

5.4 Polypropylene centrifuge tubes, Falcon 50mL, do not substitute

5.5 Stainless steel counting planchets, 2", flat

NOTE: Prior to use, the planchets are soaked in diluted Radiacwash™ for approximately three hours, drained, rinsed with deionized water, transferred to a metal pan, and placed in the drying oven until dry.

5.6 Plastic funnels

5.7 Graduated cylinders, 100mL and 1 or 2L

5.8 Pyrex™ beakers, or equivalent, 2L

5.9 Forceps

5.10 Polypropylene specimen cups, with lids, 150mL

5.11 Polypropylene specimen cups, 250mL

5.12 Eppendorf™ pipettors, or equivalent

5.13 Test tubes, 15mL polypropylene, disposable

5.14 Polyethylene test tube caps

5.15 Re-pipettor, Eppendorf™, Model 4780 or equivalent

5.16 Parafilm

5.17 Desiccator

5.18 Vortex mixer

5.19 Hot water bath

5.20 Transfer pipets

5.21 Whatman™ #42 filter papers, ashless, 90mm diameter

5.22 Qualitative fluted filter paper

5.23 Beakers, 100mL, Pyrex™, or equivalent

5.24 Analytical balance, Mettler™ AE 200, or equivalent

6. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a Threshold Limit Value (TLV) of less than 50ppm, shall be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Deionized (DI) water

6.2 Acetic acid, 17.4M, Glacial CH_3COOH, reagent grade, concentrated
TLV = 10ppm (TWA); Irritant

6.3 Ammonium hydroxide, 15M, NH_4OH, reagent grade, concentrated
TLV = 25ppm (TWA for NH_3)

6.4 Ammonium oxalate, 5%: Dissolve 25g $(NH_4)_2C_2O_4 \cdot H_2O$ in about 400mL of hot DI water. When cool, dilute to 500mL with DI water.

6.5 Ammonium sulfate, 200mg/mL: Dissolve 200g $(NH_4)_2SO_4$ in DI water and dilute to 1000mL.

6.6 Ammonium sulfide, 2%: Dilute 10mL $(NH_4)_2S$ (20-24%) to 100mL with DI water.

6.7 Standardized Barium Carrier, 16mg/mL (27mg/mL $BaSO_4$ yield)

6.8 Place a 1000mL Class A volumetric flask on a stir plate, add a stir bar and ~500mL of DI water. Add 28.5g $BaCl_2 \cdot 2H_2O$ and stir until completely dissolved, then add 5mL 16M HNO_3. Remove stir bar, rinsing with DI water, and dilute to 1000mL with DI water. Transfer to a clean, labeled 1L poly container. Document the preparation of this carrier in the Reagent Prep Logbook and Paragon's Standards and Solutions Database.
TLV = 0.5mg Ba/m^3 = 0.06ppm (TWA). Irritant

STANDARDIZATION OF Ba CARRIER BY ICP ANALYSIS
Prepare in triplicate a 1000-fold dilution of the Ba carrier using the ICP solution described in Section 6.11 below. Submit to the Metals Lab for analysis. Average the results and record in the reagent prep logbook.

6.9 Citric acid, 1M: Dissolve 210.14g of $C_6H_8O_7 \cdot H_2O$ in DI water and dilute to 1000mL.

6.10 EDTA basic reagent, 0.25M: Dissolve 80g NaOH in ~3L of DI water. Slowly add 372g of (ethylenedinitrilo)tetraacetic acid, disodium salt, dihydrate - EDTA ($C_{10}H_{14}N_2Na_2O_8 \cdot 2H_2O$), while stirring. After the salt is in solution dilute to 4L. If necessary, adjust the pH to ≥10 using a minimal volume of 10M NaOH.

6.11 ICP diluting solution (1% HNO_3 / 5% HCl). Carefully add 10mL of concentrated HNO_3 and 50mL of concentrated HCl to 940mL of DI water. Mix thoroughly.
TLV = 2ppm for conc. HNO_3 (TWA), and 5ppm for conc. HCl (ceiling). Both irritants, corrosive

6.12 Lead carrier, 15mg/mL: Dissolve 23.98g $Pb(NO_3)_2$ in DI water. Add 5mL 16M HNO_3 and dilute to 1000mL with DI water.
TLV = 0.05mg/m^3 (=0.004ppm)

6.13 Lead carrier, 1.5mg/mL: Dilute 10mL lead carrier (15mg/mL) to 100mL with DI water.
TLV = 0.05mg/m^3 (=0.004ppm)

6.14 Methyl red indicator solution: Dissolve 0.100g methyl red sodium salt powder in 100mL of DI water.

6.15 Nitric acid reagent concentrated (16M HNO_3)
TLV = 2ppm (TWA). Irritant, corrosive

6.16 Nitric acid, 6M: Slowly and carefully add 375mL of concentrated nitric acid (reagent 6.15) while stirring to 625mL of DI water.
TLV=2ppm (TWA). Irritant, corrosive

6.17 Nitric acid, 1M: Add 63mL of concentrated nitric acid while stirring to 937mL DI water.
TLV = 2ppm (TWA). Irritant, corrosive

6.18 Sodium hydroxide, 18M: Place about 500mL of DI water in a beaker in a cold water bath. Very slowly and carefully dissolve 720g of NaOH; work in the hood. The solution will boil if the NaOH is added to quickly. After the solution is cool, dilute to 1L with DI water. Store in a plastic container.
TLV = 2mg/m^3 = 1.2ppm (ceiling). Irritant

6.19 Sodium hydroxide, 10M: Follow the same procedure as above, but use 400g of NaOH instead. Store in a plastic container.
TLV = 2mg/m^3 = 1.2ppm (ceiling). Irritant

6.20 Strontium Carrier, 20mg/mL: Dissolve 48.3g $Sr(NO_3)_2$ in DI water. Add 1mL 16M HNO_3, then dilute to 1000mL with DI water.

6.21 Sulfuric acid, 18N, H_2SO_4: Very carefully and gradually, add 500mL of reagent grade concentrated sulfuric acid, while stirring, to 500mL DI water.

CAUTION: The solution will boil if the reagent is added too quickly.
TLV = 1mg/m^3 (=0.25ppm) (TWA). Irritant

6.22 Sulfuric acid, 0.1N H_2SO_4: Add 5.6mL of 18N H_2SO_4 to ~900mL of DI water. Mix well and dilute to 1L with DI water. Alternately, add 120mL of 18N H_2SO_4

to ~2L of DI water, mix well and dilute to 22L.
TLV = 1mg/m^3 (=0.25ppm) (TWA). Irritant

6.23 Yttrium carrier, 9mg /mL: Add 1.143g Y_2O_3 to a Class A volumetric flask (100mL), and add 10mL DI water. Heat to boiling and, while stirring with a magnetic stirring hot plate, add small portions of conc. HNO_3. (About 6mL is necessary to dissolve the Y_2O_3. Small additions of deionized water also may be needed to replace the water lost by evaporation). After total dissolution, add 4mL conc. HNO_3 and dilute to 100mL with DI water (1mL = 9mg/mLY^{+3}).

Standardization: In triplicate, take 0.5mL of the Yttrium carrier solution and dilute 20-fold with DI water. Determine the concentration by ICP analysis.

6.24 Strontium-yttrium mixed carrier, 0.9mg Sr and 0.9mg Y / mL

6.24.1 Prepare Solutions A and B as indicated below:

Solution A: Dilute 20 mL of yttrium carrier to 100mL, using DI water.

Solution B: Dissolve 0.4384g. $Sr(NO_3)_2$ in DI water and dilute to 100mL.

6.24.2 Combine equal volumes of Solutions A and B; 1mL = 0.9mg Sr and 0.9mg Y.

6.25 Hydrofluoric acid (HF), 48.0-51.0%, conc.
TLV = 3ppm (ceiling). Irritant, burns, bone, teeth, fluorosis

6.26 Hydrochloric acid (HCl) 12M, reagent grade
TLV = 5ppm (ceiling). Irritant, corrosive

6.27 Triton X-100™ non-ionic surfactant solution, VWR #3929-2, or equivalent

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 It is recommended that samples be preserved at the time of collection by adding enough 1M HNO_3 per liter of sample to bring the pH to 2 (15mL 1M HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days, then preserved, and held in the original container for a minimum of ~~16~~ 24 hours before analysis or transfer of the sample.

7.2 The container choice should be plastic (rather than glass) to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 AQUEOUS SAMPLE PREPARATION

8.1.1 Verify and record (on Form 631) the pH of the sample according to SOP 733.

8.1.2 1.5L is a typical sample aliquot size for this method. However, this volume may need to be reduced if matrix interference is suspected. Use a graduated cylinder to measure the sample and pour into a clean, labeled 2L beaker. If less than 1.5L is used, record volume, then dilute to 1.5L with DI water.

8.1.3 Prepare quality control (QC) samples per Section 9.

8.1.4 Place the beakers on stirring hot plates. Add a stir bar to each.

8.1.5 To each sample, add 8mL of 1M citric acid, 8-10 drops of methyl red indicator, and 2 drops of non-ionic surfactant. The solution should be pink.

8.1.6 For all sample matrices, add 10mL of lead carrier (15mg/mL), 1mL of strontium carrier, 2mL of non-standardized yttrium carrier.

8.1.7 For solid samples that have undergone the digestion procedure described in Section 8.2.1, skip to Section 8.1.8. For aqueous samples, add 2.0mL of standardized barium carrier. Prepare a reference carrier solution by adding 2.0mL of standardized barium carrier to 1.5L of DI water. Add the appropriate amount of ^{228}Ra spiking solution to samples that require it per Section 9.

8.1.8 Add 15M NH_4OH drop-wise until a definite yellow color is obtained; then add a few drops in excess.

8.1.9 Heat to incipient boiling and maintain at this temperature for 30 min. while stirring.

8.1.10 Precipitate lead and barium sulfates by adding 18N H_2SO_4 drop-wise until the pink color reappears; then add 0.25mL excess (~5 drops). Add 8mL $(NH_4)_2SO_4$. Stir constantly and maintain temperature for 30 minutes. If the indicator has been destroyed during digestion, add a few drops of methyl red indicator.

8.1.11 Remove stir bars, rinsing with 0.1N sulfuric acid, and allow the solution to cool. Let precipitate settle for at least 4 hours or preferably overnight.

8.1.12 Aspirate supernatant. Transfer precipitate to a 50mL poly centrifuge tube, rinsing the last particles out of the beaker with 0.1N H_2SO_4. Centrifuge at 3,500 rpm for 10 minutes and discard the supernatant into the laboratory sink followed by plenty of cold tap water. **NOTE – For the remainder of this procedure any reference to centrifuging means centrifuge at 3,500 rpm for 10 minutes.**

8.1.13 Wash the precipitate with 15mL 16N HNO_3, vortex, centrifuge, and discard the supernatant into the laboratory sink or into the back of a fume hood, followed with plenty of cold tap water. Repeat this washing a second time. At the analyst's discretion, additional washes may be performed to thoroughly remove interfering constituents.

8.1.14 Add 25mL EDTA basic reagent and vortex well. Heat in a hot-water bath for about 10 min., stirring occasionally to aid in dissolution. If the precipitate does not dissolve after heating on the hot-water bath, add up to four 5.0mL increments of EDTA reagent until the precipitate dissolves completely. If the precipitate persists, an additional 5.0mL of 10M NaOH may be added. Document the total volume of EDTA reagent used to dissolve the precipitate on the benchsheet. If the sample re-precipitates while cooling, add a few drops of 10M NaOH to dissolve. Vortex to mix the solution and take the aliquot for the initial ICP analysis. If solids persist, consult your Supervisor prior to filtering per SOP 712.

8.1.15 How to take initial ICP aliquot

8.1.15.1 Vortex the sample to mix thoroughly. Using a calibrated pipette, aliquot 0.1mL of sample into a clean, labeled test tube containing 9.9 or 10mL of DI water (record the volume of water used). Cover with Parafilm, and invert several times or vortex to mix completely. With a calibrated pipette, aliquot 1.0mL of the diluted sample into another clean test tube labeled with the sample ID and "i" and containing 9.0mL of ICP diluting solution. Cover with a test tube cap and mix well. Set aside until final ICP aliquot has been taken.

8.1.15.2 At this time prepare an ICP "reference carrier" (RC) sample. Thoroughly mix the reference carrier solution, prepared in Section 8.1.6, on a stir plate. Add 1.0mL of the reference carrier solution to 9.0mL of ICP diluting solution, as stated above for samples. This RC sample will be submitted with the batch samples for ICP analysis to provide a reference

concentration for the yield calculations.

8.1.16 Add 1mL of strontium-yttrium mixed carrier, and mix thoroughly. Add a few drops of 10M NaOH if any precipitate forms.

8.1.17 Add 1mL $(NH_4)_2SO_4$ and stir thoroughly. Add 17.4M acetic acid drop-wise until barium sulfate precipitates; then add 2mL excess. **Do not vortex.** Heat in a hot water bath (about 10 min.) until precipitate settles. Centrifuge and discard supernatant into the Ba/Pb waste carboy, per Section 12.2 of this SOP.

8.1.18 Add 25mL EDTA basic reagent, vortex and heat in a hot-water bath until precipitate dissolves, (additional volume of EDTA reagent may be needed if the precipitate does not dissolve completely) then repeat Step 8.1.17. *Note the time of last barium sulfate precipitation on the benchsheet; this is T1, the beginning of the actinium-228 ingrowth time.*

8.1.19 Dissolve the precipitate with 25mL EDTA basic reagent. As before (i.e., Step 8.1.18), additional EDTA reagent may be required if the precipitate does not dissolve completely. Then add 1mL of lead carrier (1.5mg/mL) and 1.0mL of standardized yttrium carrier. If $BaSO_4$ precipitates (a cloudy white solid), dissolve with a few drops of 10N NaOH. If $Y(OH)_3$ forms (a stringy, floating precipitate), dissolve with a few drops of 16M HNO_3.

NOTE: Prepare a reference carrier solution by adding 1.0mL of standardized yttrium carrier to a 50mL centrifuge tube. To this, add 25mL of 8M HNO_3 and dilute to 50mL with DI water. Cap the polypropylene tubes and routinely store for **36 hours for ingrowth of Ac-228**.

8.1.20 After the 36-hour ingrowth period, vortex the samples. Add 0.3mL (about 6 drops) $(NH_4)_2S$ and 0.5mL (about 10 drops) 10M NaOH. Cap and shake vigorously until lead sulfide precipitates. Centrifuge and decant supernatant into a clean tube. Rinse the centrifuge tubes into the Ba/Pb waste carboy. Used centrifuge tubes may be soaked in Radiacwash, rinsed in tap water and discarded in the sanitary trash.

8.1.21 In preparation to perform Step 8.1.24, place a bottle of 18M NaOH on a stir plate and mix thoroughly.

8.1.22 Add 1mL lead carrier (1.5mg/mL), 2 drops $(NH_4)_2S$, and 2 drops of 10M NaOH to repeat precipitation of lead sulfide as before. Centrifuge and filter supernatant through Whatman™ #42 filter paper, ashless, 90mm diameter, and into a clean tube. Precondition the filters

with ~1mL of DI water. After the sample has passed through the filter, rinse twice with 1mL of DI water. Discard the filters into the filter lead waste. Rinse the funnels with 1mL of DI water, collecting the filtrate into the centrifuge tube.

8.1.23 **Due to the short half-life of actinium-228, the remainder of the prep should be completed in less than 4 hours. The Counting Lab should be notified in advance of incoming samples.**

8.1.24 Add 16mL of thoroughly mixed 18M NaOH to each sample. Cap and shake well and digest in a hot water bath for about 30min. until yttrium hydroxide coagulates.

NOTE: Document time of yttrium hydroxide precipitation as T2 (time when samples come off steam bath); *this is the end of the actinium-228 ingrowth time and the beginning of actinium-228 decay time*.

8.1.25 Centrifuge and decant the supernatant into a 150mL poly specimen cup. *Save for barium yield determination (Section 8.1.27).*

8.1.26 Dissolve the precipitate with 2mL 6M HNO_3. Vortex and heat in a hot water bath for about 5min. Add 3mL DI water and re-precipitate yttrium hydroxide with 6mL 10M NaOH. Vortex and heat in a hot water bath for about 10min. until precipitate coagulates. Centrifuge and add this supernatant to the supernatant produced in the previous Step in order to determine barium yield. Using a 100mL graduated cylinder, measure this combined supernatant and record the volume on the benchsheet.

8.1.27 FINAL ICP ANALYSIS. The aliquot for final ICP analysis must be taken from the combined supernatant collected. Follow the steps outlined in Section 8.1.15 to obtain the final ICP aliquot.

Upon the return of ICP sample fractions to the prep lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the PAR wastewater treatment facility (i.e., down the laboratory sink with plenty of cold tap water). The remaining Ba supernatant from above can be disposed of into the Ba/Pb waste carboy. The test tubes and centrifuge tubes may be soaked in Radiacwash™ and rinsed with tap water. Dispose of the centrifuge tubes and test tubes in the sanitary trash.

8.1.28 Dissolve the precipitate with 2mL 1M HNO_3, vortex, and heat in a hot water bath for 5min. Additional 1M HNO_3 may be added drop wise to achieve dissolution of the precipitate. If additional 1M HNO_3 is used,

add proportionally increased volumes of DI water and 5% $(NH_4)_2C_2O_4 \cdot H_2O$ (Ammonium Oxalate) in the following Step.

8.1.29 Add 3mL of DI water and 2mL 5% $(NH_4)_2C_2O_4 \cdot H_2O$; heat about 10min. to coagulate, centrifuge, and discard supernatant into the laboratory sink followed by plenty of cold tap water.

8.1.30 Rinse precipitate with 10mL of DI water. Centrifuge and discard supernatant into the laboratory sink.

8.1.31 Add 10mL of DI water, 6 drops 1M HNO_3 and 6 drops 5% $(NH_4)_2C_2O_4 \cdot H_2O$. Heat and stir in a hot water bath for 5-6 min. The time on the water bath should be monitored carefully, as this may significantly affect the chemical yields for the samples. Centrifuge and discard supernatant into the laboratory sink.

8.1.32 Label a stainless steel planchet, per sample, and place planchets on a hot plate.

8.1.33 Add approximately 4mL of DI water to the centrifuge tubes and vortex until all of the precipitate is suspended. Working quickly to avoid the precipitate settling, remove the cap and rinse once with DI water; pour rinse into a planchet. Empty the contents of the centrifuge tube onto the planchet, rinse tube with DI water, add rinse to the planchet. The sample should be evenly distributed on the planchet. Allow solid to settle. Dry on a hot plate at setting 2 or 3. Submit planchets to the Counting Lab immediately for analysis. Used centrifuge tubes may be soaked in Radiacwash™, rinsed in tap water, and discarded in the sanitary trash.

8.1.34 After counting, place each planchet in a labeled 150mL poly cup and add approximately 10mL of 8M HNO_3 to dissolve the yttrium oxalate precipitate.

8.1.35 Thoroughly rinse the planchets with 8M HNO_3 into the poly cups. After rinsing, the planchets can be disposed of in the sanitary trash.

8.1.36 The dissolved sample and rinse is brought up to 50mL with DI water.

8.1.37 Remove a 0.5mL aliquot from each sample, including the reference carrier from the note after Step 8.1.19, into a 15mL test tube containing 9.5mL of ICP diluting solution, to bring the total volume to 10mL. The samples are then capped, shaken, and brought to the Metals Lab for yttrium analysis by ICP.

Upon the return of ICP sample fractions to the prep lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the PA wastewater treatment facility (i.e., down the laboratory sink with plenty of cold tap water). The test tubes may be soaked in Radiacwash™, rinsed with tap water, and disposed of in the sanitary trash.

8.2 SOLID SAMPLE PREPARATION

8.2.1 Verify and record (on Form 631) the condition of the sample.

8.2.2 Weigh 0.5g of dried, pulverized soil into a permanently labeled glass beaker. Record the sample weight and beaker number on the bench sheet.

8.2.3 Prepare QC samples according to Section 9.

8.2.4 Dry the beakers on a hotplate set at 2 (Samples must be completely dry prior to muffling.). Cover the beakers with a watch glass and muffle at 600°C for at least 4 hours.

8.2.5 Transfer the sample to a 250mL polypropylene cup, using at least 25mL 16N HNO_3 to rinse the beaker. Scraping with a plastic spatula may be necessary to remove all of the soil from the beaker.

8.2.6 Add 25mL HF, 25 mL 12N HCl, cover with a 100mL polypropylene cup, and heat for 4 hours on a steam bath.

8.2.7 Remove the 100mL beaker and evaporate to dryness. The 100mL beakers may be rinsed thoroughly with tap water and discarded into the sanitary trash.

8.2.8 Add 10mL 8N HNO_3, and approximately 100mL DI water to the samples while they are on the steam bath to facilitate dissolution.

8.2.9 Once the samples are fully dissolved, transfer the samples to 2L graduated cylinders using DI water to completely rinse the cups. Bring the samples to a final volume of 1500mL with DI water.

8.2.10 Transfer the samples to 2000mL beakers and proceed with aqueous sample preparation at Step 8.1.4.

8.3 PREPARATION OF CALIBRATION STANDARDS

8.3.1 Label and tare weigh 5 stainless steel 2-inch diameter flat planchets.

8.3.2 Spike between 1,000 and 10,000 dpm of NIST-traceable Sr-89 directly

onto each planchet.

NOTE: If the standard matrix is HCl, the standard must be converted to a nitric matrix during planchetting to avoid corroding the planchet. This can be accomplished by adding ~5mL 16N HNO_3 to the planchet along with the spiking solution.

8.3.3 Add 0.5mL of Sr carrier (approximately 10mg).

8.3.4 Dry on a hot plate set at "2".

8.3.5 Weigh on an analytical balance. Record the mass on the benchsheet.

8.3.6 Submit to the Counting Lab with all necessary documentation.

8.3.7 The calibration should be verified with the preparation and analysis of four method blanks and four ^{228}Ra LCSs, spiked at approximately 500dpm, performed per this SOP.

9. QUALITY CONTROL

NOTE: For solid matrices, the blank and LCS are prepared using a qualitative filter paper, instead of the 1500mL DI water used for aqueous QC.

9.1 One method blank, prepared with 1500mL of DI water, is prepared for each batch of twenty or fewer samples. To be acceptable, the method blank activity shall be less than the MDA (or, if higher, less than the contract required MDC). Samples associated with an elevated method blank are acceptable if the sample activity is greater than five times the blank activity.

9.2 One LCS, prepared with 1500mL of DI water for aqueous samples is prepared for each batch of twenty or fewer samples. The LCS activity should fall within the general range of 5-10 times the requested detection limit (default = 1pCi/L). The LCS sample accuracy (measured activity/added activity) will fall within currently established control limits, as described in the LIMS program specifications.

9.3 A duplicate is prepared at a frequency of one per ten or fewer samples. The duplicate sample DER will be within the established control limits, as described in the LIMS program specifications. Some clients may require use of RPD as a measure of precision. The duplicate sample RPD will be within specified control limits. Duplicate samples with activity levels less than 5 times the MDC will not be assessed using RPD.

9.4 Method 9320 requires that a matrix spike be prepared at a frequency of one per twenty or fewer samples. The matrix spike should fall within the general range of

5-50 times the expected sample activity. For samples that are not expected to be significantly above the default detection limit, the LCS spiking levels are appropriate for the MS as well. The MS sample recovery will fall within currently established control limits. Also, see note in Section 11.4 below.

9.5 The overall chemical yield, calculated as the product of the barium and yttrium yields, shall be 40-110%. The individual barium and yttrium yield should also fall within these limits.

9.6 Batches for which the associated QC samples do not meet established criteria may need to be rerun. A non-conformance report (NCR, SOP 928) should be filled out, the Radiochemistry Technical Manager notified and appropriate corrective action implemented and documented.

10. CALCULATIONS

10.1 Calculate the radium-228 concentration, Act, in pCi/L or pCi/g as follows:

$$Act = \frac{(SCPM - BKGCPM)(Ac * T_3/60)}{F * E * V * Y_T * D * (1 - e^{(-AcT_1)}) * (e^{(-AcT_2)}) * (1 - e^{(-AcT_3/60)})}$$

Where:

Act = sample activity (pCi/L, pCi/g)

SCPM = gross sample beta count rate (cpm)

BKGCPM = background beta count rate (cpm)

Ac = decay constant for actinium-228 = ln2 / 6.15 hours = 0.113075 h^{-1}

F = activity conversion factor from dpm (for pCi = 2.22, for Bq = 60)

E = actinium-228 detection efficiency (cpm/dpm)

V = sample aliquot (L, g)

Y_T = total chemical yield, see Section 10.8

D = decay correction for radium-228 = $e^{(-RaT4)}$

T_4 = time elapsed between sample collection (or reference date) and actinium separation T_1 (days)

Ra = decay constant for radium-228 = ln2 / 2100 days = 0.00033004 d^{-1}

T_1 = elapsed time (hours) between the start of the actinium ingrowth (T_0) and the start of actinium decay (T_1) = (T_1 - T_0)

T_2 = elapsed time (hours) between the start of the actinium decay (T_1) and the start of the sample count (T_2) = (T_2 - T_1)

T_3 = duration of sample count (min)

10.2 Calculate the one sigma associated counting uncertainty, CU, in pCi/L or pCi/g as follows:

$$Unc = \frac{\sqrt{(SCPM/T_3) + (BKGCPM/BT)}(Ac * T_3/60)}{F * E * V * Y_T * D * (1 - e^{(-AcT_1)}) * (e^{(-AcT_2)}) * (1 - e^{(-AcT_3/60)})}$$

Where:

BT = background count time

10.3 Calculate the one-sigma total propagated uncertainty (TPU), in pCi/L or pCi/g as follows:

$$TPU = \sqrt{CU^2 + (IU^2 * Act) + (PU^2 * Act)}$$

The instrument uncertainty, IU, can be found in SOP 743.

The prep uncertainty, PU, is 0.1374. This is based on SOP 743 guidelines for one gross aliquotting, four quantitative transfers, three volumetric measurements, and two ICP determinations:

$$0.1374 = \sqrt{0.05^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2 + 0.006^2 + 0.006^2 + 0.083^2 + 0.083^2}$$

10.4 Calculate the one sigma minimum detectable concentration, MDC, in pCi/L or pCi/g as follows:

$$MDC = \frac{(4.65 * \sqrt{(BKGCPM/T_3)} + 2.71)(Ac * T_3/60)}{F * E * V * Y_T * D * (1 - e^{(-AcT_1)}) * (e^{(-AcT_2)}) * (1 - e^{(-AcT_3/60)})}$$

10.5 The detection efficiency, E, is calculated as follows:

$$E = \frac{(StCPM - BKGCPM)}{StDPM}$$

10.6 Calculate the barium chemical recovery for aqueous samples, Ba, as a percentage, as follows:

$$Ba_i = V_i * ICP_i * DF$$

$$Ba_f = V_f * ICP_f * DF$$

$$Ba_{RC} = V_{RC} * ICP_{RC} * DF$$

$$Ba = \frac{Ba_f}{X} * 100$$

Where:

Ba_i = barium recovery from initial ICP aliquot (µg)

V_i = final dilution volume when taking initial ICP (mL)

ICP_i = initial barium concentration measured by ICP (µg/mL)

DF = dilution factor

Ba_f = barium recovery from final ICP aliquot (µg)

V_f = final dilution volume when taking final ICP (mL)

ICP_f = final barium concentration measured by ICP (µg/ml)

Ba_{RC} = barium recovery from RC aliquot (µg)

V_{RC} = RC final volume (mL)

ICP_{RC} = RC barium concentration measured by ICP (µg/mL)

X = either Ba_i or Ba_{RC}, whichever is greater

10.7 Calculate the yttrium chemical recovery for aqueous samples, Y, as a percentage, as follows:

$$Y_f = V_f * ICP_y * DF$$

$$Y_{RC} = V_{RC} * ICP_{yRC} * DF$$

$$Y = \frac{Y_f}{Y_{RC}} * 100$$

Where:

Y_f = yttrium recovery from final ICP aliquot (µg)

ICP_y = final yttrium concentration measured by ICP (µg/mL)

Y_{RC} = yttrium recovery from RC aliquot (µg)

ICP_{yRC} = RC yttrium concentration measured by ICP (µg/mL)

10.8 Calculate the total chemical yield, Y_T, as a percentage, as follows:

$$Y_T = Ba * Y * 100$$

For chemical yields above 100%, assume a quantitative recovery and use 100% in the yield calculation. This avoids a low bias in the final analytical results.

10.9 Calculate the actual volume, V_A, of sample analyzed (accounting for volumes of sample removed) as follows:

$$V_A = V * \frac{V_i - V_{ICP}}{V_i}$$

Where:

V_{ICP} = initial aliquot taken for ICP (mL)

11. DEVIATIONS FROM METHOD

11.1 EPA Method 904.0 addresses drinking water samples. There is no official holding time for analyses in the 900 series. This procedure is substantially compliant with Method 904.0.

11.2 Method SW846 9320 addresses ground water and waste water samples. There is a holding time of six months for SW846 9320. This procedure is substantially compliant with Method SW846 9320.

11.3 In addition to describing a procedure for aqueous samples, this SOP describes a procedure for determining Ra-228 in soil, which the laboratory employs at a client's request. Also, this SOP provides procedures for determining the chemical yield as an addition to EPA Method 904.0. This measurement increases the accuracy of the method.

11.4 Paragon routinely monitors Ba yields by ICP analysis, in which case, a matrix spike is not necessary. The client Statement of Work (SOW) should be checked for method and QC requirement specifications.

11.5 25mL of EDTA is used to dissolve the $Ba(Ra)SO_4$ precipitate. This volume ensures a complete dissolution of the precipitate in a normal sample.

11.6 Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of Paragon's internally derived acceptance criteria.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Safety glasses, and lab coats must be worn in the radiochemistry prep labs at all times.

12.1.3 Gloves, safety glasses, and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.7 below.

12.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.6 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.2 WASTE DISPOSAL

The analytical process effluent has been determined to not be hazardous in other than corrosivity except the Ba and Pb containing supernatants. These supernatants must be segregated into the Ba and Pb waste containers supplied by the Waste Disposal Coordinator.

STANDARD OPERATING PROCEDURE 748 REVISION 4

TITLE: PREPARATION OF WATER AND SOLID SAMPLES FOR THE ANALYSIS OF Fe-55 BY EICHROM METHOD FEW01

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07
QUALITY ASSURANCE MANAGER _____ DATE 9/3/07
LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, 3/2/02; Rev1, 4/7/03; Rev2, 8/27/03; Rev3, 11/29/04; Rev4, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the method for the preparation of water and solid samples for the analysis of Fe-55 using TRU® resin.

2. SUMMARY

Iron (Fe), including Fe-55, is isolated from a sample matrix using Eichrom TRU® resin, according to Eichrom Method FEW01. Fe is retained on the TRU® resin in 8N HNO_3 and is eluted from the resin with 2N HNO_3. The purified sample is mixed with liquid scintillation cocktail and analyzed on a liquid scintillation counter. An aliquot of the sample is analyzed for Fe by Inductively Coupled Plasma Atomic Emission Spectroscopy (ICP-AES) before and after purification on the column, to provide a measure of chemical yield.

Fe-55 is analyzed directly by liquid scintillation counting. No other parent nuclides or progeny are involved in this analysis. Under normal conditions, default MDCs are 50 pCi/g in solids and 50 pCi/L in waters.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 It is the responsibility of the analyst to perform the calibration for this method using recently prepared calibration standards to prevent excessive quenching. In the assessment of the instrument calibration, the quench curves should encompass the expected quench factor of freshly prepared batch QC samples.

3.3 The analyst must be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specifications related to the client, project, and test method being performed.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder information indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 The sensitivity of this procedure is limited by the fact that stable Fe is abundant in many types of samples and that a maximum of 3 mg Fe can be retained by a 2mL TRU® resin column.

4.2 Fe-59 is a beta-emitting isotope of iron that may interfere with the analysis of Fe-55. Quality assurance against this type of interference is done at the liquid scintillation counter by monitoring the higher energy beta region of the spectra, as described in SOP 704.

4.3 The presence of visible sediments in water samples may interfere with the TRU column performance. At the analyst's discretion, samples with visible sediment may be filtered with a qualitative paper filter prior to removing any sample aliquant.

5. APPARATUS AND MATERIALS

5.1 analytical balance, 0.0001g sensitivity

5.2 specimen cups, polypropylene, disposable, 110mL (Falcon 35-4014 or equivalent) and 220mL (Falcon 35-4020 or equivalent) with lids (Falcon 35-4017 or equivalent)

5.3 centrifuge tubes, 50mL, VWR brand or equivalent

5.4 centrifuge

5.5 plastic fitted funnel

5.6 glass scintillation vials, 20mL

5.7 disposable, BIO-Rad® Ion exchange columns or equivalent

5.8 test tubes, plastic

5.9 pipettes, Eppendorf® or equivalent and disposable pipet tips

5.10 graduated cylinder, plastic, 25mL

5.11 steam bath

5.12 hot plate or Environmental Express HotBlock®, or equivalent.

6. REAGENTS

NOTE: Threshold Limit Value (TLV) and other hazard information may also be given here. As stated in Section 12.1.4 below, any chemical with a TLV below 50 ppm must be worked with in a laboratory fume hood. The absence of this information does not mean that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Fe-55 spiking solution. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.2 Concentrated nitric acid, HNO_3, reagent grade. TLV = 2 ppm (TWA). Irritant, corrosive.

6.3 Concentrated hydrochloric acid, HCl, reagent grade. TLV = 5 ppm (ceiling). Irritant, corrosive.

6.4 Concentrated phosphoric acid, H_3PO_4, reagent grade. TLV = 1 mg/m^3 (= 0.25 ppm). Irritant.

6.5 Nitric acid, HNO_3, 8N: Cautiously add 500mL conc. reagent grade HNO_3 to 400mL DI water. Dilute to 1 L with DI water. TLV = 2 ppm (TWA, conc. HNO_3). Irritant, corrosive.

6.6 HNO_3, 2N: Carefully add 130mL of conc. HNO_3 to 700 mL of DI water. Dilute to 1L with DI water. TLV = 2 ppm (TWA, conc. HNO_3). Irritant, corrosive.

6.7 ICP diluting solution: Carefully add 10mL of conc. Nitric acid and 50mL of conc. Hydrochloric acid to 940mL of DI water. TLV = 5 ppm (ceiling) for HCl. Irritant, corrosive. TLV = 2 ppm (TWA) for Nitric Acid. Irritant, corrosive.

6.8 TRU® resin, 100-150µm, either pre-packed columns or bulk resin, for packing columns in the lab.

6.9 Fe carrier: 20mg Fe^{3+}/mL (dissolve 96g of $FeC_{l3} \bullet 6H_2O$ in 1.0L of 0.5N HCl)

6.10 Ultima Gold® AB scintillation cocktail

6.11 Nitromethane, reagent grade. TLV = 20 ppm.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Water samples should be collected in plastic or glass containers and acidified with nitric acid to pH <2. If water samples are collected without preservation, they should be brought to the laboratory within 5 days, and then be preserved and held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.2 Solid samples should be collected in plastic or glass containers.

8. PROCEDURE

8.1 INITIAL TREATMENT OF WATER SAMPLES

8.1.1 Ensure that the samples have been preserved, as described in Section 7.1.

8.1.2 If necessary, visibly sedimented samples may be filtered using a qualitative filter paper.

8.1.3 Aliquot approximately 110mL into a labeled 220mL specimen cup.

8.1.4 Pipet 1.0mL of the digestate from the specimen cup into a disposable test tube containing 9.0mL ICP solution, and labeled with the sample ID and "native Fe". Mix well and submit to the metals lab for ICP-AES analysis. The results of the ICP analysis will only be used to determine the appropriate sample aliquot for Fe-55 analysis.

8.1.5 Proceed directly to Step 8.3.

8.2 INITIAL TREATMENT OF SOLID SAMPLES

8.2.1 Weigh approximately 1g of sample into a 50mL centrifuge tube. Record the actual sample mass on the benchsheet.

8.2.2 Prepare QC samples for solid matrices per Section 10.

8.2.3 Add 15mL of DI water, 10mL of conc. HNO_3 and 10mL of conc. HCl to the sample.

8.2.4 Heat the sample for 1 hour on a steam bath.

8.2.5 Remove the sample from the steam bath and allow to cool.

8.2.6 Centrifuge at approximately 3,500 rpm for 10 minutes.

8.2.7 Decant the supernatant into a labeled 220mL specimen cup.

8.2.8 Add DI water to dilute the leachate solution to a final volume of 110mL. The graduations on the Falcon cups specified in Section 5.2 above have been demonstrated to be sufficiently accurate for performing this

dilution.

8.2.9 Cap the sample cup tightly and mix the contents thoroughly.

8.2.10 Pipet 1.0mL of the digestate from the specimen cup into a disposable test tube containing 9.0mL ICP solution, and labeled with the sample ID and "native Fe". Mix well and submit to the metals lab for ICP-AES analysis. The results of the ICP analysis will only be used to determine the appropriate sample aliquot for Fe-55 analysis.

8.2.11 Proceed directly to Step 8.3.

8.3 ALIQUANT DETERMINATION BASED ON NATIVE IRON CONTENT AS MEASURED BY ICP-AES

TRU® resin has the capacity to retain a maximum of 3mg Fe. The amount of sample solution that can be treated with TRU® resin is dependent on the concentration of dissolved Fe in the sample. Normally, most water samples are expected to be low in dissolved Fe. Acidic aqueous samples and leachates may be high in Fe. Sample solutions suspected to be high in Fe should be analyzed by ICP so that a reduced aliquant can be calculated that will not overload the TRU® resin column.

In this SOP, sample solutions are classified in three groups according to Fe content. Each type is treated accordingly:

Type	Fe conc. (mg/L)	Aliquot to Prepare	Stable Fe Carrier
Low	< 5	100 mL	0.1 mL of 20 mg/mL
Med.	≥ 5 and ≤ 30	100 mL	none
High	>30	determined by ICP	none

If the Fe conc. > 30 mg/L, calculate the aliquot volume to prepare for TRU® resin using the following equation:

$$A = 3\ mg * 1000\ mL / [Fe]$$

where:

A = the aliquot (mL) of sample to purify with TRU® resin

[Fe] = the Fe concentration (mg/L) in the sample measured by ICP.

In cases where non-standard aliquots are determined, based on the ICP-AES data, supporting notation should be provided on the original bench sheet and should include the sample-specific results and an example calculation. Other equivalent documentation may be acceptable, at the supervisor's discretion.

8.4 SAMPLE PREPARATION

8.4.1 Transfer the appropriate aliquot of sample solution into a disposable 220mL polypropylene cup. Record the aliquot volume (A) on the benchsheet.

8.4.2 Prepare QC samples for water samples per Section 10.

8.4.3 Spike the LCS with 100 - 500 dpm of Fe-55. The source should be a second source independent of the calibration source.

8.4.4 For samples low in Fe (< 5 mg/L), add 0.1mL of stable Fe carrier (20 mg Fe/mL) to the cup.

8.4.5 **After mixing the sample thoroughly**, pipet a 1.0mL aliquot of the solution into a test tube for "initial" ICP analysis. Dilute the 1.0mL aliquot to a final volume of 5.0 mL using ICP diluting solution (see Section 6). Mix well and label with the sample ID and "initial". The results of this ICP analysis will be used to determine the pre-separation mass of iron in the sample, and will be entered into the ICP worksheet in LIMS.

8.4.6 In addition, a replicate 0.1mL aliquot (or similar known volume from a calibrated pipettor) of stable Fe carrier is diluted with DI water to 100 mL. After mixing thoroughly, a 1.0mL aliquot of this dilution is transferred to a test tube labeled 'reference carrier', diluted up to 10.0mL using ICP diluting solution, and submitted with the "initial" ICP fractions to provide a reference concentration for the ICP calculations.

8.4.7 Any remaining sample digestate should be capped, properly labeled, returned to the sample storage area, and a new fraction should be created in the LIMS internal chain of custody, indicating that a new sample fraction was created.

8.4.8 Place the cup containing the sample on a steam bath and evaporate the sample to dryness.

8.4.9 After the sample solution has evaporated, dissolve the residue in 10mL of 8N HNO_3. Proceed to Section 8.5 for purification of Fe using TRU® resin.

8.5 ISOLATION OF Fe USING TRU® RESIN

8.5.1 Prepare a TRU® resin column for each sample in the batch. Pre-packed columns purchased from the vendor (Eichrom) can be used, or columns can be prepared in the lab.

8.5.2 To prepare the columns, attach a fitted funnel to each empty BIO-Rad® column, and add about 2 mL of bulk TRU® resin slurried in DI water. Add a 4-5 mm layer of clean silica sand over the resin bed and place a waste cup underneath each column.

8.5.3 Condition each column with 5mL of 8N HNO_3. Collect the effluent in the waste cup.

8.5.4 Transfer each sample solution from Section 8.4.9 to a prepared TRU® resin column. Collect the effluent in the waste cup.

8.5.5 Complete the transfer by rinsing each sample beaker with 5mL of 8N HNO_3. Apply the rinsate to the column. Collect the effluent in the waste cup.

8.5.6 Rinse each column with 10mL of 8N HNO_3. Collect the effluent in the waste cup. The contents may now be disposed of into the Paragon wastewater treatment facility (i.e., down the drain in the lab sinks with plenty of cold tap water).

8.5.7 Used disposable cups may be rinsed with Radiacwash® solution and tap water and re-used for collecting waste column effluent. If the cups are not needed, they may be soaked in Radiacwash®, rinsed with tap water and discarded into the sanitary trash.

8.5.8 Elute Fe by rinsing each column with 15mL of 2N HNO_3. Collect the eluate from each column in a clean, labeled 20 mL glass scintillation vial.

8.5.9 Cap each vial tightly and vortex to mix the eluate until the solution is homogeneous. Pipet a 0.10mL aliquot from each vial into a labeled test tube for "final" ICP determination of Fe. **NOTE: The solution in each vial must be well-mixed and completely homogeneous before an aliquot is removed with a pipet.** Dilute the 0.10 mL aliquot to a final volume of 10.0mL using ICP diluting solution. Mix the diluted ICP aliquot thoroughly to ensure homogeneity.

8.5.10 Submit both the "initial" and "final" ICP fractions to the metals lab for analysis.

8.5.11 Evaporate the solution in each scintillation vial from Step 8.5.9 by carefully heating on a hotplate or HotBlock®.

8.5.12 After cooling, add 0.25mL of conc. HCl, using a calibrated pipet, to each vial to dissolve the residue.

8.5.13 Once the residue has been dissolved, add 4.75mL of DI water, using a calibrated pipet. Add 2 drops of conc. H_3PO_4 and 15mL of Ultima Gold® AB scintillation cocktail to each vial. Mix thoroughly.

8.5.14 Submit the prepared samples to the Instrument Lab. The Instrument Lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704.

8.5.15 Upon the return of the ICP sample fractions to the lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the Paragon wastewater treatment facility (i.e., down the drain in the lab sinks with plenty of cold tap water). The test tubes may be rinsed with a Radiacwash® solution, followed with tap water, then discarded into the sanitary trash.

8.5.16 Submit the ICP results and the calculated chemical yields to the instrument lab.

8.5.17 Used TRU® resin columns are discarded by extruding the resin from the column and placing the resin in the established waste stream labeled "Hazardous Waste - Used Acidic Resin" in the Satellite Accumulation Area in the lab. When the satellite container is full, notify the Waste Disposal Coordinator for further instructions. Emptied columns may be soaked in a Radiacwash® solution, rinsed in tap water, then discarded into the sanitary trash.

8.6 PREPARATION OF CALIBRATION STANDARDS

Calibration standards for this method are prepared upon request from the primary operator of the liquid scintillation counter system. A series of increasingly quenched blanks and Fe-55 spiked efficiency standards are prepared in order to establish background and efficiency "quench curves".

8.6.1 EFFICIENCY QUENCH CURVE CALIBRATION

8.6.1.1. To create the efficiency quench curve standards, add approximately 300-1000 dpm Fe-55 spiking solution to each of twelve scintillation vials. The spiking solution should be traceable to NIST and should be a "second source", independent of the solution used for spiking batch QC samples.

8.6.1.2. To each scintillation vial, add 0.1mL of the same stable Fe carrier used in the normal preparation of samples and batch QC.

8.6.1.3. Take the vials to dryness on a hotplate. After drying, remove

from heat and allow to cool.

8.6.1.4. To each vial, add 0.25mL concentrated HCl, 4.75mL DI water, two drops concentrated H_3PO_4, and 15 mL Ultima Gold®AB cocktail.

8.6.1.5. Nitromethane is used as the quenching agent. Nitromethane is not added to the first vial. To the remaining vials, add nitromethane in increasing 15µL increments.

8.6.1.6. Cap the vials tightly, mix thoroughly, and submit to the Counting Lab. The Counting Lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704.

8.6.2 BACKGROUND QUENCH CURVE samples are created using the same number of scintillation vials and the same procedure used in Sections 8.6.1.1 through 8.6.1.6, omitting the addition of Fe-55 spiking solution.

8.6.3 BATCH CALIBRATION BLANKS are created, in triplicate, with each batch of samples, by following the same procedure described in 8.6.2, with the exception that the three blanks should be quenched to approximately the low, middle, and high regions of the quench curve. The results from these batch calibration blanks will be used to adjust the background quench curve, as discussed in SOP 704.

9. CALCULATIONS

9.1 Calculate the actual volume (V_A) of sample analyzed , accounting for volumes of sample removed for ICP analysis, as follows:

$$V_A = V * \frac{V_i - icp_i}{V_i} * \frac{V_f - icp_f}{V_f}$$

where:

V = initial sample aliquot (L, g)

V_i = sample dilution/digestate volume prior to taking the initial ICP aliquot (mL)

icp_i = initial aliquot taken for ICP (mL)

V_f = post-separation sample volume (mL)

icp_f = final aliquot taken for ICP (mL)

9.2 Calculate the chemical recovery (Y) as follows:

9.2.1 Calculate the initial mass of Fe present in the actual sample volume analyzed:

$$M_i = C_i * DF_i * (V_i - icp_i)$$

where:

M_i = initial pre-separation mass of Fe present in the actual sample volume analyzed (ug)
C_i = concentration of Fe in the initial aliquot taken for ICP (ug/mL)
DF_i = dilution factor for icp_i, prior to ICP analysis

9.2.2 In cases where Fe carrier was added to the sample, calculate the minimum amount of Fe that can be present after the addition of Fe carrier:

$$M_r = C_r * DF_r * Vr * (V_i - icp_i) / V_i$$

where:

Mr = reference mass of Fe present in the carrier added (ug)
Cr = concentration of Fe in the aliquot of the reference carrier taken for ICP (ug/mL)
DFr = dilution factor for the reference carrier solution, prior to ICP analysis
Vr = total volume of the reference carrier solution, prior to taking ICP aliquot

NOTE: The initial mass of Fe may be underestimated due to matrix interference in the ICP measurement of the pre-separation concentration of Fe. This is the case when the calculated initial mass of Fe (M_i) is less than the 'reference carrier' mass (M_r). In this case, the reference carrier concentration is substituted for M_i below. If the discrepancy is greater than 15%, a note about the matrix interference is made in the case narrative.

9.2.3 Calculate the final mass of Fe present in the actual sample volume analyzed:

$$M_f = C_F * DF_f * (V_f)$$

where:

M_F = final post-separation mass of Fe present in the actual sample volume analyzed (ug)
C_i = concentration of Fe in the final aliquot taken for ICP (ug/mL)
DF_i = dilution factor for icp_f prior to ICP analysis

9.2.4 Calculate the chemical yield for Fe:

$$Y = M_f / M_i$$

9.3 The activity concentration, counting uncertainty, total propagated uncertainty, and minimum detectable concentration calculations are provided in SOP 708. Per SOP 708, however, the following preparation uncertainty factor is specific to this method:

9.3.1 Preparation Uncertainty- Aqueous Samples:
The Preparation Uncertainty factor for aqueous samples is 0.0973. This is based on one gross aliquotting, two volumetric measurements, and one ICP yield determination:

$$0.0973 = \sqrt{0.05^2 + 2 * \left(0.006^2\right) + 0.083^2}$$

9.3.2 Preparation Uncertainty- Solid Samples:
The Preparation Uncertainty for solid samples is 0.1007. This is based on one gross aliquotting, one mass measurement, one quantitative transfer, three volumetric measurements, and one ICP yield determination:

$$0.1007 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 3 * \left(0.006^2\right) + 0.083^2}$$

9.3.3 In practice, these two values are substantially equivalent and the larger of the two, 0.1007, may be used for both matrices.

10. QUALITY CONTROL

Required frequency and acceptance criteria for batch QC sample is discussed in SOP 715.

10.1 One method blank sample is prepared and analyzed with every batch of up to 20 field samples. The method blank consists of an empty polypropylene cup for soils (basically a reagent blank) and 100mL DI water for aqueous samples.

10.2 One sample duplicate is prepared and analyzed with every group of up to 10 field samples. A batch of 11 – 20 samples will have two duplicates.

10.3 One blank spike (LCS) is prepared and analyzed with every batch of up to 20 field samples. An appropriate amount of Fe-55 spiking solution is spiked into an empty polypropylene cup (soils LCS) or 100mL DI water (water LCS). The spike is added before the QC sample receives any chemical treatment.

11. DEVIATIONS FROM METHOD

Modification has been made to this method to support the preparation and analysis of solid matrices.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep

labs at all times.

12.1.3 Gloves, safety glasses and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or samples or when handling potentially contaminated materials.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.2 below.

12.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.6 Care should be taken when diluting acids. Always add acid to water, ***NOT*** water to acid.

12.2 WASTE DISPOSAL

12.2.1 Wastes that are "corrosive only", such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the Paragon wastewater treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity), may be neutralized in the waste treatment facility.

12.2.2 All acid wastes not containing HF that are generated in ion exchange operations, are disposed of to the waste tanks (i.e., down the drain in the lab sinks with plenty of cold tap water) unless otherwise specified due to hazardous constituents.

13.2 TLVs and BEIs, ACGIH, 1999, Cincinnati, OH.

DOCUMENT REVISION HISTORY

8/31/07: Changed default MDC to 50 pCi/g,L (SUMMARY). Added INTERFERENCES Section 4. Clarified use of second independent source for spiking (SECTION 6). Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Sections 7.1. In PROCEDURES Section, provided for filtering sedimented waters; changed soil digestion technique to use a centrifuge tube and changed default soil aliquot to 1g; clarified initial ICP determination; reduced LCS spiking level. Removed activity, MDC, and TPU calculations from Section 9

and referenced SOP 708 instead. Included note in Section 10.3 that the LCS spike is added before the QC sample receives any chemical treatment. Added DOCUMENT REVISION HISTORY Section.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 751 REVISION 2

TITLE: **ACTINIDES – AMERICIUM / CURIUM SEPARATION – PURIFICATION BY TRU™ AND TEVA™ SPEC COLUMN**

FORMS: **NONE**

APPROVED BY:
TECHNICAL MANAGER _____ DATE 8/15/07
QUALITY ASSURANCE MANAGER _____ DATE 8/14/07
LABORATORY MANAGER _____ DATE 8-16-07

HISTORY: Rev0, 11/08/02; Rev1, 5/17/04 and 1/31/05 (no revisions); Rev2, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the isolation of Americium (Am) and Curium (Cm) in water samples, filter leachates, vegetation, and soil digestate solutions using TRU™ resin followed by purification using TEVA™ resin. Also described is the mounting of Am for quantitation by alpha spectroscopy. Before using this procedure, an aqueous or solid sample must be prepared as described in the appropriate aqueous (SOP 776) or solid (SOP 773) preparation SOP, followed by ion exchange separation per SOP 778. The Am/Cm fraction separated from the previous procedure is dissolved in 3N HNO_3 prior to separation with TRU™ resin.

2. SUMMARY

The Am/Cm fraction (from previous dissolution and ion-exchange SOPs) is dissolved in 3N HNO_3. The sample solution is passed through a TRU™ resin column containing resin that is equilibrated in 2N HNO_3. The resin is washed with 2N and 0.5N HNO_3 to complete the isolation of Am/Cm from the sample matrix. Am/Cm is stripped from the column by washing with 9N and 4N HCl. The Am/Cm is further purified from interfering rare earth elements using TEVA™ resin. Finally, the Am/Cm is co-precipitated with lanthanum fluoride and mounted on a filter membrane for quantitation by alpha spectroscopy.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specification related to the client, project, and test method being performed.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

The presence of Thorium in the sample may cause interference with the Am spectrum. When the aliquot size for analysis is larger than normal and if the sample is a sequential analysis for Pu, U, and Am, care must be taken to remove Th from the sample. If the Th is not separated from the sample, Th-228 may appear in the Am-241 Region Of Interest (ROI) and produce a false positive result. A nitrate column may be run in addition to the routine sample prep to ensure all Th is removed from the sample as needed.

5. APPARATUS AND MATERIALS

5.1 Disposable BIO-Rad™ Ion exchange columns

5.2 Plastic funnel, fitted

5.3 Repeater pipet and tips

5.4 Steambath, stainless steel

5.5 Graduated cylinder, plastic, 25mL

5.6 Suction filter apparatus for 25mm membrane

5.7 Filter membrane, 25mm, 0.1µm porosity

5.8 Stainless steel cupped planchet, 1.25 inch diameter

5.9 Hot block

5.10 Pipets, Eppendorf™ or equivalent and tips

5.11 Polypropylene beaker, disposable, 220mL

5.12 Centrifuge bottle, 250mL capacity

5.13 Glass cup, disposable, Environmental Express #SC432, or equivalent

5.14 Double-sided tape

5.15 Transfer pipets, disposable

5.16 Wash bottles

6. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a Threshold Limit Value (TLV) of less than 50ppm, shall be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Reagent water. Obtained from the laboratory's deionized (DI) water system.

6.2 Nitric acid (HNO_3), conc., reagent grade. TLV = 2ppm (TWA). Irritant, corrosive.

6.3 3N HNO_3: Cautiously add 190mL of conc. HNO_3 to approximately 600mL DI water and dilute to 1L. See above for TLV.

6.4 2N HNO_3: Cautiously add 130mL conc. HNO_3 to approximately 600mL DI water and dilute to 1L. See above for TLV.

6.5 0.5N HNO_3: Cautiously add 31mL conc. HNO_3 to 800mL DI water and dilute to 1L. See above for TLV.

6.6 Hydrochloric acid (HCl), conc., reagent grade. TLV = 5ppm (ceiling). Irritant, corrosive.

6.7 9N HCl: Cautiously add 750mL conc. HCl to 200mL DI water and dilute to 1L. See above for TLV.

6.8 4N HCl: Cautiously add 330mL conc. HCl to 500mL DI water and dilute to 1L. See above for TLV.

6.9 2N HCl: Cautiously add 170mL conc. HCl to approximately 600mL DI water and dilute to 1L. See above for TLV.

6.10 Hydrofluoric acid, HF, conc. (48%-51%), reagent grade. TLV = 3ppm.

6.11 Hydrofluoric acid (HF), 3N: Dilute 104mL conc. HF to 1L with DI water. Use a plastic graduated cylinder and store in a plastic bottle. TLV = 3ppm.

6.12 Ascorbic Acid, reagent grade.

6.13 Ascorbic acid solution: Dissolve 200mg ascorbic acid /mL DI water. Prepare fresh daily before use.

6.14 Formic acid (HCOOH), 98%, reagent grade. TLV = 5ppm.

6.15 Ammonium thiocyanate (NH_4SCN), reagent grade.

6.16 2M ammonium thiocyanate/0.1M formic acid: For every 100mL of solution, dissolve 15.2g NH_4SCN and 0.35mL 98% formic acid in 100mL DI water.

6.17 1M ammonium thiocyanate/0.1M formic acid: For every 100mL of solution, dissolve 7.6g NH_4SCN and 0.35mL 98% formic acid in 100mL DI water.

6.18 Lanthanum carrier, 0.1mg La^{+3}/mL: Dissolve 0.312g high purity $La(NO_3)2•6H_2O$ in 1000 mL of 1N HCl.

6.19 Methanol, reagent grade. TLV = 200ppm.

6.20 Silica sand.

6.21 TRU™ resin and TEVA™ resin, 100-150µ size. Purchase from Eichrom Industries, Inc.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

SOPs 773 and 776 address Sample Collection, Preservation and Handling for samples in association with this procedure.

8. PROCEDURE

8.1 PREPARATION OF SAMPLE SOLUTION FOR TRU™ RESIN

8.1.1 The acidic effluent from the preceding separation procedure should be collected in a disposable plastic beaker. Place the beaker on a steam bath and take to dryness. *Note that the sample may not completely dry.*

8.1.2 Dissolve the sample residue in 25mL of 3N HNO_3. To aid in dissolution of the residue, place the sample on the steambath for a few minutes.

8.1.3 After the sample residue is completely dissolved, add 1.0mL of 200mg ascorbic acid / mL DI water (the ascorbic acid solution must be prepared fresh daily) to each sample. Proceed to Section 8.2.

8.2 ISOLATION OF AM/CM USING TRU™ RESIN COLUMN

8.2.1 Prepare a TRU™ resin column by filling a BIO-Rad™ column to the 1.6mL mark with a slurry of TRU™ resin and DI water. Add a 4-5mm layer of clean sand to the top of the resin bed. Attach an

Environmental Express funnel to the column. Place waste cups underneath the columns.

8.2.2 Condition the column with 5mL of 2N HNO_3, discard column effluent down the drain in the lab sinks with large amounts of water.

8.2.3 Apply sample solution to the prepared TRU™ resin column, discard column effluent. The effluent may be discharged into the Paragon wastewater treatment facility (i.e., down the drain in the lab sinks with large amounts of water).

8.2.4 Rinse the sample cup with 5mL of 2N HNO_3 and add to the column, discard column effluent (down the drain in the lab sinks with large amounts of water).

8.2.5 Rinse column with 5mL of 0.5N HNO_3, discard column effluent down the drain in the lab sinks with large amounts of water.

8.2.6 Rinse column with 3mL of 9N HCl, collect column effluent in a clean disposable glass cup labeled with the sample ID and "Am/Cm-TEVA".

8.2.7 Rinse column with 20mL of 4N HCl, collect column effluent in the same labeled glass cup as above.

8.2.8 Place the glass cup containing the Am/Cm fraction on a hot block set at approximately 100˚C and heat the solution to dryness.

8.2.9 Used TRU™ resin columns are discarded by extruding the resin from the column and placing the resin in the established waste stream labeled "Hazardous Waste – Used Acidic Resin" in the Satellite Accumulation Area in the lab. When the satellite container is full, notify the Waste Management Officer for further instructions. Emptied columns may be soaked in a RadiacWash™ solution, rinsed in tap water and discarded into the sanitary trash.

8.3 PURIFICATION OF AM/CM USING TEVA™ RESIN

8.3.1 Re-dissolve the sample from Step 8.2.8 in 5mL of 2M NH_4SCN / 0.1M formic acid solution. Place the sample on the hot block for 5 minutes to ensure dissolution.

8.3.2 Prepare a TEVA™ resin column by filling a BIO-Rad™ column to the 1.6mL mark with a slurry of TEVA™ resin and DI water. Add a 4-5mm layer of clean sand to the top of the resin bed. Place waste cups beneath the columns.

8.3.3 Condition a TEVA™ resin column by passing 5mL of 2M NH_4SCN / 0.1M formic acid solution through it. Collect the effluent in a waste cup.

8.3.4 Transfer the sample solution onto the TEVA™ column using a disposable polyethylene transfer pipette. Rinse the sample container with 5mL of 2M NH_4SCN / 0.1M formic acid solution and place the sample on the hot block for 5 minutes. Apply the rinsate to the column.

8.3.5 Rinse the sample cup with two 5mL volumes of 1M NH_4SCN / 0.1M formic acid solution. Apply the rinsate to the TEVA™ column. Allow the first 5mL to pass through the column completely before applying the second 5mL. The purpose of this Step is to wash lanthanides from the column. Discard waste from Steps 8.3.3 - 8.3.5 in the ammonium thiocyanate carboy.

8.3.6 Strip Am/Cm from the column with three 5mL volumes of 2N HCl. Collect the effluent from the column in a clean polypropylene beaker labeled with the sample ID and "micro ppt for Am/Cm". Allow each portion of 2N HCl to drain completely before applying the next.

8.3.7 To decompose thiocyanate, add 2.5mL conc. HNO_3 and 7.5mL concentrated HCl to the Am strip solution. Swirl gently to mix. Place the container on a steam bath and heat until about one drop of solution remains.

8.3.8 Add 5mL conc. HNO_3 to the sample from the previous Step only if any black colored and brown colored solution is noticed and heat on the steambath until the volume is reduced to about one drop.

8.3.9 Used TEVA™ resin columns are discarded by extruding the resin from the column and placing the resin in the established waste stream labeled "Hazardous Waste – Used Acidic Resin" in the Satellite Accumulation Area in the lab. When the satellite container is full, notify the Waste Management Officer for further instructions. Emptied columns may be soaked in a RadiacWash™ solution, rinsed in tap water and discarded into the sanitary trash.

8.4 AMERICIUM/CURIUM MICRO-PRECIPITATION

8.4.1 Add 1mL conc. HCl to the dried sample residue in the cup from Section 7.3.8. Wait 15 minutes to resolubilize the residue. Add 14mL DI water to the cup and mix.

8.4.2 Add 1.0mL lanthanum carrier. Mix well. Add 5mL 3N HF. Mix well.

8.4.3 Allow sample to stand for a minimum of 15 minutes.

8.4.4 Label taped planchets with sample ID, Batch ID, and analyte.

8.4.5 Place a 25mm filter membrane on a filter funnel assembly and turn the vacuum on. Rinse with 1-2mL of methanol (this will make the filter less hydrophobic). When the methanol is almost passed through, add approximately 5mL of DI water.

8.4.6 When the water is almost passed through the filter, pass the co-precipitated sample through the filter membrane.

8.4.7 Rinse the sample cup with 10mL DI water and add to the filter funnel, once the load solution has passed through. After the rinse has passed through, rinse the filter with an additional 10mL of DI water.

8.4.8 After filtration, keep vacuum on and remove the funnel. Use a "Sharpie" marker to place a dot on the outside edge of the filter. This helps identify the right side of the filter in case the filter flips during transaction. Carefully remove the filter membrane with a pair of forceps and fix it face up on the double-sided tape that was placed on the prepared planchet. Dry the filter membrane with the planchet under the fluorescence light bulb for a minute. DO NOT KEEP THE PLANCHET FOR A LONG TIME UNDERNEATH THE LAMP AS IT MIGHT MELT THE DOUBLE SIDED TAPE.

8.4.9 The sample is analyzed by Alpha Spectroscopy and reported according to Paragon SOP 714. Submit the prepared samples and the updated benchsheet to the counting lab. The counting lab will analyze and ultimately dispose of the planchet and filter in the manner described in SOP 714.

9. QUALITY CONTROL

9.1 Method blanks, LCSs, sample duplicates and sample spikes are prepared as specified in the previous associated procedure. Refer to SOP 776 for aqueous samples (SOP 773) for solid samples.

9.2 Calibration standards are not prepared for this method, however electroplated sources are purchased from an outside vendor, Isotope Products Laboratories, and used for instrument calibration. Refer to SOP 714 for calibration standards.

10. CALCULATIONS

TPU FACTORS. As defined in SOP 708, the following preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU). The following TPUs come from the sample prep

previously completed in SOP 778, "Actinides -- Uranium, Plutonium, and Americium/Curium (partial) Sequential Separation by Ion Exchange".

10.1 Solid samples (that require initial prep using SOP 773) require a preparation uncertainty factor of 0.0665 at the one-sigma level. This factor is based on one gross aliquoting (sample homogeneity), one mass measurement, one tracer addition, two quantitative transfers and one reagent addition. See the following equation:

$$0.0665 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2}$$

10.2 Water samples (that require initial prep using SOP 776) require a preparation uncertainty factor of 0.0667 at the one-sigma level. This factor is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one tracer addition, two quantitative transfers and one reagent addition. See the following equation:

$$0.0667 = \sqrt{0.05^2 + 0.006^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2}$$

10.3 Water and solid samples prepared by TRU™ resin column require a preparation uncertainty factor of 0.0264 at the one-sigma level. This TPU is estimated from one quantitative transfer and two reagent additions. See the following equation:

$$0.0264 = \sqrt{0.025^2 + 0.006^2 + 0.006^2}$$

10.4 Water and solid samples prepared by TEVA™ columns require a preparation uncertainty factor of 0.0257 at the one-sigma level. This is based on one quantitative transfer and one reagent addition. See the following equation:

$$0.0257 = \sqrt{0.025^2 + 0.006^2}$$

10.5 Water and solid samples prepared by microprecipitation require a preparation uncertainty factor of 0.025 at the one-sigma level. This TPU is estimated from one quantitative transfer. See the following equation:

$$0.025 = \sqrt{0.025^2}$$

11. DEVIATIONS FROM METHOD

This method was developed by Paragon Analytics, using the references cited in Section 13, and contains no deviations from applicable standardized methods.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.1.3 Gloves, safety glasses and lab coats must be worn when working with any chemicals (e.g., standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

12.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.6 Use extreme care when using hydrofluoric acid (HF). Work only in a fume hood that has adequate ventilation and personnel safety features. Never inhale or allow skin or clothing to be exposed to HF fumes.

12.1.7 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.2 WASTE DISPOSAL

12.2.1 Wastes that are "corrosive only", such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the Paragon wastewater treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

12.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. This includes any excess HF from dissolution of samples and all solutions remaining from the micro precipitation process. Notify the Waste Management Officer for disposal.

12.2.3 The ammonium thiocyanate effluent that is generated using TEVA™ resin (Section 7.3) is collected in a labeled waste carboy. Notify the Waste Management Officer for disposal.

12.2.4 All acid wastes not containing HF or NH_4SCN that are generated in separation operations are disposed of to the waste tanks (i.e., down the drain) unless otherwise specified due to hazardous constituents.

STANDARD OPERATING PROCEDURE 753 REVISION 3

TITLE: **DETERMINATION OF RADIOACTIVE IODINE AND CHLORINE IN ENVIRONMENTAL SAMPLES -- EPA METHOD 902.0**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7/6/06

QUALITY ASSURANCE MANAGER _____ DATE 7/6/06

LABORATORY MANAGER _____ for KDC DATE 7/6/06

HISTORY: NEW, Rev0, 4/5/94; PCN # 195, Rev1, 4/10/02; Rev2, 4/4/03; Rev3, 7/5/06.

re-released w/o revision 3/13/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary for preparation of water and solid samples for quantitative measurement of ^{129}I and other isotopes of iodine, as well as, ^{36}Cl and other isotopes of chlorine. In the separation of iodine in water samples, this method is substantially equivalent to EPA Method 902.0, except where noted. Specifically, the EPA method does not address chemical yield determinations, and this procedure estimates chemical yields by the analysis of a spiked split of the sample. Neither does the EPA method address the preparation of solid matrices. In addition, the EPA method does not address the chemical separation or analysis of radioactive isotopes of chlorine.

2. SUMMARY

2.1 Stable iodate carrier is spiked into an acidified water or the leachate of a solid sample. The iodate is reduced to the iodide state with Na_2SO_3 and all radioactive iodine and chlorine are precipitated as AgI and AgCl. The precipitate is dissolved with zinc powder and sulfuric acid. The iodine is re-precipitated as PdI_2 and filtered. Palladium will precipitate iodide in the presence of Cl^- and Br^-, separating iodide from these halides. The filter is mounted on a planchet for beta counting. The filtrate from the PdI_2 is collected and excess SO_4 is removed by adding $BaNO_3$. The chlorine is reprecipitated as AgCl and mounted onto a planchet for beta counting.

2.2 A composite measure of the chemical yield and counting efficiency (i.e., the 'total efficiency') is determined by parallel processing of a replicate aliquot of each sample spiked with a known quantity of ^{129}I and/or ^{36}Cl. The spiked sample is referred to as the "yield spike". (Note: this spike is NOT a 'matrix spike'; a matrix spike is a QC sample and is NOT used to generate data for chemical yield corrections, but rather to provide quality control information about analyte

recovery).

2.3 Reproducibility of the process is critical in generating accurate chemical yield information. The analyst should treat all samples identically and must note any anomaly, which could cause a significant variation in yield between a sample and its associated yield spike.

2.4 If elevated sample activity is expected, the initial sample aliquot size may be reduced, or additional spike added so that the expected tracer count uncertainty does not exceed 10% of the tracer activity. Consult with a Supervisor to determine proper spiking levels for samples.

2.5 For each sample prepared, an associated yield spike is also prepared. This yield-spiked sample should be a replicate aliquot of leachate or water of the original sample and should be spiked high enough to minimize uncertainty in the total efficiency calculation (i.e., at least 10 times the expected sample activity). A typical batch of samples is named and would be spiked as follows:

02-01-123-01	
02-01-123-01DUP	
02-01-123-01SYS	1000-2000dpm ^{129}I spike and/or 1000-2000dpm ^{36}Cl
02-01-123-02	
02-01-123-02SYS	1000-2000dpm ^{129}I spike and/or 1000-2000dpm ^{36}Cl
02-01-123-03	
02-01-123-03SYS	1000-2000dpm ^{129}I spike and/or 1000-2000dpm ^{36}Cl
02-01-123-04	
02-01-123-04SYS	1000-2000dpm ^{129}I spike and/or 1000-2000dpm ^{36}Cl
CL020101-1MB	
CL020101-1LCS	**100-200**dpm ^{129}I spike and/or **100-200**dpm ^{36}Cl
CL020101-1SYS	1000-2000dpm ^{129}I spike and/or 1000dpm ^{36}Cl

(Note: for purposes of calculations, the total efficiency for the batch QC Yield Spike is applied to the blank and the LCS.)

2.6 The sample and the associated spike should be counted on the same detector. (Although calculations account for variation in detector efficiency and background, uncertainty in these corrections are eliminated when the sample and associated spike are counted on the same detector.)

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method.

This demonstration may come in the form of Supervisory/ training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 Solid samples should not be muffled due to the potential volatility of iodine and chlorine.

4.2 Glass fiber filters exhibit beta activity due to naturally occurring radionuclides, potentially including actinides and potassium-40. For iodine, three filter blanks are processed with the samples and used to determine the contribution to background and in determining background correction to be applied to samples.

5. APPARATUS AND MATERIALS

5.1 hotplates

5.2 top-loading balance, resolution to 0.01g

5.3 centrifuge

5.4 centrifuge tubes, polypropylene, 50mL

5.5 mechanical shaker

5.6 stir plates

5.7 stir bars, PTFE™-coated, magnetic

5.8 Whatman™, #41 filter paper, or equivalent

5.9 vacuum filtration apparatus, 47mm

5.10 fritted support base, 47mm

5.11 glass fiber filters, 47mm

5.12 filtering flask with side-arm, 1000mL

5.13 funnel, 300mL

5.14 clamps

5.15 Pyrex™ beakers, 1500mL or 2000mL

5.16 flat planchets, stainless steel, 2-inch diameter

5.17 Polypropylene cups, disposable, with snap-tight lid, 220mL

5.18 double-sided adhesive tape

5.19 vortex mixer

6. REAGENTS - Only reagent grade or better chemicals shall be used.

NOTE: Threshold Limit Value (TLV) and other hazard information may be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding

6.1 Deionized (DI) water, ASTM Type II

6.2 Iodate carrier (IO_3^-), 10mg/mL (as I^-): Dissolve 1.68g KIO_3 in DI water and dilute to 100mL. Store in an amber container.

6.3 Hydrochloric acid (HCl), 12M (concentrated). TLV = 5ppm (ceiling). Irritant, corrosive.

6.4 Nitric acid (HNO_3), 16M (concentrated). TLV = 2ppm, (TWA). Irritant, corrosive.

6.5 Nitric acid, 1M: Cautiously add 63mL of concentrated nitric acid to 800mL of DI water. Dilute to 1 liter. TLV = 2ppm, (TWA). Irritant, corrosive.

6.6 Hydrochloric acid, 6M: Mix 1 volume 12M HCl (conc.) with 1 volume DI water. TLV = 5ppm (ceiling). Irritant, corrosive

6.7 Palladium chloride ($PdCl_2$), anhydrous.

6.8 Palladium chloride, 0.2M: Dissolve 3.542g $PdCl_2$ in 100mL 1M HCl. TLV = 5ppm (ceiling). Irritant, corrosive.

6.9 Silver nitrate, 1.0M: Dissolve 17g $AgNO_3$ in DI water and dilute to 100mL. Store in an amber glass bottle. TLV = 0.0014ppm

6.10 Sodium sulfite, 1M: Dissolve 5g Na_2SO_3 in 40mL DI water. Prepare fresh reagent weekly.

6.11 Sulfuric acid (H_2SO_4), (concentrated). TLV = 0.25ppm (TWA). Irritant.

6.12 Sulfuric acid, 2N: Mix 1 volume conc. H_2SO_4 with 17 volumes of DI water. TLV = 0.25ppm (TWA). Irritant.

6.13 Methanol (MeOH). TLV = 200ppm. Neuropathy, vision, central nervous system effects.

6.14 Barium nitrate, $Ba(NO_3)_2$.

6.15 Zinc powder. TLV = 1.9ppm

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Although the client is responsible for conducting the sampling process, it is emphasized that water samples be collected in a manner that addresses the considerations discussed in EPA 900.0 Section Three, except that the sample should <u>not</u> be preserved by acidification with HNO_3.

7.2 The container should be amber glass to minimize exposure to light.

8. PROCEDURE

8.1 SOLIDS

8.1.1 As the samples are to be split following leaching, twice the volume of sample is leached. Weigh the appropriate mass of sample into a 220mL polypropylene cup. (The default aliquot mass is 2 grams, therefore weigh out 4 grams). Add 100mL of 1M nitric acid.

8.1.2 Allow any vigorous reaction to subside then cap each sample tightly.

8.1.3 Place the capped samples on the "Big Bill" mechanical rotator/shaker at approximately 100rpm. Shake/leach the samples overnight.

8.1.4 After leaching, filter each sample into a second, clean, labeled polypropylene cup, or other suitable container, using Whatman™ #41 filter paper. Rinse the cup and filter paper with 5mL of 1M nitric acid.

8.1.5 Gravimetrically split the samples into two equal halves. Label the first cup with the sample ID and the second cup with the replicate sample work order ID to denote the spiked sample.

8.1.6 Add 1.0mL of stable iodate carrier to each sample.

8.1.7 Add the appropriate amount of ^{129}I and/or ^{36}Cl spiking solution to the yield spike samples and the LCS.

8.1.8 Dilute each solid sample leachate to 1.0L with DI water and continue with the waters procedure in Section 8.2.3, eliminating the addition of iodate carrier.

8.2 WATERS

8.2.1 Using a graduated cylinder, measure a 1000mL aliquot of water sample and transfer to a 2000mL Pyrex™ beaker. Prepare two beakers for each sample. Label the first beaker with the sample ID and the second beaker with the replicate sample work order ID to denote the spiked sample.

8.2.2 Spike the yield spike samples and the LCS with the appropriate activity of ^{129}I and/or ^{36}Cl at this time.

8.2.3 Add 7.5mL conc. HNO_3 and 1.0mL of iodate carrier to the beaker. Place a magnetic stir bar in the beaker and mix the sample on a magnetic stir plate.

8.2.4 Add 4mL 1M Na_2SO_3 and stir for 30 minutes.

8.2.5 Add 2mL 1M $AgNO_3$ and stir for 1 hour. Allow the precipitate to settle for another hour.

8.2.6 Using a vacuum, filter the suspension through a glass fiber filter. Collect the filtrate in a waste container, provided by the Waste Disposal Coordinator, labeled "Aqueous Lab Waste". Refer to the Waste Disposal Coordinator for ultimate disposal of this waste stream when the container is full.

To minimize the potential for cross-contamination of spiked and unspiked samples, a separate filtration apparatus should be used for each sample.

8.2.7 Transfer the filter with the precipitate to a plastic specimen cup. Add 1g zinc powder, 10mL DI water and 2mL of 2N H_2SO_4. Shake on a mechanical shaker at 300rpm for at least one hour. This is a good place to stop for the day if necessary.

8.2.8 Using vacuum, filter the slurry through a glass fiber filter. Collect the filtrate in a 50mL polypropylene centrifuge tube, which is stacked on top of another centrifuge tube inside the 1000mL filtering flask. Rinse the specimen cup with a few mL of DI water to complete the transfer of the slurry to the filter.

8.2.9 Collect the filter and residue in a pan and air dry in a fume hood. otherwise scan the dried material for radioactivity with an NE Electra hand probe, per Paragon's Radiation Protection Plan (RPP). If the material is considered radioactive waste it should be transferred directly to the Waste Disposal Coordinator for ultimate disposal as "Mixed Waste", otherwise it may be disposed of in the "Contaminated Soils and Solids" waste container. Refer to SOP 003 and 315 or the Waste Disposal Coordinator for disposal when this container is full.

8.2.10 If analyzing for Chlorine skip to Step 8.2.12

8.2.11 Add 2mL of 6M HCl to the filtrate.

8.2.12 Add 1mL of 0.2M $PdCl_2$ to the filtrate.

8.2.13 Rinsing with methanol, filter the sample and collect the precipitate on a glass fiber filter. Wash alternately with 5mL portions of DI water and methanol. If analyzing for Chlorine collect the filtrate in a 50mL polypropylene centrifuge tube, which is stacked on top of another centrifuge tube inside the 1000mL filtering flask and proceed to Step 8.2.17 for the chlorine procedure. If only analyzing for Iodine, collect the filtrate in an "Aqueous Lab Waste" container provided by the Waste Disposal Coordinator. Refer to the Waste Disposal Coordinator for ultimate disposal of this waste stream when the container is full.

8.2.14 Place each sample filter in a clearly labeled 2" planchet and allow air-drying overnight. A convenient way to air-dry the samples are to place the planchets in the desiccator overnight. After the sample filter has dried, mount the filter on the planchet with double-sided adhesive tape.

8.2.15 Submit sample planchets and three blank filters mounted on planchets to the Instrumentation Lab for counting.

8.2.16 The Instrument Lab will analyze the samples and ultimately dispose of the filter and planchet in the manner described in SOP 724.

8.2.17 To the filtrate from Step 8.2.13, add approximately 0.5 grams of $Ba(NO_3)_2$ to each sample to remove any excess sulfate.

8.2.18 Centrifuge the sample at 3500rpm for 15 minutes.

8.2.19 Decant the supernatant into a clean 50mL centrifuge tube and add 2mL of $AgNO_3$ to precipitate AgCl.

8.2.20 Centrifuge the sample at 3500rpm for 15 minutes.

8.2.21 Decant the supernatant into the ^{129}I waste carboy.

8.2.22 Add 10mL of 1M HNO_3 to each sample, then vortex to wash the precipitate.

8.2.23 Centrifuge the sample at 3500rpm for 15 minutes.

8.2.24 Decant the supernatant into the ^{129}I waste carboy.

8.2.25 Add 4mL of 1M HNO_3 to each sample and vortex.

8.2.26 Working quickly to avoid settling of the precipitate, transfer each sample, rinsing with 1M HNO_3 in a wash-bottle, to a labeled stainless steel flat planchet.

8.2.27 Take the sample to dryness on a hotplate.

8.2.28 Submit to the Instrument Lab, with the appropriate documentation, for counting by gas flow proportional counter (GFPC).

9. PREPARATION OF CALIBRATION STANDARDS

9.1 IODINE CALIBRATION

9.1.1 Spike 3000-5000dpm ^{129}I into one liter of DI water (prepare 5 calibration sources).

9.1.2 Proceed to Step 8.2.3.

9.2 CHLORINE CALIBRATION

9.2.1 Spike approximately 10000dpm of ^{36}Cl into each labeled 50mL centrifuge tube (prepare 5 calibration sources).

9.2.2 Add 5mL of 1M $AgNO_3$ to each sample and mix well.

9.2.3 Centrifuge the samples at 3500rpm for 15 minutes. Decant the supernatant into the appropriate waste carboy.

9.2.4 Add 4mL of 1M HNO_3 to each sample.

9.2.5 Transfer each sample, rinsing with 1M HNO_3, to a labeled stainless steel flat planchet.

9.2.6 Take the sample to dryness on a hotplate.

9.2.7 Submit to the Instrument Lab, with the appropriate documentation, for counting by gas flow proportional counter.

10. CALCULATIONS

10.1 The **CHEMICAL YIELD** for this procedure is estimated by the analysis of a spiked split of the sample.

$$Yield = \frac{\left(\left(SSGrCPM - SSBkgCPM\right)/SSDetEff\right) - \left(\left(SmplGrCPM - BkgCPM\right)/DetEff\right)}{SpkDPM}$$

10.2 The sample **ACTIVITY** is calculated as follows:

$$\text{Activity} = \frac{\left(\text{SmplGrCPM}\right) - \left(\text{BkgCPM}\right) - \left(FiltCPM\right)}{\text{Denom}}$$

The activity calculation **DENOMINATOR** is calculated as follows:

$$\text{Denom} = \text{FinAli} * \text{Dec} * \text{ActCnv} * \text{DetEff} * \text{Yield}$$

10.3 Calculate the **ONE-SIGMA COUNTING UNCERTAINTY** as follows:

$$\text{CountingUnc.} = \frac{\sqrt{\left(\text{SmplGrCPM}/\text{SmplTime}\right) + \left(\text{BkgCPM}/\text{BkgTime}\right) + \left(FiltCPM / FiltTime\right)}}{\text{Denom}}$$

10.4 **TPU FACTORS**. As defined in SOP 743, the following 1σ preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty.

10.4.1 FOR IODINE SAMPLES:
Water samples require a preparation uncertainty factor of 0.172. This is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one tracer addition and three quantitative transfers. The estimated TPU related to the spiked split method is 15.63%. See the following equation:

$$0.172 = \sqrt{0.05^2 + 0.006^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.1563^2}$$

Solid samples require a preparation uncertainty factor of 0.173. This is based on one gross aliquotting (sample homogeneity), one mass measurement, one tracer addition and four quantitative transfers. The estimated TPU related to the spiked split method is 15.63%. See the following equation:

$$0.173 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.1563^2}$$

In practice, these values are substantially equivalent. For simplification in reporting, the larger factor of 0.173 may be conservatively used for both matrices.

10.4.2 FOR CHLORINE SAMPLES:
Water samples require a preparation uncertainty factor of 0.172. This is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one tracer addition and five quantitative transfers. The estimated TPU related to the spiked split method is 15.63%. See the following equation:

$$0.175 = \sqrt{0.05^2 + 0.006^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.1563^2}$$

Solid samples require a preparation uncertainty factor of 0.173. This is based on one gross aliquotting (sample homogeneity), one mass measurement, one tracer addition and six quantitative transfers. The estimated TPU related to the spiked split method is 15.63%. See the following equation:

$$0.177 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.1563^2}$$

In practice, these values are substantially equivalent. For simplification in

reporting, the larger factor of 0.177 may be conservatively used for both matrices.

10.5 Calculate the **ONE-SIGMA TOTAL PROPAGATED UNCERTAINTY (TPU)** as follows:

$$TPU(pCi/unit) = \sqrt{Counting\,Unc.^2 + (Activity * 0.173)^2 + (Activity * 0.056)^2}$$

This is based on SOP 743 guidelines for the TPU preparation factors described above and the in-house preparation of calibration standards.

10.6 The 2σ **MINIMUM DETECTABLE CONCENTRATION** (MDC) is calculated as follows:

$$MDC = \frac{4.65 * \sqrt{(BkgCPM + FiltCPM) * SmplTime} + 2.71}{SmplTime * Denom}$$

10.7 The 2σ **DECISION LEVEL** (DL) activity is calculated as follows:

$$DL = \frac{2.33 * \sqrt{((BkgCPM + FiltCPM) * SmplTime)}}{SmplTime * Denom}$$

where:

Activity = ^{129}I activity (default units pCi/L)
SmplGrCPM = analyte gross count rate (cpm)
SmplTime = sample count time (min)
BkgCPM = background count rate (cpm)
FiltCPM = net blank filter average count rate (cpm)
BkgTime = background count time (min)
FiltTime = blank filter count time (min)
Denom = activity calculation denominator
DetEff = sample counting efficiency
FinAli = final dilution/preparation adjusted aliquot (Note: dilution factor is included in this number to reflect the quantity of original sample taken for analysis (L)
ActCnv = activity conversion factor from DPM to desired units (2.22 for pCi, 60 for Bq)
Dec = decay factor $e^{(-\lambda t)}$ (fractional)
$\lambda = \ln 2 / t_{1/2}$
$t_{1/2}$ = half-life for ^{129}I in same units as decay time

t = decay time in same units as half-life
BkgTime = background count time (min)
SSGrCPM = spiked sample gross (cpm)
SSBkgCPM = spiked sample background (cpm)
SSDetEff = spiked sample detector efficiency
SpkDPM = spike addition DPM decay corrected to count date
Yield = fractional chemical yield

11. QUALITY CONTROL

11.1 One blank is run per batch of twenty or fewer samples (5% frequency).

11.2 One duplicate is run per batch of 10 or fewer samples (10% frequency).

11.3 One spiked blank (LCS) is run per batch of 20 or fewer samples (5% frequency).

11.4 The five calibration standards should be counted on a single detector prior to use. The data should be reviewed by the primary instrument analyst to determine any outliers. These planchets should be marked "do not use" and removed from the calibration set.

12. DEVIATIONS FROM METHOD

This SOP is substantially compliant with EPA Method 902.0 for the analysis of drinking waters. Deviations from and distinctions between this and the reference method are described below:

12.1 A measure of chemical yield is determined by spike addition to splits of each sample to address potential bias from differences in detection efficiency resulting from sample self-absorption and to minimize potential bias resulting from the presence of iodide in the water sample.

12.2 This procedure has been modified to accommodate matrices other than drinking waters. The procedure treats solubilized radioactive constituents in digestate or leachate solutions as a water sample.

12.3 One PdI_2 precipitation is carried out in this procedure whereas Method 902.0 carries out the precipitation twice.

12.4 Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of the laboratory's internally-derived acceptance criteria.

12.5 This method also addresses the separation and analysis of Cl-36, where the EPA method only addresses the separation and analysis of I-129.

13. SAFETY, HAZARADS AND WASTE DISPOSAL

13.1 SAFETY AND HAZARDS

13.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

13.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

13.1.3 Gloves, safety glasses, and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

13.1.4 Any chemicals with a TLV of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents, acids). TLVs may be found in the reference cited in Section 13.2 below.

13.1.5 All non-original containers used to hold reagents (e.g. wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

13.1.6 Care should be taken when diluting acids. Always add acids to water, not water to acids.

13.2 WASTE DISPOSAL

13.2.1 Where indicated, waste solutions should be collected in a container provided by the Waste Disposal Coordinator. Consult the Waste Disposal Coordinator for disposal of this waste stream.

13.2.2 Wastes that are “corrosive only”, such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the PAR waste water treatment facility. These materials that are “corrosive only” (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 754 REVISION 5

SOLID 5/5/07 (DAS)

TITLE: PREPARATION OF SAMPLES FOR TRITIUM ANALYSIS BY MICROWAVE OVEN

FORMS: 631, 1306 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 5/1/07

QUALITY ASSURANCE MANAGER _____ DATE 4/26/07

LABORATORY MANAGER _____ DATE 4-30-07

HISTORY: NEW, 3/23/95; Rev1, 10/08/99; Rev2, 4/26/02; Rev3, 4/04/03; Rev4, 3/15/05; Rev5, 4/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary for preparation of soil samples for measurement of water exchangeable tritium, utilizing distillation by microwave oven. This procedure is very efficient at extracting water from the solid matrix. Tritium that is bound to compounds other than water, will not be measured using this method. Oxidation of the solid to convert organic bound tritium to tritiated water may be required prior to distillation, if total tritium results are required.

2. SUMMARY

Tritium activity in the water content of a soil sample is radio assayed after separating the water from the sample by microwave heating, and the collection of the resulting vapor through condensation.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data

involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Volatile radionuclides that co-distill with the free water in a sample may lead to high bias in results. These would include, but are not limited to, low boiling organic compounds labeled with radiocarbon. The activity in the window above the region of interest (ROI) for tritium is monitored to identify samples where such interferences may be present.

4.2 Samples with very low moisture content may need to be equilibrated with tritium-free water prior to distillation. The addition of water will decrease sensitivity. The dilution affected by adding water must be accounted for in subsequent calculations of sample activity.

4.3 Avoid prolonged exposure of soil samples to air because of loss of moisture. Keep all sample containers tightly closed.

4.4 Rocky soils or those containing significant quantities of debris should be aliquotted, if possible, to exclude large rocks and other extraneous materials.

4.5 The scintillation vial is an optical surface. Any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation. These should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. All labeling must be done on the cap of the vial.

4.6 The presence of visible coloration in the distillate will act as an ‘inner filter’. This effect, known as ‘color quenching’ is an interference to the detection of the scintillation. The quench indicating parameter or (QIP, usually H-number) should be monitored and variations in quench that could correspond to greater than 10% relative bias in the efficiency, should be addressed by using standard additions to determine a sample-specific efficiency.

4.7 The presence of particulate contaminant in the final water distillate may interfere with the detection of the scintillation. This effect is known as ‘physical

quenching'. The symptoms, control limits, and corrective actions are identical to those mentioned in Section 4.6 above.

4.8 The presence of chemical contaminants in the final water distillate may inhibit scintillation. This effect is known as 'chemical quenching'. The symptoms, control limits, and corrective actions are identical to those mentioned in Section 4.6 above.

4.9 Due to the incompatibility of the matrix with microwave heating, samples containing metallic particles will need to be distilled by placing the sample in a 250mL round bottom flask, and distilled using the apparatus for water preparation.

4.10 The percent moisture value must be determined for all soil samples before starting the tritium analysis. One exception to this may be Performance Test (PT) samples. Consult with the Radiochemistry Technical Manager or designee prior to proceeding.

4.11 Sludge samples or those with an excessive amount of moisture may boil vigorously and "pop", contaminating the tubing and distillate. To avoid this, a piece of filter paper is cut to fit into the plastic jar over the sample. This will allow the moisture to pass while containing the sample. Filter paper should also be placed over the Blank and Blank Spike samples.

5. APPARATUS AND MATERIALS

5.1 pipettes, mechanical, previously calibrated per SOP 321, disposable pipette tips

5.2 dispenser, repipette, adjustable, 1-20mL

5.3 top loading balance, 0.1g sensitivity

5.4 graduated cylinder, 50mL

5.5 liquid scintillation vial, borosilicate glass, Teflon™-lined cap, 20mL

5.6 plastic jar, and cap with appropriate holes drilled for tubing in cap, also cap with no holes for storage purposes

5.7 glass beads

5.8 vacuum flask, with rubber stopper containing drilled hole for tubing

5.9 microwave, with appropriate holes drilled for tubing

5.10 1/4" outer-diameter Tygon™ tubing or equivalent

5.11 3/8" outer-diameter Tygon™ tubing or equivalent

5.12 forceps

5.13 ring stand, 3-prong clamps

5.14 desiccant tube, polyethylene. Fabricate by placing glass wool in one end of the tube, and filling with Drierite™, or equivalent desiccant. Place glass wool in the other end of the tube, to hold the desiccant in place.

5.15 glass pipette, 10mL, disposable, used as a moisture scrubber

5.16 Pyrex™ brand condenser #2400 or equivalent

5.17 spatula or disposable wooden tongue depressors

6. REAGENTS

NOTE: Threshold Limit Value (TLV) and other hazard information may also be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not mean that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding

6.1 Liquid scintillation cocktail, Ultima Gold™ LLT or equivalent

6.2 Tritium-free, laboratory deionized (DI) water

6.3 Drierite™ or equivalent desiccant. TLV = 24.45ppm (TWA)

6.4 Acetone. TLV = 500pm (TWA), irritant

6.5 Sand, quartz, Aldrich #27,473-9 (-50 to -70 mesh) or equivalent

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIME

7.1 Samples are collected and stored in tight-sealing glass jars so as to minimize the possible loss of water through evaporation

7.2 No preservation is necessary.

7.3 If elevated levels if tritium are expected, the Radiochemistry Technical Manager or designee should be contacted to ensure safe handling, and to take steps to minimize the risk of sample cross-contamination during storage and preparation.

7.4 At the current time, there is no regulatory holding time for tritium. Many sampling and analysis plans, however, apply a default holding time of 180 days for this analysis. If samples are analyzed more than 180 days after collection, this fact should be noted in the data package case narrative.

8. PROCEDURE

8.1 SAMPLE PREPARATION

8.1.1 Verify and record the sample condition on a solids sample condition form (Form 631).

8.1.2 Prior to sample preparation, a percent moisture analysis (SOP 642) should be performed on the samples to determine the appropriate aliquot size.

8.1.3 Label the caps of two sets of scintillation vials for each sample.

8.1.4 Label a clean plastic jar for each sample.

8.1.5 The amount of soil used is primarily dependent on how much soil is needed to produce 20mL of distilled water. Given the % moisture, calculate the amount of soil needed to produce this volume of distillate (assuming 100% recovery).

NOTE: Unless otherwise indicated, a maximum sample weight of 200 grams should be used regardless of the moisture content. If less than 200 grams is available, do not use the entire sample unless approved by the appropriate Project Manager. Additional deionized water may be added with a graduated cylinder or pipette in order to produce a total volume of 20mL of distilled water for testing. Any water added to a sample is noted on the benchsheet. If water is added to samples, the water should equilibrate with the solid sample overnight in the refrigerator.

8.1.6 Aliquot the calculated amount of sample into the labeled jars using a wooden tongue depressor or spatula.

8.1.7 Record the sample weight to the nearest 0.1g on the benchsheet. Keep the clean, labeled lid on the jar until ready for testing.

8.1.8 Prepare batch QC samples per Section 9.

8.1.9 Add laboratory deionized water to any samples that require it to produce 20mL of distillate.

8.1.10 Allow samples and QC to equilibrate overnight in cold storage. Be sure all jars are tightly capped to avoid tritium losses from evaporation.

8.1.11 Prior to using the microwave apparatus to distill samples, an equipment blank is prepared and analyzed per Section 8.2 to monitor potential sample contamination.

8.1.12 Replace lid with clean lid drilled with 1/4” holes. Put the jar in the microwave and connect to 1/4” tubing.

8.1.13 Connect tubing to condenser, connect tubing from moisture scrubber tube to jar, and connect desiccant tube to moisture scrubber.

8.1.14 Place a labeled scintillation vial in the vacuum flask ~half full of glass beads (to support vial) under the condenser outlet. Insert the rubber

stopper containing the condenser outlet into the vacuum flask to seal the flask.

8.1.15 Use the laboratory vacuum to apply a gentle vacuum to the flask, and turn on the water to the condenser.

8.1.16 Turn on the microwave, at 1-2 minute intervals, at full power, not allowing any condensation to form in the air intake tube.

8.1.17 As the sample heats, the vapor will condense in the condenser and drop into the scintillation vial.

NOTE: Do not dry the sample, overheat the jar, or heat too rapidly or melting of the plastic jar will occur. Be careful to keep an eye on the distillate flow through the condenser. If flow should decrease or stop, shut the microwave off

8.1.18 When sufficient distillate has been collected, turn off the microwave. 10.0mL of distillate is typically used for sample analysis, if less than 10.0mL is available, refer to Section 8.1.25 below.

8.1.19 Once distillation is complete, carefully remove the scintillation vial from the flask using a pair of forceps. Cap the vial and set it aside until ready to mix with cocktail.

8.1.20 Remove the jar containing the sample from the microwave. CAUTION: The jar will be hot. Replace the original lid and return this fraction to sample storage and document it as a tritium fraction on the chain of custody.

NOTE: Dried sample may be used for alpha spec or gamma spec.

8.1.21 Clean the setup thoroughly by flushing two or three times with DI water. Dry the apparatus with acetone prior to distilling the next sample. Collect the acetone in a flammable waste container.

8.1.22 Allow the distillate to cool completely prior to aliquotting. This will minimize tritium losses due to evaporation, and allow an accurate volumetric measurement by pipet.

8.1.23 Using a calibrated pipette (SOP 321), remove 10.0mL of the distillate collected in Step 8.1.18 above and dispense into a labeled borosilicate vial. Save the remainder of the distilled sample as a reserve.

8.1.24 Add 10mL of Ultima Gold^{TM} LLT cocktail to the vial and shake well to homogenize.

NOTE: The Ultima Gold™ dispenser is calibrated monthly to deliver 10mL using a Class A volumetric flask and recorded in the calibration logbook.

8.1.25 If there is less than 10mL of distillate available for analysis, conduct the transfer on the balance. Record the mass of the distillate added as the analytical aliquot (assuming 1g/mL). Then carefully add tritium-free water to bring the final mass of liquid in the vial to 10g. Make a note in the 'Comments' section on the benchsheet regarding dilution necessary to meet the calibration geometry.

8.1.26 Clean the surface of each vial by wiping with a lab wipe moistened with methanol or isopropyl alcohol, to remove smudges or other discolorations on the surface.

8.1.27 Without touching the surface of the glass, load the vials into the scintillation counting rack, beginning with the calibration blank.

8.1.28 Verify each vial ID and rack and position against that recorded on the benchsheet.

8.1.29 Submit the vials to the Counting Lab with all necessary documentation.

8.1.30 All samples should be dark-adapted for approximately two hours prior to counting.

8.1.31 The Counting Lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704.

8.2 EQUIPMENT BLANK

8.1.1 Between each prep batch of samples, an equipment blank is prepped and analyzed to confirm that the apparatus is not contaminated. This is accomplished by placing ~200g of sand into a sample container, adding 50mL of DI water, and processing as a sample per Section 8

8.1.2 The Counting Lab will analyze the equipment blank and return a report to the prep lab. This report is kept in the ^{3}H Equipment Blank History binder in the prep lab.

8.3 PREPARATION OF EFFICIENCY CALIBRATION STANDARDS

8.3.1 A one-point calibration source is conducted as follows: Prepare, in triplicate, a NIST-traceable tritiated water standard diluted to 50-500dpm/mL with deionized water, to a final volume of approximately 50mL. The solution is then distilled and aliquotted per SOP 700. The average efficiency is calculated as described in SOP 700.

8.3.2 A one-point efficiency is highly accurate and will be used for the calculations of all results showing a QIP result corresponding to the average observed for the calibration standard (within +/- 10% relative efficiency or, lacking this calibrated range, +/- 15 of mean H-numbers). Any sample falling outside this range will be calibrated by sample specific addition of minimum known volume (<200µL) of NIST-traceable tritiated water.

9. QUALITY CONTROL

9.1 CALIBRATION BLANK

For each batch of twenty or fewer samples, a calibration blank consisting of tritium-free water and liquid scintillation cocktail will be prepared in the same proportions as that in the samples. This sample is used to establish a population of blanks used for determining the instrumental background and shall not be distilled or subjected to any other processing. This sample is placed in the first position of the first rack of samples.

9.2 METHOD BLANK

Place 200g of clean, quartz sand into a sample container. Add 50mL of tritium-free deionized water. Process as a sample per Section 8.1. One blank is analyzed with each batch up to 20 samples, or at a minimum frequency of 5%.

9.3 LCS AND MATRIX SPIKES

9.3.1 For the LCS, place 200g of clean, quartz sand into a sample container. Add the appropriate spike volume to a graduated cylinder and bring the total volume up to 50mL with deionized water. Pour the spiking solution over the sand and shake the sand and water solution to mix. Process the LCS as a sample per Section 8.1. An LCS (i.e., blank spike) is run with each batch of samples up to 20, or at a minimum of 5% frequency.

9.3.2 Applicable acceptance limits for the LCS are 85-115%. Project-specific acceptance limits may apply and supersede default limits.

9.3.3 For matrix spike samples, evenly disperse the spiking solution over the sample. Cap the sample and shake thoroughly. Matrix spikes are prepared with each batch of samples up to 20, or at a minimum of 5% frequency. Applicable acceptance limits are 85-115%. Project-specific acceptance limits may apply and supersede default limits.

9.4 SAMPLE DUPLICATE

A duplicate sample analysis is run for each batch of up to ten samples or at a minimum frequency of 10%. If there is insufficient sample available to run a duplicate, an additional blank spike may be substituted for each duplicate.

10. DEVIATIONS FROM METHOD

This method extracts water from solid samples as described in the EPA EERF procedures manual (H-01-H-03). It is not an azeotropic distillation, and utilizes microwave radiation to generate the necessary heat to extract the water from the sample.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Microwaved samples reach high temperatures. Use appropriate thermal protective handling gear and/or allow samples to cool before handling.

11.1.2 Samples containing metallic particles will need to be distilled by the water method (SOP 700) due to the incompatibility of the matrix with microwave heating. The metal particles will superheat and lead to a breach in the distillation vessel.

11.1.3 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.4 Wear gloves, safety glasses and lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.5 Any chemicals with a TLV of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Acetone used for equipment drying is collected in a plastic container and disposed as non-halogenated laboratory waste.

11.2.2 Dump the soil from the container into a two liter wide-mouth Nalgene bottle. The container shall be labeled Post Tritium Distillation Soil Residues. Please segregate any sample with non-environmental levels of activity into separate containers from the environmental level samples. The soil residue will be analyzed for radionuclide content to determine classification as non-radioactive or radioactive. The non-radioactive samples will be disposed of in the contaminated soils and solids waste. Radioactive soils will have further analyses performed to

determine status as LLRW or Mixed Waste.

11.2.3 RADIOCHEMISTRY ANALYTICAL EFFLUENT DISPOSAL
If the distillate from the tritium soil analytical process effluent has been determined to not be hazardous, this material may be discharged into the Paragon wastewater treatment facility. Here the activity will be monitored to ensure compliance with Colorado Rules and Regulations pertaining to Radiation Control Part 4 regarding discharges to sanitary sewers.

11.2.4 Distilled sample remnants may remain in the scintillation vial until the samples have been analyzed and the results reported. Once it is determined that this fraction is no longer needed, it can be disposed of in the proper carboy labeled "C-14 and Tritium Distillate Remainders".

11.2.5 The Counting Lab staff is currently handling disposal of samples and cocktail mix. These glass vials are accumulated (intact) in a container provided by the Waste Disposal Manager.

12. REFERENCES

USEPA Eastern Environmental Radiation Facility (EERF) Procedures Manual-78-1, 1978; EPA 520/5-84-006, 1984. Adapted for microwave use at Paragon by Steve Workman.

DOCUMENT REVISION HISTORY

4/27/06: Revision 5. Added LIMS program specification language (3.3). Added spatula or disposable wooden tongue depressors to equipment list (5.17). Added hold time comment (7.4) consistent with SOP 700. Changed Step 8.1.19 to a NOTE following Step 8.1.17. Reordered Section 9 (moved Method Blank to 9.2). Reordered WASTE DISPOSAL (moved Acetone to 11.2.1; moved RADIOCHEMISTRY ANALYTICAL EFFLUENT DISPOSAL to 11.2.3). Corrected EERF Manual reference (Section 12), both previous references were actually the same thing. Added DOCUMENT REVISION HISTORY. Attached Forms.

STANDARD OPERATING PROCEDURE 755 REVISION 9

TITLE: DETERMINATION OF TECHNETIUM-99 IN SOLID AND WATER/AQUEOUS SAMPLES

FORMS: 302 (use current iteration)

APPROVED BY:
TECHNICAL MANAGER _____ DATE 7/21/08
QUALITY ASSURANCE MANAGER _____ DATE 7/20/08
LABORATORY MANAGER _____ DATE 7/21/08

HISTORY: Rev0, PCN 211, 4/8/94; Rev1, PCN #559, 11/9/95; Rev2, 10/6/99; Rev3, 1/26/00; Rev4, 4/26/02; Rev5, 11/08/02; Rev6, 4/04/03; Rev7, 5/17/04; Rev8, 5/3/06; Rev9, 7/17/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the preparation of environmental solid and water samples for quantitative measurement of Technetium-99 (^{99}Tc).

2. SUMMARY

2.1 ^{99}Tc in the form of the TcO_4^{-1} (pertechnate ion) is extracted from acidified water samples by passing the sample through a column containing Eichrom TEVA Resin™. ^{99}Tc in the form of the TcO_4^{-1} ion is extracted from a dried and ground solid sample by leaching in 1M HNO_3 and passing the leachate through a column containing Eichrom TEVA Resin™.

2.2 After the sample has been extracted, the resin is transferred from the column into a liquid scintillation (LS) vial. LS cocktail is added to the resin and ^{99}Tc is measured by liquid scintillation counting. A short-lived gamma emitter, Tc-99m, is used as a tracer for this procedure. Technicium-99m is spiked into the sample at the beginning of the procedure and is quantified in the final prepared vial by gamma counting.

2.3 Samples that are known or suspected to be high in Th-234 may require additional cleanup by hydroxide precipitation because Th-234 is a beta-emitting radioisotope that can interfere in the determination of ^{99}Tc by LSC. Samples that are high in natural uranium are likely to also be high in Th-234 because Th-234 is a daughter of U-238.

3. RESPONSIBILITIES

3.1 Technicium-99m is a short-lived isotope, with a 6.02 hour half-life, and must be ordered in advance, for delivery on each day that the method is performed. It is the responsibility of the analyst performing the method to place the order for Tc-99m, under the direction of the Radiation Safety Officer (RSO), or other licensed user of radioactive materials, and to inform the RSO upon receipt of the Tc-99m in the lab.

3.2 It is the responsibility of the analyst performing the method to notify the instrument lab gamma technician in advance of the number of samples arriving and the expected delivery date and time. This allows the gamma technician to schedule adequate instrument time to analyze the short-lived Tc-99m tracer.

3.3 It is the responsibility of the analyst performing the method to ensure that the Tc-99m solution and subsequent dilutions are stored inside the lead shield in the radioactive standards lab for at least four days prior to disposal. The standard and subsequent dilutions must be labeled with the receipt date prior to storage.

3.4 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.5 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specifications related to the client, project, and test method being performed.

3.6 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.7 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.8 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 All radionuclides that undergo beta emission (including ^{14}C, ^{32}P, ^{35}S, and ^{90}Sr) are effectively removed using Eichrom TEVA Resin™ unless they are present in the sample at exceptionally high levels.

4.2 Tritium can be extracted along with technetium due to the absorption of tritium-labeled compounds by the resin. Interference by tritium can be eliminated by setting the counting window for ^{99}Tc above the maximum beta emission energy for tritium.

4.3 Samples should be acidified with nitric acid prior to analysis. Acidification has been shown to reduce adsorption of Tc by polyethylene containers (see Reference 13.4). Pertechnate (TcO_4^{-1}) is readily soluble and is the predominant species of technetium under oxidizing conditions.

4.4 Samples that are high in natural uranium can contain significant Th-234. Since Th-234 undergoes beta decay with an emission energy similar to that of ^{99}Tc, additional separation steps may be required for samples high in natural uranium (and Th-234).

4.5 When a ^{99m}Tc tracer is used, the decay product is ^{99}Tc. Care should be taken to ensure that the amount of ^{99m}Tc used does not contribute measurable quantities of ^{99}Tc to the analytical fraction. See Section 8.1.1.1 for details.

4.6 The production of a ^{99m}Tc standard may occasionally result in the contamination of the standard with the ^{99}Mo parent. The reference vials used to calibrate the gamma spectrometer in this procedure should also be counted on the liquid scintillation counter, as described in Section 10.2, to ensure that ^{99}Mo or other interfering radionuclides are not present in the ^{99m}Tc standard.

4.7 Soluble organic constituents in the sample can interfere with the chemical separation process, causing low chemical yields, and can cause quenching during liquid scintillation counting. Organic constituents can be removed by muffling at 600° for four hours, or until complete removal of organic material is achieved. If the samples are to be muffled, organic material such as potting soil must be added to the QC samples to prevent volatilization of technetium. Alternately, organics can be removed by passing the sample solution through a column containing Eichrom Pre-Filter Resin™ prior to extraction with TEVA Resin™.

4.8 The scintillation vial is an optical surface. Any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation. These should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. All labeling must be done on the cap of the vial.

4.9 The presence of visible coloration will act as an ‘inner filter’. This effect, known as ‘color quenching’, is an interference to the detection of the scintillation. The presence of particulate contamination in the final sample may interfere with the detection of the scintillation. This effect is known as ‘physical quenching’. The presence of chemical contaminants in the sample may inhibit scintillation. This effect is known as ‘chemical quenching’.

4.10 The quench indicating parameter or (QIP) (H-number or SQPe number) should be monitored and variations in quench that could correspond to greater than 10% relative bias in the efficiency should be addressed by using standard additions to determine a sample specific efficiency.

5. APPARATUS AND MATERIALS

5.1 specimen cups, polypropylene, disposable, 100mL and 220mL

5.2 scintillation vials, glass, 20mL

5.3 graduated cylinder, 25 mL

5.4 tongue depressor

5.5 transfer pipet, 2mL

5.6 Eppendorf™ pipet, and disposable pipet tips

5.7 repeater pipet, and disposable pipet tips

5.8 column (BIO-RAD™ catalog no. 731-1553)

5.9 Whatman™ #41 filter paper, or equivalent

5.10 pipet bulb

5.11 analytical balance

5.12 steam bath

5.13 hot plate

5.14 syringe with hypodermic needle, 10mL

5.15 centrifuge tube, 250mL

5.16 centrifuge

5.17 funnels, both fitted and glass

5.18 vortex mixer

5.19 microliter syringe

6. REAGENTS - **Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids)**

6.1 Tc-99m (metastable Tc-99). Must be obtained "fresh" from the vendor on the day needed for use because the half-life is very short ($T_{½}$ = 6.02 hrs).

6.1.1 Open the lead shield (pig) and carefully withdraw a 1mL aliquot of the Tc-99m primary standard from the vial using a 10mL syringe fitted with a hypodermic needle.

6.1.2 Dispense the aliquot of Tc-99m into a disposable specimen cup containing approximately 100mL DI water. Cap and mix well. This creates approximately a 100X intermediate dilution.

6.1.3 Using a 10mL syringe, transfer approximately 10mL of the intermediate dilution into another disposable specimen cup that contains approximately 70mL of DI water. Cap and mix well. This creates approximately an 800X working dilution.

6.1.4 Remove the adhesive label from the Tc-99m delivery and attach it to a Quality Assurance Summary Sheet (QASS, Form 302), which should accompany the benchsheet.

6.2 ^{99}Tc spiking standard for LCS and matrix spike/matrix spike duplicate.

6.3 De-ionized (DI) water, ASTM Type II, or equivalent.

6.4 Hydrogen peroxide, H_2O_2, 30%.

6.5 Ferric chloride carrier, 20mg Fe^{3+}/mL. Dissolve 96g $FeCl_3 \cdot 6H_2O$ in one liter of 0.5M HCl.

6.6 Ammonium hydroxide, NH_4OH, conc., reagent grade.

6.7 Concentrated hydrofluoric acid, HF. TLV = 3ppm.

6.8 Concentrated nitric acid, HNO_3. TLV = 2ppm.

6.8.1 1.0M HNO_3: Carefully add 63mL of concentrated HNO_3 to 800mL of DI water and dilute to a final volume of 1000mL with DI water.

6.8.2 0.1M HNO_3: Carefully add 100mL of 1M HNO_3 to 800mL of DI water and dilute to a final volume of 1L with DI water.

6.8.3 0.01M HNO_3: Carefully add 10mL of 1M HNO_3 to 800mL of DI water and dilute to a final volume of 1L with DI water.

6.9 0.5M HF / 0.02M HNO_3: Carefully add 17.8mL of conc. HF and 20mL of 1M HNO_3 to 800mL of DI water and dilute to a final volume of 1L with DI water.

6.10 TEVA Resin™ chromatographic resin, 50-100um particle size, Eichrom Industries.

6.11 Pre Filter Resin™, 50-100um particle size, Eichrom Industries.

6.12 Ultima Gold AB™ liquid scintillation cocktail

6.13 Methanol, reagent grade. Used with laboratory wipes to clean outside surface of

liquid scintillation vials. Flammable. TLV = 200 ppm.

6.14 Nitromethane, reagent grade. Necessary only when a Quench curve (Section 9) is prepared. Flammable. TLV = 20 ppm..

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 It is recommended that water samples be preserved at the time of collection by adding enough conc. HNO_3 per liter of sample to bring the pH to less than 2 (2mL of conc. HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days, then preserved, and held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.3 Solid samples are dried (105°C) for a minimum of 4 hours and ground for homogenization according to SOP 721. An experiment to investigate the volatilization of ^{99}Tc from soil during drying was carried out under Paragon internal work order 03-13-020. Results demonstrated that Tc-99m spiked onto a soil sample was not volatilized after heating overnight at 105°C.

7.4 The container choice should be plastic (rather than glass) to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

NOTES: For any samples where pre-screening activity or other knowledge is available and indicates alpha activity **in excess of 100dpm (45pCi)** a $Fe(OH)_3$ precipitation will be carried out in order to co-precipitate and remove Th-234.

For any samples where pre-screening activity is available and indicates alpha activity **in excess of 1000 dpm (450 pCi)** a $Fe(OH)_3$ precipitation and a 0.5M HF/0.02M HNO_3 rinse will be carried out for Th-234 decontamination.

8.1 WATER PREPARATION

8.1.1 Obtain “fresh” Tc-99m (metastable Tc-99) from the supplier, preferably at the beginning of the same day that the samples are to be prepared. Dilute the Tc-99m stock solution as necessary to a Tc-99m activity that is appropriate for spiking into samples.

8.1.1.1 The activity of Tc-99m added to each sample should not be such that the Tc-99m will decay to a ^{99}Tc activity which is greater than 1/3 the requested detection limit for liquid scintillation counting. Typically 600-1,000pCi (at the

reference time of standard dilution) is sufficient.

8.1.1.2 The activity of Tc-99m added to each sample should result in an activity that is approximately 10 times the detection limit on the gamma spectroscopy instrument (600-1,000 pCi/sample and 6,000–10,000pCi/reference vial). The three reference vials should be counted on the same gamma detector for a sufficient period of time to acquire a total of 10,000 counts which is approximately 1% (1σ) counting uncertainty. Samples should be counted for a sufficient period of time to acquire 5% (1σ) counting uncertainty. Results for all samples must be decay corrected to the same date and time.

8.1.2 Measure an appropriate aliquot of sample into a clean beaker of suitable size (the default aliquot for water is 250mL).

NOTE: If a water sample is observed to contain solid particles, filter the sample through qualitative filter paper and measure an aliquot of the filtrate for ^{99}Tc analysis. Unless specifically instructed otherwise by the client, only the aqueous portion of a water sample is prepared for ^{99}Tc analysis.

8.1.3 Using an Eppendorf™ pipet, trace each sample with 0.1mL of the Tc-99m solution prepared in Step 8.1.1. Trace each reference vial with 1.0mL of the same Tc-99m solution. Refer to Section 8.4 for the preparation of the standard reference vials. Also, spike the LCS with 1.0mL of ^{99}Tc standard spiking solution (approximately 500dpm/mL) as well as any MS/MSD samples that have been requested.

8.1.4 For routine water samples that are clear and colorless, go directly to Step 8.3 (separation by TEVA Resin™). Non-routine samples must be handled on a case-by-case basis.

8.1.5 If the sample has known or suspected alpha activity greater than 100dpm proceed to Step 8.2.10, otherwise go to Step 8.3.

8.1.6 Turbid samples may require more rigorous filtering. Unusual aqueous samples may contain dissolved organic constituents that can cause quenching in liquid scintillation counting. Dissolved organics can be destroyed by heating with H_2O_2 (Step 8.1.6.1.) or removed by passing the sample through a column containing pre-filter resin (Step 8.1.6.2.). The analyst must document in a QASS (Form 302) any procedures used to treat non-routine samples.

8.1.6.1 Peroxide digestion to destroy organics: Add 10mL of 30% H_2O_2 for every 1L of sample (if the sample aliquot is 250mL, add 2.5mL of H_2O_2 solution). Heat the sample on a hotplate for approximately 1 hour. Stir the sample occasionally. If bubbling due to decomposition of H_2O_2 has not stopped as the sample cools, continue heating until bubbling ceases.

8.1.6.2 Prepare a pre-filter column as follows: transfer Eichrom Pre-filter Resin™ as a slurry with DI water to an empty BIO-RAD™ column until the bottom stem section is filled (2.0mL). Attach a fitted funnel to the column. Place a regular funnel, with a Whatman™ 41 filter in it, on top of the fitted funnel and rinse the column with DI water. Place a clean, labeled beaker under the column. Pass the sample solution through the column, collecting the effluent in the beaker. Rinse the column with DI water and collect.

8.2 SOIL AND SOLID PREPARATION

8.2.1 Obtain and prepare "fresh" Tc-99m (metastable Tc-99) from the supplier, as described in 8.1.1.

8.2.2 Weigh an appropriate aliquot of dried and ground sample into a 220mL polypropylene specimen cup (the default aliquot is 2 grams).

8.2.3 Using an Eppendorf™ pipet, trace each sample with 0.1mL of the Tc-99m solution prepared in Step 8.1.1. Trace each reference vial with 1.0mL of the same Tc-99m solution. Refer to Section 8.4 for the preparation of the standard reference vials. Also, spike the LCS with 1.0mL of ^{99}Tc standard spiking solution (approximately 500dpm/mL) as well as any MS/MSD samples that have been requested.

8.2.4 To the sample in the specimen cup add 40mL of 1N HNO_3. Place a 100mL polypropylene beaker on top of 220mL beaker as a cap to cover the sample.

8.2.5 Place the sample on a steam bath to heat for about ½ hour.

8.2.6 Remove the samples from the steam bath and carefully add 5mL of 30% H_2O_2 solution to the sample, in 1mL increments. For dark samples add the 5mL of 30% H_2O_2 dropwise. **The addition of H_2O_2 can cause a vigorous reaction! Be cautious and alert. Always wear gloves and protective eyewear.**

8.2.7 Once foaming has subsided place the 100mL beaker back down on top

of the sample beaker. Resume heating for about 1½ hours. Carefully observe the sample for a few minutes and watch for evidence of foaming.

8.2.8 After the sample has been heated for a total of about 2hrs. remove the sample from the steambath and allow to cool.

8.2.9 If the sample is suspected or known to be high in Th-234, go to Step 8.2.10, otherwise go to Step 8.2.11.

8.2.10 Separate Th-234 from ^{99}Tc by co-precipitation with $Fe(OH)_3$. Quantitatively transfer the sample in the disposable beaker to a 250mL centrifuge bottle. To the sample add 1mL of 20mg/mL ferric iron carrier, then carefully add about 5mL of concentrated NH_4OH to precipitate $Fe(OH)_3$. Swirl to mix. After the $Fe(OH)_3$ has completely formed, centrifuge the sample for about 15 minutes @ 3500rpm. The supernatant will be used for further analysis below. The precipitate may be discarded.

8.2.11 If it is the analyst's judgment that the leachate from Step 8.2.9 or supernatant from Step 8.2.10 has significant color (yellow or brown), the sample should be passed through a column containing Eichrom Pre-Filter Resin™ (Step 8.2.12). If the analyst judges that the filtrate does not have significant color (the sample is clear), go directly to Step 8.3.

8.2.12 Prepare a pre-filter column as follows: transfer the pre-filter resin as a slurry with DI water to an empty BIO-RAD™ column until the bottom stem section is about half full (1.0mL). Attach a fitted funnel to the column. Place a regular funnel, with a Whatman™ 41 filter in it, on top of the fitted funnel and rinse the column with DI water. Transfer the sample leachate solution to the column, rinsing with DI water to complete the transfer. Collect the effluent from the column in a clean, labeled polypropylene specimen cup.

8.3 SEPARATION OF TC-99

8.3.1 For each sample prepare a TEVA resin™ column as follows: transfer the TEVA Resin™ as a slurry with DI water to an empty BIO-RAD column until the bottom stem section is filled (2.0mL). Attach a fitted funnel to the column. Place a regular funnel, with a Whatman™ 41 filter in it, on top of the fitted funnel and rinse the column with 5mL of 0.1M HNO_3.

8.3.2 Transfer each sample solution to a prepared TEVA resin™ column through the Whatman™ 41 filter. Complete the transfer by rinsing with DI water. Discard the effluent from the column down the lab sink with

plenty of cold water.

8.3.3 In cases where pre-screening activity is available and indicates alpha activity **in excess of 1000dpm,** the following rinse will be carried out: after the sample has completely passed through, rinse the column with 25mL of 0.5M HF/0.02M HNO_3. Discard the effluent from the column. The purpose of this step is to remove residual Th-234 from the column.

8.3.4 After the sample solution has completely passed through, rinse the column with 50mL of 0.01M HNO_3. Discard the effluent from the column.

8.3.5 Using a pipet bulb to apply pressure to the orifice of the column, carefully force the TEVA Resin™ out of the column into a clean LS vial. To complete the transfer, plug the column orifice with a small red cap and pipet 3.0mL of 0.1M HNO_3 into the column. After swirling transfer the 0.1M HNO_3 rinsate out of the column into the LS vial.

8.3.6 To the vial add 15mL of Ultima Gold AB™ LS cocktail. Cap the vial and mix thoroughly by inversion and vortexing. Wipe the outside of each vial with methanol to ensure a clean optical surface.

NOTE: The final volume of the samples, the reference for yield determination, and the calibration vials for calibration in the LS vial should always be kept constant (the standard volume used is 19mL as detailed below).

- 15mL Ultima Gold AB™ LS cocktail.
- Resin slurried with DI water, which contains approximately 1mL of liquid in its pore space.
- 3mL of 0.1M HNO_3 or in the case of a standard or calibration vial – a volume of ^{99}Tc standard and a volume of 0.1M HNO_3 which brings the final volume of acid + standard to 3mL.

8.4 PREPARATION OF REFERENCE STANDARD VIALS FOR GAMMA COUNTING

NOTE: Reference standard vials should be prepared at the time of spiking/tracing samples.

8.4.1 Prepare three Tc-99m reference standard vials for gamma counting as follows: Into three clean LS vials, pipet the appropriate volume of Tc-99m spiking solution, as described in Section 8.2.1 or 8.1.1. Add a

volume of 0.1M HNO_3 to the vial that will result in a final volume of 3mL. Typically, this is 1mL standard + 2mL 0.1M HNO_3. Add the same amount of wet, unused, TEVA Resin™, slurried in DI water, as that used in the columns prepared for the samples. Cap the vial and mix thoroughly by inverting and vortexing.

8.4.2 Submit the sample vials, Tc-99m reference standard vials, and benchsheet to the instrument lab for analysis of Tc-99m tracer by gamma counting and analysis of ^{99}Tc by LS counting. **It is extremely important that gamma analysis of Tc-99m be done within 24 hours since Tc-99m has a very short half-life (6.02 hrs).** The instrument lab should allow a time period of at least 72 hours to elapse from the spike date/time until beta analysis of the samples by LSC. This time may be shortened with the Department Manager's approval.

9. PREPARATION OF CALIBRATION VIALS (FOR QUENCH CURVE)

Twelve spikes and twelve blanks are prepared with increasing volumes of nitromethane for calibration. Details follow:

9.1 Blank preparation: Add the same amount of wet, unused, TEVA Resin™, slurried in DI water, as that used in the columns prepared for the samples (Section 8.3.1) to each of twelve vials (Blk1-Blk12). Add 3mL 0.1M HNO_3 and 15mL Ultima Gold AB™ LS cocktail to each vial. Blank1 vial does not receive nitromethane. Add nitromethane to each subsequent vial in 15µL increments (i.e., Blk2 receives 15µL, Blk3 receives 30µL, and so on). Cap the vial and mix thoroughly by inverting and vortexing to homogenize. Wipe the outside of each vial with methanol in ensure a clean optical surface.

9.2 Spike Calibration Vial preparation: Add the same amount of wet, unused TEVA Resin™, slurried in DI water, as that used in the columns prepared for the samples (Section 8.3.1) to each of twelve vials (S1-S12). Add a known volume of ^{99}Tc standard (approximately 1500dpm) to each vial. Add a volume of 0.1M HNO_3 to the vial which will result in a final volume of standard + 0.1M HNO_3 of 3mL. Spike1 vial does not receive nitromethane. Add nitromethane to each subsequent vial in 15µL increments (i.e., S2 receives 15µL, S3 receives 30µL, and so on). Cap the vial and mix thoroughly by inverting and vortexing to homogenize. Wipe the outside of each vial with methanol to ensure a clean optical surface.

10. QUALITY CONTROL

10.1 Acceptance criteria for QC samples and other quality indicating parameters can be found in SOP 715 and in the LIMS program specifications.

10.2 One method blank is prepared and analyzed per batch of 20 samples (5% frequency).

In the event that the method blank analysis results in activity above the calculated MDC, the three reference vials used to calibrate the gamma spectrometer should be counted on the LSC for the same length of time as the blank. The results of these counts will be used to determine whether the blank activity is due to laboratory contamination, or due to the potential contamination of the Tc-99m source, as described in Section 4.6. The Department Manager should be consulted in the interpretation of the count data.

10.3 One sample duplicate is prepared and analyzed per 10 samples (10 % frequency).

10.4 One LCS (spiked blank) is prepared and analyzed per batch of 20 samples (5% frequency). If there is insufficient sample to prepare a sample duplicate, a duplicate spiked blank (LCS-D) should be substituted.

11. CALCULATIONS

11.1 TPU FACTORS

As defined in SOP 743, the following 1σ preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty:

11.1.1 Water samples require a preparation uncertainty factor of 0.0564. This factor is based on one gross aliquotting (sample homogeneity), one volumetric measurement, one pipetting of Tc-99m standard, and one quantitative transfer. See the following equation:

$$0.0564 = \sqrt{0.05^2 + 0.006^2 + 0.004^2 + 0.025^2}$$

11.1.2 Soil samples require a preparation uncertainty factor of 0.0561. This factor is based on one gross aliquotting (sample homogeneity), one mass measurement, one pipetting of Tc-99m standard, and one quantitative transfer. See the following equation:

$$0.0561 = \sqrt{0.05^2 + 0.003^2 + 0.004^2 + 0.025^2}$$

11.1.3 To simplify analytical reporting, the larger of the two preparation uncertainties calculated above, 0.0564, will be used for both soil and water matrices.

11.2 CHEMICAL YIELD

11.2.1 Technicium-99m should be analyzed by gamma spec (140.5 keV) as soon as possible after sample preparation. The three reference vials should be counted on the same gamma detector for a sufficient period of time to acquire a total of 10,000 counts which is approximately 1% (1σ) counting uncertainty. Samples should be counted for a sufficient period of time to acquire 5% (1σ) counting uncertainty, or 400 counts.

Results for all samples must be decay corrected to the same date and time.

11.2.2 Chemical yield is calculated as the sample result for Tc-99m divided by the mean of the Tc-99m results for three reference standards prepared in Step 8.4.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Technicium-99m is a strong gamma emitting radionuclide and must be stored in a lead shield for at least 72 hours after receipt to allow for decay prior to disposal.

12.1.2 The building is equipped with a safety shower, eyewash station, fire extinguisher and fire blanket as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

12.1.3 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.4 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.1.5 Gloves, safety glasses and a lab coat must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.1.6 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.7 below.

12.1.7 All non-original containers used to hold reagents (e.g. wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.8 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.2 WASTE DISPOSAL

12.2.1 The instrument lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704. Emptied columns may be soaked in a RadiacWash® solution, rinsed in tap water and discarded into the sanitary trash.

12.2.2 Sample effluent from Section 8 can be disposed of by discharging into the PAR waste water treatment facility (i.e., down the laboratory sink with plenty of cold tap water), unless special instruction is given in the project instructions by the RSO.

12.2.3 Wastes that are "corrosive only", such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the Paragon waste water treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

12.2.4 The Tc-99m standard, which is delivered in a sterile saline solution, can be disposed of in the sanitary sewer AFTER allowing complete decay of the Tc-99m for at least one week. The glass ampoules may be discarded into the lab's broken glass receptacle.

DOCUMENT REVISION HISTORY

4/10/06: RESPONSIBILITIES updated to include ordering, use, storage, and disposal of Tc-99m and notifications to the instrument lab and the RSO. Muffling temperature was changed to 600°C. Other clerical changes were made to clarify the language. DOCUMENT REVISION HISTORY added.

9/27/07: Published SOP was amended as follows: Section 7.2 - updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57).

7/17/08: Incorporated previous amendment into SOP. Fixed header (was an error in previous published file) so that proper updated iteration is shown throughout. Removed PAR SOP 743 (TPUs) from Section 13 REFERENCES. Added DOE Method RS551 citation to REFERENCES. Added Form.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 758 REVISION 2

TITLE: DETERMINATION OF PROMETHIUM-147 IN WATER

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7/21/06

QUALITY ASSURANCE MANAGER _____ DATE 7/21/06

LABORATORY MANAGER _____ DATE 7-21-06

HISTORY: NEW, 4/14/94; Rev1, 7/7/2003; Rev2, 7/24/06.

1. SCOPE AND APPLICATION

This standard operating procedure describes the steps necessary for preparation of environmental water samples for quantitative measurement of Pm-147.

2. SUMMARY

The sample is spiked with samarium (Sm) carrier. Pm, Sm and other rare earth elements (REE) are initially pre-concentrated by co-precipitation with $Fe(OH)_3$. Promethium is isolated, along with other REEs, by passage through two anion exchange columns (nitrate and chloride) and by coprecipitation with SmF_3. The SmF_3 is dissolved for beta counting of the Pm-147 on a low background liquid scintillation counter (LSC). Chemical yield is determined by inductively coupled plasma atomic emission spectroscopy (ICP-AES) analysis of Sm.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specifications related to the client, project, and test method being performed.

3.3 It is the responsibility of the preparation technician to coordinate with the metals Department to facilitate the determination of chemical yields by ICP analysis.

3.4 It is the responsibility of the LSC instrument technician to properly optimize the

instrument window settings (regions of interest, ROI) so as to eliminate or reduce the potential interference from other beta-emitting rare earth isotopes, such as Sm-151.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who perform this procedure to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented, and approved by the Department Manager.

4. INTERFERENCES

Note that the chemical separation process described in this SOP does not separate Pm from other rare earth elements (REE), such as Sm-151.

5. APPARATUS AND MATERIALS

5.1 combination magnetic stirring/heating plate

5.2 steam bath

5.3 PTFE™-coated magnetic stirring bars (cleaned per SOP 720)

5.4 Pasteur pipets, disposable

5.5 mechanical pipets, Eppendorf™, or equivalent

5.6 centrifuge bottles, conical, polypropylene, 250mL

5.7 specimen cups, polypropylene, 220mL

5.8 Pyrex™ beaker, 1L

5.9 scintillation vials, low-potassium borosilicate glass, 20mL

5.10 test tubes, plastic with caps, 20mL

5.11 analytical balance with resolution to 0.0001g

5.12 ion exchange columns, disposable, Environmental Express #R10204 or equivalent

5.13 glass beads, solid, 3mm diameter

5.14 fitted funnels

5.15 graduated cylinder, 500mL or 1L

5.16 centrifuge

6. REAGENTS - All reagents must be, at minimum, reagent grade

6.1 Deionized (DI) water, obtained from Paragon's DI water system

6.2 Nitric acid (HNO_3), conc. reagent grade. TLV=2ppm. Irritant, corrosive.

6.3 Nitric acid (HNO_3), 8M: Cautiously add 1000mL conc. HNO_3 to 900mL DI water. Dilute to 2L with DI water. TLV=2ppm. Irritant, corrosive.

6.4 HNO_3, 2M: Cautiously add 130mL conc. HNO_3 to approximately 600mL DI water and dilute to 1L. TLV=2ppm. Irritant, corrosive.

6.5 Hydrochloric acid (HCl), conc. TLV=5ppm (ceiling). Irritant, corrosive.

6.6 Hydrochloric acid (HCl), 10M: Cautiously add 830mL conc. HCL to approximately 100mL of DI water and dilute to 1L. TLV=5ppm (ceiling). Irritant, corrosive.

6.7 ICP Diluting Solution: Carefully add 10mL of conc. nitric acid and 50mL of conc. hydrochloric acid to 940mL of DI water. TLV=5ppm (ceiling) for HCl irritant, corrosive. TLV=2ppm (TWA) for nitric acid, irritant, corrosive.

6.8 Ammonium hydroxide (NH_4OH), 15M, conc. TLV=25ppm (for ammonia).

6.9 Hydrofluoric acid (HF), 29M, conc. TLV=3ppm (ceiling). Irritant, burns, bone, teeth, fluorosis.

6.10 Sodium hydroxide (NaOH) TLV=2 mg/m^3 = 1.2 ppm (ceiling), irritant.

6.11 Sodium hydroxide (NaOH), 6M: Cautiously dissolve 120g NaOH pellets in 500mL of DI water. Allow solution to cool. Store in a plastic container. TLV=2 mg/m^3 = 1.2 ppm (ceiling), irritant.

6.12 Boric acid (H_3BO_3)

6.13 Boric acid, 1M: Dissolve 30.9g H_3BO_3 in 500mL of DI water.

6.14 Ammonium bifluoride (NH_4HF_2)

6.15 Ammonium bifluoride (NH_4HF_2), 1M: Dissolve 22.8g NH_4HF_2 in 500mL of DI water.

6.16 Samarium (Sm_2O_3), **primary standard grade**.

6.17 Samarium carrier (10mg Sm/mL): Dissolve 1.160g of primary standard grade Sm_2O_3 in conc. reagent grade HNO_3 and dilute with DI water to 100mL in a Class A volumetric flask.

6.18 Samarium ICP calibration standard (20µg/mL): Pipet 0.20mL of 10mg/mL Sm carrier into a Class A 100mL volumetric flask and bring to volume with DI water. To be delivered upon request to the metals Department for calibration of the ICP.

6.19 Iron chloride ($FeCl_3.6H_20$)

6.20 Ferric iron carrier (5mg Fe^{+3}/mL): Dissolve 24.2g $FeCl_3.6H_2O$ in 1 L of 0.5M HCl.

6.21 Methanol (CH_3OH). TLV=200 ppm. Neuropathy, vision, central nervous system effects.

6.22 Ultima Gold AB™ liquid scintillation cocktail.

6.23 Anion exchange resin, AG 1x8, Bio-Rad® or equivalent.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 It is recommended that samples be preserved at the time of collection by adding enough HNO_3 to bring the pH to less than 2. The volume of nitric acid should be minimized to avoid significant dilution of the sample. If samples are to be collected without preservation, they should be brought to the laboratory within 5 days then preserved, with a minimum volume of concentrated HNO_3, to a pH less than 2. After preservation, the samples should be held in the original container for a minimum of ~~16~~ 24 hours before analysis or transfer of the sample.

7.2 The container choice should be plastic (rather than glass) to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 Using a graduated cylinder, measure a 500mL aliquot (or other appropriate volume) of water sample into a 1L Pyrex™ beaker. Record the sample volume on the benchsheet. Place a PTFE™-coated magnetic stir bar into the beaker. Place the beaker on a stirring/heating plate and begin stirring.

8.2 Prepare quality control (QC) samples per Section 11.

8.3 **How to take initial ICP aliquot**: Prior to adding any reagents to the sample, use a calibrated mechanical pipet to remove 1mL of sample and place into a clean test tube labeled with the sample ID and "initial ICP". Dilute to 10mL with ICP diluting solution. Cap and invert tube several times to mix thoroughly. Set aside until final ICP aliquot has been taken.

8.4 Acidify the sample to pH less than 2 with conc. HNO_3.

8.5 Spike the field and QC samples with 1mL of Sm carrier (10mg Sm/mL). Record the Sm carrier ID, spike volume, and pipet ID on the benchsheet.

8.6 In addition, a replicate 1mL aliquot (or similar known volume from a calibrated pipet) of Sm carrier is diluted with 5mL conc. nitric acid and DI water to the default volume used for the water samples. After mixing thoroughly, a 1 mL aliquot of this dilution is transferred to a culture tube labeled 'reference carrier', diluted up to 10mL with ICP diluting solution, and submitted with the initial samples to provide a reference concentration for the ICP calculations below.

8.7 Add 1mL of 5mg/mL ferric iron carrier.

8.8 Heat the solution to just below boiling for 10-15 minutes then make basic (pH~11) by adding 6M NaOH to precipitate $Fe(OH)_3$. Turn the stir mechanism off and remove stir bar. Allow precipitate to settle to the bottom of the beaker for 15-20 minutes.

8.9 After the precipitate has settled, decant the aqueous portion away from the precipitate. Reduce the volume to approximately 200mL or less with **minimal** loss of precipitate. If this cannot be accomplished without significant loss of precipitate, the option is to perform multiple centrifugations to separate the supernatant from the precipitate. The aqueous portion of the sample can be disposed down the drain in the fume hood with large amounts of water.

8.10 Transfer the remaining solution containing the precipitate to a labeled 250mL centrifuge bottle.

8.11 Rinse the sample beaker with a **minimum amount** of deionized water and add the rinse to the centrifuge bottle.

8.12 Centrifuge the samples at approximately 3500rpm for 15 minutes. Discard the supernatant down the drain with large amounts of cold water unless otherwise specified due to hazardous or radioactive waste concerns.

8.13 Precondition the frit of a disposable plastic column (approximately 15mm I.D., 18mL capacity) with methanol up to the 1cm line. Using a wash bottle, fill the column with a slurry (resin/DI water) of AG 1x8 anion exchange resin to a settled depth of approximately 7cm. Cover the top of the resin bed with glass beads to a depth of approx. 2cm to hold the resin in place. Attach a fitted funnel to each column.

8.14 Condition the column with two 10mL aliquots of 8M HNO_3.

8.15 Add 10mL of 8M HNO_3 to dissolve the $Fe(OH)_3$. After the precipitate is dissolved, load the solution onto the anion exchange column. Collect the effluent from the column in a 220mL polypropylene beaker.

8.16 Complete quantitative transfer by repeating Step 8.15 two more times.

8.17 Rinse the column 4 times with 10mL of 8M HNO_3.

8.18 Convert the effluent collected in Sections 8.15–8.17 to the chloride form by evaporating the solution to dryness on a steam bath and dissolving the residue in 30mL of 10M HCl.

8.19 Prepare an anion exchange column per Section 8.13.

8.20 Condition the column with two 10mL aliquots of 10M HCl.

8.21 Load the solution from Step 8.18 onto an anion exchange column. Rinse the beaker twice with 10mL of 10M HCl and apply the rinsate to the column. Collect the effluent from the column in a 250mL centrifuge bottle

8.22 Rinse the column four times with 10mL of 10M HCl, collecting the effluent in the same centrifuge bottle from Step 8.21.

8.23 To the effluent in the centrifuge bottle add approximately 60mL of DI water.

8.24 Add conc. NH_4OH as needed to bring to pH~11. Sm will precipitate as $Sm(OH)_3$. NOTE: Add NH_4OH **very slowly**, this is a very vigorous reaction. Centrifuge and discard the supernatant.

8.25 Dissolve the $Sm(OH)_3$ precipitate in 5mL of 2M HNO_3. Dilute with about 10mL of DI water.

8.26 Add 1mL of 1M NH_4HF_2 and three drops of conc. HF to precipitate SmF_3.

8.27 Using DI water, selectively balance the centrifuge tubes to minimize the addition of DI water.

8.28 Centrifuge at 3500rpm for 15 minutes and discard the supernatant.

8.29 Dissolve the SmF_3 precipitate by adding 1mL of conc. HNO_3 and 2mL of 1M H_3BO_3. Heat the centrifuge bottle on a steambath to aid dissolution.

8.30 Dilute the solution with 3mL of DI water. Centrifuge the sample for about 5 minutes @ 3000 rpm to bring all of the sample solution to the bottom of the centrifuge bottle.

8.31 Document the total volume in the centrifuge tube on the benchsheet.

8.32 **How to take final ICP aliquot**: After making certain that the solution in the centrifuge bottle is well mixed, pipet a 0.10mL aliquot of the solution into a 20mL plastic vial. Dilute the aliquot to 10mL with ICP blank solution. Label the vial with the sample ID and "final Sm". Present this solution and the standard prepared in Section 6.18 to the metals Department for ICP analysis of Sm to determine chemical yield.

8.33 Pipet a 5mL aliquot from the centrifuge bottle into a labeled scintillation vial.

8.34 Add 15mL of Ultima Gold AB™ cocktail to each sample. Cap and mix thoroughly.

8.35 Wipe the scintillation vials clean using methanol.

8.36 Submit the vials, and associated documentation, to the instrument lab for liquid

scintillation counting.

9. PREPARATION OF CALIBRATION STANDARDS

When needed for instrument calibration, prepare calibration standards as follows.

9.1 Background Calibrations

9.1.1 Prepare twelve method blanks with varying amounts of Sm carrier solution added at the beginning of the separation process, with increasing increments of carrier at approximately 0.25, 0.50, 0.75, 1.0, 1.5, and 2mL. Each level of carrier should be prepared in duplicate.

9.1.2 After ICP yield determinations have been completed and the background calibration vials have been counted on the liquid scintillation counter, the yield-corrected carrier volumes are plotted against the observed count rate to generate a calibration curve describing the expected background count rate for the sample-specific chemical yield.

9.2 Efficiency Calibrations

9.2.1 Prepare three calibration sources, which have been prepared as method LCSs, with the addition of 1,000 – 10,000 dpm NIST traceable Pm-147.

9.2.2 ICP yield determinations are used to correct the known activity value in the calculation of the counting efficiency.

10. CALCULATIONS

10.1 Calculate the barium chemical recovery for aqueous samples, Y, as a percentage, as follows:

$$Y_i = V_i * ICP_i * DF$$

$$Y_f = V_f * ICP_f * DF$$

$$Y_{RC} = V_{RC} * ICP_{RC} * DF$$

$$Y = \frac{Y_f}{Y_i + Y_{RC}} * 100\%$$

where:

V_i = initial sample volume (mL)

Y_i = samarium recovery from initial ICP aliquot (µg)

ICP_i = initial samarium concentration measured by ICP (µg/mL)

DF = dilution factor

V_f = final sample volume (mL)

Y_f = samarium recovery from final ICP aliquot (µg)

ICP_f = final samarium concentration measured by ICP (µg/mL)

Y_{RC} = samarium recovery from RC aliquot (µg)

V_{RC} = RC final volume (mL)

ICP_{RC} = RC samarium concentration measured by ICP (µg/mL)

10.2 Calculate the actual volume, V_A, analyzed for each sample (accounting for volumes of sample removed) as follows:

$$V_A = V * \frac{V_i - icp_i}{V_i} * \frac{5}{V_f}$$

where:

V = sample aliquot (L, g)

V_i = sample final dilution volume (mL)

icp_i = initial aliquot taken for ICP (mL)

V_f = sample volume in EDTA (mL)

And 5 is the volume, in mL, specified in Section 8.33.

10.3 Calculate the activity, A, in picoCuries per liter, as follows:

$$A = \frac{(GCPM - BKGCPM)}{2.22 * v * y * e * decay}$$

where:

GCPM = Gross counts per minute

BKGCPM = Background counts per minute

v = volume

y = chemical yield

e = efficiency for Pm-147

decay = decay factor

10.4 Calculate the one-sigma total propagated uncertainty, TPU, in picocuries per liter

as follows:

$$TPU = \sqrt{CU^2 + (PU * A)^2 + (IU * A)^2}$$

where:

CU = Counting uncertainty

PU = Prep uncertainty

IU = Instrument uncertainty

A = Activity

10.4.1 Calculate the one-sigma counting uncertainty, CU, as follows:

$$CU = \frac{\sqrt{\frac{GCPM}{CT} + \frac{BKGCPM}{BKGCT}}}{2.22 * v * y * e * decay}$$

where:

CT = Count time

BKGCT = Background count time

10.4.2 The Preparation Uncertainty, PU, is 10.93%. This is based on one gross aliquot, one volumetric measurement, one ICP determination, one spike/carrier addition, three quantitative transfers, and one pipetting.

$$0.1093 = \sqrt{0.05^2 + 0.006^2 + 0.083^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.004^2}$$

10.4.3 Instrument Uncertainty, IU, is based on SOP 743 and is 5.61%.

10.5 Calculate the Minimum Detectable Concentration, MDC, as follows:

$$MDC = \frac{4.65 * \sqrt{BKGCPM * CT} + 2.71}{2.22 * v * y * e * decay * CT}$$

11. QUALITY CONTROL

11.1 One blank is prepared per batch of 20 samples or less (5% frequency) and is prepared by aliquotting 500mL of DI water.

11.2 One sample duplicate is run per batch of 10 samples or at a 10% frequency.

11.3 One spiked blank is run per batch of 20 samples or less (5% frequency) and is prepared by aliquotting 500mL of DI water. Spike with Pm-147 at a known activity, close to 500dpm. NOTE**:** Spike the LCS as in Step 8.5.

12. DEVIATIONS FROM METHOD

As this is a proprietary technique, there are no deviations to be noted from a published method.

13. SAFETY, HAZARDS AND WASTE DISPOSAL

13.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

13.2 Wear gloves, safety glasses, and lab coat when working with any samples or chemicals or when handling materials or equipment potentially contaminated with chemicals.

13.3 All work involving NH_4OH and acids should be done in a fume hood, as well as any work with material that has a Threshold Limit Value (TLV) less than 50ppm.

13.4 Care should be taken when diluting acids. Unless the method explicitly directs you to do otherwise, **always add acids to water**, not water to acids.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 760 REVISION 6

TITLE: PREPARATION OF SOLID SAMPLES BY POTASSIUM PYROSULFATE FUSION

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER Renee Valles DATE 7/21/08
QUALITY ASSURANCE MANAGER Dee Schatz DATE 7/20/08
LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: Rev0, 4/29/02; Rev1, 12/24/02; Rev2, 8/26/03; Rev3, 10/3/2003; Rev4, 5/17/04; Rev5, 7/24/06; Rev6, 7/18/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes a method for the total dissolution of solid samples using potassium pyrosulfate fusion. A fusion cake is first produced with potassium fluoride, which is effective in dissolving silica and refractory silicates and some metallic oxides. In the final steps of the procedure, a pyrosulfate fusion is obtained that decomposes refractory oxides and volatilizes remaining HF and silica.

2. SUMMARY

A solid sample is decomposed completely with potassium fluoride in a 100mL platinum dish. The cake is then transposed with sulfuric acid and sodium sulfate to a pyrosulfate fusion with simultaneous volatilization of hydrogen fluoride and silicon tetrafluoride. The resulting fusion cake is dissolved in 2N hydrochloric acid. Actinides are co-precipitated with iron hydroxide and are sequentially isolated using anion exchange resin as outlined in the appropriate standard operating procedure.

3. RESPONSIBILITIES

3.1 The fumes evolved in this procedure are extremely hazardous and must be properly contained and exhausted in a laboratory fume hood. It is the responsibility of the technician performing this work to ensure that the fume hood being used is turned on, functioning properly, has a current calibration, and is used appropriately.

3.2 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review. These procedures are to be performed only by personnel who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the preparation of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 Be careful to keep the platinum dish out of the oxidizing portion of the flame. With the flame set low, keep the dish either above or below the apex of the oxidizing portion of the flame.

4.2 The platinum crucible is difficult to handle. Hold the crucible at the edge (inside and out), with platinum tipped tongs. **To ensure that no contamination occurs between samples, the tongs are cleaned after every sample. After fusing the sample, allow the tongs to cool. Then, rinse the tongs first with Radiacwash and then DI water. Dry the tongs with a clean paper towel**.

4.3 When lighting the blast burner, turn on the gas first, then slowly turn up the air and watch the flame. A low blue flame contains large amounts of O_2 and is very hot.

4.4 If a large mantle of high velocity gases from the burner is allowed to envelop the crucible, the liquid flux will be blown too high in the dish and **a crust will form on the outside rim of the dish and cannot be recovered.**

5. APPARATUS AND MATERIALS

5.1 Top loading balance, 0.01g sensitivity

5.2 Hot plates

5.3 Plastic funnels

5.4 Platinum crucibles, 100mL

5.5 Muffle furnace

5.6 Watch glasses

5.7 Fisher blast burner, or equivalent

5.8 Pipettes, Eppendorf or equivalent

5.9 Pipet tips

5.10 Wash bottles

5.11 Graduated cylinder, plastic, 25mL

5.12 Compressed air tank, with regulator and hose

5.13 Natural gas tank, with regulator or propane connected directly to blast burner

5.14 Ring stand, with Ni-Cr wire triangle

5.15 Desiccator (for reagents)

5.16 Weighing dishes, aluminum

5.17 Centrifuge bottles, 250mL

5.18 Flitz® metal polish

5.19 Dremmel® tool

5.20 Nylon bristle brushes, Forney Industries, Inc., Cat. No. 60240, or equivalent.

5.21 Filter papers, Whatman® #41

5.22 Transfer pipets, disposable

5.23 Plastic stir rods

5.24 Whatman Ashless Powder

6. REAGENTS

Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

6.1 Deionized (DI) water, ASTM Type II.

6.2 Hydrofluoric acid, HF, 48%. TLV = 3ppm

6.3 Citric Acid, 1M (for cleaning crucibles): Dissolve 210.14g of $C_6H_8O_7$ in DI water. Dilute to 1000mL.

6.4 Nitric acid, HNO_3, concentrated. TLV = 2ppm

6.5 Hydrochloric acid, HCl, concentrated. TLV = 5ppm

6.6 2M HCl: Cautiously add 170mL conc. HCl to approximately 600mL DI water

and dilute to 1L. TLV = 5ppm

6.7 Sulfuric acid, H_2SO_4, concentrated. TLV = 0.25ppm

6.8 Potassium fluoride, anhydrous. TWA = 2.5mg/m^3 as F

6.9 Sodium sulfate, anhydrous

6.10 Fe carrier (20mg Fe^3+/mL): Dissolve 96g of $FeCl_3 \bullet 6H_2O$ in 1.0L of 0.5N HCl.

6.11 Radiacwash® detergent or equivalent

6.12 Ammonium hydroxide, NH_4OH, 15N (conc.), reagent grade. TLV = 25ppm (for ammonia)

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

No sample collection, preservation, or handling requirements are specific to this method.

8. PROCEDURE

8.1 POTASSIUM PYROSULFATE FUSION

If greater than 1.0 gram of sample is needed for analysis, proportionally increase reagents. For example, if a 2.0 gram aliquot is prepared, double the amount of all other reagents used during the fusion process.

8.1.1 Weigh a 1.0g aliquot of sample (dried and ground per SOP 336), into a tared 100mL platinum crucible.

8.1.2 Fold a Whatman® #41 filter paper and place it into the crucible designated for the blank and LCS.

8.1.3 Using calibrated pipettes (SOP 321), add the appropriate volume of tracing and spiking solutions for the requested analysis. If there is standing liquid in the crucible after spiking and tracing, it is advisable to absorb this liquid by adding Whatman Ashless Powder, prior to muffling, to avoid splattering of the sample.

8.1.4 Cover each crucible with a watch glass and muffle at 600°C for at least 1 hour.

8.1.5 After cooling, remove the crucibles from the furnace and, using a marker, label the watch glass with the crucible ID. Place the watch glass aside on a clean surface for later use. Add 1.0mL of concentrated nitric acid around the edge of the sample in the crucible.

8.1.6 Using a transfer pipet, add approximately 3-6mL of 48% HF (concentrated HF) to wet the sample thoroughly and evaporate to NEAR dryness on a hotplate. DO NOT allow the sample to bake onto the dish.

8.1.7 Sprinkle 6g of anhydrous potassium fluoride over the residue. Fuse over a hot flame on a blast burner until a clear melt is obtained, swirling GENTLY to mix. Heat about 4 minutes to fusion temperature (approximately 900°C) and another 2 minutes to complete dissolution. Place the sample on a ring stand to cool.

8.1.8 While the melt is still warm, add at least 7mL (or about 3 transfer pipets full) of concentrated sulfuric acid drop wise down the edges of the dish to wash sample residue down the walls of the dish. If needed, additional sulfuric acid can be added up to a maximum of 15mL.

8.1.9 PREVENT FROTHING IN THE NEXT STEP. Be prepared to set the dish in a cold water bath if it threatens to froth over the sides of the dish. The crucible can also be set on a heat insulating pad to cool.

8.1.10 Using the blast burner, pass the crucible slowly over a cool flame (low compressed air) or heat on a hot plate set between 230°C-280°C, until vigorous reaction subsides and the melt from Step 8.1.7 has completely dissolved.

8.1.11 Place the sample on a hot plate (setting of 7) and add 4.0g of anhydrous sodium sulfate.

8.1.12 Over the blast burner, swirling gently, continue heating until a clear pyrosulfate fusion is obtained. The thick, almost solid, sample will dissolve to a thin one that is easily boiled. Then, increase the temperature as fast as boiling will permit until a clear solution is achieved. The sample will be a dark red, but clear, solution when finished. The blank and LCS will generally have a light pink appearance at this Step.

DO NOT HEAT LONGER THAN NECESSARY TO MINIMIZE DISSOLUTION OF PLATINUM FROM THE CRUCIBLE.

CAUTION: Large amounts of hydrogen fluoride and silicon tetrafluoride are expelled from the sample. Be sure to use a properly operating fume hood.

8.1.13 Set the dish on a ring stand and allow the sample to cool and solidify.

8.1.14 Place the sample on the hot plate (setting 180°C-200°C) with the crucible's watch glass cover used during muffling, leaving slightly off to vent the sample. Fill the crucible ¾ full with 2M HCl.

8.1.15 When the solid sample has entirely dissolved (~5 to 6 hours), transfer the sample solution to a 250mL centrifuge bottle using a clean plastic

funnel.

8.1.16 Rinse the crucible with additional 2M HCl and add this rinse to the centrifuge bottle for a quantitative transfer. Do not fill the centrifuge bottle more than 150mL. If this occurs, the bottle may be placed on the steambath with the cap off to evaporate the sample to less than 150mL.

8.1.17 Add 2mL of ferric chloride carrier (20mg Fe^{3}+/mL). Add DI water to the centrifuge bottle to bring the total volume to ~200mL. (This dilution helps prevent a vigorous reaction from occurring between the acidic sample solution and the conc. NH_4OH to be added in the next step.)

8.1.18 Note: A great deal of heat can be generated at this step of adding a base to an acidic solution. Slowly add ~50 mL of conc. NH_4OH to form $Fe(OH)_3$ precipitate. If a precipitate does not form after adding the 50mL of NH_4OH, consult an appropriate supervisor. Balance the centrifuge bottles with DI water and allow the sample in the bottle to cool before centrifuging.

8.1.19 Centrifuge the samples for 12 minutes at approximately 3500 rpm. Discard the supernatant (avoid losing any precipitate). Further separations are now performed following the appropriate actinides separation SOP 778 or 777.

8.2 CLEANING PROCEDURE FOR PLATINUM CRUCIBLES

NOTE: When cleaning the crucibles, NEVER use anything abrasive such as scrubbing pads, that will scratch the platinum.

8.2.1 After the samples have been quantitatively transferred from the crucible (Step 8.1.16), rinse the crucible with tap water to remove residual acid.

8.2.2 Soak the crucibles in Radiacwash® for 30-60 minutes.

8.2.3 Rinse the crucibles with DI water and place them in a large beaker. Crucibles should be placed in a single layer, not stacked. Add enough 1M citric acid solution to completely cover the crucibles. Place the beaker containing the crucibles on a hot plate and cover with a watch glass or an aluminum pie pan. Boil for a minimum of 1 hour.

8.2.4 After cooling, rinse the crucibles with DI water and dry. Discard the citric acid down the laboratory sink, flushing with cold water.

8.2.5 Re-shape the crucible using the provided epoxy form.

8.2.6 Using a Dremmel® tool fitted with a nylon-bristled polishing brush and

FLITZ® polishing compound, polish the crucibles until visible scratches and oxidation are removed.

8.2.7 Buff with a clean, soft cloth until a mirrored finish is obtained. Repeat Step 8.2.5 above, if necessary.

9. CALCULATION OF TPU FACTORS

The preparation uncertainty factors for this method are generally equivalent to those factors affecting samples that undergo a normal acid dissolution. Consequently, no additional consideration should be made for this method.

10. QUALITY CONTROL

Acceptance criteria for QC samples may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.1 One blank sample is prepared and analyzed with every batch of 20 field samples or less.

10.2 One sample duplicate is prepared and analyzed with every batch of 10 field samples or less.

10.3 One spiked blank sample (LCS) is prepared and analyzed with every batch of 20 field samples or less.

10.4 Where required, a well-characterized solid refractory reference material is analyzed with a frequency of approximately every 100 samples. Results are compared to expected values to ensure adequate fusion of the solid sample is being obtained.

11. DEVIATIONS FROM METHOD

This is a proprietary, confidential procedure developed by Paragon. Therefore, there are no deviations from a promulgated method.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 The fumes evolved in this procedure are extremely hazardous and must be properly contained and exhausted in a laboratory fume hood. It is the responsibility of the technician performing this work to ensure that the fume hood being used is turned on, functioning properly, has a current calibration, and is used appropriately.

12.1.2 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.3 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.1.4 Gloves, safety glasses and a lab coat must be worn when working with any chemicals (e.g., standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.1.5 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.6 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.7 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.2 WASTE DISPOSAL

12.2.1 Wastes that are "corrosive only", such as sulfuric acid waste, are disposed of by discharging into the Paragon waste water treatment facility. These "corrosive only" materials have been identified as having no hazardous components or characteristics other than corrosivity, and may, therefore, be neutralized in the waste treatment facility.

12.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. Notify waste management staff for disposal.

12.2.3 All acid wastes not containing HF that are generated in sample dissolution steps, are disposed of to the waste tanks (i.e., down the drain), unless otherwise specified due to hazardous constituents.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 765 REVISION 4

TITLE: **SEPARATION AND ANALYSIS OF ^{237}NEPTUNIUM IN ENVIRONMENTAL MATRICES**

FORMS: **NONE**

APPROVED BY:
TECHNICAL MANAGER _____ DATE 8/31/06
QUALITY ASSURANCE MANAGER _____ DATE 8/31/06
LABORATORY MANAGER _____ DATE 8-31-06

HISTORY: Rev0, PCN #314, 12/28/94; Rev1, 10/8/99; Rev2, 4/10/02; Rev3, 4/7/03 and 1/31/05 (no revisions); Rev4, 9/1/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedure for the separation and purification of ^{237}Np in environmental samples using anion exchange chromatography and precipitation of this analyte for quantification by alpha spectroscopy.

2. SUMMARY

Solid samples are digested according to SOP 773 and water samples are prepared according to SOP 776 prior to this procedure. Pretreatment of solid samples (drying and grinding) is described in SOP 721. The actinides are co-precipitated with an iron hydroxide precipitate. Neptunium (Np) is separated and purified by anion exchange chromatography. The purified Np is co-precipitated with lanthanum fluoride (LaF_3) and mounted on a filter membrane for alpha spectroscopy counting.

Since there is no suitable alpha-emitting isotope of Neptunium available for use as a yield tracer, the chemical yield is determined using the method of standard additions. Replicate aliquots of each sample are transferred to a beaker. A yield spike (i.e., a known activity of NIST-traceable ^{237}Np) is added to one sample aliquot, while the replicate is processed unspiked. A composite measure of the chemical yield and counting efficiency (i.e., the 'total efficiency') is determined for the yield spike sample using results obtained for the sample pair. ***Note that reproducibility of the process is critical in generating accurate chemical yield information. The analyst should treat all samples identically and must note any anomaly, which could cause a significant variation in yield between a sample and its associated yield spike.*** Also note that the yield spike is NOT a 'matrix spike'. A matrix spike is a quality control (QC) sample and is NOT used to generate data for chemical yield corrections, rather, the matrix spike is used to provide quality control information about analyte recovery.

3. RESPONSIBILITIES

3.1 It is the responsibility of the laboratory staff to perform these tasks according to

this SOP and to complete all documentation required for review. Preparation, analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, or the performance of precision and accuracy tests, or by other suitable means.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalous or out-of-control events. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 The presence of any significant quantities of suspended solids is a physical interference. Samples containing perceptible quantities of suspended solids will be filtered prior to initiation of preparation and analysis.

4.2 The presence of a significant amount of ^{234}U in the sample may interfere with the ^{237}Np region of interest (ROI) in the analytical spectrum.

5. APPARATUS AND MATERIALS

5.1 Ion exchange columns, plastic, disposable, with fitted funnels

5.2 Filter membrane, 0.1µm, 25mm diameter, polypropylene

5.3 Suction filter for 25mm membrane

5.4 Repeator pipet, 0.5mL and 1.5mL, Eppendorf™ or equivalent, and pipet tips

5.5 Centrifuge bottles, 250mL

5.6 Wash bottle

5.7 Double-sided tape

5.8 Stainless steel planchets, 1.25" diameter

5.9 pH paper (strips)

5.10 Rubber policeman

5.11 Petri dishes

5.12 Plastic cups, 220mL, disposable

5.13 Glass beads

5.14 Vortex mixer

5.15 Centrifuge

5.16 Steam bath

5.17 Laboratory forceps

5.18 Fluorescent heat lamp

5.19 RadiacWash® solution

6. REAGENTS

NOTE: Threshold Limit Value (TLV) and other hazard information may be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Anion exchange resin, AG 1X8, 50-100 mesh, available from Biorad or Eichrom (or equivalent)

6.2 Ammonium hydroxide (NH_4OH), 15N (conc.) TLV = 25ppm (for NH_3)

6.3 Deionized (DI) water, obtained from the laboratory's DI water system

6.4 Ferric chloride carrier, 20mg Fe^{+3}/mL. Made in-house by dissolving 96g of $FeCl_3$•6 H_20 in 1000mL of 0.5N HCl. PEL = 0.15ppm

6.5 Hydrochloric acid (HCl), 12M (conc.). ACS reagent grade. TLV = 5ppm (ceiling)

6.6 HCl, 1M: Add 83mL conc. HCl to approximately 800mL of DI water. Bring to a final volume of 1L with DI water. Mix well.

6.7 HCl, 0.5M: Add 42mL conc. HCl to approximately 800mL of DI water and bring to 1L volume with DI water. Mix well.

6.8 Hydrofluoric acid (HF), 48%-51% (conc.). TLV = 3ppm

6.9 HF, 3M: Carefully dilute 104mL conc. HF to 1L with DI water. Use plastic

graduated cylinder and storage bottle. TLV = 3ppm (for concentrated HF)

6.10 Nitric acid (HNO_3), 16M (conc.) ACS reagent grade. TLV = 2ppm

6.11 Lanthanum carrier, 0.1mg La^{3+}/mL: Made in-house by dissolving 0.312g high purity $La(NO_3)_3 \cdot 6H_2O$ per 1000mL 1M HCl. Document in RadChem Reagent Prep Logbook and Paragon's Standards & Solutions database.

6.12 ^{237}Np, NIST-traceable

6.13 Methanol, reagent grade. TLV = 200ppm

6.14 Polyethylene glycol (PEG), average molecular weight 2000g/mol, 0.25 M: Make in-house by dissolving 50g of PEG in 40mL of DI water. Dilute to 100mL with DI water. Note that placing the container on a stirrer with a stir bar will help dissolve the PEG in water.

6.15 Hydrogen peroxide (H_2O_2), 30%, reagent grade. TLV = 1ppm. Potential carcinogen, irritation, pulmonary edema, central nervous system effects.

6.16 Ammonium Iodide (NH_4I) in concentrated HCl: Weigh out 0.73g of NH_4I and dissolve in 100mL of conc. HCl.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLD TIME

7.1 It is recommended that samples be preserved at the time of collection by adding enough concentrated HNO_3 to the sample to lower the sample's pH to less than 2. Addition of 5mL conc. HNO_3 per liter of sample is usually sufficient. If samples are to be collected without preservation, they should be brought to the laboratory within 5 days of collection and then preserved and held in the original container for a minimum of ~~16~~ 24 hrs before analysis or transfer of the sample from the original container.

7.2 The sample container should preferably be plastic rather than glass. This prevents loss due to breakage during transport and handling and minimizes any possible losses due to analyte plate out on container walls.

7.3 There is no regulatory holding time for this method. Paragon recommends a default holding time of 180 days for waters. There is no holding time for solids.

8. PROCEDURE

8.1 CREATION OF SAMPLE ALIQUOTS AND YIELD SPIKES

8.1.1 Two identical volumes (default -- 1.0L or a 2.0g equivalent of digestate) of each sample are aliquotted. Label the first volume per the RadChem ID convention of yy - mm - wo# - s# (e.g., 02-12-123-12). Add a "YS" designation to the labeled ID of the second aliquot of sample (e.g., 02-12-123-12-YS), to denote the replicate aliquot of sample that is spiked for yield determination.

8.1.2 Yield spikes should routinely contain at least 5-10 times the expected

activity of the associated field or QC sample. For routine environmental samples, the yield spike activity should be ~30-50dpm. A typical batch of samples is named and would be spiked as follows:

0212123-1	unspiked
0212123-1-YS	~30dpm of ^{237}Np spike added
0212123-2	unspiked
0212123-2-YS	~30dpm of ^{237}Np spike added
0212123-3	unspiked
0212123-3-YS	~30dpm of ^{237}Np spike added
0212123-3DUP	unspiked
AS040305-1MB	QC sample (method blank)
AS040305-1YS	yield spike aliquot for method blank, ~30dpm of ^{237}Np spike added
AS040305-1LCS	QC sample (laboratory control sample), ~5dpm of 237Np spike added

8.2 PURIFICATION BY ANION EXCHANGE

8.2.1 Dissolve the iron hydroxide precipitate from the previous dissolution procedure in 50-100mL of concentrated HCl. For samples with suspected high plutonium (Pu) content, dissolve the precipitate in 50-100mL of conc. HCl/NH_4I solution

8.2.2 Sample matrix constituents such as silicates may cause a cloudy or foamy appearance when the samples are dissolved in HCl. Samples may be compared with the QC samples of that batch for differences in appearance. If samples are noticeably different from the batch QC, a PEG treatment may be conducted as explained in Step 8.2.3 below, to keep the sample constituents from blocking column flow. Perform this treatment on the entire batch of samples, as well as the QC. If samples are clear, proceed to Step 8.2.4.

8.2.3 <u>PEG Treatment</u>: After quantitatively transferring the sample to a centrifuge bottle, add 3mL of 0.25M PEG to each sample. Vortex to mix and place samples in a refrigerator for ~30 minutes. The silicates will be trapped by the chelating action of the PEG and will slowly settle as a glassy precipitate in the bottom of the centrifuge bottle. Centrifuge the sample for 5 minutes at 3500rpm.

8.2.4 Prepare an ion exchange column (70mm X 10mm I.D.) using AG 1X8 anion exchange resin. Fill the disposable plastic column with resin to a

settled depth of 7cm. Cover the top of the resin bed with a 1-2cm layer of clean glass beads. Securely attach a fitted funnel to each column. Place a waste beaker under the column.

8.2.5 Label each column with the sample ID using a Sharpie marker.

8.2.6 Condition the column with 50mL of concentrated HCl. Discard the effluent in the drain inside the fume hood with large amounts of cold water (this flushes the effluent into the Paragon wastewater treatment system).

8.2.7 Slowly pour the sample from the centrifuge bottle into the funnel. Discard column effluents into the drain inside the fume hood with large amounts of cold water (discharges to the Paragon wastewater treatment system).

8.2.8 Rinse the column with 20mL of concentrated HCl/NH_4I solution. *This Step should be performed only after the original sample has completely passed through the column.* Discard column effluents into the drain with a large amount of cold water.

8.2.9 Rinse the column with 20mL of concentrated HCl/NH_4I solution an additional two times. Discard the effluent into the drain inside the fume hood with plenty of cold water.

8.2.10 Rinse the column with 25mL of concentrated HCl and discard the column effluents into the drain inside the fume hood with plenty of cold water.

8.2.11 Strip the Neptunium with three 20mL volumes of 1M HCl. Collect this strip solution in a clean plastic cup that is labeled with the sample ID and "Np mic". Add 10mL of concentrated HNO_3 to the Np micro cup and take it to dryness on the steam bath.

8.2.12 Used resin columns are discarded by extruding the resin from the column and placing the resin in the established waste stream labeled "Hazardous Waste – Used Acidic Resin" in the Satellite Accumulation Area in the lab. When the satellite container is full, notify the Waste Management Officer for further instructions. Emptied columns may be soaked in a RadiacWash® solution, rinsed in tap water and discarded into the sanitary trash.

8.2.13 Used disposable cups may be rinsed with RadiacWash® solution and tap water and re-used for collecting waste column effluent. If the cups are not needed, they may be soaked in RadiacWash®, rinsed with tap water and discarded into the sanitary trash.

8.3 MICROPRECIPITATION OF NEPTUNIUM

8.3.1 Dissolve the sample residue from the Np micro cup using 1mL of concentrated HCl. If necessary, heat the cup on a steam bath for few minutes for a better dissolution - do not allow the sample to go dry.

8.3.2 Add 14mL of DI water to the cup and mix well.

8.3.3 Add 1.0mL of lanthanum carrier and swirl gently.

8.3.4 Add 1.0mL of 30% hydrogen peroxide and 5mL of 3N HF and swirl to mix.

8.3.5 Allow samples to sit for 30 minutes to complete micro-precipitation.

8.3.6 Assemble the micro-precip funnel with 0.1µm, 25mm filter paper. Turn the vacuum on and pre-rinse the filter paper with few mL of methanol. This will make the filter less hydrophobic. When the methanol is almost passed through the filter, add approximately 5mL of DI water.

8.3.7 When the water is almost passed through the filter, pass the co-precipitated sample through the filter membrane.

8.3.8 Rinse the sample cup with 10mL DI water and add to the filter funnel, once the load solution has passed through. After the rinse has passed through, rinse the filter with an additional 10mL of DI water.

8.3.9 After filtration, keep vacuum on and remove the funnel. Use a "Sharpie" marker to place a dot on the outside edge of the filter. This helps identify the right side of the filter in case the filter flips during transaction. Carefully remove the filter membrane with a pair of forceps and fix it face up on the double-sided tape that was placed on the planchet. Dry the filter membrane with the planchet under the fluorescence light bulb for a minute. DO NOT KEEP THE PLANCHET FOR A LONG TIME UNDERNEATH THE LAMP AS IT MIGHT MELT THE DOUBLE SIDED TAPE.

8.3.10 Discard the waste in the suction flask into the appropriate waste carboy.

9. CALCULATIONS

9.1 The standard alpha spectroscopy calculations defined in SOP 714 are used with the following modifications -- the chemical yield is calculated from the results of the spike addition as follows:

$$CY = \frac{(C_{YS} / (T_{YS} * Eff_{YS})) - (C_S / (T_S * Eff_S))}{DPM}$$

where:

CY	=	fractional chemical yield
C_{YS}	=	net ^{237}Np counts from the spiked sample (cts)
T_{YS}	=	time elapsed for the count of the spiked sample (min)
Eff_{YS}	=	fractional detector efficiency for the spiked sample
C_S	=	net ^{237}Np counts from the sample (cts)
T_S	=	time elapsed for the count of the sample (min)
Eff_S	=	fractional detector efficiency for the sample
DPM	=	dpm ^{237}Np yield spike added per unit mass or volume (DPM/L or DPM/g)

9.2 TPU FACTORS

As defined in SOP 743, the following 1σ preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU).

9.2.1 Water samples (that require initial prep using SOP 776) require a preparation uncertainty factor of 0.192. This is based on one gross aliquotting (sample homogeneity), one volumetric measurement, one tracer addition, two quantitative transfers and one reagent addition. The TPU factor is modified to reflect the uncertainty in the measurement due to the use of yield spikes in the determination of chemical yield. 0.18 = 1σ estimated uncertainty in chemical yield. See the following equation:

$$0.192 = \sqrt{0.05^2 + 0.006^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2 + 0.18^2}$$

9.2.2 Solid samples (that require initial prep using SOP 773) also require a preparation uncertainty factor of 0.192. This is based on one gross aliquotting (sample homogeneity), one mass measurement, one tracer addition, two quantitative transfers and one reagent addition. The TPU factor is modified to reflect the uncertainty in the measurement due to the use of yield spikes in the determination of chemical yield. 0.18 = 1σ estimated uncertainty in chemical yield. See the following equation:

$$0.192 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2 + 0.18^2}$$

10. QUALITY ASSURANCE REQUIREMENTS

10.1 One Method Blank must be analyzed with each batch of 20 or fewer samples. Acceptance criteria are described in SOP 714 or in the applicable client statement of work (SOW).

10.2 One Laboratory Control Sample (LCS) must be analyzed with each batch of 20 or fewer samples. Acceptance criteria are described in the SOP 714 or in the applicable client SOW.

10.3 Sample Duplicates are processed at a minimum frequency of 10%. Acceptance criteria are described in the SOP 714 or in the applicable client SOW. If insufficient sample is provided to perform sample duplicates, an LCS Duplicate may be run in lieu of the sample duplicate.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFTEY AND HAZARDS

11.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

11.1.2 Safety glasses, and lab coats must be worn in the radiochemistry prep labs at all times.

11.1.3 Gloves, safety glasses, and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.2 below.

11.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

11.1.6 Use extreme care when using hydrofluoric acid (HF). Work only in a fume hood that has adequate ventilation and personnel safety features. Never inhale or allow skin or clothing to be exposed to HF fumes.

11.1.7 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

11.2 WASTE DISPOSAL

11.2.1 Wastes that are "corrosive only" " (i.e., have no hazardous components or characteristics other than corrosivity), such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the Paragon wastewater treatment facility, where they may be subsequently neutralized.

11.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. This includes any excess HF from dissolution of samples and all solutions remaining from the micro precipitation process. Notify the Waste Management Officer for disposal.

11.2.3 All acid wastes NOT containing HF that are generated in ion exchange operations are disposed of to the waste tanks (down the drain) unless otherwise specified due to hazardous constituents.

12. METHOD COMPLIANCE

This is a proprietary procedure developed by Paragon. Therefore, there are no deviations from promulgated methods for this procedure.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 766 REVISION 6

TITLE: **WITNESSING THE ADDITION OF CARRIERS, TRACERS, AND STANDARDS IN RADIOCHEMISTRY SAMPLES**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/4/06

QUALITY ASSURANCE MANAGER _____ DATE 8/4/06

LABORATORY MANAGER _____ DATE 8-4-06

HISTORY: Rev0, 12/14/94; Rev1, PCN #345, 1/26/95; Rev2, 10/5/99; Rev3, 4/10/02; Rev4, 3/28/03; Rev5, 5/17/04; Rev6, 8/4/06. re-released w/o revision 7/17/08 DAS

1. SCOPE AND APPLICATION

This procedure describes the actions necessary to add carriers, tracers, and spiking solutions to samples being prepared for radiochemistry analyses.

2. SUMMARY

Element-specific carriers and isotopic tracers are added to samples being prepared for radiochemistry analyses, where available and necessary to the method. Laboratory Control Samples (LCS, Blank spike) are created by addition of a spike solution containing one or more of the target analytes. Target tracer and spike values are determined on a case-by-case basis. Specific spike and tracer solution activity values can be obtained from the reference spreadsheet (r:\forms\mda_list.xls). Target carrier concentrations are specified in the individual method SOPs. This procedure provides generic guidance for spike and tracer additions.

2.1 Carrier, tracer, and spike additions are witnessed by an analyst other than the primary analyst to ensure that all samples receive the correct volume and type of carrier, tracer, and/or spike solution. The witness must initial and date the appropriate section of the LIMS benchsheet.

2.2 Occasionally, a suitable element-specific tracer or carrier may not be available for use (e.g., ^{237}Np analysis). In these cases, a replicate split of each field and QC sample may be spiked and processed parallel to the original sample. The spike recovery (corrected for native sample activity) is used to generate chemical yield corrections for calculation of sample results. Alternately, a single matrix spike may be prepared, per batch of samples, at the Technical Manager's direction.

2.3 Calibrations of Eppendorf™ pipettes shall be verified immediately prior to use (SOP 321).

2.4 Carrier, tracer, and spike verification and expiration should be confirmed before a solution is released for general use in the laboratory (SOPs 300, 798).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst performing this procedure to remove from service and to notify the Department Manager, any pipette for which the calibration cannot be reliably verified.

3.2 It is the responsibility of the analyst performing this procedure, and the witnessing technician, to assure that all samples in the batch, including the batch QC samples, receive the appropriate volume of the correct solutions.

3.3 It is the responsibility of the analyst performing this procedure, and the witnessing technician, to prevent the use of expired or non-conforming carriers, tracers, and spiking solutions.

3.4 It is the responsibility of the Department Technical Manager to review the NIST traceability certificate and to evaluate the working-level dilution for the presence of interfering radionuclides.

3.5 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review.

3.6 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.7 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Tracer activity amounts may require adjustment if knowledge of the sample activity indicates potential for dramatic mismatches between the tracer amount and sample activity. Carrier amounts may require adjustments based on the expectation of interfering native sample constituents. Likewise, sample volumes may require adjustment to avoid excessive planchet activity, or other potential matrix interference issues.

4.2 Occasionally, nuclides specified as tracer in this and other SOPs may be sought as

target analytes. In such cases, samples are routinely traced using the nuclides otherwise designated as spikes, and LCS and matrix spike (MS) samples are spiked with the target analyte. The parallel analysis of splits of each sample may be necessary to determine the concentration or presence of 'interfering' native analyte in the sample. Results are calculated by correcting the added nuclide (non-target analyte used as tracer) amount for the native activity of that nuclide in the sample.

4.3 The NIST certificate for all radioactive standards should be reviewed by Supervisory and Management personnel prior to determining appropriate spiking levels. Some standards contain measurable amounts of impurities in the form of the actual analytes of interest. For example, the ^{243}Am tracing solution may contain ^{241}Am impurities. If ^{241}Am is the analyte of interest, care must be taken to ensure that the amount of ^{241}Am impurities introduced with the tracer solution is significantly below the client's requested detection limit.

5. APPARATUS

Pipettes, Eppendorf™ or equivalent, various volumes

6. REAGENTS

NIST-traceable or equivalent spiking and tracing solutions and reagent grade carriers, specific to the analysis to be performed as specified in the individual SOPs.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

Not applicable.

8. PROCEDURE

8.1 Prior to the addition of carriers, tracers, and spiking solutions, a LIMS benchsheet will have been generated that indicates the samples to be analyzed and includes the required information about the tracer and the spike to be used. In addition, the appropriate sample aliquots will have been transferred to the proper container for digestion/preparation, per the SOP for that method.

8.2 Arrange for another analyst to watch and witness the addition of tracer and spike solutions. The spike witness must verify that:

8.2.1 Each carrier, tracer, and standard solution is properly labeled and not expired at the time of use. Radioactive standards must have a printed label, issued by the Department Manager, indicating that the verification procedure has been successfully completed. Carrier solutions may have hand-written labeling. The expiration date of the standard should be written on the benchsheet by the witnessing analyst.

8.2.2 The solution ID, radionuclides or carrier element, reference concentration, pipette ID and volume added have been recorded

properly on the benchsheet and match the spiking action.

8.2.3 Carrier, tracer and/or spike information corresponds with each sample listed on the benchsheet.

8.2.4 The witness must initial and date the appropriate section of the benchsheet after witnessing the addition of carriers, tracers, and spiking solutions.

8.2.5 If applicable, the information is then transferred to LIMS.

9. QUALITY ASSURANCE

Quality Assurance requirements for this procedure are contained in the appropriate actinides preparation SOP.

10. DEVIATION FROM METHOD

This is a proprietary procedure developed by and for Paragon. Therefore, there are no deviations from promulgated methods.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

All empty radionuclide standard solutions are disposed of by rinsing the standard container a minimum of three times with tap water. The container must be surveyed prior to release. Please note that all labels and markings must be defaced or removed prior to disposal.

12. REFERENCES

Not applicable.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 767 REVISION 7

TITLE: SAMPLE PREPARATION -- FILTER LEACHING

FORMS: 631 (use current iteration)

APPROVED BY:
TECHNICAL MANAGER _____ DATE 5/2/07
QUALITY ASSURANCE MANAGER _____ DATE 5/2/07
LABORATORY MANAGER _____ DATE 5-2-07

HISTORY: Rev0, PCN #400, 3/25/95; Rev1, PCN #556, 10/25/95; Rev2, 10/6/99; Rev3, 1/26/00; Rev4, 4/26/02; Rev5, 4/4/03; Rev6, 11/29/04; Rev7, 4/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary to prepare filters for multi-tests by leaching where total dissolution is not required.

The use of this procedure (i.e., nitric acid digestion, wet-ashing, muffling) is not appropriate for the preparation of leachates for certain tests such as tritium, carbon-14, radioiodine, technetium-99, or other nuclides that may be volatilized in an acidic environment or at elevated temperatures. Hence, this procedure may need to be modified to prevent volatilization of the analyte or to provide an appropriate matrix for subsequent processes.

All non-destructive testing must be completed and acceptable prior to initiation of destructive testing procedures. Depending on the mix of tests requested, it may be necessary to physically divide (cut) filters to allow for dissolution in two or more chemical systems.

2. SUMMARY

Many filters received by Paragon require multiple tests, or multiple filters (composites) are run for one or more tests utilizing the same client identification. Because the contaminants on these filters may or may not be homogeneously distributed, a method is necessary to ensure that a representative portion of the filter is measured for all tests. By leaching the filter in nitric acid and bringing the resultant volume to 1L, it is possible to aliquot a representative portion for each required analytical process.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform this procedure according to this SOP and to document all anomalous conditions on a Quality Assurance Summary Sheet (QASS, Form 302) or Non-Conformance Report (NCR, Form 313) and to obtain Supervisory approval in matters that affect data quality.

3.2 It is the responsibility of the Group Supervisor or Department Manager to notify the Project Manager in cases where data quality may be affected so that the Project Manager has ample opportunity to notify the client and discuss alternative analytical strategies.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

4. INTERFERENCES

Filters with high organic content may require the addition of hydrogen peroxide and/or muffling at approximately 450°C, prior to leaching, to facilitate dissolution of analytes in nitric acid.

5. APPARATUS AND MATERIALS

5.1 graduated cylinder, 1L

5.2 funnel, 15cm

5.3 filter paper, fluted

5.4 Pyrex® beakers, various sizes

5.5 ribbed watch glasses

5.6 hot plate

6. REAGENTS

6.1 Nitric acid, HNO_3, reagent grade, conc. TLV = 2ppm (TWA). Irritant, corrosive.

6.2 Nitric acid, 8N: Cautiously add 500mL conc. HNO_3 to 400mL DI water. Dilute to 1L with DI water. See above for TLV information.

6.3 Nitric acid, 1N: Cautiously add 63mL conc. HNO_3 to 800mL DI water. Dilute to 1L with DI water. See above for TLV information.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIME

7.1 The exact media used for sampling is typically determined and provided by the client. Filter samples are typically received in envelopes or other suitable containment.

7.2 No thermal (i.e., chilling) or chemical preservation is required.

7.3 See client specifications and individual analysis procedures for holding time requirements.

8. PROCEDURE

8.1 Read the project instructions to determine what information about the filter is required, (i.e., weight, # of filters, etc.). Always count the number of filters of each sample, and document on the sample condition form (Form 631).

8.2 Place filters in a 250mL beaker or larger if needed.

8.3 Add enough 8N HNO_3 to cover the filters.

8.4 Cover with a ribbed watch glass, and place the beakers on a hot plate. Bring to near boiling.

8.5 Maintain heat for half an hour.

8.6 Cool and transfer the liquid to a 1L graduated cylinder, using a funnel and fluted filter paper. Triple rinse the filters and beaker with 1N HNO_3, quantitatively transferring the rinsate to the 1L graduated cylinder.

8.7 Bring the leachate to full volume (1L) using 1N HNO_3. If volume is larger than 1L, evaporate leachate in a beaker on a hotplate to below 1 L, then dilute to 1L with 1N HNO_3.

8.8 Aliquot leachate as necessary.

9. QUALITY CONTROL

Refer to LIMS program specifications (project instructions) for QC sample requirements.

10. DEVIATIONS FROM METHOD

None. This procedure was developed in-house by Paragon.

11. SAFETY, HAZARDS, AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Use extreme care when handling nitric acid. Work in a fume hood with adequate ventilation. Wear appropriate eye, face and body protection.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

11.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 RADIOCHEMISTRY ANALYTICAL EFFLUENT DISPOSAL
The sample preparation process effluent has been determined to not be hazardous other than corrosive. This material after all testing is completed and the proper archiving times have been met, may be discharged into the Paragon wastewater treatment facility. Here the solution will be neutralized prior to discharge and the activity will be monitored to ensure compliance with Colorado Rules and Regulations pertaining to Radiation Control, Part 4, regarding discharges to sanitary sewers.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOP. Please note that all labels and markings must be defaced prior to disposal.

12. REFERENCES

None.

STANDARD OPERATING PROCEDURE 772 REVISION 4

TITLE: **PREPARATION OF WATER AND SOIL SAMPLES FOR THE ANALYSIS OF CARBON-14 USING POTASSIUM PERMANGANATE – EPA EERF METHOD C-01**

FORMS: **631** **(use current iteration)**

APPROVED BY:
TECHNICAL MANAGER _____ DATE 8/16/07
QUALITY ASSURANCE MANAGER _____ DATE 8/12/07
LABORATORY MANAGER _____ DATE 8/16/07

HISTORY: Rev0, 3/17/95; Rev1, 3/24/00; Rev2, 4/26/02; Rev3, 4/07/03 and 3/15/05 (format updated); Rev4, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedures used to prepare soil and water samples for the determination of ^{14}C. This procedure is based on Eastern Environmental Radiation Facility (EERF) Procedures Manual Method C-01.

2. SUMMARY

A measured aliquot of the sample is placed in a digestion tube. The organic and inorganic carbon in the sample is oxidized to CO_2 using sulfuric acid and potassium permanganate. The CO_2 gas is absorbed in a base solution. An aliquot of the base solution is added to a liquid scintillation cocktail. The sample is counted for low energy beta activity using a liquid scintillation counter (LSC).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specifications related to the client, project, and test method being performed.

3.3 Final review and sign-off of the data are performed by the Department Manager or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is satisfactory. Any errors that are

found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 The normal sample size for waters is 25mL to achieve a standard detection limit of 500pCi/L. Samples should not be preserved with acid. ^{14}C in inorganic forms cannot be determined in water samples that are received with an acid preservative because the addition of acid to a sample containing ^{14}C may result in the production and loss of $^{14}CO_2$ from the sample.

4.2 The normal sample size for soils is 1.0g to achieve a standard detection limit of 20pCi/g. Samples are routinely dried and ground per SOP 721.

4.3 Some organic compounds in solid matrices could become volatile during the drying stage, which may result in a low bias in the analytical results.

4.4 A maximum of 300 mg of carbon can be trapped by the system described in this SOP.

4.5 Incomplete recovery of carbon may result if the flow rate through the system is too fast or if the system is not properly sealed during use.

4.6 All glassware must be cleaned according to glassware washing SOP 720, and thoroughly dried prior to use in this procedure. Distillation apparatus should be thoroughly cleaned with Hydroxylamine Hydrochloride, as needed, to remove buildup of visible residues in the flasks.

4.7 The scintillation vial is an optical surface. Any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation. These should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. All labeling must be done on the cap of the vial.

4.8 The presence of visible coloration in the distillate will attenuate the light emitted from the scintillation cocktail. This effect, known as color quenching, is an interference to the detection of the scintillation. The quench indicating parameter or QIP (usually H-number or SQPe) should be monitored and variations in quench which could correspond to greater than 10% relative bias in the efficiency should be addressed by using standard additions to determine a sample specific efficiency.

4.9 The presence of particulate contaminant in the trap solution may interfere with the detection of the scintillation. This effect is known as 'physical quenching'. The symptoms, control limits, and corrective actions are identical to those mentioned in Section 4.7 above.

4.10 The presence of chemical contaminants in the trap solution may inhibit scintillation. This effect is known as 'chemical quenching'. The symptoms, control limits, and corrective actions are identical to those mentioned in Section 4.7 above.

5. APPARATUS AND MATERIALS

5.1 Midi cyanide distillation apparatus, including digestion tubes, cold finger, frit, and other glassware

5.2 vacuum pump or house vacuum

5.3 scintillation vials, low potassium borosilicate glass, 20mL, Wheaton™, or similar

5.4 graduated cylinder, 25 and 50mL

5.5 pipettors, 1mL, 5mL

5.6 pipet tips

5.7 pH paper, wide range

5.8 dispenser, repipette, 1-20mL adjustable, Brinkman™, or similar

5.9 aluminum weighing dish

5.10 plastic cups with lids, 100mL

5.11 analytical balance, capable of weighing to 0.0001g

6. REAGENTS

- Threshold Limit Value (TLV) and other hazard information may also be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Deionized (DI) Water, ASTM Type II or equivalent, obtainable from the laboratory's DI water system.

6.2 <u>5% (w/v) Potassium permanganate ($KMnO_4$) solution</u>: Dissolve 5g reagent grade $KMnO_4$ in 100mL DI water. Use a magnetic stirring bar and stir plate to speed dissolution.

6.3 <u>Sulfuric acid, 18N</u>: Cautiously add 500mL conc. H_2SO_4 to 500mL DI water. Allow to cool.

TLV = 0.25ppm. Irritant, corrosive. The Chemical Hygiene Plan requires the use of a rubber apron and face shield when handling concentrated sulfuric acid.

6.4 Scintillation cocktail - Ultima Gold™ LLT chemiluminescence-resistant cocktail or other equivalent.

6.5 ^{14}C standard solution, glucose form, approximately 100 $^{dpm}/_{mL}$, accurately calibrated.

6.6 Hydroxylamine Hydrochloride, 12%: Dissolve 12 g of $NH_2OH \bullet HCl$ in DI water, dilute to 100 mL final volume.
Severe irritant, reactive, corrosive, flammable.

6.7 Ammonium hydroxide base solution, 1N: Add 67 mL conc. NH_4OH to 500mL DI water. Dilute to 1L with DI water and mix well. Prepare fresh as needed.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Environmental and water samples for carbon analysis should be collected in amber glass containers. **The samples should not be chemically preserved.**

7.2 Keep all sample containers tightly closed. If samples are to be stored for an extended period of time, refrigeration is recommended to prevent biological growth in the sample.

7.3 At the current time, there is no regulatory holding time for ^{14}C. Many sampling and analysis plans, however, apply a default holding time of 180 days for this analysis. If samples are analyzed more than 180 days after collection, this fact should be noted in the case narrative.

8. PROCEDURE

8.1 SOLIDS PREPARATION

Solids are dried and ground per SOP 721 when appropriate. Record the condition of the sample on the sample condition form (Form 631).

Weigh 1g solid into a weighing dish using an analytical balance. Record weight to nearest 0.0001g on the benchsheet. A smaller aliquot must be weighed out for solids that have an unusually high total C content (>10%). Add the contents of the weighing dish to a clean, labeled digestion tube. Rinse the residue in the dish into the tube with a minimum of DI water. Proceed to Section 8.3.

8.2 WATERS PREPARATION

Check sample pH with wide range pH test paper. Record pH of each sample on the sample condition form (Form 631).

Water sample aliquots are measured with a graduated cylinder and transferred to clean, dry digestion tubes. The normal aliquot volume for water samples is 25mL. *A larger aliquot up to 50mL may be used to meet client detection criteria, but use caution when distilling on the Midi apparatus, as samples will have a tendency to overflow.* Proceed to Section 8.3.

8.3 SAMPLE PREPARATION

8.3.1 Prepare a Laboratory Control Sample (LCS) and a matrix spike (MS) per Section 9.2 below.

8.3.2 Label the receiving digestion tubes and fill with 50mL of freshly made 1N NH_4OH solution.

8.3.3 Finish assembling the distillation apparatus, ensuring a tight seal in the ground glass fittings. Start the water flow to the condensers at a flow rate of approximately 60gph (gallons/hour). Open the vacuum valve to begin aeration. Set vacuum so that the flow rate through the system is slow but continuous using the individual adjustable valves.

8.3.4 Add 5mL 5% $KMnO_4$ and 5mL 18N H_2SO_4 to the sample digestion tube through the air intake orifice.

8.3.5 Turn on the power to the Midi distillation apparatus. Turn on the heat to the digestion block by turning the timer knob. Set timer to 40 minutes.

8.3.6 Maintain the gas flow through the system by adjusting the vacuum, if necessary. The flow rate should be as slow as possible while avoiding backup.

8.3.7 Watch for foaming in the digestion tubes. Slowly turn down (or off) vacuum to any cell that foams excessively. Foaming may indicate excess carbon in the sample.

8.3.8 Continue to apply vacuum to the system and allow the cooling water to run for about fifteen minutes after the timer shuts the heating block off.

8.4 PREPARATION OF DISTILLATE FOR LIQUID SCINTILLATION COUNTING

8.4.1 Remove the fritted sparger from the 1N NH_4OH trap solution. Allow the fluid to drain back into the tube, with the aid of a pipet bulb, if necessary.

8.4.2 Pour the trap solution into a labeled 100mL poly cup. Dispose of the sample digestate into the carboy labeled “Carbon-14 Distillation and Tritium Distillation Waste”. Wash the glassware per SOP 720.

8.4.3 Label the cap of a 20mL glass scintillation vial for each sample.

8.4.4 Pipet a 5.0mL aliquot of the 1N NH_4OH trap solution from each sample into the scintillation vial. The remaining trap solution may be stored in the poly cup, capped, until the samples have been analyzed. After

satisfactory review of the data, the solution may be discarded into the carboy labeled "Carbon-14 and Tritium Distillate Remainders".

8.4.5 Add 15mL of Ultima Gold LLT^{TM}cocktail using a calibrated bottle-top dispenser.

8.4.6 Attach the labeled lid and shake each vial to mix well. Wipe off the outside of each vial using a laboratory wipe wetted with methanol.

8.4.7 Place the vials prepared for counting in a numbered rack, which fits into the LSC instrument.

8.4.8 Submit the samples to the Counting Lab where they will be analyzed and ultimately disposed of in the manner described in SOP 704.

9. QUALITY CONTROL

9.1 CALIBRATION

9.1.1 Repipettor calibration: The repipette dispenser is checked monthly (SOP 321) by dispensing a 10mL aliquot of scintillation cocktail into a 10mL graduated cylinder. The volume should be 10mL +/- 0.1mL, apply minor adjustment as necessary. Record the verification check in the pipet calibration logbook.

9.1.2 Efficiency calibration: While instructions are provided in Section 9.1.2.1 below for the preparation of a single point calibration standard, a quench curve is preferable and should be the default calibration unless otherwise instructed by the Radiochemistry Manager. Instructions for the preparation of a quench curve are provided in Section 9.1.2.2.

9.1.2.1 A single-point calibration is conducted as follows: At least 3 replicate standards are prepared by diluting ~ 500-5000dpm of NIST-traceable ^{14}C standard solution to the desired volume with 1N NH_4OH (default = 5mL, maximum using cocktails currently available). An appropriate volume of scintillation cocktail is added such that a stable emulsion will be formed (default = 15mL, minimum ratio of cocktail:sample, for Ultima-Gold LLT^{TM} = 3:1). The average efficiency is calculated as described below. Three Initial Calibration Verification (ICV) samples are prepared as described above, using an independent second source as the spiking standard, when available. The ICVs are submitted with the calibration vials. The radiometric recovery for the ICVs must meet the normal LCS acceptance

criteria for this method, as specified in the LIMS "Paragon Standard" program specification.

A single-point efficiency is accurate and may be used for the calculation of all results showing a QIP result corresponding to the average observed for the calibration standard (within +/- 10% relative efficiency or, lacking this calibrated range, +/- 15 of mean H# or SQPe number).

9.1.2.2 Quenched standards for the preparation of the quench curve are prepared as follows: Label 24 glass liquid scintillation vials (12 are spiked and 12 are for background). Spike 12 of the vials with ~500-5,000 dpm of NIST-traceable ^{14}C standard. Dilute to 5mL with 1N NH_4OH. Add nitromethane (or other suitable quenching agent) in 15µl increments ranging from 0µl to 165µl. Add 15mL of Ultima Gold LLT™ cocktail, cap, and shake to mix well.

For the 12 background vials, add a representative volume of the spike solution diluent, bring to a final volume of 5mL with 1N NH_4OH, then add nitromethane in the same increments as stated above. Add 15mL of cocktail, cap, and shake to mix well. Submit prepared vials to the Counting Lab. Three Initial Calibration Verification (ICV) samples are prepared as described above, using an independent second source as the spiking standard, and submitted with the calibration vials. In addition, the three ICVs should be quenched at the low, middle, and high ranges of the quench curve. The radiometric recovery for the ICVs must meet the normal LCS acceptance criteria for this method, as specified in the LIMS "Paragon Standard" program specification.

9.1.3 Background calibration (reagent blank): For single point calibrations, three reagent blanks are prepared and analyzed with each batch of efficiency calibration sources and each batch of samples, in the same solution ratios. These results are used to background-correct the current analysis batch.

In the use of quench curves, three reagent blanks are prepared and analyzed with each batch of samples. These results are used for batch-specific adjustments to the background quench curve, as described below:

9.1.3.1 Obtain a volume of blank (no radioactive standard added) diluent that was used to prepare the calibration standard solution.

9.1.3.2 To each scintillation vial, add blank diluent, 1N NH_4OH, and cocktail in the same ratios used in the efficiency calibration sources.

9.1.3.3 When using a quench curve, the three reagent blanks should be quenched at the low, middle, and high ranges of the quench curve.

9.1.3.4 The three reagent blanks are submitted for each preparation batch and counted for a time period equal to or longer than the longest sample count. For a single-point calibration, the average of these reagent blanks is used as the background correction for that particular batch. When using a quench curve, the average difference between the three reagent blank values and the corresponding points on the quench curve should be used to adjust the quench curve (up or down) for the current analytical batch.

9.1.3.5 For samples counted in the default calibration geometry, cpm results (as well as blank ID, batch, and QIP result) of the reagent blank count are entered into a spreadsheet (r:\inst\lsc*\CB's_BKGD_WIN2_CKS\rb_C14.xls, where * denotes the instrument used to count the reagent blanks), and compares each blank to historical control limits established from the first 30 data points in the population (+/- 3 sigma). The preparation of background calibration vials used in a quench curve calibration is described in Section 9.1.2.2 above.

9.2 QC SAMPLE PREPARATION

9.2.1 Method Blanks are analyzed at a frequency of 5% (i.e., one per 20 field samples) with a minimum of one per batch. Water and soil blanks consist of 25mL DI water.

9.2.2 LCSs are analyzed at a frequency of 5% (i.e., one per 20 field samples) with a minimum of one per batch. Spike ^{14}C at approximately 500dpm per LCS. Record the exact spike volume on the benchsheet. Spiked water blanks and soil blanks are prepared using 25mL of DI water. Appropriate spiking levels are approximately 10 times the requested minimum detectable concentration.

9.2.3 Matrix spikes are analyzed at the rate of one per batch of 20 or fewer samples. ^{14}C is spiked at approximately 500dpm. Record the exact spike volume on the benchsheet. If elevated ^{14}C activity in the sample is suspected, ensure that the spiking level is at least 4-10 times the estimated sample activity concentration.

9.2.4 Analyze one duplicate sample for every 10 samples or fewer for each matrix.

10. CALCULATIONS

10.1 The sample activity is calculated as described in SOP 708 -- Calculations for Radioanalytical Results.

10.2 The 1σ Total Propagated Uncertainty (TPU) is reported in association with each result. See SOP 708 for details regarding determination of the TPU.

10.2.1 TPU FACTORS. As defined in SOP 708, the following one-sigma preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU).

10.2.2 For water analyses the preparation uncertainty, per SOP 708 is 0.0509. This is based on one homogeneity estimate, one volumetric measurement of the sample volume, one volumetric measurement of the trap solution, and one pipetting of the trap solution aliquot for analysis.

$$0.0509 = \sqrt{0.05^2 + 0.006^2 + 0.006^2 + 0.004^2}$$

10.2.3 For soil analyses the preparation uncertainty, per SOP 708 is 0.0506. This is based on one homogeneity estimate, one gravimetric measurement of the sample mass, one volumetric measurement of the trap solution, and one pipetting of the trap solution aliquot for analysis.

$$0.0506 = \sqrt{0.05^2 + 0.003^2 + 0.006^2 + 0.004^2}$$

10.2.4 In practice, these values are substantially equivalent and the greater of the two, 0.0509, will be used for reporting both matrices.

10.3 The Minimum Detectable Concentration (MDC) and Decision Level (DL) activity are calculated as described in SOP 708.

10.4 The efficiency used for calculation of sample results is calculated as shown in the equation below:

$$\text{DetEff} = \frac{\text{Net Cpm}}{\text{SpkDPM}}$$

NOTE: Multiple standards are prepared and the measured values averaged for use in sample calculations.

For a quench curve calibration, the calculated efficiencies for each individual standard should be tabulated (in a spreadsheet, for example) and the data should be fit to a function that minimizes the difference between the individual data point and the fitted value. In no case should this difference be greater than 10%, except with the approval of the Department Technical Manager.

11. DEVIATIONS FROM METHOD

This procedure is compliant with Eastern Environmental Radiation Facility (EERF) Procedures Manual Method C-01 for water samples. The method has been modified to accommodate small aliquots of solid materials.

12. SAFETY HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

12.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

12.1.3 Cracked glassware should not be used in the Midi apparatus due to the risk of implosion under vacuum.

12.1.4 The spargers and plastic tubing should be rinsed with DI water. Allow to dry before next use.

12.1.5 The digestion tubes should be washed with lab detergent and rinsed with DI water. Allow to dry before next use.

12.1.6 Any chemicals with a TLV of less than 50ppm shall be worked within a laboratory fume hood (e.g., solvents and acids).

12.1.7 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.2 WASTE DISPOSAL

12.2.1 All empty radionuclide standard solutions are disposed of by rinsing the standard container a minimum of three times. The container must be surveyed prior to release. Please note that all labels and markings must be defaced or removed prior to disposal.

12.2.2 The residual sample in the digestion tube may be rinsed into the waste carboy provided by the Waste Compliance Officer. Rinse with a minimum of tap water in order to reduce the volume of waste produced.

12.2.3 Scintillation cocktails should not be disposed of down the drain but instead placed in a properly labeled carboy.

12.2.4 Vials of sample/cocktail mixture may be accumulated (intact) in a container provided by the Waste Compliance Officer.

DOCUMENT REVISION HISTORY

6/04/07: Added this DOCUMENT REVISION HISTORY. Added LIMS program specification language. Changed the prep and analysis of the background determination (Section 9.1.3), and revised targeted spiking levels (Sections 9.1.2, 9.2).

8/12/07: Removed activity, TPU, and MDC calculations and referenced SOP 708 -- Calculations for Radioanalytical Results instead. Added Forms.

TITLE: **TOTAL DISSOLUTION OF SOLIDS FOR THE RADIOCHEMICAL DETERMINATION OF ACTINIDES AND OTHER NON-VOLATILE RADIONUCLIDES**

FORMS: **709**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 5/1/07

QUALITY ASSURANCE MANAGER _____ DATE 4/26/07

LABORATORY MANAGER _____ DATE 4-30-07

HISTORY: Rev0, 4/14/95; Rev1, PCN #532, 9/28/95; Rev2, PCN #561, 11/14/95; Rev3, 9/08/97; Rev4, 3/24/00; Rev5, 10/19/00; Rev6, 10/24/01; Rev7, 1/03/02; Rev8, 4/07/03; Rev9, 3/15/05; Rev10, 4/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the total dissolution of solids for the quantitative radiochemical measurement of actinides and other non-volatile constituents. After dissolution has been completed, the analytes are purified and prepared as described in the appropriate standard operating procedure.

This procedure is also amenable to dissolution of soils, non-soil solids, air filters, and materials containing significant organic content (biota, vegetation, oils, etc.).

2. SUMMARY

Samples are dried and ground per SOP 721 to a fine particle size. All solid samples are reported on a "dry weight" basis unless otherwise requested by client. Filters can be cut into pieces that will fit into muffling containers. **Where appropriate,** organic matter is removed by combustion in a muffle furnace.

Tracers are added and dissolution is accomplished using nitric, hydrochloric, and hydrofluoric acids. When actinides are being determined, a hydroxide co-precipitation is performed to pre-concentrate actinides and remove constituents that do not form insoluble hydroxides. The hydroxide precipitate is then re-dissolved and further purification is performed. Because any solid prepared by SOP 721 is dried prior to sieving, grinding, and dissolution, solid samples are automatically obtained on a dry weight basis.

A reagent blank is prepared with this procedure and used as a method blank in subsequent separations.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP

and to complete all documentation required for review.

3.2 Personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method perform analysis and interpretation of the results. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/ analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Combustible materials may flash-ignite during muffling and lead to uncontrolled sample loss or sample cross contamination. A slow ramped muffling procedure and covering the sample with a watch glass can be used to address this problem.

5. APPARATUS AND MATERIALS

5.1 Pyrex™ glass beakers, 50mL

5.2 muffle furnace

5.3 pipettes, Eppendorf™ or equivalent

5.4 polypropylene beakers, 110mL and 220mL

5.5 centrifuge bottles, 250mL

5.6 steam bath constructed to allow immersion of lower half of 220mL polypropylene beaker into steam

5.7 wash bottles

5.8 top loading balance, 0.01g sensitivity

5.9 centrifuge

5.10 vortex mixer

5.11 volumetric dispensers (Dispensette^{TM} or equivalent) designed for handling concentrated HNO_3 and HCl

5.12 graduated cylinder, plastic, 25mL

5.13 pH indicating paper, wide range (0-14 pH units)

5.14 RadiacWash^{TM}

5.15 liquid cleaning soap

5.16 analytical balance - to calibrate the pipettes

5.17 watch glasses

5.18 transfer pipets, plastic, disposable

5.19 plastic stir rods

5.20 filter paper, ashless

5.21 furnace gloves

5.22 long tongs

5.23 steam bath

6. REAGENTS

Threshold Limit Value (TLV) and other hazard information may also be given here. The absence of this information does not imply that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding. As stated in Section 11.1.4 of this SOP, any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood.

6.1 TRACERS AND CARRIERS

High purity, standardized solutions traceable to NIST are diluted to approximately 10-40dpm/mL of activity for tracing and spiking solutions. Solutions of the following elements/isotopes may be utilized:

- **Pu-ISO**: ^{242}Pu is the tracer and ^{239}Pu is the spike for the LCS.
- **U-ISO**: ^{232}U is the tracer and ^{238}U is the spike for the LCS.
- **Am-241/Cm-244**: ^{243}Am is the tracer and ^{241}Am and/or ^{244}Cm is the spike for the LCS.
- **Th-ISO**: ^{229}Th is the tracer and ^{230Th} is the spike for the LCS.

- **Other Tests**: Spikes, tracers and carriers are defined in the applicable preparation SOP for the test being performed.

6.2 Nitric acid, HNO_3, concentrated, 16N, reagent grade. TLV = 2ppm (TWA). Irritant, corrosive.

6.3 Hydrofluoric acid, HF, concentrated, 29N, reagent grade. TLV = 3ppm (ceiling). Irritant, burns, bone, teeth, fluorosis.

6.4 Hydrochloric acid, HCl, concentrated, 12N, reagent grade. TLV= 5ppm (ceiling). Irritant, corrosive.

6.5 Boric acid, H_3BO_3, reagent grade.

6.6 Ammonium hydroxide, NH_4OH, concentrated, 15N, reagent grade. TLV = 25ppm for ammonia (TWA). Irritant.

6.7 Ferric chloride carrier, 20mg Fe^{3+}/mL: Dissolve 96g $FeCl_3 \bullet 6H2O$ in one liter of 0.5N HCl.

6.8 Deionized (DI) water, from the laboratory's DI water systems..

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 The minimum sample size required for this procedure is 30 grams. If samples scheduled for this procedure have a high moisture content (they are very wet or are sludge-like materials), more sample (up to 60 grams) may be required to properly perform this procedure. If the analysis procedure requires the generation of sample duplicates or sample matrix spikes, additional sample aliquots will be needed to generate these quality control (QC) samples.

7.2 The sample collection containers should be clean glass or plastic with a screw-cap top. They should be of adequate size to hold the required sample weight for this procedure.

7.3 The samples processed through this procedure do not need to be chilled or chemically preserved during shipment or storage unless otherwise required by project-specific requirements.

7.4 See client specifications and individual analysis procedures for holding time requirements.

8. PROCEDURE

8.1 Samples that require grinding are processed through the grinding steps of SOP 721. According to the analyst's judgment, samples with high organic content may be muffled prior to dissolution. Solid samples with high organic content characteristically are dark in color, are oily, or contain visible organic material

(i.e., vegetation).

8.2 SAMPLE ALIQUOT

8.2.1 Samples that do not require muffling can be aliquoted directly into a 220mL plastic cup. Weigh a 2g up to 10g aliquot (to the nearest 0.01g) of the ground sample into a clean, labeled 220mL plastic cup.

8.2.2 **IMPORTANT**: For samples that require muffling, the Pyrex™ brand glass beaker number (all labware to be used for muffling must have a permanent ID engraved on its surface) is written on the benchsheet in association with the corresponding sample number. For the blank and blank spike, a beaker containing a piece of ashless filter paper will be muffled.

Weigh a 2g up to 10g aliquot (to the nearest 0.01g) of the ground sample into **the corresponding** labeled Pyrex™ beaker. Filters should be cut or folded such that they fit into the bottom of the beaker. Cover the dishes using watch glasses to protect the content from material that could drop into the sample during the muffling.

8.2.3 Consult the Spike/Tracer Data Sheet (R:\forms\mda_list.xls) for information about the volume/activity and standard identification to be used. Add calibrated volumes of tracer and spike solutions to samples, blank and blank spike as per SOP 766 (Alpha Spectroscopy) or other appropriate SOP. For samples that require muffling, proceed to Section 8.2.4 of this SOP. If muffling is not necessary, proceed to Section 8.3.3 of this SOP. **NOTE: In cases where a common digestion of the sample is required for multiple analyses in addition to alpha spectroscopy, skip this Step; the spiking and tracing of the samples are performed after muffling, at Step 8.3.4.**

8.2.4 Place the beaker without the watch glass on a hot plate and take to dryness to prevent splattering in the muffle furnace.

8.2.5 Place the beaker with a watch glass in the muffle furnace and heat at 550- 600°C for at least 4 hours after the furnace reaches full temperature. Highly organic materials (or oil matrices) should be muffled overnight. Filters should be muffled at a setting of 450 ºC for a minimum of 12 hours.

8.3 SAMPLE DISSOLUTION

8.3.1 Where applicable, carefully remove dish from the muffle furnace using thick furnace gloves and long tongs. Allow the samples to cool.

8.3.2 After cooling, wet the sample in the beaker using conc. HNO_3 to

prevent any loss of powdered sample during transfer. Transfer the ignited sample to a 220mL polypropylene beaker using a plastic stir rod and about 25mL of conc. HNO_3. For the blank and blank spike, the corresponding empty beaker will be rinsed with acid just like the samples.

8.3.3 For samples that were not muffled, carefully add 25mL of conc. HNO_3 to the sample in the plastic cup and proceed to Section 8.3.5 of this SOP.

8.3.4 If the spiking and tracing of the samples was done prior to muffling, skip this Step, otherwise, consult the Spike/Tracer Data Sheet (R:\forms\mda_list.xls) for information about the volume/activity and standard identification to be used. Add calibrated volumes of tracer and spike solutions to samples, blank and blank spike as per SOP 766 (Alpha Spectroscopy) or other appropriate SOP.

8.3.5 Add 25mL of conc. HCl to each beaker using a volumetric dispenser. Using a **plastic** graduated cylinder, carefully add 25mL of conc. HF to each beaker. **Do not bring HF into contact with any type of laboratory equipment made of glass because HF will dissolve glass.**

8.3.6 Place a 110mL polypropylene beaker as a cover onto the 220mL beaker containing the sample.

8.3.7 Allow the samples to pre-digest about 1 hour at room temperature in a fume hood to allow any vigorous reaction to subside.

8.3.8 Place the beakers on the steam bath and heat for four (4) hours, with the hot plates set at at least 5, with the covers in place. Rinse (with DI water) and remove the cover. Allow the sample to go to dryness. After sample has dried, there should be a visible white residue on the bottom of the beaker. If significant amounts of non-white solids are observed in the container, an additional 25mL of HF, 25mL of HCl, and 25mL of HNO_3 are added and this Step (8.3.8) is repeated.

8.3.9 If actinides are being performed by alpha spectroscopy, continue with Section 8.3.10. If other tests such as gamma or non-routine tests are to be performed, the solution is taken to dryness, and the appropriate SOP must be consulted before continuing with the analysis. A Senior analyst may be consulted regarding conversion from the $HNO_3 \mid HCl \mid HF$ system to other appropriate solutions prior to continuing.

8.3.10 Remove from the steam bath and add 10mL conc. HNO_3, 100-150mL DI water (to solubilize the solids) and 2g H_3BO_3. Mix well by swirling contents of beaker. Return beakers to steam bath for approximately 15 minutes to warm solution and enhance dissolution of salts.

8.3.11 Transfer sample to a 250mL labeled centrifuge bottle using deionized water.

8.3.12 Using a repeater pipet, add 2mL of ferric chloride carrier. If the sample size is more than 2.0g, the addition of iron carrier may be skipped as the sample may have enough iron content to make a sufficient amount of precipitate.

8.3.13 Add 20-25mL of conc. NH_4OH to form an $Fe(OH)_3$ precipitate. Make sure that the precipitate forms and that the solution is basic. If there are any doubts, check the solution with pH paper. If no precipitate forms, keep adding NH_4OH dropwise with a transfer pipet until a precipitate does form.

8.3.14 Centrifuge the sample for 15 minutes at approximately 3500rpm. Discard the supernatant (avoid losing any precipitate). Further separations are now performed following the appropriate separation SOP.

9. QUALITY CONTROL

9.1 One reagent blank is prepared per batch of 20 samples or at a 5% frequency.

9.2 One sample duplicate is prepared per batch of 10 samples or at a 10% frequency. If there is insufficient sample for a duplicate, a blank spike will be prepared.

9.3 One laboratory control sample (spiked blank) is prepared for each batch of 20 samples (5% frequency) with a range of 10 to 30 dpm of analyte.

9.4 The same blank and duplicate may serve for any batch in which multiple analytes are being determined.

NOTE: Project-specific requirements may supersede default QC requirements.

10. DEVIATIONS FROM METHOD

This is a proprietary procedure developed by Paragon Analytics. Therefore, there are no deviations from promulgated methods for this procedure.

11. SAFETY HAZARDS AND WASTE

11.1 SAFETY AND HAZARDS

11.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

11.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep. labs at all times.

11.1.3 Gloves, safety glasses and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

11.1.4 Any chemicals with a TLV of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

11.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with the compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.6 Use extreme care when using hydrofluoric acid (HF). Work only in a fume hood that has adequate ventilation and personnel safety features. **Never inhale or allow skin or clothing to be exposed to HF fumes.**

11.1.7 Care should be taken when diluting acids. **Always add acids to water, NOT water to acid**.

11.2 WASTE DISPOSAL

11.2.1 Wastes that are "corrosive only," such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the Paragon wastewater treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

11.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. This includes any excess HF from dissolution of samples and all solutions remaining from the micro precipitation process. Notify the Waste Disposal Manager for disposal.

11.2.3 All acid wastes not containing HF that are generated in ion exchange operations are disposed of into the wastewater tank system (i.e., down the drain), unless instructed otherwise due to identified or suspected hazards.

STANDARD OPERATING PROCEDURE 774 REVISION 1

TITLE: **$^{59/63}$NI IN WATER AND SOIL SAMPLES USING EICHROM NICKEL RESIN**

FORMS: **631, 311** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER Renee Kellogg DATE 7/21/08

QUALITY ASSURANCE MANAGER Deb Schatz DATE 7/20/08

LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: DRAFT 1/12/04, NEW, Rev0, 2/27/06; Rev1, 7/18/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references, Eichrom™ Method NIW01, Rev. 1.1, describes a procedure to determine ^{63}Ni in aqueous and solid matrices. It can also be used to analyze samples for ^{59}Ni. The method utilizes Eichrom™ Ni resin, which complexes the Ni in a sample with dimethylglyoxime (DMG). The DMG complex can be stripped from the resin and used to measure the Ni activity in the samples by liquid scintillation counting (LSC).

2. SUMMARY

A portion of the sample is removed for inductively coupled plasma (ICP) atomic emission spectrometry determination of the pre-separation concentration of nickel in the sample. An aliquot of the sample is digested in acid and taken to dryness. The sample is re-dissolved and run through a Ni resin column. The Ni-DMG complex is eluted from the column, taken to dryness, and re-dissolved prior to aliquotting a portion for counting by liquid scintillation.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of supervisory/ training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Cobalt and other metals that form complexes with DMG may be interferences to this method, as they may take up sites within the resin and not allow Ni-DMG complexes to form. ICP results should be closely monitored for interfering metals. Reduced aliquot sizes may be necessary in some cases to remediate poor recoveries.

4.2 The pH of the solution loaded onto the resin column is very important. Samples that have not been adjusted to a high enough pH (9-11) will run through the column without forming the Ni-DMG complex. If this should begin to occur, the pH can be adjusted while the sample is on the column to prevent gross nickel losses. Any Ni losses will be measured by ICP.

4.3 The scintillation vial is an optical surface. Any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation. These should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. **All labeling must be done on the cap of the vial.**

4.4 The quench indicating parameter (QIP) (usually H-number) should be monitored and variations in quench that could correspond to greater than 10% relative bias in the efficiency, should be addressed by using standard additions to determine a sample-specific efficiency.

4.1.1 The presence of visible coloration in the final sample will act as an ‘inner filter’. This effect, known as ‘color quenching’ is an interference to the detection of the scintillation.

4.1.2 The presence of chemical contaminants in the sample may inhibit scintillation. This effect is known as ‘chemical quenching’.

4.1.3 The presence of particulate contamination in the final sample may interfere with the detection of the scintillation. This effect is known as ‘physical quenching’.

5. APPARATUS AND MATERIALS

5.1 analytical balance, capable of reading to 0.0001g

5.2 graduated cylinder, 500mL

5.3 plastic cups, 150 and 250mL

5.4 test tubes, disposable, 15mL

5.5 transfer pipettes, plastic, ~3mL

5.6 Pasteur pipettes, glass

5.7 adjustable mechanical pipette, disposable pipette tips

5.8 steam bath

5.9 Parafilm™

5.10 beakers, glass, 400mL

5.11 centrifuge

5.12 centrifuge tubes with caps, 50mL

5.13 pH paper

5.14 repeater pipettors

5.15 scintillation vials, low-potassium borosilicate glass, 20mL

5.16 liquid scintillation counting racks

5.17 sand, clean, laboratory

5.18 Kimwipes™

5.19 Bio-Rad™ columns
To prepare for use: Add Ni resin to the column as a slurry with deionized water to the 1.8mL mark. Place a small layer of clean laboratory sand on top to hold the resin in place. Store in a capped 250mL plastic cup with a small amount of DI water to prevent drying.

6. REAGENTS

NOTE: TLV and other hazard information may also be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 NIST-traceable ^{59}Ni or ^{63}Ni spiking solution (source independent from that used for calibration)

6.2 Deionized (DI) water

6.3 Nickel + cobalt carrier, standardized: Dissolve 5.0g $Ni(NO_3)_2 \cdot 6H_2O$ and 5.0g $Co(NO_3)_2 \cdot 6H_2O$ in deionized (DI) water and dilute to 1000mL.

TLV for Ni = 0.04ppm (TWA) and the TLV for Co = 0.008ppm (TWA).

Standardization of Ni + Co carrier by ICP analysis: Prepare in triplicate a 1000-fold dilution of the Ni + Co carrier using the ICP solution described in Section 6.13 below. Submit to the metals lab for analysis. Average the results and record in the Reagent Prep Logbook.

6.4 Ammonium citrate, 1M: Dissolve 226.19g ammonium citrate in approximately 800mL of water and dilute to 1L. Note: The pH of this reagent may be adjusted to 9-11 using concentrated NH_4OH after preparation or just prior to use.

6.5 Ammonium citrate, 0.2M: Dissolve 45.24g ammonium citrate in approximately 800mL of water and dilute to 1L. Note: The pH of this reagent may be adjusted to 9-11 using concentrated NH_4OH after preparation or just prior to use.

6.6 Ammonium Hydroxide, 15N NH_4OH (conc.)
TLV = 25ppm (TWA for NH_3)

6.7 Hydrochloric acid, 12N: HCl (conc.)
TLV = 5ppm (ceiling)

6.8 Hydrochloric acid, 1N: Add 8mL of concentrated HCl to approximately 500mL of water and dilute to 1L
TLV = see Section 6.7

6.9 Nitric acid, concentrated (16N), ACS grade
TLV = 2ppm (TWA) Irritant, corrosive

6.10 Nitric acid, 8N: Cautiously add 500mL of reagent grade concentrated HNO_3 to approximately 400mL of DI water and dilute to 1.0L
TLV = see Section 6.9

6.11 Nitric Acid, 3N: Add 191mL of concentrated HNO_3 to approximately 500mL of water and dilute to 1L
TLV = see Section 6.9

6.12 Liquid scintillation cocktail, Ultima Gold LLT™ or equivalent

6.13 ICP diluting solution: Add 10mL 16N HNO_3 and 50mL 12N HCl to approximately 500mL of DI water. Then bring to 1L with DI water
TLV = See Sections 6.7 and 6.9

6.14 Methanol, reagent grade

TLV = 200ppm (TWA)

6.15 Eichrom™ Ni resin, 100-150µm

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Liquids: A sample should be collected in a manner that will provide the most representative sample. Collect a 1liter sample in a plastic container, from a free - lowing source when possible.

7.2 Although the client is responsible for conducting the sampling process, it is emphasized that water samples be collected in a manner that addresses the considerations discussed in EPA 900.0 Section Three or Chapter Nine of EPA SW-846, as appropriate. Also, it is recommended that samples be preserved at the time of collection by adding enough 1N HNO_3 to the sample to bring it to pH 2 (15mL 1N HNO_3 per liter of sample is usually sufficient). If not preserved upon collection, then the sample should be preserved within 5 days. If preservation is delayed, hold samples for a minimum of 24 hours after preservation to solubilize any possible activity on the container.

7.3 For a dissolved sample analysis, use a 0.45-micron membrane filter to remove the solids from the sample. Then acidify the sample with nitric acid to a pH < 2.0.

7.4 The container should be plastic rather than glass to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 AQUEOUS SAMPLE PREPARATION

8.1.1 Verify and record the pH of the sample on a liquid sample condition form (Form 631) according to SOP 733.

8.1.2 It may be necessary to filter the samples through a 0.45µm or other filter prior to analysis if excessive solids are present in the sample. Consult with the Radiochemistry Supervisor or Project Manager prior to analysis of heavily-sedimented samples.

8.1.3 Using a graduated cylinder, aliquot the sample into a labeled 400mL beaker. A sample aliquot of 300mL is typical for this method, but may need to be reduced due to matrix interference or volume limitations. All samples should be brought to a final volume of 300mL

8.1.4 Prepare batch QC samples per Section 10.

8.1.5 Using a calibrated pipette (SOP 321), add Ni spiking solution per Section 10.2.2 to LCS and any matrix spikes; add 1mL Ni + Co carrier

solution to all samples. Record all pertinent spiking information on the benchsheet (expiration dates, pipettes, solution IDs).

NOTE: A "reference carrier" should also be prepared by adding 1mL Ni + Co carrier to 300mL of DI water. Mix thoroughly, remove 1mL of solution and dilute to 10mL as stated in Step 8.1.7 for samples. Submit with samples for ICP analysis to provide a reference concentration for the yield calculations.

8.1.6 Place the sample on a stirring hotplate, add a stir bar, and stir at a moderate speed to thoroughly mix the sample.

8.1.7 How to take initial ICP aliquot: Use a calibrated pipette (SOP 321) to remove 1mL of sample and place into a clean test tube labeled with the sample ID and "initial ICP". Dilute to 10mL with ICP diluting solution. Cover with ParafilmTM and invert tube several times to mix thoroughly. Set aside until final ICP aliquot has been taken.

8.1.8 Remove the stir bar from the sample, rinsing with DI water.

8.1.9 Evaporate the sample to dryness. Be sure the sample does not boil or bake while on the hotplate.

8.1.10 Add 5mL 12N HCl to convert nitrate salts to chloride salts.

8.1.11 Evaporate the samples to dryness - **do not bake!**

8.1.12 Dissolve the residue in 5mL 1N HCl. Add an additional 5mL 1N HCl, if necessary, to dissolve all of the residue.

8.1.13 Proceed to Section 8.3 of this SOP.

8.2 SOLID SAMPLE PREPARATION

8.2.1 Verify and record the sample condition on a solids sample condition form (Form 631).

8.2.2 Solid samples used in this method should be dried and ground per SOP 721 prior to analysis. If the samples are not conducive to grinding, consult with the Radiochemistry Supervisor prior to analysis of samples.

8.2.3 Weigh 0.5g of solid into a labeled centrifuge tube. Record this initial weight on the benchsheet.

8.2.4 Prepare batch QC samples per Section 10.

8.2.5 Using a calibrated pipette (SOP 321), add Ni spiking solution per Section 10.2.2 to the LCS and any matrix spikes. Add 1mL Ni + Co carrier solution to all samples. Record all pertinent spiking information on the benchsheet (expiration dates, pipettes, solution IDs).

NOTE: A "reference carrier" should also be prepared by adding 1mL Ni + Co carrier to a centrifuge tube and bringing to a final 50mL volume with 10mL 8N HNO_3 and 39mL DI water. Mix thoroughly, remove 1mL of solution and dilute to 10mL as stated in Step 8.2.13 for samples. Submit with samples for ICP analysis to provide a reference concentration for the yield calculations.

8.2.6 Carefully add 10mL 8N HNO3 to each tube. **Watch out for vigorous reaction.**

8.2.7 Place the samples on the steam bath and digest for an hour with the caps on loosely.

8.2.8 Remove the samples from the steam bath and allow to cool. Vortex the samples to mix well and centrifuge them for 10 minutes.

8.2.9 Decant the leachate from the tubes into new, labeled centrifuge tubes.

8.2.10 Rinse the soil left in the original tube with 10mL DI water, mix and centrifuge, and decant the rinsate into the new tube from Step 8.2.9.

8.2.11 Bring all tubes from Step 8.2.10 up to a 50mL final volume with DI water.

8.2.12 The tubes containing the leached soil may be dried in a fume hood and disposed of in the proper SAA waste container, depending on prescreen radioactivity information.

8.2.13 How to take initial ICP aliquot: Use a calibrated pipette (SOP 321) to remove 1mL of sample and place into a clean test tube labeled with the sample ID and "initial ICP". Dilute to 10mL with ICP diluting solution. Cover with Parafilm™ and invert tube several times to mix thoroughly. Set aside until final ICP aliquot has been taken.

8.2.14 Transfer the samples to clean, labeled 250mL plastic cups, rinsing the centrifuge tubes with DI water.

8.2.15 Take the samples to dryness on the steambath - **do not bake!**

8.2.16 Add 5mL 12N HCl while the samples are still on the steambath to convert nitrate salts to chloride salts.

8.2.17 Evaporate the samples to dryness on the steambath- do not bake!

8.2.18 Dissolve the residue in 5mL 1N HCl. Add an additional 5mL 1N HCl, if necessary, to dissolve all of the residue.

8.2.19 Proceed to Section 8.3 of this SOP.

8.3 SEPARATION OF NI USING EICHROM NICKEL RESIN

NOTE: Wherever the method indicates an ammonium citrate solution, regardless of concentration, an ammonium citrate solution that has already been adjusted to pH 9-11 should be used. Be sure to check the pH of the solution just prior to use.

8.3.1 Add 1mL 1M ammonium citrate. Add 15N NH4OH dropwise until the pH of the sample is between 9-11. This usually takes about 10-15 drops. Check the pH of the sample using a glass Pasteur pipette to remove as little of the sample as possible.

8.3.2 Place a prepared, labeled Bio-Rad™ column in a rack for each sample. See Section 5.20 for column preparation. Place a cup or a waste tray under each column.

8.3.3 Condition each column with 5mL 0.2M ammonium citrate.

8.3.4 Load the sample onto the appropriate column using a transfer pipette. A red band will appear on the column as the Ni-DMG complex forms. The sample should be loaded as soon as possible after adjusting the pH in Step 8.3.1. If the sample is allowed to sit for too long, the sample may buffer to a lower pH.

NOTE: The pH of the solution on the column is crucial to the success of this method. The pH of the sample should be between 9-11 prior to loading on the column. If the pH is too low, the sample will drain through the column. If this occurs, the drainage may be stopped by adding the first 0.2M ammonium citrate rinse from Step 8.3.5 to the column. Since recovery is monitored by ICP, the amount of Ni lost will be accounted for. Document the event on a QASS (SOP 928).

8.3.5 Rinse the cup with 5mL 0.2M ammonium citrate. Add the rinse to the column.

8.3.6 Repeat Step 8.3.5 two more times.

8.3.7 Rinse the column with 5mL 0.2M ammonium citrate.

8.3.8 The eluate from Steps 8.3.3-8.3.7 has been determined not to be hazardous other than corrosivity. It may be discharged down the laboratory sink with plenty of tap water.

8.3.9 Strip Ni from the column using 10mL 3N HNO_3 (added in 5mL increments) into labeled 250mL plastic cups. The sample has been completely dissolved when the red band disappears entirely. If necessary, add additional 3N HNO_3 in 5mL increments until the red band is completely eluted from the column

8.3.10 The resin is inactive at this point and the column may be dried and emptied into the resin waste container.

8.3.11 Dry the samples on a steambath. Be sure not to bake the samples, as a hard, black residue may result.

8.3.12 Re-dissolve the samples with 0.25mL 16N HNO_3 and 5.75mL DI water.

NOTE: Since there is no pipette that will accurately deliver 5.75mL, this step currently takes three pipettes to perform. Calibrate three pipettes (SOP 321) in the following volumes: 0.25, 5.0, and 0.75mL. The use of three pipettes is reflected in the TPU calculation.

8.3.13 How to take final ICP aliquot: Swirl the sample to mix thoroughly. Using a calibrated pipette (SOP 321), aliquot 0.1mL of sample into a clean test tube labeled with the sample ID and "final ICP". Dilute with 9.9 or 10mL of ICP diluting solution, cover with Parafilm™, and invert several times to mix completely. Be sure to note the final volume of the dilution. Submit the initial and final test tubes to the metals lab with proper bench sheets for analysis.

8.3.14 Swirl the sample to mix thoroughly and pipette a 5.0mL aliquot into a labeled scintillation vial (label the cap only) using a calibrated pipette (SOP 321).

8.3.15 The remainder of sample after performing Step 8.3.14 must be disposed of in the appropriate SAA container.

8.3.16 Add 15mL Ultima Gold LLT™ scintillation cocktail to each vial, close tightly, and shake to mix thoroughly.

8.3.17 Clean the outside of the scintillation vial using a lint-free lab wipe and methanol to remove dust, smudges, and fingerprints; place the vials in liquid scintillation racks.

8.3.18 Deliver the samples to the counting lab with the necessary documents. Place the racks in the liquid scintillation counter and allow at least 3 hours for samples to "dark-adapt" prior to counting. The counting lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704.

9. CALCULATIONS

9.1 CORRECTED SAMPLE VOLUME CALCULATION (V_c)

The sample aliquot volume to be used in calculating the final result must be reduced slightly because aliquots were removed from the sample for chemical recovery determination. Also, not all of the final purified solution is pipetted into the scintillation vial for counting.

$$V_c = V_i\left(\frac{V_1 - ICP_i}{V_1}\right)\left(\frac{V_2 - ICP_f}{V_2}\right)\left(\frac{V_a}{V_2 - ICP_f}\right)$$

where:

V_i = Initial sample aliquot (typically 300mL for aqueous samples, 0.5g for solid samples)

V_1 = Sample dilution volume for initial ICP (typically 300mL for aqueous samples, 50mL for solid samples)

ICP_i = Volume removed for initial ICP (typically 1mL)

V_2 = Sample dilution volume for final ICP (typically 6mL)

ICP_f = Volume removed for final ICP (typically 0.1mL)

V_a = Volume submitted for LSC analysis (typically 5mL)

9.2 CHEMICAL RECOVERY DETERMINATION (Y)

Calculate the percent nickel recovered as follows:

$$m_i = (V_1)(C_i)(DF_1)\left(\frac{V_1 - ICP_i}{V_1}\right)$$

$$m_f = (V_2)(C_f)(DF_2)$$

where:

m_i = Mass of initial Ni present in sample (μg)
C_i = Concentration of Ni in initial ICP aliquot ($^{\mu g}/_{mL}$)
DF_1 = Dilution factor (due to dilution made in Steps 8.1.7 or 8.2.13, typically 10)
m_f = Mass of final Ni present in sample (μg)
C_f = Concentration of Ni in final ICP aliquot ($^{\mu g}/_{mL}$)
DF_2 = Dilution factor (due to dilution made in Step 8.3.13, typically 100 or 101)

NOTE: The mass of Ni present in the reference carrier (m_{RC}) is calculated in the same manner as that of m_i. Volumes and dilution factors are typically the same for samples and the reference carrier. Be sure to note differences on the benchsheet, if any. If $m_{RC} > m_i$, m_{RC} is substituted for m_i in the denominator of the yield calculation.

$$Y = \frac{m_f}{m_i} \times 100\%$$

10. QUALITY CONTROL

10.1 REPIPETTOR CALIBRATION

The re-pipette dispenser is checked monthly, before use, by dispensing a 10mL aliquot of scintillation cocktail into a 10mL graduated cylinder. The volume should be 10mL +/- 0.1mL; if not, adjust the dispenser and re-check. Record the calibration check in the pipette calibration logbook (Form 311).

10.2 EFFICIENCY CALIBRATION

10.2.1 **A one-point calibration source is conducted as follows:** Prepare six blank samples (three for spikes and three for blanks) as described in Sections 8.1 and 8.3, without spiking samples (no ICP recovery is necessary for these). Spike three empty LSC vials with a NIST traceable Ni standard. The spiking level should be 6-10 times the standard MDC. Dry down the vials slowly on a hotplate. Using a calibrated pipette (SOP 321), add 5mL of the prepared blank solution to each vial. Add 15mL UG LLTTM scintillation cocktail to bring the vials to a standard geometry. **The average efficiency is calculated as described below.**

A one-point efficiency is highly accurate and will be used for the calculation of all results showing QIP results corresponding to the average observed for the calibration standard (within +/- 10% relative efficiency or lacking this calibrated range, +/- 15 of mean H-numbers). Any sample falling outside this range will be calibrated by sample specific addition of a minimum known volume (<200μL) of NIST traceable Ni spiking solution. The efficiency from sample specific standard additions is calculated as defined in Section 9.3.

10.2.2 **Background calibration (reagent blank):** An aliquot of 0.67N HNO_3 equivalent to the calibration geometry is transferred to a scintillation vial independent of the preparation process and cocktail added such that the calibration geometry is reproduced. One calibration blank is submitted for each preparation batch and counted for a time period equal to or longer than the longest sample count. For samples counted in the default calibration geometry (5mL water + 15mL cocktail), cpm results (as well as blank ID, batch, and QIP result) of the calibration blank count are entered into a spreadsheet which tracks the running mean of the last seven calibration blanks, and compares each blank to historical control limits established from the first 20 data points in the population (+/- 3 sigma). The current running mean of the calibration blank cpm is used as the background in the calculation of associated results for the associated prep batch.

10.3 BATCH QC PREPARATION

Acceptance criteria for QC samples may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.3.1 A blank, prepared in 300mL of DI water for aqueous samples, and an empty centrifuge tube for solid samples, must be analyzed with each batch of 20 or fewer field samples (i.e., at a five percent frequency).

10.3.2 One blank spike (LCS), prepared in 300mL of DI water for aqueous samples, and an empty centrifuge tube for solid samples, must be analyzed with each batch of 20 or fewer field samples (i.e., at a 5 percent frequency). The spiking level for LCSs should be at least 4-10 times the requested MDA, or 50-100 pCi, whichever is larger.

10.3.3 Duplicate sample analyses will be performed at a minimum frequency of ten percent. If there is insufficient sample volume for this frequency of duplicates, LCS duplicates may serve as a measure of batch reproducibility.

11. DEVIATIONS FROM METHOD

11.1 A procedure for chemical recovery determination by ICP measurement has been added to the method.

11.2 A procedure for the digestion and subsequent analysis of solid samples using Ni resin has been added to the method.

11.3 The Eichrom^{TM} Ni resin method states that the critical pH for loading samples onto the column is 8-9. It has been determined experimentally that this range is not high enough. The critical pH has been changed to 9-11.

12. SAFETY, HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Safety glasses, lab coats and gloves should be worn in the laboratory at all times.

12.1.2 Use care when handling mineral acids (e.g. HNO_3, H_2SO_4). Work only in a fume hood with adequate ventilation and wear appropriate eye, face, and body protection.

12.2 WASTE DISPOSAL

12.2.1 A SAA container is available for disposal of sample remainders after the aliquot has been removed for analysis.

12.2.2 Other process waste, as indicated in Section 8, may be discarded into the laboratory wastewater treatment facility.

STANDARD OPERATING PROCEDURE 776 REVISION 11

TITLE: PREPARATION OF WATER SAMPLES FOR ACTINIDES

FORMS: 631, 719 ~~(use current iteration)~~

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/7/07

LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, PCN #504, 7/10/95; Rev1, PCN #533, 9/28/95; Rev2, 9/9/97; Rev3, 4/30/98; Rev4, 3/24/00; Rev5, 10/19/00; Rev6, 10/24/01; Rev7, 4/29/02; Rev8, 4/4/03; Rev9, 1/31/05; Rev10, 9/8/06; Rev11, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes procedures for preparation of environmental and drinking waters for analysis of actinides. The SOP is based on EPA Method 908.0 for the preparation of waters for the separation of uranium. This SOP addresses only the initial concentration steps and is applicable to uranium, plutonium, thorium, americium, and curium.

2. SUMMARY

The water sample is made acidic by adding HCl and the sample is boiled to eliminate carbonate and bicarbonate ions. The actinides are co-precipitated with ferric hydroxide and separated from the sample. Once the hydroxide precipitate is centrifuged and the supernatant decanted as waste, further steps are performed per the appropriate actinide separation and purification SOPs 765, 777, 778 or 782. Please note that procedures for tracing and spiking samples are found in SOP 766.

3. RESPONSIBILITIES

3.1 It is the responsibility of the laboratory staff to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, performance of precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard

criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 The presence of significant quantities of suspended solids is a physical interference. Samples containing perceptible quantities of suspended solids are filtered prior to initiation of preparation and analysis. If the sample needs to be analyzed including sediments, a modified procedure should be followed. This modified procedure will involve a soil digestion procedure to accommodate the sediment portion of the liquid.

4.2 The presence of significant quantities of carbonate (or bicarbonate) may complex uranium and interfere with the chemical exchange and co-precipitation steps. The routine addition of acid to samples followed by boiling should purge carbonates from the sample and address the interference.

5. APPARATUS AND MATERIALS

5.1 Pyrex™ beakers, 400mL and 1500mL - 2000mL or other appropriate size

5.2 Watch glasses

5.3 Stirring hot plates

5.4 Graduated cylinder, 1.0L

5.5 Stir bars

5.6 Centrifuge bottles, 250mL

5.7 Wash bottles

5.8 Repeator Eppendorf™ pipet or equivalent and disposable pipet tips

5.9 pH paper, acidic

5.10 Muffle furnace

6. REAGENTS

NOTE: Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

6.1 Deionized (DI) water, obtained from the laboratory's deionized water system.

6.2 Nitric Acid (HNO_3), conc., reagent grade.

6.3 Ammonium hydroxide (NH_4OH), 15N, (conc.). TLV = 25ppm (for NH_3)

6.4 Ferric chloride carrier, 20mg Fe^{+3}/mL HCl. Made in-house by dissolving 96g $FeCl_3 \bullet 6H_2O$ per 1000mL of 0.5N

6.5 Hydrochloric acid (HCl), 12N, (conc.), specific gravity 1.19, 37.2%, reagent grade. TLV = 5ppm (ceiling)

6.6 Actinides Tracer and Spike Solutions. High purity, NIST-traceable or equivalent, approximately 10-30dpm/mL activity (unless otherwise specified). A second source for tracer and/or spiking solutions should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification). Tracer and spiking nuclide defaults are as follows:

6.6.1 For Pu-239/240, Pu-238 Tracer = Pu-242, Spike = Pu-239

6.6.2 For U-238, U-235/236, U-233/234, Tracer = U232, Spike = Nat-U

6.6.3 For Am-241, Tracer = Am-243 or Cm-244, Spike = Am-241

6.6.4 For Th-232, Th-230, Th-228, Tracer = Th-229 Spike = Th-230

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

It is recommended that samples be preserved at the time of collection by adding enough 1N HNO_3 to adjust the pH of the sample to less than 2. Addition of 5mL conc. HNO_3 per liter of sample is usually sufficient. If samples are to be collected without preservation, they should be brought to the laboratory within 5 days of collection and then preserved and held in the original container for a minimum of 24hrs before analysis or transfer of the sample from the original container (SOP 733). The container should preferably be plastic rather than glass. This prevents loss due to breakage during transport and handling and minimizes any possible losses due to analyte plate out on container walls.

8. PROCEDURE

8.1 DISSOLVED ANALYSIS

8.1.1 Before starting the procedure, check the pH of the sample. If the sample is unpreserved, add 5mL concentrated HNO_3 or enough to make the sample pH<2.

If the sample was not preserved, hold sample for 24 hours before aliquotting (refer to SOP 733 for sample preservation procedure).

If significant solids are present, filter the sample through a fluted qualitative filter paper (refer to SOP 721).

8.1.2 Aliquot 1.0L of sample (or appropriate volume adjusted to reach MDA or account for sample activity) into a Pyrex™ beaker. Record the volume of each sample on the benchsheet.

8.1.3 Consult the benchsheet for information about the volume, activity and standard identification to be used for tracing and spiking. Add calibrated volumes of tracer and spike solutions to the samples, blank and blank spike per SOP 766.

NOTE: It is important protocol to always add QC spikes *before* any chemical treatments applied during sample processing.

8.1.4 Add 5mL 12N HCl.

8.1.5 Using a repeater pipet (verify pipet per SOP 321), add 2mL of ferric chloride carrier.

8.1.6 Place a stir bar in each beaker, cover with a watch glass and set each sample on a hotplate. Stir and heat the water sample to boiling. When samples begin to boil, turn heat down to just maintain boiling temperature. Boil for 30 minutes.

8.1.7 After boiling sample for 30 minutes, turn hotplate heat setting to off and allow samples to stir and cool for 15-20 minutes.

8.1.8 After sample has sufficiently cooled, slowly add concentrated NH_4OH (carbonate free) to the sample. Add NH_4OH until the $Fe(OH)_3$ precipitate forms and turbidity persists while stirring continues. Then add an additional 10mL of NH_4OH. Turn the stir mechanism off and remove stir bar. Allow precipitate to settle to the bottom of the beaker for 15-20 minutes.

8.1.9 After the precipitate has settled, decant the aqueous portion away from the precipitate. Reduce the volume to approximately 200mL or less with **minimal** loss of precipitate. If this cannot be accomplished without significant loss of precipitate, the option is to perform multiple centrifugations to separate the supernatant from the precipitate. The aqueous portion of the sample can be discharged to Paragon's wastewater system (i.e., disposed down the drain in the fume hood with

large amounts of water).

8.1.10 Transfer the remaining solution containing the precipitate to a labeled 250mL centrifuge bottle.

8.1.11 Rinse the sample beaker with a **minimum amount of deionized** water and add the rinse to the centrifuge bottle.

8.1.12 Centrifuge the samples at approximately 3500rpm for 15 minutes. Discard the supernatant down the drain with large amounts of cold water unless otherwise specified due to hazardous or radioactive waste concerns.

8.1.13 Proceed to the appropriate separation and purification procedure, SOP 765, 777, 782 or 778.

8.2 TOTAL ANALYSIS

8.2.1 Before starting the procedure, check the pH of the sample. If the sample is unpreserved, add 5mL concentrated HNO_3 or enough to make the sample pH<2 and hold for 16 hours. Refer to SOP 733 for sample preservation procedure.

8.2.2 Shake the sample container to homogenize and mix the sediment and measure a volume of one liter (or other appropriate volume to reach requested detection limits) of the water sample to be analyzed. Record the volume on the benchsheet.

8.2.3 Consult the benchsheet for information about the volume, activity and standard identification to be used for tracing and spiking. Add calibrated volumes of tracer and spike solutions to the samples, blank and blank spike as per SOP 766.

8.2.4 Heat the sample on a hot plate at a low temperature and take it to near dryness. Transfer the sample into a 400mL Pyrex™ glass beaker using 8N HNO_3. Heat the sample to dryness.

8.2.5 If the sediment portion contains any organic material, the samples should be muffled. If muffling is required, cover the sample with a ribbed watch glass and muffle the sample at approximately 600°C for at least 4 hours.

8.2.6 From this point, follow the soil digestion procedure outlined in SOP 773. Following solid digestion, refer to the appropriate actinides separation SOPs (765, 777, 778, or 782) for further separation.

9. CALCULATIONS

TPU FACTORS. As defined in SOP 708, the 1σ preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU).

10. CALIBRATION STANDARDS

Calibration standards are not required for this procedure.

11. QUALITY CONTROL

11.1 A method blank, utilizing one liter of DI water, is prepared with each batch of up to 20 field samples (i.e., at a five-percent frequency).

11.2 One laboratory control sample (LCS or blank spike), prepared in one liter of DI water, is prepared with each batch of up to 20 field samples (i.e., at a five-percent frequency). Consult the Spike/Tracer Data Sheet Table for identification and volume of spiking standard.

11.3 Duplicate sample analyses are prepared at a minimum frequency of ten-percent, with at least one duplicate for each batch. If there is insufficient sample volume for this frequency of duplicates, a blank spike duplicate may serve as a measure of batch reproducibility.

12. DEVIATIONS FROM METHOD

12.1 This method has been modified from EPA Method 908.0 to enable determination of total uranium concentration of the sample by alpha spectroscopy. A known quantity of Uranium-232 tracer is equilibrated with the sample prior to separation. The tracer activity is used to calculate the concentration of uranium isotopes in the sample. The total uranium concentration is calculated as the sum of the U-234/235/238 activities.

12.2 Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of the lab's internally derived acceptance criteria.

13. SAFETY, HAZARDS AND WASTE DISPOSAL

13.1 SAFETY AND HAZARDS

13.1.1 Read the MSDSS prior to preparing standards or using any solvents or reagents for the first time.

13.1.2 Wear gloves, safety glasses, and lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

13.1.3 Care must be used during handling of mineral acids (e.g., HCl) and

caustic solutions (e.g., ammonium hydroxide). Proper hand, body and face protection shall be worn and operations carried out in a fume hood with adequate ventilation.

13.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

13.1.5 Any non original containers may be used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health ,Flammability, and Reactivity ratings, and date.

13.2 WASTE DISPOSAL

The water actinide preparation process has been determined to not be hazardous, other than corrosivity. This material may be discharged into the Paragon waste tanks. Here the solution will be neutralized prior to discharge and the activity will be monitored to ensure compliance with Colorado Rules and Regulations pertaining to Radiation Control Part 4 regarding discharges to sanitary sewers.

14.2 TLVs and BEIs, ACGIH, 1999, Cincinnati, OH.

DOCUMENT REVISION HISTORY

9/11/06: No technical changes, minor clerical corrections made. Augmented LIMS program specification language. Added DOCUMENT REVISION HISTORY section. Attached Forms.

8/31/07: Clarified use of second independent source for spiking (SECTION 6), clarified order (switched 8.1.3 and 8.1.4) and added note that it is important protocol to add spikes before any chemical processing. Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Sections 7 and 8.1. Removed activity calculations from SECTION 9 and referenced SOP 708 instead.

STANDARD OPERATING PROCEDURE 777 REVISION 9

TITLE: **ACTINIDES -- THORIUM AND PLUTONIUM SEQUENTIAL SEPARATION BY ANION EXCHANGE**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07
QUALITY ASSURANCE MANAGER _____ DATE 9/3/07
LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, 7/10/95; Rev1, PCN #534, 9/08/95; Rev2, 5/22/97; Rev3, 10/02/00; Rev4, 12/10/01; Rev5, 3/11/02; Rev6, 4/10/02; Rev7, 4/07/03; Rev8, 3/15/05; Rev9, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the sequential separation and purification of thorium (Th) and/or plutonium (Pu), including ^{241}Pu, using anion exchange chromatography for quantification by alpha spectroscopy. Before using this procedure, an aqueous or solid sample must be prepared as described in one of the appropriate sample preparation SOPs.

2. SUMMARY

2.1 The ferric hydroxide precipitate (from previous dissolution SOPs) is dissolved in either hydrochloric acid or nitric acid depending on the column to be used. The sample solution is passed through a column containing anion exchange resin that is pre-equilibrated in either 9M HCl or 8M HNO_3. If Th and Pu are run sequentially or only Pu is being analyzed, a chloride column is utilized, followed by a nitrate column. If only Th is needed, a nitrate column can be used without the further purification provided by a chloride column (please see Section 4.3, for further discussion). The chloride column does not reatain Th, which passes directly through the column when the sample is loaded. Pu is retained on a chloride column and is selectively stripped with an HCl/NH_4I solution. Th and Pu are retained on a nitrate column while other sample constituents pass through. The resin is rinsed with 8M HNO_3 to complete the isolation of Th and Pu from the sample solution. The Th and Pu remain on the column, and other interferents are discarded with the rinsate.

2.2 After loading on the nitrate column, Th is selectively stripped by rinsing with 9M HCl. Finally, Pu is stripped from the column by rinsing with 0.5M HCl. The purified Th and Pu are co-precipitated with lanthanum fluoride and mounted on a filter membrane for quantification by alpha spectroscopy. Either of the two elements, Pu or Th, can be isolated using this procedure. If ^{241}Pu is being analyzed, the Pu filters can be removed from their planchets, after performing the

^{242}Pu yield determination by alpha spectroscopy, and placed into a liquid scintillation vial with 0.1M HCl and Ultima Gold™ LLT cocktail and counted for beta-emitting ^{241}Pu. When spiking samples for ^{241}Pu, it is important to note that the detection limit is significantly higher for liquid scintillation counting than for alpha spec. Therefore, the spiking level should be much higher (about 500dpm vs. 10dpm). Consult the Instrument Lab for appropriate spiking levels, if necessary. If a particular element (Th or Pu) is not an analyte of interest, the column eluate (strip solution) is discarded as lab waste, rather than collected for analysis, at that step of the procedure.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of supervisory training and review, the performance of precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Pu can exist in several different oxidation states in aqueous solutions. Pu must be present as Pu(IV) to be successfully purified by anion exchange chromatography, as described in this procedure. It is therefore essential that as little time as

possible elapse between the addition of $NaNO_2$ (in dissolution/concentration procedures) and completion of the anion exchange process.

4.2 In 8M HNO_3, Th and Pu(IV) form negatively charged complexes (anions) with NO^{3-} ions. Therefore, in 8M HNO_3, Th and Pu(IV) are retained by the anion exchange resin. In 9M HCl, Pu(IV) forms negatively charged complexes with Cl^- ions but Th does not. Hence, when the anion exchange column is washed with 9M HCl, Pu is retained by the resin and Th elutes.

4.3 In some cases, sample matrix constituents may interfere with the complete purification of Th on a single nitrate column. At the analyst's discretion, both the chloride and nitrate columns may be run, as if a Th/Pu sequential analysis were being performed. In this case, the chloride column may remove significant interferences to the nitrate column separation technique. No plutonium fraction is collected and the chloride column feed solution effluent and subsequent rinses are collected for further nitrate column purification.

4.4 The presence of lanthanides could be a significant interference in the analysis of Th, which is not addressed in the routine separation process. Lanthanides are stripped from the column along with the Th fraction. During micro-precipitation these lanthanides that are native to the sample are combined with the lanthanum carrier added as a reagent and an excessive amount of lanthanide-fluoride precipitate is formed and deposited on the filter membrane. This excessive precipitate may cause a "mass attenuation" problem in the spectrum, which significantly degrades spectral resolution. If the sample has significant lanthanides present, the Th fraction must be further purified as described in Section 8.3 below.

4.5 In some cases, the sequential separation of Pu and Am is desirable. When ^{241}Pu is one of the Pu analytes of interest, however, caution must be used in the creation of the batch LCS samples. Plutionium-241 is a beta-emitting radionuclide that produces ^{241}Am as the first daughter product. Consequently, the ^{241}Pu spiking solution contains significant ^{241}Am activity, which will confound the accurate quantification of ^{241}Am in the LCS. The most convenient approach, when creating batch LCSs in a sequential Pu/Am analysis where ^{241}Pu is also required, is to create the Pu and Am LCSs separately. Create a single Am LCS, traced with ^{243}Am and spiked with ^{241}Am, and a single Pu LCS, traced with ^{242}Pu and spiked with <u>both</u> ^{239}Pu and ^{241}Pu. Other tracing and spiking schemes may be acceptable, with supervisory approval.

5. APPARATUS AND MATERIALS

5.1 Ion exchange columns, plastic, disposable, Environmental Express™ R1020 or equivalent

5.2 Filter paper, Whatman™ 41 or equivalent

5.3 Fitted funnel, disposable

5.4 Plastic funnel

5.5 Glass beads, 3mm diameter

5.6 Suction filter apparatus, polysulfone filter holder and funnel, 25mm, or equivalent

5.7 Membrane filter, 0.1µm pore size, 25mm

5.8 Cupped planchets, stainless steel, 32mm diameter

5.9 Heat lamp

5.10 Pipettors, Eppendorf™ or equivalent

5.11 Wash bottles

5.12 Graduated cylinder, plastic, 25mL

5.13 Vortex mixer

5.14 Centrifuge bottles, 250mL disposable, conical

5.15 Hot plate

5.16 Steam bath

5.17 Forceps, fine tipped

5.18 Tape, double-sided

5.19 pH paper

5.20 Scintillation vials, glass

5.21 Kimwipes™

5.22 Plastic cups, disposable, 220mL

6. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a Threshold Limit Value (TLV) of less than 50 ppm, shall be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Ammonium Iodide, NH_4I, reagent grade. TLV = 25 ppm (TWA, as NH_4; STEL = 35 ppm). Irritant.

6.2 Nitric acid, HNO_3, 8M: Cautiously add 500mL conc. reagent grade HNO_3 to 400mL DI water. Dilute to 1L with DI water. TLV = 2 ppm (TWA, conc. HNO_3). Irritant, corrosive.

6.3 Nitric acid, HNO_3, 3M: Cautiously add 190mL of conc. HNO_3 to approximately 600mL DI water and dilute to 1L. See 6.2 above for TLV.

6.4 HCl/NH_4I Reagent: Dissolve 0.73g of NH_4I (reagent grade) in 100mL of 9M HCl. ***MAKE FRESH DAILY.***

6.5 Hydrochloric acid, HCl, concentrated. TLV = 5 ppm. Irritant, corrosive.

6.6 9M HCl: Cautiously add 750mL conc. reagent grade HCl to 100mL DI water. Dilute to 1L with DI water. See 6.5 above for TLV.

6.7 6N HCl: Cautiously add 500mL conc. reagent grade HCl to 400mL DI water. Dilute to 1L with DI water. See 6.5 above for TLV.

6.8 1M HCl: Cautiously add 83mL conc. reagent grade HCl to 800mL DI water. Dilute to 1L with DI water. See 6.5 above for TLV.

6.9 0.1M HCl: Cautiously add 8.3mL of conc. reagent grade HCl to 900mL DI water. Dilute to 1L with DI water. See 6.5 above for TLV.

6.10 0.5M HCl: Cautiously add 42mL conc. reagent grade HCl to 800mL DI water. Dilute to 1L with DI water. See 6.5 above for TLV.

6.11 Hydrofluoric acid, HF, 3M: Dilute 104mL conc. reagent grade HF to 1L with DI water. Use plastic graduated cylinder and storage bottle. TLV = 3 ppm (ceiling, conc. HF). Irritant, burns, bone, teeth, fluorosis.

6.12 Hydrogen peroxide, H_2O_2, 30% reagent grade. TLV = 1 ppm. Potential carcinogen, irritation, pulmonary edema, central nervous system effects.

6.13 Anion exchange resin, 1X8 Eichrom™ resin or equivalent.

6.14 Lanthanum carrier, 0.1 mg La^{3+}/mL: Dissolve 0.078 g high purity $La(NO_3)_3 \bullet 6H_2O$ in 250mL of 1M HCl.

6.15 Polyethylene glycol, average molecular weight of 2000 g/mole (0.25 M): Dissolve 50 g in 40mL DI water and dilute to 10 0mL with DI water.

6.16 Sodium nitrite, $NaNO_2$, saturated: Dissolve 85 g of $NaNO_2$ in 100mL of DI water. MAKE FRESH DAILY.

6.17 Ultima Gold™ LLT cocktail.

6.18 Methanol, reagent grade. TLV = 200 ppm. Neuropathy, vision, central nervous system effects.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

Not applicable for this procedure. See the appropriate sample preparation SOP.

8. PROCEDURE

8.1 PURIFICATION BY ANION EXCHANGE-CHLORIDE COLUMN

8.1.1 **NOTE:** If analyzing for Th only, skip this Section and proceed to Section 8.2.1 of this SOP. Estimate the volume of the ferric hydroxide precipitate in the bottom of the conical 250mL centrifuge bottle. To dissolve the precipitate, add three times the volume of conc. HCl and mix by vortexing. Add 50mL of 9M HCl to assist in solubilizing any salts that may be present. Final volume depends on the amount of ferric hydroxide precipitate.

8.1.2 Sodium nitrite must be added to the sample prior to loading the sample on the column. The column separation must then be carried out on the same day. Add 3 drops of sodium nitrite to each sample.

8.1.3 Sample matrix constituents such as silicates may cause a cloudy or foamy appearance when the samples are dissolved in HCl. Samples may be compared with the QC samples of that batch for differences in appearance. If samples are noticeably different from the batch quality control (QC) samples, a polyethylene glycol (PEG) treatment may be conducted as explained in Section 8.1.4 to keep the sample constituents from blocking column flow. Perform this treatment on the QC samples as well. If samples are clear, proceed to Section 8.1.5.

8.1.4 PEG Treatment: Add 3mL of 0.25M polyethylene glycol to the sample. Vortex to mix and place samples in a cooler for ~30 minutes. The silicates will be trapped by the chelating action of the PEG and will slowly settle as a glassy precipitate at the bottom of the centrifuge bottle. Centrifuge the sample for 5 minutes at a 3500 rpm setting.

8.1.5 Precondition the frit of a disposable plastic column (approximately 15 mm I.D., 18mL capacity) with methanol up to the 1 cm line. Using a wash bottle, fill the column with a slurry (resin/DI water) of AG 1x8 anion exchange resin to a settled depth of approximately 7 cm. Cover the top of the resin bed with glass beads to a depth of approximately 2 cm to hold the resin in place.

8.1.6 Place a fitted plastic funnel on top of the ion exchange column. Place a regular funnel on the top of the fitted funnel. Fold a Whatman™ 41 filter paper and place it inside the funnel. Wet the filter paper with 9M HCl.

8.1.7 Condition the resin with 50 mL of 9M HCl. Discard the effluent down the back of the hood (discharges into Paragon's wastewater treatment system) followed with plenty of cold water.

8.1.8 If Th analysis is required, place a clean specimen cup, labeled with the sample ID and "Th", under the column. If Th analysis is not required place an empty waste collection cup under the column.

8.1.9 Load the sample solution onto the column through the filter. If the volume is more than 100 mL, pour the sample into the filter in portions until the entire solution has passed through the filter and the resin bed. If analyzing for Th, collect the effluent and the subsequent rinses in a clean, labeled cup. If not analyzing for Th, discard the column effluent and rinses into the appropriate waste container.

8.1.10 Rinse the centrifuge bottle two times with 20 mL volumes of 9M HCl. Add the first rinse to the filter (and column). Allow the first rinse to pass completely through the column before adding the second rinse. After the second rinse has passed through the column, discard the filter. Dry the filter on a tray and dispose of it in the contaminated soils and solids bucket.

8.1.11 Rinse the column with six additional 20mL volumes of 9M HCl. An additional 220 mL cup may be necessary to collect all of the rinses. This cup should also be labeled with the complete sample ID and "Th". The cups can be designated "A" and "B". Heat the cups containing the Th fraction on a steam bath until the volume is reduced enough to allow the sample to fit into one cup. Quantitatively transfer the sample solution, using 9M HCl to rinse, into one cup. Continue heating on a steam bath until dry. If Th is not to be analyzed, the effluent may be discarded as waste (i.e., down the drain with plenty of cold water).

8.1.12 To strip the Pu from the column, rinse the column with three 20mL portions of HCl/NH_4I reagent. (Allow each rinse to pass completely through the column before adding the next). Collect the effluent from these rinses in a clean 220 mL cup labeled with the sample ID and "Pu".

8.1.13 Add 10mL of conc. HNO_3 to the Pu fraction and take to dryness on a steam bath.

8.1.14 Used resin columns are treated and disposed, as described in Section 8.2.11.

8.1.15 Once the Th and Pu fractions have gone to complete dryness, dissolve the residue in 1mL of concentrated nitric acid. Add 50mL of 8M HNO_3 and 3 drops of sodium nitrite to the Pu fraction. The Th and Pu fractions will be further purified on separate nitrate columns. Proceed to Section 8.2.3.

8.2 PURIFICATION BY ANION EXCHANGE-NITRATE COLUMN

8.2.1 If analyzing for Th only, a chloride column is not usually necessary (please see section 4.3 for further discussion). The Th will be sufficiently isolated by using a nitrate column only. Estimate the volume of the ferric hydroxide precipitate in the bottom of the conical 250 mL centrifuge bottle that was produced in the previous prep SOP. To dissolve the precipitate, add an equal volume of concentrated nitric acid and mix by vortexing. Add 50mL of 8M HNO_3 to bring the solution to volume.

8.2.2 If analyzing for Th only, sample matrix constituents such as silicates may cause a cloudy or foamy appearance when the samples are dissolved in HNO_3. Samples may be compared with the QC samples of that batch for differences in appearance. If samples are noticeably different from the batch QC, a PEG treatment may be conducted as explained in Section 8.1.4 above to keep the sample constituents from blocking column flow. Perform this treatment on the QC samples as well. If samples are clear, proceed to Section 8.2.3.

8.2.3 Precondition the frit of a disposable plastic column (~15 mm I.D. with 18mL capacity) with methanol up to the 1 cm mark. Using a wash bottle containing a slurry of AG 1 X 8 anion exchange resin and DI water, fill the column to a settled depth of about 7 cm. Cover the top of the resin bed with glass beads to a depth of ~2 cm to hold the resin in place. Precondition the resin with 50 mL of 8M HNO_3 and discard the effluent down the back of the hood followed by plenty of water.

8.2.4 Firmly twist a fitted plastic funnel on top of the column. If samples have already gone through a chloride column, filtering is not necessary. For Th that is going on a nitrate column only, place a regular funnel on top of the fitted funnel and place a folded Whatman™ 41 filter inside. Wet the filter paper with 8M HNO_3.

8.2.5 Load the sample onto the column in portions. Rinse the cup or centrifuge bottle with 25mL of 8M HNO_3. Add this rinse to the column. Repeat this rinse. If applicable, the filter paper can be removed after the first rinse.

8.2.6 Rinse the column with a third 25mL volume of 8M HNO_3. Discard the column effluent down the drain with plenty of water unless otherwise specified.

8.2.7 Rinse the resin four times with 20mL volumes of 9M HCl. Allow each rinse to pass completely through the column before adding the next rinse. If the samples are being analyzed for thorium collect the column effluent in a 220 mL plastic disposable beaker, or other suitable

container, labeled with the sample ID and the symbol "Th". Dispose of this fraction down the drain followed with plenty of water if Th is not needed.

8.2.8 Heat the solution, containing the Th, to dryness on a steam bath. If lanthanides are present in the Th fraction, follow the procedure explained under Section 8.3 below, otherwise, the Th fraction can be taken to microprecipitation.

8.2.9 If analyzing for plutonium, strip the Pu by rinsing the resin three times with 20mL volumes of 0.5N HCl. Allow each rinse to pass completely through the column before adding the next. Collect the column effluent in a 220mL plastic disposable container, or other suitable container, labeled with the sample ID and the symbol "Pu".

8.2.10 Take the solution to dryness by heating on a steam bath. This sample fraction is now ready for Pu microprecipitation.

8.2.11 Used Resin columns are discarded by extruding the resin from the column and placing the resin in the established waste stream labeled "Hazardous Waste - Used Acidic Resin" in the Satellite Accumulation Area in the lab. When the satellite container is full, notify the site Waste Compliance Officer for further instructions. Emptied columns may be soaked in a RadiacWash™ solution, rinsed in tap water and discarded into the sanitary trash.

8.2.12 Used disposable cups may be rinsed with RadiacWash™ solution and tap water and re-used for collecting waste column effluent. If the cups are not needed they may be soaked in RadiacWash™, rinsed with tap water and discarded into the sanitary trash.

8.3 PROCEDURE TO CLEAN UP LANTHANIDES FROM THORIUM

8.3.1 The Th fraction from Step 8.2.8 is dissolved in 10mL of 3N nitric acid.

8.3.2 Prepare TEVA resin column: Fill disposable Bio-Rad™ ion exchange column to the 1.6mL mark. The TEVA resin is transferred into the column as a slurry with water. A layer of clean silica sand is placed on top of the resin bed to keep the resin in place.

8.3.3 Condition the TEVA column with 10mL of 3N nitric acid.

8.3.4 Transfer the sample solution onto the TEVA column using a transfer pipette. Wait until the entire sample has passed through the column before proceeding to the next step.

8.3.5 Rinse the sample cup with 5mL of 3N nitric acid and pass that solution through the TEVA column.

8.3.6 Repeat the preceding step one more time.

8.3.7 Replace the waste collection cup with a clean, labeled cup in order to strip the Th fraction. The cup should be labeled with the sample ID and "Th micro".

8.3.8 Strip Th from the column using three 5mL (15mL total) rinses of 9N HCl.

8.3.9 Add 5mL of 6N HCL to the column to strip any remaining Th from the column and collect it in the same cup.

8.3.10 Heat the Th fraction on the steam bath and take it to dryness. After drying the sample, proceed with Th microprecipitation.

8.4 THORIUM MICRO-PRECIPITATION

8.4.1 Add 1.0mL of concentrated HCl to the sample beaker labeled Th (from Step 8.2.8 or 8.3.10). Mix well to resolubilize the dried sample.

8.4.2 The plastic cup may be placed on a steam bath for about five minutes to aid dissolution. However, do not let the sample go completely dry. Add 14mL of DI water and mix well

8.4.3 Add 1.0mL lanthanum carrier. Mix well. Add 5mL 3N HF. Mix well. This will co-precipitate the thorium as La(Th)F.

8.4.4 Allow sample to stand for a minimum of 15-20 minutes.

8.4.5 Place a 25mm filter membrane on the supporting screen that sits on the top of the tapered funnel stem. Lock the funnel stem with a 25mm polysulfone filter funnel using a twist lock coupling, and turn the vacuum on. Rinse with 1-2mL methanol. (This will make the filter less hydrophobic.) Rinse further with DI water. NOTE: Do not let the filter membrane go dry before pouring the sample through.

8.4.6 Using suction, filter the precipitate through the filter membrane.

8.4.7 Rinse the sample beaker once with 5mL DI water and add to the filter funnel. After the sample has passed through, rinse the filter with an additional 10-15mL of DI water.

8.4.8 After filtration, remove the funnel, then turn the vacuum off. At the technician's discretion, a "Sharpie" marker may be used to print a mark on the edge of the filter. This helps identify the right side of the filter

in case the filter is dropped while transferring it to a planchet. Mount the filter membrane, **face up**, (side with the mark) on a 32mm stainless steel cupped planchet with double-sided adhesive tape. Dry the filter membrane under the heat lamp to dry any acid residue.

8.4.9 Submit the prepared samples and the updated benchsheet to the Instrument Lab, for analysis and subsequent disposal per SOP 714.

8.5 PLUTONIUM MICRO-PRECIPITATION

8.5.1 Add 1.0mL conc. HCl to the sample beaker containing the Pu fraction (from Step 8.2.10). Mix well to solubilize the dried sample.

8.5.2 If necessary, the cup may be placed on a steam bath for five minutes or until the residue breaks up. However, do not allow the sample to go completely dry. Add 14mL of DI water and mix well.

8.5.3 Add approximately 1.0mL of H_2O_2 and swirl gently.

8.5.4 Add 1.0mL lanthanum carrier. Mix well. Add 5mL 3N HF. Mix well. This will co-precipitate the plutonium as La(Pu)F.

8.5.5 Allow sample to stand for 15-20 minutes.

8.5.6 Place a 25mm filter membrane on the support screen that sits on the top of the tapered funnel stem. Lock the funnel stem with a 25mm polysulfone filter funnel using a twist lock coupling and turn the vacuum on. Rinse with 1-2mL alcohol. (This will make the filter less hydrophobic.) Rinse further with DI water. NOTE: Do not let the filter membrane to become dry before pouring the sample through.

8.5.7 Using suction, filter the co-precipitated sample through the filter membrane.

8.5.8 Rinse the sample beaker once with 5mL DI water and add to the filter funnel. After the sample has passed through, rinse the filter with an additional 10-15mL of DI water.

8.5.9 After filtration, remove the funnel, then turn the vacuum off. At the analyst's discretion, a "Sharpie" marker may be used to print a mark on the edge of the filter. This helps identify the right side of the filter in case the filter is dropped while transferring it to a planchet. Mount the filter membrane, **face up**, (side with the mark) on a 1.25in stainless steel cupped planchet with double-sided adhesive tape. Dry the filter membrane under the heat lamp to dry any acid fumes.

8.5.10 Submit the prepared samples and the updated benchsheet to the Instrument Lab. The Instrument Lab will analyze and ultimately dispose of the planchet and filter in the manner described in SOP 714.

8.6 PREPARATION OF SAMPLES FOR β-EMITTING Pu-241 LIQUID SCINTILLATION COUNTING

8.6.1 When the Instrument Lab has completed counting the micro-precipitated Pu samples for alpha-emitting Pu and the data has been reviewed and deemed acceptable for reporting, the samples and QC will be relinquished back to the Actinides Lab.

8.6.2 Carefully remove the sample filter membrane and double-sided tape with a pair of forceps and place into a properly labeled scintillation vial.

8.6.3 Add 5mL of 0.1N HCl to the vial containing the filter to help facilitate dissolution of the LaF_3 micro-precipitate on the filter.

8.6.4 Add 15mL of Ultima Gold™ LLT cocktail. Cap the vials tightly and invert several times to homogenize. Wipe the vials clean with a Kimwipe and methanol. Submit the vials and a ^{241}Pu liquid scintillation benchsheet to the Instrument Lab for analysis. The Instrument Lab will ultimately dispose of the scintillation vials in the manner described in SOP 704.

9. QUALITY CONTROL

Not applicable for this part of the procedure. Quality control samples are prepared prior to initiation of this SOP. See the appropriate sample preparation SOP for the kinds and numbers of QC samples prepared for this analysis.

10. CALCULATIONS

TPU FACTORS. As defined in SOP 708, the following one-sigma preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU).

10.1 Water samples (that require initial prep using SOP 776) require a preparation uncertainty factor of 0.0667. This is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one tracer addition, two quantitative transfers and one reagent addition. See the following equation.

$$0.0667 = \sqrt{0.05^2 + 0.006^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2}$$

10.2 Solid samples (that require initial prep using SOP 773) require a preparation uncertainty factor of 0.0665. This is based on one gross aliquoting (sample

homogeneity), one mass measurement, one tracer addition, two quantitative transfers and one reagent addition. See the following equation.

$$0.0665 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2}$$

In practice, these two TPU factors are substantially equivalent. To simplify the data reporting procedure, the greater of the two (0.0667) may be used for both matrices.

11. DEVIATIONS FROM METHOD

This is a proprietary procedure developed by Paragon. The procedure draws upon several source methodologies. Therefore, there are no deviations from promulgated methods to be noted.

12. SAFETY HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.1.3 Gloves, safety glasses, and lab coats must be worn when working with any chemicals (e.g., standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.1.4 Any chemicals with a TLV of less than 50ppm shall be used in a laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.3 below.

12.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with the compound name, NFPA Health, Flammability and Reactivity ratings, and date.

12.1.6 Use extreme care when using hydrofluoric acid (HF). Work only in a fume hood that has adequate ventilation and personnel safety features. Never inhale or allow skin or clothing to be exposed to HF fumes. Immediately report any contact with HF to the lab Supervisor and Health & Safety Manager.

12.1.7 Care should be taken when diluting acids. **Always add acids to water, NOT water to acid.**

12.2 WASTE DISPOSAL

12.2.1 Wastes that are “corrosive only,” such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the Paragon

wastewater treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

12.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. This includes any excess HF from dissolution of samples and all solutions remaining from the micro precipitation process. Notify the Waste Compliance Officer for disposal.

12.2.3 All acid wastes not containing HF that are generated in ion exchange operations are disposed of to the waste tanks (i.e., down the drain) unless otherwise specified due to hazardous constituents.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 778 REVISION 12

TITLE: ACTINIDES – URANIUM, PLUTONIUM AND AMERICIUM/CURIUM (PARTIAL) SEQUENTIAL SEPARATION BY ION EXCHANGE

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2/28/07

QUALITY ASSURANCE MANAGER _____ DATE 2/28/07

LABORATORY MANAGER _____ DATE 3-1-07

HISTORY: Rev0, PCN #506, 7/10/95; Rev1, PCN #535, 9/28/95; Rev2, 9/25/96; Rev3, 7/14/97; Rev4, 1/26/00; Rev5, 11/2/00; Rev6, 10/24/01; Rev8, 11/8/02; Rev9, 3/6/04; Rev10, 11/29/04; Rev11, 10/5/06; Rev12, 3/1/07.

1. SCOPE AND APPLICATION

Pretreatment and digestion of solids are described in SOP 721 - Solids Preparations For Radiochemistry Analysis, and SOP 773 - Dissolution Of Solids For The Determination Of Actinides. The preparation of waters is described in SOP 776. The procedure for tracing and spiking samples is found in SOP 766. At the conclusion of the preceding pretreatment and digestion steps, uranium, americium, curium, and plutonium are co-precipitated with ferric hydroxide.

This standard operating procedure (SOP) describes the sequential separation and purification of uranium (U), plutonium (Pu), and americium (Am)/curium (Cm) using anion exchange and the mounting of uranium for quantification by alpha spectroscopy (see SOP 777 for further details regarding the purification and mounting of the Pu). Where americium analysis is required, without curium, the separation and mounting of the americium fraction collected in this procedure is found in SOP 751. Where curium analysis is required, refer to SOP 780.

2. SUMMARY

The ferric hydroxide precipitate from previous dissolution procedures is dissolved in hydrochloric acid (HCl). The sample solution is passed through a column containing anion exchange resin that is equilibrated in 9N HCl. U and Pu are retained by the resin while other sample constituents, including Am/Cm, pass through. The resin is washed with 9N HCl to complete the isolation of U and Pu from the sample matrix. Pu is selectively stripped from the column by washing with a 9N HCl/NH_4I solution. Pu may be further purified by separation on a nitrate column as described in SOP 777. Finally, U is stripped by washing the resin with 0.5N HCl. The purified U and Pu are co-precipitated with lanthanum fluoride and mounted on a filter membrane for quantification by alpha spectroscopy. Any of the elements, Am, Pu, or U, can be isolated separately

using this procedure. The final steps of collecting rinses from the column are ignored if that respective element is not to be isolated for analysis.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 as well as the LIMS program specifications related to the client, project, and test method being performed.

3.3 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of supervisory training and review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Pu can exist in several different oxidation states in aqueous solutions. Pu must be present as Pu(IV) to be successfully purified by anion exchange as described in this procedure. It is essential that as little time as possible elapse between the addition of $NaNO_2$ (in the dissolution/concentration procedures) and completion of the anion exchange process.

4.2 In 9N HCl, U and Pu(IV) form negatively charged complexes (anions) with the ion-exchange chromatography resin. Therefore, in 9N HCl, U and Pu(IV) are retained by the anion exchange resin. In 9N HCl/NH_4I, Pu(IV) is reduced to Pu(III) which does not form the anionic complex. Hence, when the anion exchange column is washed with 9N HCl/NH_4I, Pu is eluted while U is retained. The subsequent washing of the column with 0.5N HCl breaks the U chloride complex and the U elutes from the column.

4.3 Excessive amounts of iron in the sample may co-precipitate with uranium, causing high precipitate masses and poor peak resolution in the analysis. This situation is avoided by reducing the iron in the microprecipitation stage with ascorbic acid in excess.

4.4 Excessive amounts of titanium chloride in the micro-precipitation steps will contribute additional mass to the lanthanum fluoride precipitate. This, in turn, may cause significant degradation of the alpha peak resolution in the analysis.

5. APPARATUS AND MATERIALS

5.1 plastic fitted funnels, disposable, Environmental Express #R10304 or equivalent

5.2 filter paper, Whatman® 41 or equivalent

5.3 laboratory funnel, plastic

5.4 glass beads, solid, 3mm diameter

5.5 vacuum filter apparatus for 25mm membrane ("The Whale")

5.6 filter, polypropylene, Environmental Express #F250100pp or equivalent

5.7 Stainless steel cupped planchet, 32 mm diameter

5.8 pipettes, Eppendorf® or equivalent, with disposable pipet tips

5.9 centrifuge bottles, disposable, conical, 250mL

5.10 transfer pipets, disposable

5.11 ion exchange columns, disposable, Environmental Express #R10204 or equivalent

5.12 plastic cups, disposable, 220mL

5.13 double-sided tape

5.14 steam bath

5.15 hot plate

5.16 vortex mixer

5.17 centrifuge

6. REAGENTS

NOTE: Threshold Limit Value (TLV) and other hazard information may be given here. The absence of this information does not imply that the substance is not hazardous. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The employee should be familiar with all pertinent Material Safety Data Sheets (MSDSs) before proceeding.

6.1 Methanol, reagent grade. TLV=200 ppm. Neuropathy, vision, central nervous

system.

6.2 Hydrochloric acid (HCl), concentrated, 12N. TLV=5 ppm (ceiling, conc. HCL).

6.3 9N HCl: Cautiously add 1500mL conc. reagent grade HCl to 500mL DI water. TLV=5 ppm (ceiling, conc. HCL).

6.4 0.5N HCl: Cautiously add 83mL conc. reagent grade HCl to approximately 1 liter DI water, bring to a final volume of 2L with DI water. Mix thoroughly. TLV=5 ppm (ceiling, conc. HCL).

6.5 Hydrofluoric acid (HF), 3N: Dilute 104mL conc. reagent grade HF to 1L with DI water. Use plastic graduated cylinder and storage bottle. TLV=3 ppm (ceiling, conc. HF). Irritant, burns, teeth, fluorosis.

6.6 Ammonium Iodide (NH_4I), reagent grade

6.7 Titanium Chloride ($TiCl_3$), 20% solution, reagent grade

6.8 Anion exchange resin, AG 1x8, Eichrom® or equivalent

6.9 Lanthanum Carrier, 0.1mg La^{3+}/mL: Dissolve 0.312g high purity $La(NO_3)_2 \bullet 6H_2O$ in 1000mL of 1N HCl. Prepare in a 1L volumetric flask.

6.10 HCl/NH_4I Reagent: Dissolve 0.73g NH_4I, reagent grade, in 100mL 9N HCl. Make fresh daily.

6.11 Nitric Acid, HNO_3, concentrated, 16N, reagent grade. TLV=2 ppm (TWA, conc. HNO_3). Irritant, corrosive.

6.12 Nitric acid, 8N: Cautiously add 500mL conc. reagent grade HNO_3 to 400mL DI water. Dilute to 1L with DI water. See TLV information above.

6.13 Safranine-O, 1% stock solution, reagent grade

6.14 Polyethylene glycol, average molecular weight 2000 g/mole (PEG 2000), 0.25M: Dissolve 50g PEG in 40mL of DI water and dilute to 100mL with DI water.

6.15 Deionized (DI) water, generated in-house by the DI water system.

6.16 Ascorbic Acid Solution, saturated: Add just enough DI water to dissolve approximately 2 grams of ascorbic acid. MAKE FRESH DAILY.

6.17 Sodium nitrite ($NaNO_2$), saturated: Dissolve 8.5g of $NaNO_2$ in 10mL of DI water. MAKE FRESH DAILY.

6.18 Hydrogen Peroxide, H_2O_2, 30%, reagent grade. TLV=1 ppm. Potential carcinogen, irritant, pulmonary edema, central nervous system effects.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

The samples should be collected according to an approved sampling plan.

8. PROCEDURES

8.1 PURIFICATION BY ANION EXCHANGE

8.1.1 Estimate the volume of the ferric hydroxide precipitate in the bottom of the conical 250mL centrifuge bottle. To dissolve the precipitate, add three times the volume of conc. HCl and mix thoroughly. Add 50mL 9N HCl to assist in solubilizing any salts that may be present. Final volume depends on the amount of ferric hydroxide precipitate.

8.1.2 If analyzing for Pu, add 3 drops of sodium nitrite to each sample, otherwise, skip this Step.

8.1.3 Sample matrix constituents such as silicates may cause a cloudy or foamy appearance when the samples are dissolved in HCl. Samples may be compared with the quality control (QC) samples of that batch for differences in appearance. If samples are noticeably different from the batch QC, a PEG treatment may be conducted as explained in Step 8.1.4 below, to keep the sample constituents from blocking column flow. Perform this treatment on the entire batch of samples, as well as, the QC. If samples are clear, proceed to Step 8.1.5.

8.1.4 PEG Treatment: Add 3mL of 0.25M polyethylene glycol to the sample. Mix and place samples in a cooler for ~ 30 minutes. The silicates will be trapped by the chelating action of the PEG and will slowly settle as a glassy precipitate at the bottom of the centrifuge bottle. Centrifuge the sample for 5 minutes at 3500 rpm.

8.1.5 MAKING THE ION-EXCHANGE COLUMN
Assemble a column support apparatus (PVC pipe). Twist a fitted plastic funnel tightly on top of a disposable plastic column (15mm I.D., 18mL capacity) and place into the pre-drilled holes in the PVC pipe. Position a waste cup under the column. Precondition the frit of the column with methanol up to the 1cm line. Using a squeeze bottle, fill the column with a slurry of AG 1x8 anion exchange resin that is a 1:1 ratio of resin to DI water. The final settled depth should be approximately 7cm. Add a layer of ~ 1-2 cm of glass beads to hold the resin in place.

8.1.6 Place a regular funnel on the plastic fitted funnel. Fold a Whatman® 41 filter paper and place it inside the regular funnel.

8.1.7 Condition the column by adding 50mL of 9N HCl through the filter paper. The effluent may be poured down the drain in the lab hoods with plenty of cold tap water. *If Am/Cm is to be analyzed, place a clean 220 mL plastic cup labeled with the sample ID and the notation "Am" under the column.* Otherwise, the waste cups may be left in place and the collected effluent may be discarded into the appropriate waste container. Load the sample solution onto the column by pouring the sample in portions through the filter until the entire solution has passed through the filter and the resin bed.

8.1.8 Rinse the column four times with 20 mL volumes of 9N HCl. Add the first two rinses from the centrifuge bottle to the filter (and column). After the solution has passed through, remove the filter and regular funnel. Filters should be dried on a tray in the hood, scanned, and disposed of in the proper waste bucket. Allow each rinse to pass completely through the column before adding the next rinse. *If americium is to be analyzed, collect the rinses in the "Am" plastic specimen cup. Take this fraction to dryness on a steam bath and proceed to SOP 751. If curium is to be analyzed, collect the rinses in the "Am/Cm" cup, take this fraction to dryness, and proceed to SOP 780.*

8.1.9 If analyzing for Pu, rinse the column with an additional four 20mL volumes of 9N HCl, collecting the effluent into a waste cup. Discard this rinse down the drain with plenty of cold water. This rinse should wash any residual Th (which will cause an interference in the Pu spectra) in the column through the resin bed. A nitrate column will be run on all Pu samples, following the chloride column, in order to remove interfering Th.

8.1.10 Rinse the resin with three 20 mL portions of HCl/NH_4I Reagent. Allow each rinse to pass completely through the column before adding the next. If the samples are being analyzed for plutonium, collect the column effluent from these rinses in a 220mL plastic specimen cup labeled with the sample ID and the symbol "Pu".

Add 10mL of conc. HNO_3 to the Pu fraction collected from the column. Dry the Pu fraction on a steam bath. When dry, dissolve residue in 1mL of concentrated nitric acid. Add 50mL of 8N nitric acid and 3 drops of sodium nitrite. Proceed to SOP 777 Section 8.2.3.

8.1.11 If analyzing for U, rinse the column with two 20mL volumes of 9N HCl, collecting the effluent into a waste cup. Discard this rinse down the drain with plenty of water. This rinse should wash any residual NH_4I through the resin bed.

8.1.12 Strip the U by rinsing the resin with four 20mL volumes of 0.5N HCl. Collect the column effluent in a 220mL polypropylene cup, or other suitable container, labeled with the sample ID and the symbol "U". Add 2.5mL of concentrated HNO_3 and 7.5mL of concentrated HCl to the "U" fraction and take it to dryness by heating on a steam bath. Proceed to Section 8.2 below.

8.2 URANIUM MICRO-PRECIPITATION

8.2.1 In the micro-precipitation lab, add 1mL conc. HCl to the sample cup. Mix well. Let stand for 15-20 minutes to resolubilize the residue. If sample does not completely dissolve during this time, it may be necessary to place the plastic cup on a steam bath for a few minutes.

8.2.2 Add 14mL of DI water and mix well.

8.2.3 Add 1.5mL of lanthanum carrier.

8.2.4 Add ascorbic acid solution drop wise, with swirling, until any yellow color from remaining ferric iron disappears. Add approximately 1mL extra.

8.2.5 Add one drop of Safranine-O indicator solution to each sample and mix thoroughly.

8.2.6 Add approximately 0.5mL of $TiCl_3$ and swirl constantly. The solution should lose the Safranine-O color and be reasonably colorless. If the solution does not lose the Safranine-O color, up to 5 additional drops may be added while swirling until the color changes. If the solution still does not become reasonably colorless, proceed to the next step.

8.2.7 Add 5mL 3M HF. Mix well.

8.2.8 Allow sample to stand for approximately 20 minutes. If the Safranine-O color returns during this period, add up to an additional 5 drops $TiCl_3$, drop wise while swirling, until the solution again loses the Safranine-O color. If the solution does not lose the Safranine-O color, document the appearance on a Quality Assurance Summary Sheet and proceed to the next step.

8.2.9 Label planchets and petri dish with sample ID, batch ID and analyte.

8.2.10 Turn the vacuum on low (about ¼ to ½ turn). Place a 25mm filter membrane on the support screen that sits on top of the tapered funnel stem. Lock the funnel stem with a 25mm polysulfone filter funnel using a twist lock coupling. Using a squeeze bottle, thoroughly rinse the filter with methanol (this will make the filter less hydrophobic.)

Before the filter goes dry from the methanol rinse, add at least 5mL of DI water.

8.2.11 Before the water rinse completely passes the filter, transfer the coprecipitated sample to the filter apparatus.

8.2.12 After the sample passes through the filter, rinse the sample cup once with approximately 10mL of DI water and add to the filter funnel, once the sample has passed completely through the filter. After the first rinse has passed completely through the filter, rinse the sides of the funnel with approximately 10mL of DI water.

8.2.13 After filtration, keep the vacuum on and remove the funnel. A "Sharpie" marker may be used to place a dot on the outside edge of the filter. This helps identify the right side of the filter in case the filter flips during the transaction. Carefully remove the filter membrane with a pair of forceps and fix it face up on the double-sided tape that was mounted on the planchet. Dry the mounted filter membrane under a heat lamp on low setting until dry. THE FILTERS MUST BE THOROUGHLY DRY TO PREVENT DAMAGE TO THE ALPHA SPECTROMETRY DETECTORS. HOWEVER, DO NOT LEAVE THE PLANCHET UNDERNEATH THE HEAT LAMP FOR TOO LONG AS IT MIGHT DEFORM THE FILTER OR MELT THE DOUBLE SIDED TAPE.

8.2.14 Rinse the support screens with dilute RadiacWash® followed by a thorough rinse with DI water. The PVC pipe containing the sample waste must be drained into the appropriate HF waste carboy after the completion of each batch of samples to avoid overflow.

8.2.15 Used polysulfone funnels are soaked in concentrated RadiacWash®, gently cleaned with a non-abrasive sponge, soaked in a dilute RadiacWash® solution, and then rinsed thoroughly with DI water.

8.2.16 Arrange the planchets in a labeled petri dish and submit the prepared samples and the updated benchsheet to the Counting Lab. The Counting Lab will analyze and ultimately dispose of the planchets and filters in the manner described in SOP 714.

9. CALCULATIONS

TPU FACTORS. As defined in SOP 743, the following one-sigma preparation uncertainty factors should be applied during the final reporting stage of the uranium analysis as a component of the Total Propagated Uncertainty (TPUs for plutonium and americium analyses are defined in SOPs 777 and 751, respectively):

9.1 Water samples (that require initial prep using SOP 776) require a preparation uncertainty factor of 0.0711. This factor is based on one gross aliquoting (sample homogeneity), one volumetric measurement (initial aliquot), one tracer addition by pipetting, one tracer activity determination, and three quantitative transfers (hydrox. ppt. from beaker, cent. bottle to column, and from cup to filter in microppt.). See the following equation:

$$0.0711 = \sqrt{0.05^2 + 0.006^2 + 0.004^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2}$$

9.2 Solid samples (that require initial prep using SOP 773) require a preparation uncertainty factor of 0.0709. This factor is based on one gross aliquoting (sample homogeneity), one mass measurement (initial aliquot), one tracer addition by pipetting, one tracer activity determination, three quantitative transfers (digestion cup to cent. tube, tube to column, cup to filter in microppt.). See the following equation:

$$0.0709 = \sqrt{0.05^2 + 0.003^2 + 0.004^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2}$$

9.3 In practice, the water and solid sample TPU values are substantially equivalent. For simplification in reporting, the first factor of 0.0711 shall be used for both matrices.

10. QUALITY CONTROL

Refer to SOP 773 for the "Dissolution of Solids for the Determination of Actinides" and SOP 776 for the "Preparation Of Water Samples For Actinides".

11. DEVIATIONS FROM METHOD

This method is substantively compliant with ASTM method D3972 and DOE U-02 in the chemical separation, which is performed by anion exchange chromatography. The ASTM method, however, specifies electro-deposition as the technique for presenting the sample for analysis. This method uses microprecipitation, which is substantively compliant with DOE U-02 except that the DOE method uses neodymium fluoride as the precipitate, where this method uses lanthanum fluoride. The two are believed to be equivalent, particularly in light of the use of the radioactive tracers used for chemical yield determination.

12. SAFETY HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Safety glasses, lab coats and gloves must be worn when working in the radiochemistry prep. labs.

12.1.3 Any chemicals with a TLV of less than 50ppm shall be worked with in

the laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.4 below.

12.1.4 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.1.5 Use extreme care when using hydrofluoric acid (HF). Work only in a fume hood that has adequate ventilation and personnel safety features. Never inhale or allow skin or clothing to be exposed to HF fumes.

12.1.6 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.2 WASTE DISPOSAL

12.2.1 Wastes that are "corrosive only", such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into Paragon's wastewater treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) are neutralized in the waste treatment facility.

12.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. This includes any excess HF from dissolution of samples and all solutions remaining from the micro precipitation process. Notify the Waste Compliance Officer for disposal.

12.2.3 All acid wastes not containing HF that are generated in ion exchange operations are disposed of to the wastewater treatment system (i.e., down the drain with plenty of tap water) unless otherwise specified due to hazardous constituents.

DOCUMENT REVISION HISTORY

10/5/06: Deviations Section updated to discuss electro-deposition vs. microprecipitation.

3/1/07: Rev12. Added some additional detail to INTERFERENCES. Added direction to use methanolic column for Cm separations. Clarified acid additions and reagent volumes in microprecipitation, with instructions for completing QASSs. Also updated TPU factors.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 780 REVISION 8

TITLE: **ACTINIDES - AMERICIUM / CURIUM SEPARATION -- PURIFICATION BY METHANOLIC ANION EXCHANGE AND TEVA SPEC COLUMN**

FORMS: **NONE**

APPROVED BY:
TECHNICAL MANAGER Renee Hallez08 DATE 7/21/08
QUALITY ASSURANCE MANAGER Dan Schenk DATE 7/20/08
LABORATORY MANAGER K. Thiel DATE 7/21/08

HISTORY: Rev0, 11/8/95; Rev1, 4/19/96; Rev2, 5/3/96; Rev3, 1/26/00; Rev4, 10/19/00; Rev5, 3/14/02; Rev6, 4/7/03; Rev7, 7/5/06; Rev8, 7/18/08.

1. SCOPE AND APPLICATION

This procedure describes the isolation of americium (Am) and curium (Cm) in water samples, filter leachates, vegetation, and soil digestate solutions using methanolic anion exchange followed by purification using TEVA-Resin. Also described is the mounting of Am onto a filter membrane for quantification by alpha spectroscopy. Before using this procedure, an aqueous or solid sample must be prepared as described in one of the appropriate sample dissolution and ion exchange separation SOPs. The Am/Cm fraction separated from the preceding procedure should be co-precipitated with ferric hydroxide or calcium oxalate prior to separation by methanolic anion exchange.

2. SUMMARY

For normal water samples, soil samples and filter leachates, the Am/Cm fraction from previous dissolution and ion-exchange SOPs is co-precipitated as iron hydroxide and dissolved in 1N HNO_3/93% methanol solution. For soil samples with higher interference of constituents, such as iron and samples with larger aliquots, Am in the acidic solution from previous prep SOPs is precipitated with calcium oxalate. The precipitate is ignited in a muffle furnace and the ash is dissolved in 1N HNO_3/93% methanol solution. The sample solution is passed through a column containing anion exchange resin that is equilibrated in 1N HNO_3/93% methanol. Am/Cm is held by the resin while other sample constituents pass through. The resin is washed with 1N HNO_3/93% methanol to complete the isolation of Am/Cm from the sample matrix. Am/Cm is stripped from the column by washing with 8N HNO_3. The Am/Cm is further purified from interfering rare earth elements using TEVA resin. Finally, the Am/Cm is co-precipitated with lanthanum fluoride and mounted on a filter membrane for quantification by alpha spectroscopy.

NOTE: *After the methanolic anion exchange column has been prepared, the separation procedure should be carried out without interruption. In other*

words, the analyst should plan to begin the procedure early enough so that the methanolic column work can be done from start to finish in the same workday.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

The presence of Thorium in the sample may be an interference. When the aliquot size for analysis is larger than normal (default = 2g), and if the sample is a sequential analysis of Pu, U, and Am, care must be taken to remove Th from the sample. Th-228 may appear in the Am-241 Region Of Interest (ROI) and give a false positive if Th-228 is not sufficiently removed from the sample. The analyst must run a nitrate column (SOP 777), prior to running a methanolic column to remove Th if the sample is known to have elevated levels of Th activity.

5. APPARATUS AND MATERIALS

5.1 Ion exchange columns, disposable

5.2 Filter paper, Whatman™ #41 or equivalent

5.3 Filter paper, Whatman™ #42 or equivalent

5.4 Funnel, plastic

5.5 Glass beads, solid, 3mm diameter

5.6 Silica sand

5.7 Pyrex™ beaker, 250 and 600mL

5.8 Watchglasses, Pyrex™

5.9 Suction filter apparatus for 25mm membrane

5.10 Polypropylene filter membrane, 0.1 μm porosity, 25mm

5.11 Cupped planchets, stainless steel, 1.25in diameter

5.12 Drying oven, set at 105+5°C

5.13 Muffle Furnace, set at approximately 600°C

5.14 Pipets, Eppendorf™, or equivalent

5.15 Pipets, transfer, plastic

5.16 Centrifuge bottle, 250mL capacity

5.17 Centrifuge, capable of 3500rpm spin

5.18 Wash bottles

5.19 Graduated cylinder, plastic, 25mL

5.20 Polypropylene beaker, disposable, 220mL

5.21 Hot plates / magnetic stir plates

5.22 Magnetic stir bars, Teflon™-coated

5.23 Steambath

5.24 Disposable BIO-Rad® Ion exchange columns, or equivalent

5.25 SharpieTM marker, or equivalent

5.26 Double-sided tape

6. REAGENTS

Only reagent grade or better chemicals shall be used. Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents, acids).

6.1 Deionized (DI) water, obtained from the laboratory's deionized water system

6.2 HNO_3, conc. TLV = 2ppm. Irritant, corrosive.

6.3 HNO_3 8N: Dilute 500mL conc. HNO_3 with 500mL DI water. TLV = 2ppm. Irritant, corrosive.

6.4 HCl, conc. TLV = 5ppm (ceiling). Irritant, corrosive.

6.5 HCl, 2N: Dilute 150mL conc. HCl with 750mL DI water. TLV = 5ppm (ceiling). Irritant, corrosive.

6.6 Ammonium hydroxide, NH_4OH, conc. TLV = 25ppm for ammonia. Irritant.

6.7 Hydrofluoric acid, HF, 3N: Dilute 104mL conc. HF to 1L with DI water. *Use a plastic graduated cylinder and store in a plastic bottle.* TLV = 3ppm (ceiling). Irritant, bones, teeth, fluorosis.

6.8 Methanol, MeOH, 99.8%. TLV = 200ppm. Neuropathy, vision, central nervous system effects.

6.9 Formic acid, 98%. TLV= 5ppm (TWA). Irritant.

6.10 Ammonium oxalate or oxalic acid. TLV = $1mg/m^3$ (TWA for oxalic acid). Irritant, burns.

6.11 1N HNO_3/93% methanol: For 160mL of solution, dilute 10mL conc. HNO_3 with 150mL of methanol. Prepare daily as needed. TLV = 2ppm (HNO_3). Irritant, corrosive.

6.12 Ferric chloride carrier, 20mg Fe^{+3}/mL. Dissolve 96g $FeC_{l3}•6H_2O$ in one liter of 0.5N HCl. TLV = 5ppm (ceiling). Irritant, corrosive.

6.13 2M ammonium thiocyanate/0.1M formic acid, 2M NH_4SCN/0.1M HCOOH: For every 100mL of solution dissolve 15.2g NH_4SCN and 0.35mL 98% formic acid in 100mL DI water. TLV= 5ppm (TWA). Irritant.

6.14 1M ammonium thiocyanate/0.1M formic acid, 1M NH_4SCN/0.1M HCOOH: For every 100mL of solution dissolve 7.6g NH_4SCN and 0.35mL 98% formic acid in 100mL DI water. TLV= 5ppm (TWA). Irritant.

6.15 Lanthanum carrier, 0.1mg La^{+3}/mL: dissolve 0.2337g high purity $La(NO_3)_2•6H_2O$ in 250mL of 1N HCl. TLV = 5ppm (ceiling). Irritant, corrosive.

6.16 TEVA resin®, 100-150µ size

6.17 Anion exchange resin, AG 1x8, Eichrom™ or equivalent.

6.18 Calcium carrier solution, 50mg Ca/mL: Dissolve 295g $Ca(NO_3)_2•4H_2O$ in 1000mL DI water.

6.19 Methyl violet indicator, 0.02% aqueous

7. PROCEDURE

7.1 SAMPLE PRE-TREATMENT FOR SOIL/SOLID SAMPLES OF LARGE ALIQUOT SIZE

7.1.1 Sample aliquots greater than 2g and samples with excess iron may need additional pre-treatment in the form of a calcium oxalate precipitation
7.1.2 for removal of excess iron and aluminum. If a typical aliquot size was taken, interferences are not expected, proceed to Section 6.2.

7.1.3 The acidic effluent from the preceding chloride or nitrate column separation procedure should be collected in a 600mL Pyrex™ beaker. Dilute the solution by adding DI water so that the final acid concentration is less than 3N.

7.1.4 To the sample solution, add 1.0mL of Ca carrier (50mg Ca) and 5g of either ammonium oxalate or oxalic acid.

7.1.5 Place the beaker containing the sample on a magnetic stir plate. Place a magnetic stir bar in the beaker and begin agitation. Begin adding concentrated NH_4OH to the sample using a wash bottle to neutralize the acidity. Continue to add concentrated NH_4OH until a precipitate just begins to form. If reddish brown $Fe(OH)_3$ precipitate forms, add 8N HNO_3 dropwise from a wash bottle to lower the pH. At the endpoint, the sample should be cloudy with a **white calcium oxalate precipitate**.

7.1.6 At this point, add 2mL of methyl violet indicator. The solution color should be blue due to the methyl violet indicator. The exact indicator color can be obtained either by adding acid or base. NOTE: the purpose of this Step is to precipitate Am/Cm with calcium oxalate at a pH low enough that iron and aluminum stay in solution.

7.1.7 To recover the precipitate, pour the sample through a Whatman™ #42 filter paper (or equivalent). Complete the transfer by rinsing the beaker with DI water.

7.1.8 After all the solution has passed through, place the filter + precipitate in a beaker (same beaker as above can be used) and dry in a drying oven.

7.1.9 Cover the beaker containing the filter + precipitate with a Pyrex™ watch glass and place in a muffle furnace. The beaker ID must be marked permanently (ink will burn off). Record the beaker ID corresponding to the sample ID on the benchsheet. Ignite the sample by heating at approximately 600°C for at least 1 hr.

7.1.10 Allow the beaker + ash to cool. Dissolve the ash in about 3mL of conc. HNO_3. After the ash is completely dissolved, dilute the acid solution with 45mL of methanol. Proceed to Step 7.3.1.

7.2 WATER/FILTERS, AND SOIL/SOLID SAMPLES WITH STANDARD ALIQUOT SIZE

7.2.1 The acidic effluent from the preceding chloride or nitrate column separation procedure should be collected in a disposable plastic beaker. Place the container on a steam bath and take to dryness. Dissolve the residue in 5-10mL of conc. HNO_3 and add 100 to 125mL of DI water. Add 1.0mL of iron carrier to the sample solution. Transfer the solution to a 250mL centrifuge bottle. Rinse the cup with DI water and add to the centrifuge bottle. Precipitate ferric hydroxide using an excess of NH_4OH. Centrifuge at approximately 3500rpm for at least 15 minutes. Discard the supernatant.

7.2.2 Dissolve the ferric hydroxide precipitate in 3mL of conc. HNO_3. After the precipitate is completely dissolved, dilute the acid solution with 45mL of methanol and proceed to step 7.3.1. If the precipitate does not dissolve completely, add an additional volume of conc. HNO_3 and increase the volume of methanol **proportionally**. If the precipitate requires more than 9mL of conc. HNO_3 and 135mL of methanol, consult your Supervisor for alternative method to handle this situation.

7.3 ISOLATION OF Am BY METHANOLIC ANION EXCHANGE

7.3.1 Combine the needed volume of anion exchange resin with twice the volume of 1N HNO_3/93% methanol solution in a plastic bottle with a screw cap. Tighten the cap securely and let the resin condition overnight. *Do not allow the resin to be exposed to air.*

7.3.2 Pour the resin slurry into a disposable column and let settle to a resin bed height of approximately 10cm.

7.3.3 Insert a fitted plastic funnel on top of the ion exchange column. Place a layer of glass beads on top of the resin bed. **NOTE**: **Do not allow the resin to dry out at any point in the procedure.**

7.3.4 Condition the resin bed by rinsing the column with 40mL of 1 N HNO_3/93% methanol solution.

7.3.5 Load the sample solution from Step 7.1.10 or 7.2.2 onto the column through the filter. Pour the sample into the column until the entire solution has passed through the resin bed.

7.3.6 Rinse the centrifuge bottle two times with 20mL volumes of 1N HNO_3/93% methanol solution. Add the first rinse to the column. Allow the first rinse to pass completely through the column before adding the second rinse. Rinse the column with a third 20mL volume of 1N HNO_3/93% methanol solution. Discard the column effluent into the **methanolic waste receptacle**.

7.3.7 Strip Am/Cm by passing three 20mL volumes *of 8N HNO_3* through the column. Allow each rinse to drain completely before adding the next rinse. Collect the effluent in a *plastic beaker* labeled with the sample ID and "Am/Cm-TEVA". Discard the used column and resin into the resin waste receptacle.

7.3.8 Place the beaker containing the Am/Cm fraction on a steam bath and heat the solution to dryness.

7.4 PURIFICATION OF Am/Cm USING TEVA RESIN

7.4.1 Fill a BioRad® column (or equivalent) to the 1.6mL mark with a slurry of TEVA™ resin and DI water. Add a 4-5mm layer of clean silica sand to hold the resin in place.

7.4.2 Re-dissolve the sample from Step 7.3.8 in 10mL of 2M NH_4SCN/0.1M formic acid solution. Allow the sample to stand or heat briefly on the steam bath to ensure dissolution.

7.4.3 Condition a TEVA™ resin column by passing 5mL of 2M NH_4SCN/0.1M formic acid solution through it.

7.4.4 Transfer the sample solution onto the TEVA™ column in two portions using a disposable polyethylene transfer pipette. Rinse the sample container with 1mL of 2M NH_4SCN/0.1M formic acid solution. Apply the rinsate to the column. Repeat the rinse one more time with 2M NH_4SCN/0.1M formic acid solution to complete the transfer.

7.4.5 Rinse the sample cup with two 5mL volumes of 1M NH_4SCN/0.1M formic acid solution. Apply the rinsate to the TEVA™ column. Allow the first 5mL to pass through the column completely before applying the second 5mL. The purpose of this Step is to wash lanthanides from the column.

7.4.6 Strip Am/Cm from the column with three, 5mL volumes of 2N HCl. Collect the effluent from the column in a clean polypropylene beaker labeled with the sample ID and "micro for Am/Cm". Apply the 2N HCl in three 5mL portions. Allow each portion to drain completely before applying the next.

7.4.7 To decompose thiocyanate, add 2.5mL conc. HNO_3 and 7.5mL conc. HCl to the Am strip solution. Swirl gently to mix. Place the samples on a steam bath and heat until the volume is reduced to about one drop.

7.4.8 Add 5mL conc. HNO_3 to the sample from the previous Step only if any black or brown colored residue is noted and heat on the steam bath until the volume is reduced to about one drop.

7.5 AMERICIUM MICRO-PRECIPITATION

7.5.1 Add 1mL conc. HCl to the sample beaker from Step 6.4.7 or 6.4.8. Heat on the steam bath to aid in dissolution. Add 14mL DI water to the beaker.

7.5.2 Add 1.0mL lanthanum carrier. Mix well. Add 5mL 3N HF. Mix well.

7.5.3 Allow sample to stand for 30 minutes.

7.5.4 Place a 25mm filter membrane on a filter funnel assembly and turn the vacuum on. Rinse with 1-2mL methanol (this will make the filter less hydrophobic), followed by ~10mL of DI water. NOTE: *Do not let the filter become dry before pouring the sample through.*

7.5.5 Using suction, filter the co-precipitated sample through the filter membrane.

7.5.6 Rinse the sample beaker once with 5mL DI water and add to the filter funnel. After the sample has passed through, rinse the filter with an additional 10-15mL of DI water.

7.5.7 After filtration, turn the vacuum off. Remove the funnel. A "Sharpie" marker may be used to place a dot on the outside edge of the filter. This helps identify the right side of the filter in case the filter flips during the transfer. Carefully remove the filter membrane with a pair of forceps and fix it face up on the double-sided tape on a planchet. Dry the filter membrane with the planchet under a heat lamp until the filter is dry.

7.5.8 NOTE: DO NOT HEAT THE PLANCHET FOR TOO LONG - THE FILTER AND DOUBLE-SIDED TAPE MAY MELT.

7.5.9 The sample is analyzed by Alpha Spectroscopy and reported according to Paragon (PAR) SOP 714. Submit the prepared samples and the updated benchsheet to the Counting Lab. The Counting Lab will analyze and ultimately dispose of the planchet and filter in the manner described in SOP 714.

8. PREPARATION OF CALIBRATION STANDARDS

Calibration standards are not prepared for this method, however electroplated sources are purchased from an outside vendor, Isotope Products Laboratories, and used for instrument calibration. Refer to SOP 714 for calibration standards.

9. CALCULATIONS

As defined in SOP 743, the following one-sigma preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total

Propagated Uncertainty (TPU). TPU calculations for the chloride column along with soil/water preparation run previous to this method are stated in SOP 778.

9.1 Methanol columns require a preparation uncertainty factor of 0.0359. This is based on two quantitative transfer and one reagent addition. See the following equation:

$$0.0359 = \sqrt{0.025^2 + 0.025^2 + 0.006^2}$$

9.2 TEVA™ columns require a preparation uncertainty factor of 0.0257. This is based on one quantitative transfer and one reagent addition. See the following equation:

$$0.0257 = \sqrt{0.025^2 + 0.006^2}$$

9.3 Samples prepared according to SOP 778 have an additional preparation uncertainty of 0.1020 for a final TPU prep factor of 0.1111, as shown below:

$$0.1111 = \sqrt{0.0359^2 + 0.0257^2 + 0.1020^2}$$

10. QUALITY CONTROL

Acceptance criteria for QC samples and other quality indicating parameters can be found in SOP 715 and in the LIMS program specifications.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

11.1.2 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

11.1.3 Gloves, safety glasses, and lab coats must be worn when working with any chemicals (*e*.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

11.1.4 Any chemicals with a TLV of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents, acids).

11.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

11.1.6 Use extreme care when using hydrofluoric acid (HF). Work only in a fume hood that has adequate ventilation and personnel safety features. **Never inhale or allow skin or clothing to be exposed to HF fumes.**

11.1.7 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

11.2 WASTE DISPOSAL

11.2.1 Wastes that are "corrosive only", such as glacial acetic acid and sulfuric acid waste, are disposed of by discharging into the PAR waste water treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

11.2.2 Hydrofluoric acid at any concentration is collected in a labeled waste carboy. This includes any excess HF from dissolution of samples and all solutions remaining from the micro precipitation process. Notify the Waste Disposal Coordinator for disposal.

11.2.3 The methanolic effluent that is generated in the anion exchange process is collected in a labeled waste carboy. Notify the Waste Disposal Coordinator for disposal.

11.2.4 The ammonium thiocyanate effluent that is generated using TEVA^{TM} resin is collected in a labeled waste carboy. Notify the Waste Disposal Coordinator for disposal.

11.2.5 All acid wastes not containing HF, MeOH or NH_4SCN that are generated in separation operations are disposed of to the waste tanks (down the drain) unless otherwise specified due to hazardous constituents.

STANDARD OPERATING PROCEDURE 783 REVISION 8

TITLE: RADIUM-226 IN AQUEOUS AND SOIL MATRICES -- RADON EMANATION TECHNIQUE -- METHOD EPA 903.1

FORMS: 302, 631 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/4/07

LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: NEW, Rev0, 3/31/96; Rev1, 12/26/96; Rev2, 1/10/99; Rev3, 9/21/01; Rev4, 4/7/03; Rev5, 9/22/03; Rev6, 4/10/0; Rev7, 9/11/06; Rev8, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references, EPA Method 903.1, describes a procedure to determine ^{226}Ra in soil and aqueous matrices. The method is based on the emanation and scintillation counting of ^{222}Ra and progeny produced by the decay of ^{226}Ra.

Due to the potential difficulty in obtaining a complete dissolution of some solid matrices, it is recommended that ^{226}Ra in soils and solids be routinely analyzed directly by gamma spectroscopic determination of ^{214}Pb and ^{214}Bi progeny. Radon emanation in soils should be performed only at the specific request of the client.

2. SUMMARY

2.1 The ^{226}Ra in aqueous samples is concentrated and separated by coprecipitation with barium sulfate. Prior to separation, a portion of the sample is removed for inductively coupled plasma atomic emission spectrometry (ICP-AES) determination of the preparation concentration of barium in the sample. The $Ba[Ra]SO_4$ precipitate is dissolved in basic EDTA solution, placed in a 40mL VOA vial, purged of any existing ^{222}Ra, and stored to allow quantitative in-growth of ^{222}Ra. After in-growth, the radon is purged into an alpha scintillation cell. The short-lived ^{222}Ra progeny are allowed to come to equilibrium with the parent radon (~4hrs) before the scintillation cell is counted for alpha activity. The 4hr in-growth period also allows for the decay of other radon isotopes.

2.2 In solids, ^{226}Ra is liberated from the solid matrix by a total digestion of the solid. The sample is muffled, transferred to a polypropylene beaker and digested in the presence of strong acids. After digestion, the sample is transferred to a VOA vial, purged, and counted, as stated in Section 8.1.

2.3 The absolute measurement of ^{226}Ra is effected by calibrating the scintillation cell (and emanation system) with a solution of NIST-traceable ^{226}Ra. Each alpha detector/cell combination must be calibrated individually and the cell constants applied to the specific detector/cell pairs when calculating results.

2.4 The detection limit for this method is dependent upon sample aliquot, sample count time, length of the in-growth period, the scintillation system background activity, and detection efficiency. The routine minimum detectable activity (MDA) is 1.0pCi/L for aqueous samples, and 1.0pCi/g for solid samples.

2.5 As a result of fluctuation of the background due to build-up and decay of Rn and its progeny, dedicated backgrounds must be counted for each detector/cell combination prior to emanation of each sample.

2.6 The emanation apparatus is set up as shown in Figure 1.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, performance of precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 There are no known radiometric interferences to this method. Samples such as heavily sedimented samples and high brine content samples may require special treatment or a reduced aliquot prior to initiation of chemical separation procedures, as they might require more than 30mL of solvent to dissolve.

4.2 Water samples with high concentrations of sulfate-forming cations may present barium chemical recovery problems, but do not interfere with radiometric recovery in samples.

4.3 Soil samples in which visible precipitate accumulates in the bubbler during the ingrowth period may cause a low bias in the final results, as Ra-226 and the associated Rn-222 progeny may be sequestered in the precipitate and consequently be unavailable for radon emanation. Samples with visible sediment at the time of emanation require that the client be informed of the potential bias in the analytical results. Corrective action may involve either of the following options:

4.3.1 Disclose the potential bias to the analytical results in the case narrative and submit the results with that qualification.

4.3.2 Re-prepare the sample at a reduced aliquot, with a corresponding increase in detection limits. The reduced aliquot should be estimated at the sample mass that is unlikely to form precipitate in the bubbler.

4.4 Scintillation cells should be stored for at least four hours after purging with helium before background counts can be obtained. If cells are not stored for at least four hours before background counting, radon and its progeny that are not completely purged from the cell will not be in secular equilibrium and the background may be biased high, resulting in a low bias to the final analytical results.

5. APPARATUS AND MATERIALS

5.1 scalar, Ludlum Model 1000, or equivalent

5.2 photo multiplier tube, Ludlum Model 182, or equivalent

5.3 Tygon^{TM} tubing, various sizes

5.4 glass wool

5.5 gas regulator valve, 3000 PSIG, max

5.6 multi-turn needle valves, 75 PSIG, max, Cole Parmer, or equivalent

5.7 VOA vials, with septum lids, 40mL

5.8 vacuum pump, 2-Stage, GE, or equivalent

5.9 scintillation cells

5.10 stirring hotplate

5.11 laboratory balance, resolution 0.01g

5.12 centrifuge tubes

5.13 graduated cylinder, 1L

5.14 beakers, Pyrex™, 100mL and 1.5 or 2L sizes, or similar

5.15 specimen cups, polypropylene, 100mL and 250mL sizes

5.16 spatulas, plastic

5.17 test tubes, disposable, with polyethylene test tube caps, 15mL

5.18 BD™ syringe ,with luer-lock tip, or equivalent, 3mL

5.19 Deflected-point septum penetration needles

5.20 stopcocks

5.21 BD™ insulin syringe, 30 gauge x 8 mm, 0.5cc, short needle

5.22 Pipette, 1.0mL and 0.1mL sizes, with disposable pipette tips

5.23 Whatman™ filter paper, #42 (90mm), or similar

5.24 Parafilm™

5.25 stir bars

5.26 watch glasses

5.27 vortex mixer

5.28 Drierite™, or indicating desiccant, 10-20 mesh

6. REAGENTS

NOTE: TLV and other hazard information may also be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Distilled or deionized (DI) water, ASTM Type-II, or equivalent

6.2 Ascarite, drying reagent, 8-20 mesh.
TLV = 2mg/m3 = 1.22ppm (NaOH, ceiling)

6.3 Barium carrier, 16mg/mL, standardized: Dissolve 28.46g $BaCl_2 \cdot 2H_2O$ in DI water. Add 5mL 16NHNO_3 and dilute to 1000mL with DI water. See Paragon SOP 712 for standardization procedure.
TLV = 0.5mg Ba/m3 = 0.06ppm (TWA). Irritant.

6.4 EDTA reagent, basic 0.25M: Dissolve 20g NaOH in 750mL water and slowly add 93g Na2EDTA· 2H2O. Heat and stir until dissolved, filter through coarse filter paper and dilute to 1L in DI water. Adjust pH to 10 with sodium hydroxide. Irritant.

6.5 Helium, gas. Ultra high purity, 99.999%.

6.6 Hydrochloric acid (HCl), 12N, conc.
TLV = 5ppm (ceiling).

6.7 Nitric Acid (HNO_3), 16N, conc.
TLV = 2ppm (TWA). Irritant, corrosive.

6.8 ^{226}Ra standard solution, Traceable to NIST, or equivalent: Prepare stock dilution of approximately 50pCi/mL. Prepare one source for calibration purposes, and a different independent source for spiking purposes.

6.9 Sulfuric acid, 18N: Carefully add 500mL 36N H_2SO_4 to approximately 450mL of DI water. Dilute to 1L with DI water.

NOTE: A rubber apron and face shield must be worn when handling concentrated H_2SO_4. Add H_2SO_4 slowly with stirring to prevent boiling due to liberation of heat during mixing.
TLV = 1mg/m3 = 0.25ppm (TWA). Irritant.

6.10 Sulfuric acid, 0.1N: Dilute 120mL 18N H_2SO_4 to 22L with DI water.
TLV = 1 mg/m3 = 0.25ppm (TWA). Irritant.

6.11 Nitric Acid, 8N: Carefully add 500mL of concentrated HNO_3 to approximately 400mL of DI water. Then bring to 1 liter with DI water.
TLV = 2ppm (TWA). Irritant, corrosive.

6.12 ICP diluting solution: Add 10mL 16N HNO_3 and 50mL 12N HCl to approximately 500mL of DI water. Bring to 1 liter with DI water.
TLV = See Sections 6.6 and 6.7.

6.13 Hydrofluoric acid (HF), 48.0-51.0%, conc.
TLV = 3ppm (ceiling). Irritant, burns, bone, teeth, fluorosis.

NOTE: Employees must be familiar with the HF burn kit location and use before performing this procedure.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Liquids: A sample should be collected in a manner that will provide the most representative sample. Collect a 2 liter sample in a plastic container, from a free-flowing source when possible.

7.1.1 For a total sample analysis, preserve the sample with nitric acid to a pH<2.0 upon collection (15mL 1N HNO_3 / 1L H_2O). If not preserved upon collection, then the sample should be preserved within 5 days. For a total sample analysis, preserve the sample with nitric acid to a pH<2.0 upon collection (15mL 1N HNO_3 / 1L H_2O). If not preserved upon collection, then the sample should be preserved within 5 days. If preservation is delayed, hold samples for a minimum of 24 hours after preservation.

7.1.2 For a "dissolved" sample analysis, use a 0.45µm membrane filter to remove the solids from the sample. After filtering, acidify the sample with nitric acid to a pH<2.0.

7.2 Solids: Preservation is not required. A representative sample of 25-50 grams should be submitted for analysis.

8. PROCEDURE

8.1 CALIBRATION

8.1.1 BACKGROUND CALIBRATION

Prior to each sample analysis, the cell is purged with helium and stored for at least four hours. The number of background counts associated with the alpha scintillation cell is then obtained by counting the cell in the detector to be used. The background calibration must be counted for a duration equal to or longer than the planned sample count. If the sample and background count times differ (e.g. if the sample count is shorter than the background count), the number of background counts should be adjusted to match the sample count time. Record this adjustment on a Quality Assurance Summary Sheet (QASS), Form 302. The count rate of the empty cell is employed as the background count rate in calculated results.

8.1.2 PLATEAU CALIBRATION (OPERATING VOLTAGE DETERMINATION)

The purpose of the plateau calibration is to determine the optimum operating voltage for the photomultiplier tube. This optimized operating voltage minimizes the detector background, while stabilizing the counting efficiency, under normal operating conditions. Plateau calibrations must be performed prior to initial use of the instrument and at least annually, prior to the efficiency calibrations.

8.1.2.1 Adjust the voltage setting on the scalar to a low voltage of approximately 500 volts.

8.1.2.2 Count the daily check source for one minute and record the number of counts in the maintenance logbook.

8.1.2.3 Increase the voltage by 100 volt increments, repeating the previous Step each time.

8.1.2.4 Continue to increase the operating voltage past 1,000 volts until the count rate significantly increases, indicating that the voltage is no longer on the plateau. Do not exceed 1,500 volts.

8.1.2.5 Plot the voltage against the gross counts on a scatter plot.

8.1.2.6 Repeat the process described above, removing the daily check source and counting an empty detector instead. Count times should be increased to five minutes and the range of voltages need only encompass the "flat" part of the plateau.

8.1.2.7 Select an operating voltage on the "flat" part of the plateau, where the background count rate is lowest.

8.1.2.8 If the operating voltage is changed from the existing setting for sample analyses, all detector/cell combinations must be recalibrated for counting efficiency.

8.1.3 EFFICIENCY CALIBRATION

The calibration constant of each detector-scintillation cell combination must be determined, using NIST-traceable ^{226}Ra solution. This calibration is performed at least annually. The constant is determined as follows:

8.1.3.1 Prepare calibration sources by adding 25mL EDTA to a 40mL VOA vial. Be sure to prepare enough sources to count one in each cell and a few extra sources in case a cell needs to be recalibrated. Calibration sources may only be used once then must be discarded in the "Pb/Ba Aqueous Hazardous Waste" container.

8.1.3.2 Spike the samples with approximately 200dpm of ^{226}Ra spiking solution. The samples should be purged with helium to ensure that no radon is present prior to radon in-growth, see Section 8.2. The samples may be sealed immediately

after spiking, without purging with helium, as long as they are stored for at least 26 days to achieve >99% in-growth.

8.1.3.3 The calibration constant is a composite measure of the emanation efficiency of the sample, the collection efficiency of the system, and the counting efficiency of the cell. The calibration procedure is conducted, similar to sample measurements, after the alpha emitting radon daughters have come to equilibrium with ^{222}Ra (i.e., 4 hours after transfer to the scintillation cell). The duration of the calibration count should be sufficient to allow the collection of at least 10,000 counts. Record the detector, cell ID, count start time, and count duration on the appropriate benchsheets and logbook. If a given cell is to be used with multiple detectors, it may be recounted in those detectors and calibration constants generated for each detector/cell combination.

NOTE: If a cell is to be calibrated in multiple detectors, a background measurement must be obtained for that cell in each detector prior to transferring and counting the sample.

8.1.3.4 Each detector-scintillation cell combination should be calibrated with a NIST-traceable ^{226}Ra standard at least annually.

8.1.3.5 See Section 9.5.6 for calibration constant calculations.

8.1.4 INITIAL CALIBRATION VERIFICATION (ICV) AND CONTINUING CALIBRATION VERIFICATION (CCV)

8.1.4.1 ICV and CCV sources are prepared in the same manner as efficiency calibration sources, see Section 8.1.3, using an independent second source, instead of the calibration source.

8.1.4.2 To verify that the efficiency calibration is valid, count one ICV source per cell in each detector after the calibration is complete. As with the calibration sources, ICVs may be counted for the same sample in multiple detectors, as long as a background measurement is made for the cell in a specific detector.

8.1.4.3 Calculations for ICV sources are the same as those in Section 9 for samples, assuming a 100% chemical yield.

8.1.4.4 The efficiency determined for a specific cell in a specific detector is used to determine the radiometric recovery for each ICV. The radiometric recovery must be within ±15%; if the radiometric recovery is > ±10%, approval must be obtained from the Radiochemistry Technical Manager before the cell can be used.

8.1.4.5 CCVs are analyzed once every twenty analytical runs on each detector/cell combination and are subject to the same acceptance criteria as ICVs. If a CCV falls outside the ±15% acceptance criteria, the CCV is repeated. If the failure is confirmed, the cell is removed from service until it is recalibrated.

8.1.5 DAILY CHECK SOURCE
A NIST-traceable Thorium source is counted long enough to acquire at least 2,000 counts before and after samples are counted each day, bracketing the sample counts to ensure that the detector and scalar are working properly.

8.2 AQUEOUS SAMPLE PREPARATION

8.2.1 Verify and record (on Form 631) the pH of the sample according to SOP 733.

8.2.2 Using a graduated cylinder, aliquot the sample into a labeled 1.5L or 2L beaker. A sample aliquot of 1L is typical for this method, but may need to be reduced due to matrix interference or volume limitations. All samples should be brought to a final volume of 1L with DI water. Add a stir bar to each beaker and place on a stirring hot plate.

8.2.3 Prepare QC samples according to Section 10.

8.2.4 HOW TO TAKE INITIAL ICP ALIQUOT

8.2.4.1 Prior to adding any reagents, spikes, or carriers to the sample, use a calibrated pipette to remove 1mL of sample and place into a clean test tube filled with 9mL of ICP diluting solution and labeled with the sample ID and “i”, to indicate the initial ICP aliquot. Cover with a test tube cap and invert tube several times to mix thoroughly. Set aside until final ICP aliquot has been taken.

8.2.4.2 A “reference carrier” (RC) should also be prepared by adding 1mL Ba carrier to 1L of DI water. Mix thoroughly, remove 1mL of solution and dilute to 10mL as stated above

for samples. Submit with samples for ICP analysis to provide a reference concentration for the yield calculations.

8.2.5 To each water sample, add 20mL of 12N HCl, 1.0mL barium carrier, and appropriate amount of spiking solution to LCS and any MS samples. Cover with a watch glass and heat to a gentle boil.

8.2.6 Cautiously, with vigorous stirring, add 25mL 18N H_2SO_4. Continue boiling and stirring at least 10 minutes. Remove from heat. Remove stir bar, rinsing with 0.1N H_2SO_4. Let precipitate settle overnight, or at least four hours (overnight is recommended).

8.2.7 Aspirate the supernatant into the PAR waste water treatment facility.

8.2.8 Slurry the precipitate and transfer to a labeled centrifuge tube with a minimum amount of 0.1N H_2SO_4. Centrifuge at 3500rpm for 10-15 minutes and discard supernatant into the PAR wastewater treatment facility. Wash twice with 15mL of 0.1N H_2SO_4. Centrifuge and discard washes into the PA wastewater treatment facility.

8.2.9 Add 25mL basic EDTA reagent, heat in a water bath and stir well until dissolved. After dissolution, remove from the steam bath and allow the samples to cool.

NOTE: If the precipitate is difficult to dissolve, additional EDTA can be added; however, the maximum volume of EDTA that may be used is 30mL, as the VOA vials are only 40mL. Record the volume of EDTA used on the benchsheet.

8.2.10 HOW TO TAKE FINAL ICP ALIQUOT

8.2.10.1 Vortex the sample to mix thoroughly. Using a calibrated pipette, aliquot 0.1mL of sample into a clean, labeled test tube containing 9.9 or 10mL of DI water (record the volume of water used). Cover with Parafilm, and invert several times to mix completely. With a calibrated pipette, aliquot 1.0mL of the diluted sample into another clean test tube labeled with the sample ID and "f" and containing 9.0mL of ICP diluting solution. Cover with a test tube cap and mix well. Submit the initial and final test tubes to the Metals Lab with proper bench sheets for analysis.

8.2.10.2 Upon the return of ICP sample fractions to the radiochemistry lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the PAR waste water treatment facility (i.e., down the

laboratory sink with plenty of cold tap water). The test tubes may be soaked in a Radiacwash™ solution, rinsed with tap water and discarded into the sanitary trash. The tubes containing the intermediate, DI water diluted, sample may be disposed of in the same manner.

8.2.11 Transfer the solution remaining after Step 8.2.10 to a labeled VOA vial using approximately 2.5mL EDTA to rinse the centrifuge tube. The centrifuge tubes may be soaked in Radiacwash™, rinsed, and discarded into the sanitary trash.

8.2.12 Purge the samples in the VOA vials for approximately 20 minutes with helium to remove any radon from the solution prior to sealing the vial.

8.2.13 Seal the VOA vial and record the date and time that the purge ended as t_1, beginning of ^{222}Ra in-growth, on the benchsheet. Store the solution for at least 4 days for in-growth of ^{222}Ra (typical storage time is 7 days, full in-growth is achieved after 30 days).

8.2.14 At the end of the storage period, fill the upper half of a modified 3mL syringe with Drierite™ to about the 2.5mL mark and the lower half with ascarite to about the 3mL mark. Place a small amount of glass wool in the end of the syringe to secure the drying agents. The column is a single use column and can be discarded in the sanitary trash after transferring the sample. Store unused columns in the desiccator.

8.2.15 Assemble the radon emanation apparatus (see Figure 1), including a scintillation cell with a current background measurement, see Section 8.1. Evacuate the scintillation cell by applying vacuum to the cell for about 10 seconds and transfer the vacuum to the VOA vial after attaching it to the emanation apparatus by quickly opening and closing the stopcock on the cell.

8.2.16 Adjust the helium pressure to deliver a minimum flow rate. Fill the helium feed line with helium. Puncture the septum of the VOA vial with the helium feed needle.

8.2.17 After bubbling has subsided, gradually open the scintillation cell stopcock. Allow bubbling to proceed at a rate, as determined by experience, such that 15 to 20 minutes are required to complete the transfer. When the bubbling subsides the apparatus is essentially at ambient pressure.

8.2.18 When the system is at ambient pressure, remove the helium feed needles, close the scintillation cell stopcock, and dissemble the

apparatus. Record the ending transfer date and time as t_2, beginning of ^{222}Rn progeny in-growth, on the benchsheet.

8.2.19 Store the scintillation cell for at least 4 hours to ensure equilibrium between ^{222}Rn and its progeny, and to allow other isotopes of radon and their progeny to decay. Count the alpha scintillations from the cell in a scintillation cell counter with a light-tight enclosure that protects the photomultiplier tube. Record the beginning of the counting date and time on the benchsheet to correct for the decay of ^{222}Rn.

NOTE: After each analysis, flush the cell thoroughly with helium for at least 1 minute and store at atmospheric pressure to remove radon from the cell and prevent the build-up of radon daughter products. The cell must be stored for at least four hours prior to re-use.

8.3 PREPARATION OF SOLID SAMPLES

8.3.1 Weigh 1-4 grams dried, pulverized soil into a permanently labeled glass beaker. Typical aliquot size is 2.0g but may be adjusted due to MDA or matrix interference considerations. Record the sample weight and beaker number on the benchsheet.

8.3.2 Prepare QC samples according to Section 10.

8.3.3 Dry the beakers on a hotplate set at 2. Samples must not have any standing liquid prior to muffling. Cover the beakers with a watch glass and muffle at 600°C for at least 4 hours.

8.3.4 Transfer the sample to a 250mL polypropylene specimen cup, using at least 20mL 16N HNO_3 to rinse the beaker. Scraping with a plastic spatula may be necessary to remove all of the soil from the beaker.

8.3.5 Add 20mL HF, cover with a 100mL polypropylene specimen cup, and heat for 4 hours on a steam bath.

8.3.6 Remove the 100mL cup and evaporate to dryness. The 100mL cups may be rinsed thoroughly with tap water and discarded into the sanitary trash.

8.3.7 Add 10mL 8N HNO_3 to the samples while they are on the steam bath to facilitate dissolution. The samples may be covered with a 100mL polypropylene cup to prevent evaporation.

8.3.8 Transfer the solution to a labeled VOA vial, rinsing the beaker with three 5mL rinses of 8N HNO_3, for a total volume of 25mL. The

250mL cups may be soaked in Radiacwash™, rinsed, and discarded into the sanitary trash.

NOTE: If the digestate residue is difficult to dissolve, additional 8N HNO_3 can be added; however, the maximum volume of 8N HNO_3 that may be used is 35mL, as the VOA vial capacity is only 40mL.

8.3.9 Proceed to Step 8.2.12.

9. CALCULATIONS

9.1 Calculate the actual volume, V_A, of sample analyzed for aqueous samples (accounting for volumes of sample removed) as follows (Note: The actual volume for solid samples is the same as the initial sample volume because no sample is removed during the process):

$$V_A = V * \frac{V_i - icp_i}{V_i} * \frac{V_f - icp_f}{V_f}$$

where:

V = sample aliquot (L, g)

V_i = sample final dilution volume (mL)

icp_i = initial aliquot taken for ICP (mL)

V_f = sample volume in EDTA (mL)

icp_f = final aliquot taken for ICP (mL)

9.2 Calculate the barium chemical recovery for aqueous samples, Y, as a percentage, as follows (barium chemical recovery is assumed to be 100% for solid samples):

$$Y_i = (V_i - V_{ICP}) * ICP_i * DF$$

$$Y_f = V_f * ICP_f * DF$$

$$Y_{RC} = V_{RC} * ICP_{RC} * DF$$

$$Y = \frac{Y_f}{Y_i + Y_{RC}} * 100\%$$

where:

Y_i = barium recovery from initial ICP aliquot (µg)

V_{ICP} = volume removed for ICP analysis

ICP_i = initial barium concentration measured by ICP (µg/mL)

DF = dilution factor

Y_f = barium recovery from final ICP aliquot (µg)

ICP_f = final barium concentration measured by ICP (µg/mL)

Y_{RC} = barium recovery from RC aliquot (µg)

V_{RC} = RC final volume (mL)

ICP_{RC} = RC barium concentration measured by ICP (µg/mL)

9.3 The sample activity concentration, counting uncertainty, instrument uncertainty, and minimum detection concentration calculations are provided in SOP 708.

9.4 TPU FACTORS
As defined in SOP 708, calculate the one-sigma (1σ) Total Propagated Uncertainty (TPU) as follows:

9.4.1 Aqueous Samples: Require a 1σ preparation uncertainty factor of 0.110. This is based on one gross aliquot, one volumetric measurement, one ICP determination, one spike/carrier addition, three quantitative transfers, one pipetting and two reagent additions:

$$0.110 = \sqrt{.05^2 + .006^2 + .083^2 + .025^2 + .025^2 + .025^2 + .025^2 + .004^2 + .006^2 + .006^2}$$

9.4.2 Solid Samples: Require a 1σ preparation uncertainty factor of 0.071. This is based on one gross aliquot, one mass measurement, one spike/carrier addition, and three quantitative transfers:

$$0.071 = \sqrt{0.05^2 + 0.003^2 + 0.025^2 + 0.025^2 + 0.025^2 + .025^2}$$

9.4.3 Instrument Uncertainty (IU):

The IU is 0.054. This is based on the in-house preparation of calibration standards, counting reproducibility, counting efficiency, and dead time estimates:

$$0.054 = \sqrt{0.05^2 + 0.01^2 + 0.015^2 + 0.01^2}$$

10. QUALITY CONTROL

Per Paragon protocol, spikes are added before the sample receives any chemical treatment. Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.1 A blank, prepared in one liter of DI water for aqueous samples, must be analyzed with each batch of 20 or fewer field samples (i.e., at a five percent frequency). No matrix is used for blanks used in soil batches - muffle an empty 100mL beaker.

10.2 One blank spike (LCS), prepared in one liter of DI water for aqueous samples, and a Whatman™ filter paper for solid samples, must be analyzed with each batch of 20 or fewer field samples (i.e., at a 5 percent frequency). The spiking level for LCSs should be at least 4-10 times the requested MDA, or 100dpm, whichever is larger.

10.3 For solid samples, at least one matrix spike (MS) should be prepared for each batch of 20 samples (i.e., at a 5 percent frequency). If there is more than one type of solid matrix in the batch, an additional MS should be prepared for each type of matrix present. The spiking level should be at least 4-10 times the expected activity of the sample, or 100dpm, whichever is larger.

10.4 Duplicate sample analyses will be performed at a minimum frequency of ten percent. If there is insufficient sample volume for this frequency of sample duplicates, LCS duplicates may serve as a measure of batch reproducibility.

11. DEVIATIONS FROM METHOD

11.1 This SOP meets the requirements of EPA Method 903.1 for water samples. In addition to describing a procedure for aqueous samples, this SOP describes a procedure for determining ^{226}Ra and its progeny in soil, which the laboratory employs at a client's request. Also, this SOP provides procedures for determining the chemical yield as an addition to EPA Method 903.1. This measurement increases the accuracy of the method.

11.2 Only 1.0mL of barium carrier, instead of 2.0mL, is added to aqueous samples. The lesser amount of carrier facilitates dissolution of the precipitate in EDTA. Since Ba yield is determined by ICP, this amount is more than sufficient for $Ba(Ra)SO_4$ precipitation and Ba chemical recovery measurement.

11.3 25mL of EDTA is used to dissolve the $Ba(Ra)SO_4$ precipitate. This volume ensures a complete dissolution of the precipitate in a normal sample. For difficult matrices, up to 35mL may be used to dissolve the precipitate.

11.4 A 40mL VOA vial is used for sample storage and transfer instead of a radon bubbler. There is essentially no difference in the function of these two pieces of apparatus. VOA vials are more cost effective and easier to store, so a larger number of samples may be stored at once.

11.5 Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of the lab's internally derived acceptance criteria.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Safety glasses, lab coats and gloves should be worn in the laboratory at all times.

12.1.2 Use care when handling mineral acids (e.g., HNO_3, H_2SO_4). Work only in a fume hood with adequate ventilation and wear appropriate eye, face, and body protection.

12.1.3 Radon is an odorless, colorless gas. Care should be taken when handling samples where there is a possibility of radon buildup in the container (e.g., purging samples in VOA vials prior to in-growth). Work in a well ventilated area, preferably a fume hood.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

12.2 WASTE DISPOSAL

12.2.1 Four Satellite Accumulation Area (SAA) containers are available for disposal of samples after the results are reported. (One each for radioactive and non-radioactive aqueous samples and solid samples.)

12.2.2 Other process waste, as indicated in Section 8, may be discarded into the PAR waste water treatment facility.

DOCUMENT REVISION HISTORY

4/10/06: Calibration frequency reduced from every 20 analyses to annually with the adoption of CCVs every 20 analyses. Plateau calibration procedure described. Soil digestate changed from EDTA to HNO_3. LIMS Program Specification directive added to 'Responsibilities' Section. Added DOCUMENT REVISION HISTORY.

9/11/06: Added comment to INTERFERENCES describing corrective action for solid digestates that precipitate in the bubble apparatus.

8/31/07: Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Section 7.1. Removed activity and MDC calculations from Section 9 and referenced Paragon SOP 708 instead. Added statements to Section 10 that per Paragon protocol, spikes are added before the sample receives any chemical treatment, and acceptance limits for quality control parameters may vary per client specifications, consult applicable LIMS program specification.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 784 REVISION 0

TITLE: DETERMINATION OF RADIUM-228 PER EPA METHOD 904.0 – DRINKING WATER COMPLIANCE

FORMS: 631 (use most current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 10/5/06

QUALITY ASSURANCE MANAGER _____ DATE 10/5/06

LABORATORY MANAGER _____ DATE 10-5-06

HISTORY: New, Rev0, 10/5/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references -- EPA Method 904.0 -- describe the measurement of radium-228 in drinking waters. This technique is devised so that the beta activity from actinium-228, which is produced by the decay of radium-228, can be determined and related to the activity concentration of radium-228 present in the sample.

To quantify actinium-228 and thereby determine radium-228, the efficiency of the beta counter for measuring the very short half-lived actinium-228 (average beta energy of 0.404MeV), is to be calibrated with a beta source of comparable average beta energy such as Sr-89 (average beta energy of 0.589MeV).

If desired, the determination of radium-226 may be conducted on the purified radium solution prior to barium sulfate precipitation determination of the chemical yield. Methods 903.1, 903.0, and their equivalent methods in SW-846, HASL, or Standard Methods, are compatible with this approach.

2. SUMMARY

2.1 The radium isotopes in a water sample are collected by co-precipitation of barium and lead sulfate and purified by re-precipitation out of a basic EDTA solution. After a 36-hour period to allow for the ingrowth of actinium-228, lead is removed as PbS, actinium is carried on yttrium (Y) as the hydroxide and mounted as the oxalate, and quickly beta counted (~6 hours) to minimize decay of the short-lived Ac-228.

2.2 If radium-226 according to EPA Method 903.0 or 903.1 is requested, the supernatant containing radium following separation of the Y/Ac is taken into SOP 712 or 783, as appropriate.

3. RESPONSIBILITIES

3.1 **It is the responsibility of the preparation chemist and instrument analyst to perform this method in strict accordance with this SOP and to complete all documentation required for review.**

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 The **preparation chemist** shall notify the Instrument Lab Gas-Flow Proportional Counter analyst in advance of the number of samples arriving and the expected delivery date and time. This allows the analyst to schedule adequate instrument time to analyze the short-lived Ac-228 analyte.

3.4 It is the responsibility of the instrument analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715, as well as the LIMS program specifications related to the client, project, and test method being performed.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the **preparation or analysis** of the samples. Any discrepancies must be noted and corrective action taken and documented.

3.6 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

4. INTERFERENCES

4.1 As indicated in EPA Method 904.0, performance studies show that the presence of strontium/yttrium-90 in a water sample will lend a positive bias to the measured radium-228 activity.

4.2 Excess barium in the sample may interfere with an accurate chemical yield determination.

4.3 The presence of significant quantities of dissolved constituents that may form insoluble sulfate precipitates interferes with the proper separation of radium and the subsequent quantification of Ra-228. In this case, reduced sample volumes may be required to minimize the matrix interference effects.

4.4 The presence of sediments in the preserved sample is a significant interference to this method. Drinking water protocols indicate that the entire sample should be analyzed so that the dose estimates to the consumer are representative of the actual water that is consumed. Consequently, the analysis of sedimented water samples may result in a significant bias to the analytical results, and these results may not be representative of the dose received by the consumer.

4.5 The presence of significant quantities (>500mg) of suspended solids in a sample may interfere with collection of the barium sulfate precipitate, which may result in a low chemical yield in the analytical process.

5. DEVIATIONS FROM THE METHOD

Chemical yields in this method are performed at Paragon Analytics by ICP analysis of the Ba and Y carriers, rather than by the gravimetric determination described in EPA 904.0. This avoids potential biases in the yield determinations presented by interfering constituents and the observed inconsistencies in the hydration factor of the dried yttrium oxalate precipitate.

6. APPARATUS AND MATERIALS

6.1 Stirring hot plate

6.2 Magnetic stir bars

6.3 Centrifuge

6.4 Centrifuge tubes, polypropylene, Falcon™, 50mL, Do Not Substitute

6.5 Counting planchets, stainless steel, flat, 2”

NOTE: Prior to use, the planchets are soaked in diluted Radiacwash™ for approximately three hours, drained, rinsed with deionized water, transferred to a metal pan, and placed in the drying oven until dry.

6.21 Volumetric flask, 1L

6.22 Analytical balance, Mettler™ AE 200, or equivalent

6.23 **pH paper, wide range**

7. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a Threshold Limit Value (TLV) of less than 50ppm, shall be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

7.1 Deionized (DI) water, **obtained from the laboratory's DI water system**

7.2 Acetic acid, 17.4M, Glacial CH_3COOH, reagent grade, concentrated
TLV = 10ppm (TWA); Irritant

7.3 Ammonium hydroxide, 15M, NH_4OH, reagent grade, concentrated
TLV = 25ppm (TWA for NH_3)

7.4 Ammonium oxalate, 5%: Dissolve 25g $(NH_4)_2C_2O_4 \cdot H_2O$ in about 400mL of hot DI water. When cool, dilute to 500mL with DI water.

7.5 Ammonium sulfate, 200mg/mL: Dissolve 200g $(NH_4)_2SO_4$ in DI water and dilute to 1000mL.

7.6 Ammonium sulfide, 2%: Dilute 10mL $(NH_4)_2S$ (20-24%) to 100mL with DI water.

7.7 Standardized Barium Carrier, 16mg/mL (27mg/mL $BaSO_4$ yield)

7.7.1 PREPARATION: Place a 1000mL Class A volumetric flask on a stir plate, add a stir bar and ~500mL of DI water. Add 28.5g $BaCl_2 \cdot 2H_2O$ and stir until completely dissolved, then add 5mL 16M HNO_3. Remove stir bar, rinsing with DI water, and dilute to 1000mL with DI water. Transfer to a clean, labeled 1L poly container. Document the

preparation of this carrier in the Reagent Prep Logbook and Paragon's Standards and Solutions Database.
TLV = 0.5mg Ba/m^3 = 0.06ppm (TWA). Irritant

7.7.2 STANDARDIZATION OF Ba CARRIER BY ICP ANALYSIS: Prepare in triplicate a 1000-fold dilution of the Ba carrier using the ICP solution described in Section 7.10 below. Submit to the Metals Lab for analysis. Average the results and record in the reagent prep logbook.

7.8 Citric acid, 1M: Dissolve 210.14g of $C_6H_8O_7 \cdot H_2O$ in DI water and dilute to 1000mL.

7.9 EDTA basic reagent, 0.25M: Dissolve 80g NaOH in ~3L of DI water. Slowly add 372g of (ethylenedinitrilo)tetraacetic acid, disodium salt, dihydrate - EDTA ($C_{10}H_{14}N_2Na_2O_8 \cdot 2H_2O$), while stirring. After the salt is in solution dilute to 4L. If necessary, adjust the pH to ≥10 using a minimal volume of 10M NaOH.

7.10 ICP diluting solution (1% HNO_3 / 5% HCl). Carefully add 10mL of concentrated HNO_3 and 50mL of concentrated HCl to 940mL of DI water. Mix thoroughly.
TLV = 2ppm for conc. HNO_3 (TWA), and 5ppm for conc. HCl (ceiling). Both irritants, corrosive

7.11 Lead carrier, 15mg/mL: Dissolve 23.98g $Pb(NO_3)_2$ in DI water. Add 5mL 16M HNO_3 and dilute to 1000mL with DI water.
TLV = 0.05mg/m^3 (=0.004ppm)

7.12 Lead carrier, 1.5mg/mL: Dilute 10mL lead carrier (15mg/mL) to 100mL with DI water.
TLV = 0.05mg/m^3 (=0.004ppm)

7.13 Methyl orange indicator solution: Dissolve 0.100g methyl orange powder in 100mL of DI water.

7.14 Nitric acid reagent concentrated (16M HNO_3)
TLV = 2ppm (TWA). Irritant, corrosive

7.15 Nitric acid, 6M: Slowly and carefully add 375mL of concentrated nitric acid while stirring to 625mL of DI water.
TLV=2ppm (TWA). Irritant, corrosive

7.16 Nitric acid, 1M: Add 63mL of concentrated nitric acid while stirring to 937mL DI water.
TLV = 2ppm (TWA). Irritant, corrosive

7.17 Sodium hydroxide, 18M: Place about 500mL of DI water in a beaker in a cold water bath. Very slowly and carefully dissolve 720g of NaOH; work in the hood. **The solution will boil if the NaOH is added too quickly.** After the solution is cool, dilute to 1L with DI water. Store in a plastic container.
TLV = 2mg/m^3 = 1.2ppm (ceiling). Irritant

7.18 Sodium hydroxide, 10M: Follow the same procedure as above, but use 400g of NaOH instead. Store in a plastic container.
TLV = 2mg/m^3 = 1.2ppm (ceiling). Irritant

7.19 Strontium Carrier, 20mg/mL: Dissolve 48.3g $Sr(NO_3)_2$ in DI water. Add 1mL 16M HNO_3, then dilute to 1000mL with DI water.

7.20 Sulfuric acid, 18N, H_2SO_4: Very carefully and gradually, add 500mL of reagent grade concentrated sulfuric acid, while stirring, to 500mL DI water. **The solution will boil if the reagent is added too quickly.**
TLV = 1mg/m^3 (=0.25ppm) (TWA). Irritant

7.21 Sulfuric acid, 0.1N H_2SO_4: Add 5.6mL of 18N H_2SO_4 to ~900mL of DI water. Mix well and dilute to 1L with DI water. Alternately, add 120mL of 18N H_2SO_4 to ~2L of DI water, mix well and dilute to 22L.
TLV = 1mg/m^3 (=0.25ppm) (TWA). Irritant

7.22 Yttrium carrier, 9mg /mL: Add 11.43g Y_2O_3 to a Class A volumetric flask (1L), and add 100mL DI water. Heat to boiling and, while stirring with a magnetic stirring hot plate, add small portions of conc. HNO_3. (About 50mL may be necessary to dissolve the Y_2O_3. Small additions of deionized water also may be needed to replace the water lost by evaporation). After total dissolution, add 40mL conc. HNO_3 and dilute to 1000mL with DI water (1mL = 9mg/mLY^{+3}).

STANDARDIZATION: In triplicate, take 0.5mL of the Yttrium carrier solution and dilute 20-fold with DI water. Determine the concentration by ICP analysis.

7.23 Strontium-yttrium mixed carrier, 0.9mg Sr and 0.9mg Y / mL

7.23.1 Prepare Solutions A and B as indicated below:

Solution A: Dilute 20 mL of yttrium carrier to 100mL, using DI water.

Solution B: Dissolve 0.4384g. $Sr(NO_3)_2$ in DI water and dilute to 100mL.

7.23.2 Combine equal volumes of Solutions A and B; 1mL = 0.9mg Sr and 0.9mg Y.

7.24 Triton X-100™ non-ionic surfactant solution, VWR #3929-2, or equivalent

8. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

8.1 It is recommended that samples be preserved at the time of collection by adding enough 1M HNO_3 per liter of sample to bring the pH to 2 (15mL 1M HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days, then preserved, and held in the original container for a minimum of ~~16~~ 24 hours before analysis or transfer of the sample.

8.2 The container choice should be plastic (rather than glass) to prevent loss due to breakage during transportation and handling.

9. PROCEDURE

9.1 AQUEOUS SAMPLE PREPARATION

9.1.1 Verify and record (on Form 631) the pH of the sample according to SOP 733.

9.1.2 1.5L is a typical sample aliquot size for this method. However, this volume may need to be reduced if matrix interference is suspected. Use a graduated cylinder to measure the sample and pour into a clean, labeled 2L beaker. If less than 1.5L is used, record volume, then dilute to 1.5L with DI water.

9.1.3 Prepare quality control (QC) samples per Section 10, adding the appropriate amount of ^{228}Ra spiking solution to the samples that require it.

9.1.4 Place the beakers on stirring hot plates. Add a stir bar to each.

9.1.5 To each sample, add 8mL of 1M citric acid and 8-10 drops of methyl orange indicator. The solution should be red.

9.1.6 For all sample matrices, add 10mL of lead carrier (15mg/mL), 1mL of strontium carrier, 2mL Barium carrier, and 2mL of non-standardized yttrium carrier.

9.1.7 Prepare a Ba carrier reference solution by adding 2.0mL of standardized barium carrier to 1.5L of DI water.

9.1.8 Heat to incipient boiling and maintain at this temperature for 30min, while stirring.

9.1.9 Add 15M NH_4OH drop-wise until a definite yellow color is obtained; then add a few drops in excess.

9.1.10 Precipitate lead and barium sulfates by adding 18N H_2SO_4 drop-wise until the red color reappears; then add 0.4mL excess (~8 drops). Add 8mL 15M $(NH_4)_2SO_4$. Stir constantly and maintain temperature (approx. 90°C) for 30 minutes. If the indicator has been destroyed during digestion, add a few drops of methyl orange indicator.

9.1.11 Remove stir bars, rinsing with 0.1N sulfuric acid, and allow the solution to cool. Let precipitate settle for at least 4 hours, preferably overnight.

9.1.12 Aspirate supernatant. Transfer precipitate to a 50mL poly centrifuge tube, rinsing the last particles out of the beaker with 0.1N H_2SO_4. Centrifuge at 3,500 rpm for 10 minutes and discard the supernatant into the laboratory sink followed by plenty of cold tap water. **NOTE: For the remainder of this procedure, any reference to centrifuging means centrifuge at 3,500 rpm for 10 minutes.**

9.1.13 Wash the precipitate with 15mL 16N HNO_3, vortex, centrifuge, and discard the supernatant into the laboratory sink or into the back of a fume hood, followed with plenty of cold tap water. Repeat this washing a second time. At the analyst's discretion, additional washes may be performed to thoroughly remove interfering constituents.

9.1.14 Add 25mL EDTA basic reagent and vortex well. Heat in a hot-water bath for about 10min., stirring occasionally to aid in dissolution. If the precipitate does not dissolve after heating on the hot-water bath, add up to an additional 5.0mL of 10M NaOH dropwise, until the precipitate dissolves. If the precipitate persists, add up to four 5.0 mL increments of basic EDTA until the precipitate dissolves. If the sample re-precipitates while cooling, add a few drops of 10M NaOH to dissolve. Document the total volume of NaOH/EDTA solution used to dissolve the precipitate on the benchsheet. Vortex to mix the solution and take the aliquot for the initial ICP analysis. If solids persist, consult your Supervisor prior to filtering per SOP 712.

9.1.15 HOW TO TAKE INITIAL ICP ALIQUOT

9.1.15.1 Vortex the sample to mix thoroughly. Using a calibrated pipette, aliquot 0.1mL of sample into a clean, labeled test tube containing 9.9 or 10mL of DI water (record the volume of water used). Cover with Parafilm™, and invert several times or vortex to mix completely. With a calibrated pipette, aliquot 1.0mL of the diluted sample into another clean test tube labeled with the sample ID and "i" and containing 9.0mL of ICP diluting solution. Cover with a test tube cap

and mix well. Set aside until final ICP aliquot has been taken.

9.1.15.2 At this time, prepare an ICP "reference carrier" (RC) sample. Thoroughly mix the reference carrier solution (Section 9.1.7) on a stir plate. Add 1.0mL of the reference carrier solution to 9.0mL of ICP diluting solution, as stated above for samples. This RC sample will be submitted with the batch samples for ICP analysis to provide a reference concentration for the yield calculations.

9.1.16 Add 1mL of strontium-yttrium mixed carrier, and mix thoroughly. Add a few drops of 10M NaOH if any precipitate forms.

9.1.17 Add 1mL $(NH_4)_2SO_4$ and stir thoroughly. Add 17.4M acetic acid drop-wise until barium sulfate precipitates; then add 2mL excess. **Do not vortex.** Heat in a hot water bath (about 10min.) until precipitate settles. Centrifuge and discard supernatant into the Ba/Pb waste carboy, per Section 13.2 of this SOP.

9.1.18 Add 25mL EDTA basic reagent, vortex and heat in a hot-water bath until precipitate dissolves, (additional volume of EDTA reagent may be needed if the precipitate does not dissolve completely) then repeat steps 9.1.16 and 9.1.17. *Note the time of last barium sulfate precipitation on the benchsheet; this is T1, the beginning of the actinium-228 ingrowth time.*

9.1.19 Dissolve the precipitate with 25mL EDTA basic reagent. As before (i.e., Step 9.1.14), additional EDTA reagent may be required if the precipitate does not dissolve completely. Then add 1.0mL of standardized yttrium carrier and 1mL of lead carrier (1.5mg/mL). If $BaSO_4$ precipitates (a cloudy white solid), dissolve with a few drops of 10N NaOH. If $Y(OH)_3$ forms (a stringy, floating precipitate), dissolve with a few drops of 16M HNO_3.

NOTE: Prepare a reference carrier solution by adding 1.0mL of standardized yttrium carrier to a 50mL centrifuge tube. To this, add 25mL of 8M HNO_3 and dilute to 50mL with DI water.

Cap the polypropylene tubes and routinely store for **36 hours for ingrowth of Ac-228**.

9.1.20 After the 36-hour ingrowth period, add 0.3mL (about 6 drops) $(NH_4)_2S$ and vortex the samples. Add 0.5mL (about 10 drops) 10M NaOH, cap

and shake vigorously until lead sulfide precipitates. If precipitate fails to form, additional 10M NaOH may be added dropwise, with vigorous stirring, until the precipitate forms. After the precipitate forms, add 10 drops 10M NaOH in excess. Centrifuge and decant supernatant into a clean tube. Rinse the centrifuge tubes into the Ba/Pb waste carboy. Used centrifuge tubes may be soaked in Radiacwash™, rinsed in tap water and discarded in the sanitary trash.

9.1.21 In preparation to perform Step 9.1.24, place a bottle of 18M NaOH on a stir plate and mix thoroughly.

9.1.22 Add 1mL lead carrier (1.5mg/mL), 0.1mL (approx. 2 drops) $(NH_4)_2S$, and 3-4 drops of 10M NaOH, to repeat precipitation of lead sulfide as before. Centrifuge and filter supernatant through Whatman™ #42 filter paper, ashless, 90mm diameter, and into a clean tube. Precondition the filters with ~1mL of DI water. After the sample has passed through the filter, rinse twice with 1mL of DI water. Discard the filters into the filter lead waste. Rinse the funnels with 1mL of DI water, collecting the filtrate into the centrifuge tube.

9.1.23 **Due to the short half-life of actinium-228, the remainder of the prep should be completed in less than 4 hours. The Counting Lab should be notified in advance of incoming samples.**

9.1.24 Add 16mL of thoroughly mixed 18M NaOH to each sample. Cap and shake well and digest in a hot water bath for about 30min until yttrium hydroxide coagulates.

NOTE: Document time of yttrium hydroxide precipitation as T2 (time when samples come off steam bath); *this is the end of the actinium-228 ingrowth time and the beginning of actinium-228 decay time*.

9.1.25 Centrifuge and decant the supernatant into a 150mL poly specimen cup. *Save for barium yield determination (Section 9.1.26).*

9.1.26 Dissolve the precipitate with 2mL 6M HNO_3. Vortex, then heat in a hot water bath for about 5min. Add 3mL DI water and re-precipitate yttrium hydroxide with 6mL 10M NaOH. Vortex and heat in a hot water bath for about 10 min until precipitate coagulates. Centrifuge and add this supernatant to the supernatant produced in the previous Step in order to determine barium yield. Using a 100mL graduated cylinder, measure this combined supernatant and record the volume on the benchsheet.

9.1.27 FINAL ICP ANALYSIS. The aliquot for final ICP analysis must be taken from the combined supernatant collected. Follow the steps outlined in Section 9.1.15.1 to obtain the final ICP aliquot.

Upon the return of ICP sample fractions to the prep lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the PAR wastewater treatment facility (i.e., down the laboratory sink with plenty of cold tap water). The remaining Ba supernatant from above can be disposed of into the Ba/Pb waste carboy. The test tubes and centrifuge tubes may be soaked in Radiacwash™ and rinsed with tap water. Dispose of the centrifuge tubes and test tubes in the sanitary trash.

9.1.28 Dissolve the precipitate with 2mL 1M HNO_3, vortex, and heat in a hot water bath for 5min. Additional 1M HNO_3 may be added drop wise to achieve dissolution of the precipitate. If additional 1M HNO_3 is used, add proportionally increased volumes of DI water and 5% $(NH_4)_2C_2O_4 \cdot H_2O$ (Ammonium Oxalate) in the following Step.

9.1.29 Add 3mL of DI water and 2mL 5% $(NH_4)_2C_2O_4 \cdot H_2O$; heat about 10min to coagulate, centrifuge, and discard supernatant into the laboratory sink followed by plenty of cold tap water.

9.1.30 Rinse precipitate with 10mL of DI water. Centrifuge and discard supernatant into the laboratory sink.

9.1.31 Add 10mL of DI water, 6 drops 1M HNO_3 and 6 drops 5% $(NH_4)_2C_2O_4 \cdot H_2O$. Heat and stir in a hot water bath for 5-6 min. **The time on the water bath should be monitored carefully, as this may significantly affect the chemical yields for the samples.** Centrifuge and discard supernatant into the laboratory sink.

9.1.32 Label a stainless steel planchet for each sample, and place planchets on a hot plate.

9.1.33 Add approximately 4mL of DI water to the centrifuge tubes and vortex until all of the precipitate is suspended. Working quickly to avoid the precipitate settling, remove the cap and rinse once with DI water; pour rinse into a planchet. Empty the contents of the centrifuge tube onto the planchet, rinse tube with DI water, add rinse to the planchet. The sample should be evenly distributed on the planchet. Allow solid to settle. Dry on a hot plate at setting 2 or 3. Submit planchets to the Counting Lab immediately for analysis. Used centrifuge tubes may be soaked in Radiacwash™, rinsed in tap water, and discarded in the

sanitary trash.

9.1.34 After counting, place each planchet in a labeled 150mL poly cup and add approximately 10mL of 8M HNO_3 to dissolve the yttrium oxalate precipitate.

9.1.35 Thoroughly rinse the planchets with 8M HNO_3 into the poly cups. After rinsing, the planchets can be disposed of in the sanitary trash.

9.1.36 The dissolved sample and rinse is brought up to 50mL with DI water.

9.1.37 Remove a 0.5mL aliquot from each sample, including the reference carrier from the note after Step 9.1.19, into a 15mL test tube containing 9.5mL of ICP diluting solution, to bring the total volume to 10mL. The samples are then capped, shaken, and brought to the Metals Lab for yttrium analysis by ICP.

Upon the return of ICP sample fractions to the prep lab, and after satisfactory review of the chemical yield data, the ICP fractions may be discharged into the PAR wastewater treatment facility (i.e., down the laboratory sink with plenty of cold tap water). The test tubes may be soaked in Radiacwash™, rinsed with tap water, and disposed of in the sanitary trash.

9.2 PREPARATION OF CALIBRATION STANDARDS

9.2.1 Label and tare weigh 5 stainless steel 2-inch diameter flat planchets.

9.2.2 Spike between 1,000 and 10,000dpm of NIST-traceable Sr-89 directly onto each planchet.

NOTE: If the standard matrix is HCl, the standard must be converted to a nitric matrix during planchetting to avoid corroding the planchet. This can be accomplished by adding ~5mL 16N HNO_3 to the planchet along with the spiking solution.

9.2.3 Add 0.5mL of Sr carrier (approximately 10mg).

9.2.4 Dry on a hot plate set at "2".

9.2.5 Weigh on an analytical balance. Record the mass on the benchsheet.

9.2.6 Submit to the Counting Lab with all necessary documentation.

9.2.7 The calibration should be verified with the preparation and analysis of four method blanks and four ^{228}Ra LCSs, spiked at approximately

500dpm, performed per this SOP.

10. QUALITY CONTROL

NOTE: For solid matrices, the blank and LCS are prepared using a qualitative filter paper, instead of the 1500mL DI water used for aqueous QC.

10.1 One method blank, prepared with 1500mL of DI water, is prepared for each batch of twenty or fewer samples. To be acceptable, the method blank activity shall be less than the MDA (or, if higher, less than the contract required MDC). Samples associated with an elevated method blank are acceptable if the sample activity is greater than five times the blank activity.

10.2 One LCS, prepared with 1500mL of DI water for aqueous samples is prepared for each batch of twenty or fewer samples. The LCS activity should fall within the general range of 5-10 times the requested detection limit (default = 1pCi/L). The LCS sample accuracy (measured activity/added activity) will fall within currently established control limits, as described in the LIMS program specifications.

10.3 A duplicate is prepared at a frequency of one per ten or fewer samples. The duplicate sample DER will be within the established control limits, as described in the LIMS program specifications. Some clients may require use of RPD as a measure of precision. The duplicate sample RPD will be within specified control limits. Duplicate samples with activity levels less than 5 times the MDC will not be assessed using RPD.

10.4 The overall chemical yield, calculated as the product of the barium and yttrium yields, should be 40-110%. The individual barium and yttrium yield should also fall within these limits.

10.5 Batches for which the associated QC samples do not meet established criteria may need to be rerun. A non-conformance report (NCR, SOP 928) should be filled out, the Radiochemistry Technical Manager notified, and appropriate corrective action implemented and documented.

11. CALCULATIONS

11.1 Calculate the radium-228 concentration, Act, in pCi/L or pCi/g as follows:

$$Act = \frac{(SCPM - BKGCPM)(Ac * T_3/60)}{F * E * V * Y_T * D * (1 - e^{(-AcT_1)}) * (e^{(-AcT_2)}) * (1 - e^{(-AcT_3/60)})}$$

where:

Act = sample activity (pCi/L, pCi/g)

SCPM = gross sample beta count rate (cpm)

BKGCPM = background beta count rate (cpm)

Ac = decay constant for actinium-228 = ln2 / 6.15 hours = 0.113075 h^{-1}

F = activity conversion factor from dpm (for pCi = 2.22, for Bq = 60)

E = actinium-228 detection efficiency (cpm/dpm)

V = sample aliquot (L, g)

Y_T = total chemical yield, see Section 11.8

D = decay correction for radium-228 = $e^{(-RaT4)}$

T_4 = time elapsed between sample collection (or reference date) and actinium separation T_1 (days)

Ra = decay constant for radium-228 = ln2 / 2100 days = 0.00033004 d^{-1}

T_1 = elapsed time (hours) between the start of the actinium ingrowth (T_0) and the start of actinium decay (T_1) = (T_1 - T_0)

T_2 = elapsed time (hours) between the start of the actinium decay (T_1) and the start of the sample count (T_2) = (T_2 - T_1)

T_3 = duration of sample count (min)

11.2 Calculate the one sigma associated counting uncertainty, CU, in pCi/L or pCi/g as follows:

$$Unc = \frac{\sqrt{(SCPM/T_3) + (BKGCPM/BT)}(Ac * T_3/60)}{F * E * V * Y_T * D * (1 - e^{(-AcT_1)}) * (e^{(-AcT_2)}) * (1 - e^{(-AcT_3/60)})}$$

where:

BT = background count time

11.3 Calculate the one-sigma total propagated uncertainty (TPU), in pCi/L or pCi/g as follows:

$$TPU = \sqrt{CU^2 + (IU^2 * Act) + (PU^2 * Act)}$$

The instrument uncertainty, IU, can be found in SOP 743.

The prep uncertainty, PU, is 0.1374. This is based on SOP 743 guidelines for one gross aliquotting, four quantitative transfers, three volumetric measurements, and two ICP determinations:

$$0.1374 = \sqrt{0.05^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.025^2 + 0.006^2 + 0.006^2 + 0.006^2 + 0.083^2 + 0.083^2}$$

11.4 Calculate the one sigma minimum detectable concentration, MDC, in pCi/L or pCi/g as follows:

$$MDC = \frac{(4.65 * \sqrt{(BKGCPM/T_3)} + 2.71)(Ac * T_3/60)}{F * E * V * Y_T * D * (1 - e^{(-AcT_1)}) * (e^{(-AcT_2)}) * (1 - e^{(-AcT_3/60)})}$$

11.5 The detection efficiency, E, is calculated as follows:

$$E = \frac{(StCPM - BKGCPM)}{StDPM}$$

11.6 Calculate the barium chemical recovery for aqueous samples, Ba, as a percentage, as follows:

$$Ba_i = V_i * ICP_i * DF$$

$$Ba_f = V_f * ICP_f * DF$$

$$Ba_{RC} = V_{RC} * ICP_{RC} * DF$$

$$Ba = \frac{Ba_f}{X} * 100$$

where:

Ba_i = barium recovery from initial ICP aliquot (µg)

V_i = final dilution volume when taking initial ICP (mL)

ICP_i = initial barium concentration measured by ICP (µg/mL)

DF = dilution factor

Ba_f = barium recovery from final ICP aliquot (µg)

V_f = final dilution volume when taking final ICP (mL)

ICP_f = final barium concentration measured by ICP (µg/ml)

Ba_{RC} = barium recovery from RC aliquot (µg)

V_{RC} = RC final volume (mL)

ICP_{RC} = RC barium concentration measured by ICP (µg/mL)

X = either Ba_i or Ba_{RC}, whichever is greater

11.7 Calculate the yttrium chemical recovery for aqueous samples, Y, as a percentage, as follows:

$$Y_f = V_f * ICP_y * DF$$

$$Y_{RC} = V_{RC} * ICP_{yRC} * DF$$

$$Y = \frac{Y_f}{Y_{RC}} * 100$$

where:

Y_f = yttrium recovery from final ICP aliquot (µg)

ICP_y = final yttrium concentration measured by ICP (µg/mL)

Y_{RC} = yttrium recovery from RC aliquot (µg)

ICP_{yRC} = RC yttrium concentration measured by ICP (µg/mL)

11.8 Calculate the total chemical yield, Y_T, as a percentage, as follows:

$$Y_T = Ba * Y * 100$$

For chemical yields above 100%, assume a quantitative recovery and use 100% in the yield calculation. This avoids a low bias in the final analytical results.

11.9 Calculate the actual volume, V_A, of sample analyzed (accounting for volumes of sample removed) as follows:

$$V_A = V * \frac{V_i - V_{ICP}}{V_i}$$

where:

V_{ICP} = initial aliquot taken for ICP (mL)

12. DEVIATIONS FROM METHOD

EPA Method 904.0 addresses drinking water samples. There is no official holding time for analyses in the 900 series. This procedure is substantially compliant with Method 904.0.

12.1 This SOP provides procedures for determining the chemical yield by ICP as an addition to EPA Method 904.0. This measurement increases the accuracy of the method.

12.2 25mL of EDTA is used to dissolve the $Ba(Ra)SO_4$ precipitate. This volume

ensures a complete dissolution of the precipitate in a normal sample.

12.3 Where EPA drinking water methodologies are required by the client, the LCS recovery acceptance criteria shall be ±20%, irrespective of Paragon's internally derived acceptance criteria.

13. SAFETY, HAZARDS AND WASTE DISPOSAL

13.1 SAFETY AND HAZARDS

13.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

13.1.2 Safety glasses, and lab coats must be worn in the radiochemistry prep labs at all times.

13.1.3 Gloves, safety glasses, and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

13.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 14.2 below.

13.1.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

13.1.6 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

13.2 WASTE DISPOSAL

The analytical process effluent has been determined to not be hazardous in other than corrosivity except the Ba and Pb containing supernatants. These supernatants must be segregated into the Ba and Pb waste containers supplied by the Waste Disposal Coordinator.

STANDARD OPERATING PROCEDURE 785 REVISION 4

TITLE: TOTAL ACTIVITY IN ENVIRONMENTAL MATRICES

FORMS: 631 use current iteration

APPROVED BY:

TECHNICAL MANAGER Renee Vallejos DATE 7/21/08
QUALITY ASSURANCE MANAGER Dib Schantz DATE 7/20/08
LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: NEW, Rev0, 3/12/03; Rev1, 12/3/03; Rev2, 5/17/04; Rev3, 8/16/06; Rev4, 7/18/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the method used to determine the total activity of non-volatile radionuclides in solid or liquid matrices. The total activity is determined via liquid scintillation counting (LSC) with the approximate window setting from channel 50 to channel 999. Total activity matrix spikes and laboratory control samples (LCSs) are prepared with Tc-99 (a pure beta-emitter). Total activity of non-volatile beta-emitting radionuclides is achieved by adjustment of the analytical region of interest.

2. SUMMARY

2.1 WATERS

Water samples are routinely analyzed on a "total" or "unfiltered" basis (i.e., unless specifically requested by the client, water samples are not filtered prior to preparation). An aliquot of water is evaporated in a liquid scintillation vial, taken to near dryness, and re-dissolved in dilute nitric acid. Ultima Gold AB™ cocktail is added and total activity determined via liquid scintillation counting (LSC).

2.2 LEACHATES OR DIGESTATES

Following preparation, sample leachates or digestates are determined as described in Section 2.1 above for waters.

2.3 NON-AQUEOUS OR MIXED PHASE LIQUIDS

Non-aqueous liquids are analyzed and reported on an 'as received' basis. They may be treated as waters as long as the physical or chemical characteristics of the sample are amenable to safe evaporation with the eventual addition of nitric acid. Questionable cases should be addressed to the Radiochemistry Manager, Project Manager, or Health and Safety Manager prior to initiation of analysis.

2.4 SOILS AND NON-SOIL SOLIDS (hereafter referred to as "solids")

Solids are analyzed on a 'dry weight' basis. Samples are prepared as stated in SOP 702 - Gross Alpha and Gross Beta in Environmental Matrices, with the

exception that Tc-99 is used for the total activity matrix spike and LCS.

2.5 AIR FILTERS
Air Filters are processed in a manner similar to solids except they need not be weighed and the units are reported on a default basis as "per filter."

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 The prepared scintillation vials are prone to building up pressure and rupturing in storage. It is the responsibility of the instrument analyst to dispose of the scintillation vials as soon as is practical after review and verification of the data, preferably within 60 days after preparation.

3.5 It is the responsibility of all personnel who work with samples utilizing this method to note any anomalous or out-of-control events associated with the preparation and analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 Radionuclides that are volatile during evaporation in nitric acid will not be dependably measured. This method is not applicable to the determination of H-3 or C-14. Other problematic nuclides include radioisotopes of iodine, cesium, and polonium.

4.2 Samples should be evaporated slowly and at low temperatures in order to avoid splattering.

4.3 Sample solutions in a beaker should be slowly evaporated to ***near*** dryness (≤5mL). Avoid evaporating the sample to complete or hard dryness, which could lead to analyte loss resulting from poorly soluble residues in the beaker, as well as volatilization of the Tc-99 spiking analyte.

4.4 Sample solutions in a liquid scintillation vial should be slowly evaporated just to dryness. This will require close observation as the sample approaches dryness. Avoid evaporating the sample to hard dryness, which could lead to analyte loss resulting from the volatilization of the Tc-99 spiking analyte.

4.5 The routine solids leaching procedure may not address radioactive constituents bound in the solid matrix of the sample. More aggressive digestion procedures may be necessary if a total dissolution of the sample is required (see SOP 721).

4.6 Non-aqueous liquid, non-soil solids, and samples with high organic content may not be amenable to this procedure.

4.7 The scintillation vial is an optical surface. Any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation. These should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. All labeling must be done on the cap of the vial.

4.8 The quench indicating parameter (QIP) (usually H-number) should be monitored. Variations in quench that could correspond to greater than 10% relative bias in the efficiency should be addressed either by the use of a quench curve or the method of standard additions.

4.8.1 The presence of visible coloration in the final sample will act as an ‘inner filter’. This effect, known as ‘color quenching’ is an interference to the detection of the scintillation.

4.8.2 The presence of particulate contamination in the final sample may interfere with the detection of the scintillation. This effect is known as ‘physical quenching’.

4.8.3 The presence of chemical contaminants in the sample may inhibit scintillation. This effect is known as ‘chemical quenching’.

5.12 Hot plate

5.13 Steam bath

5.14 Wash bottles

5.15 Graduated cylinders

5.16 Desiccator

5.17 Transfer pipettes, ~3mL, plastic, disposable

5.18 Beakers, 500 and 1000mL

5.19 Vortex mixer

6. REAGENTS

NOTE: Threshold Limit Value (TLV) and other hazard information may also be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Deionized (DI) water

6.2 Methanol, reagent grade

6.3 Ultima Gold AB™ liquid scintillation cocktail

6.4 Tc-99 spiking solution, NIST traceable (source is different than that used for calibration)

6.5 Nitric acid, concentrated (16M), ACS grade

TLV = 2 ppm (TWA). Irritant, corrosive.

6.6 Nitric acid, 8M: Carefully add 500mL concentrated nitric acid to 500mL DI water.

TLV = 2 ppm (TWA). Irritant, corrosive.

6.7 Nitric acid, 2M: Carefully add 125mL concentrated nitric acid to 500mL DI water, and bring to a final volume of 1.0L with DI water.

TLV = 2 ppm (TWA). Irritant, corrosive.

6.8 Nitric acid, 1M: Carefully add 62.5mL concentrated nitric acid to 500mL DI water, and bring to a final volume of 1.0L with DI water.

TLV = 2 ppm (TWA). Irritant, corrosive.

6.9 Nitromethane, reagent grade.

TLV = 20 ppm (TWA). Extremely hazardous, highly reactive, highly flammable, flash-back hazard, carcinogen.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 It is recommended that samples be preserved at the time of collection by adding enough HNO_3 to bring the pH to less than 2. The volume of nitric acid should be minimized to avoid significant dilution of the sample. If samples are to be collected without preservation, they should be brought to the laboratory within 5 days then preserved, with a minimum volume of concentrated HNO_3, to a pH less than 2. After preservation, the samples should be held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.2 The container should be plastic rather than glass to prevent loss due to breakage during transportation and handling.

8. PROCEDURE

8.1 PROCEDURE FOR WATERS

8.1.1 Verify with pH paper that the sample has been properly preserved to a pH <2. Record the pH on the sample condition form (Form 631). Record all appropriate information such as pH, unusual appearance, sedimentation, etc., on the sample condition form.

NOTE: If the pH is $\geq$ 2, acidify to pH <2 with conc. HNO_3. Record the acid addition and the final pH on sample condition form. The date and time of acidification must be noted. Return the sample to storage for at least 24 hours before repeating Step 8.1.1.

8.1.2 Prepare quality control (QC) samples per Section 10.

8.1.3 For default detection limits of 1000 pCi/L, a 10mL sample is required. In this case, aliquot 10mL of sample directly to a liquid scintillation vial and proceed to Step 8.1.7. If a sample aliquot larger than 20mL is required, proceed to Step 8.1.4.

8.1.4 If a sample aliquot of greater than 20mL is required, transfer an aliquot of water to a clean, labeled beaker.

8.1.5 Place the samples on a hot plate and evaporate until approximately 5mL of sample remains. Transfer the sample to a liquid scintillation

vial with a transfer pipette.

8.1.6 Rinse the beaker three times with 5mL 1M HNO_3 and transfer each rinse to the vial.

8.1.7 Evaporate the samples just to dryness on a hot plate over low heat (approximate setting of 3). Allow the samples to cool before proceeding.

8.1.8 Add 2mL 2M HNO_3 to each vial. If necessary, re-dissolve the sample residue over low heat with the caps placed loosely on the vials.

8.1.9 Allow the samples to cool. Add 18mL Ultima Gold AB™ cocktail to each vial, cap tightly, and shake thoroughly to homogenize. Wipe the outside of each vial with methanol in ensure a clean optical surface.

8.1.10 Deliver the samples to the Counting Lab with the necessary documents. Place the racks in the liquid scintillation counter and allow at least 3 hours for samples to "dark adapt" prior to counting. The Counting Lab will analyze and dispose of the scintillation vials, within 60 days, in the manner described in SOP 704.

8.2 PROCEDURE FOR SOLIDS

8.2.1 Solid samples are routinely ground before taking an aliquot for analysis. See SOP 721 for soil preparation procedure. Analysis is routinely reported on a dry-weight basis.

NOTE: In such cases where the client requests gross alpha/beta analysis and total activity analysis, sample preparation as described in SOP 702 may be used. The digestate prepared in SOP 702 may be used for both analyses, although an additional total activity matrix spike and LCS are prepared.

8.2.2 Weigh 3g of solid sample to the nearest 0.0001g into a labeled 50mL centrifuge tube.

8.2.3 Prepare QC samples per Section 10.

8.2.4 Slowly add 8M HNO_3 to yield a total volume of 30mL. Be sure to account for the volume of spiking solutions (i.e., the LCS would receive only 29mL of nitric acid if it already contained 1mL of spiking solution). Some samples may react vigorously with the acid; it may be necessary to add the acid in small increments.

8.2.5 Mix to homogenize the solid and acid solution.

8.2.6 Heat the samples on a steam bath with caps on loosely for one hour. Allow samples to cool, then mix by vortexing.

8.2.7 Centrifuge at approximately 3500 rpm for 10 minutes and filter the supernatant using VWR Grade 313 fluted paper, or equivalent, into a new, labeled centrifuge tube.

8.2.8 Transfer 5mL of the sample leachate obtained in the previous step to a clean, labeled liquid scintillation vial.

8.2.9 Evaporate the samples just to dryness on a hot plate over low heat (approximate setting of 3). Allow the samples to cool before proceeding.

8.2.10 Add 2mL 2M HNO_3 to each vial. If necessary, re-dissolve the sample residue over low heat on a hot plate with the caps placed loosely on the vials.

8.2.11 Allow the samples to cool. Add 18mL Ultima Gold AB™ cocktail to each vial, cap tightly, and shake thoroughly to homogenize. Wipe the outside of each vial with methanol to ensure a clean optical surface.

8.2.12 Deliver the samples to the Counting Lab with the necessary documents. Place the racks in the liquid scintillation counter and allow at least 3 hours for samples to "dark adapt" prior to counting. The Counting Lab will analyze and dispose of the scintillation vials, within 60 days, in the manner described in SOP 704.

9. PREPARATION OF CALIBRATION VIALS (FOR QUENCH CURVE)

Twelve spike and twelve blank vials are prepared with increasing volumes of nitromethane for calibration.

9.1 Blank calibration vial preparation: Add 2mL of 2M HNO_3 to each of twelve blank vials, labeled BLK1-BLK12. Blank vial 1 does not receive nitromethane. Nitromethane is added to each subsequent vial in 30 µL increments (i.e., BLK2 receives 30µL; BLK3 receives 60µL and so on, up to BLK12, which receives 330µL of nitromethane). Add 18mL Ultima Gold AB™ liquid scintillation cocktail to each vial. Cap tightly and shake each vial to homogenize. Wipe the outside of each vial with methanol to ensure a clean optical surface.

9.2 Spike calibration vial preparation: Add a known volume of Tc-99 standard (consult with the liquid scintillation counter primary operator for appropriate spike activities to be used) to each of twelve blank spike vials, labeled S1-S12. Then add an appropriate amount of 2M HNO_3 to each vial to bring the total volume to 2mL. Spike vial 1 does not receive nitromethane. Nitromethane is added to each subsequent vial in 30µL increments (i.e., S2 receives 30µL; S3 receives 60µL and so forth, up to S12, which receives 330µL of nitromethane). Add 18mL of Ultima Gold AB™ liquid scintillation cocktail to bring the final volume of acid + standard + cocktail of each vial to 20mL. Cap tightly and shake each vial to homogenize. Wipe the outside of each vial with methanol to ensure a

clean optical surface.

9.3 Deliver the quench curve vials to the counting lab with the necessary documents. Place the racks in the liquid scintillation counter and allow at least 3 hours for samples to "dark adapt" prior to counting. The counting lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704.

10. QUALITY CONTROL

Acceptance criteria for QC samples may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.1 **Calibration blanks** will be run at a frequency of three per batch. Calibration blanks are prepared directly in the scintillation vials and consist of 2mL 2M HNO_3, and 18mL Ultima Gold AB™ liquid scintillation cocktail, each quenched with approximately 50µL nitromethane. The count data from the calibration blanks will be used to adjust the background quench curve for batch-specific background corrections.

10.2 **Method blanks** will be run at a frequency of five percent (i.e., one per 20 field samples), with a minimum of one per batch. Method blanks for water consist of deionized (DI) water and match the largest sample volume used. Nitric acid is added to the method blank, as it is to the samples, prior to evaporation. Method blanks for solids consist of 30mL of 8N nitric acid.

10.3 **Duplicate** (or replicate) samples will be run at a frequency of ten percent, with a minimum of one per batch. Client requested duplicate analyses shall be run as required and may count as the QC replicates for that batch.

10.4 **Laboratory Control Samples** (LCSs) will be run at a frequency of five percent, with a minimum of one per batch. The spiking levels are determined according to specific data quality objectives for the work being performed, but will generally be 5-10 times the required minimum detectable concentration (MDC) for the respective analyte, or at an activity level roughly equivalent to levels expected to be observed in the samples. The volume for the water LCS is as large as the largest sample volume. The water LCS consists of deionized water and the appropriate volume of spiking solution. The LCS for solids consists of the spike volume brought up to 30mL with 8N nitric acid.

10.5 **Matrix Spike** (MS) will be run at a frequency of five percent with a minimum of one per batch. The spiking levels are generally the same as that used for the LCS. The volume for the water MS is as large as the sample volume of the spike sample. The water MS consists of the sample and the appropriate volume of spike solution. The MS for solids consists of 3g of the solid sample and the spike volume brought up to 30mL with 8N nitric acid.

11. CALCULATIONS

As defined in SOP 743, the following 1σ preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU):

11.1 Water samples require a preparation uncertainty factor of 0.0505. This factor is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one quantitative transfer, and one pipetting. See the following equation:

$$0.0505 = \sqrt{0.05^2 + 0.006^2 + 0.004^2}$$

11.2 Soil samples require a preparation uncertainty factor of 0.0566. This factor is based on one gross aliquoting (sample homogeneity), one mass measurement, one volumetric measurement, two pipetting, and one quantitative transfer. See the following equation:

$$0.0566 = \sqrt{0.05^2 + 0.003^2 + 0.006^2 + 0.004^2 + 0.004^2 + 0.025^2}$$

These two preparation uncertainty factors are substantially equivalent and to simplify analytical reporting, the larger of the two preparation uncertainties calculated above, 0.0566, will be used for both soil and water matrices.

Additional information pertaining to calculations for radioanalytical results can be found in PAR SOP 708.

12. SAFETY HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.1.2 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.2 below.

12.1.3 The building is equipped with a safety shower, eyewash station, fire extinguisher and fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

12.1.4 Safety glasses, lab coats and gloves should be worn in the laboratory at all times.

12.1.5 Use care when handling strong acids (e.g., HNO3, HCl, etc.). Work only in a fume hood with adequate ventilation and wear appropriate eye, face, and body protection. Care should be taken when diluting

acids. Always add acids to water, NOT water to acid.

12.1.6 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at a minimum with: (1) the compound name, (2) NFPA Health, Flammability and Reactivity ratings, and (3) expiration date.

12.2 WASTE DISPOSAL

12.2.1 The liquid effluent from the solid procedure has been determined to not be hazardous other than corrosivity. This material may be discharged into the lab wastewater treatment facility. Here the solution will be neutralized prior to discharge and the activity will be monitored to ensure compliance with Colorado Rules and Regulations, pertaining to Radiation Control Part 4, regarding discharges to sanitary sewers.

12.2.2 Solids and filtered residues should be accumulated in the appropriate container in the designated satellite accumulation area to await further disposal, per consultation with the Waste Disposal Coordinator.

13.1 This is a proprietary SOP developed by Paragon Analytics.

13.2 TLVs and BEIs, ACGIH, 1999, Cincinnati, OH.

DOCUMENT REVISION HISTORY

8/16/06: LIMS program specification language augmented. Standard aliquot sizes reduced to more closely match the Paragon standard MDCs; consequently, the volume reduction, quantitative transfer to the scintillation vial, and the associated TPU factor was changed. Other clerical changes made. DOCUMENT REVISION HISTORY added.

7/18/08: Various clerical changes made. Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Sections 7.1 and 8.1.1. Removed calculations from this SOP and referenced SOP 708 instead. Added QC limits comments as introduction to Section 10.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 786 REVISION 5

TITLE: **GROSS ALPHA IN WATER BY COPRECIPITATION METHOD -- SM 7110C**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07
QUALITY ASSURANCE MANAGER _____ DATE 9/3/07
LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, 7/15/97; Rev1, 11/2/00; Rev2, 4/26/02; Rev3, 8/27/03; Rev4, 9/11/06; Rev5, 8/31/07.

1.0 SCOPE AND APPLICATION

This SOP describes the procedure used to analyze water samples with high dissolved solids content for gross alpha activity by coprecipitation according to Standard Methods for the Analysis of Water and Wastewater, Method 7110C.

2.0 SUMMARY

An aliquot of water is acidified with sulfuric acid and boiled vigorously for 10 minutes to outgas carbon dioxide and ^{222}Radon from the sample. Barium carrier is added to precipitate barium sulfate and the sample is digested while warming to 50°C for 30 minutes. Iron carrier is then added and the sample is neutralized with ammonium hydroxide and is heated and stirred for another 30 minutes to coprecipitate other alpha emitters with iron hydroxide carrier. The precipitate is filtered, dried and counted for alpha activity.

3.0 RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data

involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4.0 INTERFERENCES

4.1 Alpha-emitting radionuclides are coprecipitated on barium sulfate and iron hydroxide, thereby separating the alpha-emitting radionuclides from other sample dissolved solids. The combined precipitates are mounted and counted for alpha activity. Relatively large samples can be analyzed so that sensitivity is improved and counting time is minimized.

NOTE: Polonium is not dependably measured using this method. Thus, other methodologies should be used if the contribution by these nuclides to gross alpha activity is required

4.2 Suspended solids should be removed by filtration prior to chemical separation. Small quantities of suspended solids may be accommodated by this method provided that the range of the attenuation curve is not exceeded.

4.3 Soluble ions that coprecipitate and add to the mixed barium sulfate and iron hydroxide precipitate weights result in reduced sample capacity and elevated detection limits. Small quantities of excess coprecipitated solids may be accommodated by this method provided that the range of the attenuation curve is not exceeded.

4.4 Iron hydroxide precipitates collected on membrane filters without a holding agent may flake when dried and can be easily lost from the filter. Approximately 5mg of paper pulp fiber are added to the sample to help stabilize the iron hydroxide precipitate on the filter. The use of glass fiber filters will prevent loss of precipitate because the rough surface of the filters help to secure the precipitate.

4.5 Minimize filtration time to prevent more air from being drawn through the filter than necessary if counting the same day is planned. Likewise, allow at least 3 hours for decay of radon progeny before beginning the count.

4.6 A significant positive bias for low level samples (less than 5pCi/L) was found in laboratory tests.

5.0 APPARATUS AND MATERIALS

5.1 stirring hot plate

5.2 stir bars

5.3 Eppendorf® pipettors or equivalent, with disposable pipet tips

5.4 beakers, Pyrex® or similar, 1.5 or 2L

5.5 fiber filters, glass, Gelman® Type A/E filter membranes, Millipore® Type AP, or Whatman® Type 934-AH or other equivalent, 0.45µm pore size , 47mm diameter

5.6 planchets, stainless steel, 5cm diameter

6.0 REAGENTS

NOTE: TLV and other hazard information may also be given here. Any chemical with a Threshold Limit Value (TLV) below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that a substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Deionized water, from the laboratory deionized water system.

6.2 Ammonium hydroxide, 6N. Dilute 400mL reagent grade NH_4OH to 1L with deionized water.
TLV= 25ppm for NH_3. Irritant.

6.3 Barium carrier, 5mg Ba^{+2}/mL. Dissolve 4.4g $BaCl_2 \cdot 2H_2O$ in 500mL DI water.
TLV = 0.06ppm (TWA). Irritant.

6.4 Bromocresol purple. Dissolve 0.2121g of the water-soluble reagent and 29.6988g NaOH in 500mL DI water.

6.5 Iron carrier, 5mg Fe^{+3}/mL. Dissolve 12.1g $FeCl_3 \cdot 6H_2O$ in 200mL DI water, containing 2mL 16N Nitric acid. Dilute to 500mL.
TLV = 0.15ppm, irritant

6.6 Nitric acid, concentrated, 16N.
TLV = 2ppm (TWA), irritant, corrosive

6.7 Sulfuric acid, 1N. Dilute 56mL of 18N H_2SO_4 to 1L with DI water.
TLV = 0.25ppm, irritant, corrosive

6.8 Paper pulp/water mixture. Place 1g of paper pulp in a plastic container and dilute to 1L. Add 5 drops of diluted detergent. Stir vigorously for 3 hours before using. This mixture should be stirring when an aliquot is taken.

6.9 Diluted detergent, 1:4. Dilute any commercial water-soluble detergent or wetting agent with DI water.

6.10 NIST-traceable ^{241}Americium standard solutions: One source for calibration, and a second source for laboratory control samples (LCSs).

7.0 SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 It is recommended that samples be preserved at the time of collection by adding enough 1N HNO_3 to the sample to bring it to pH 2 (15mL 1N HNO_3 per liter of sample is usually sufficient). If samples are to be collected without preservation, they should be brought to the laboratory within 5 days and then preserved and held in the original container for a minimum of 24hrs before analysis or transfer of the sample.

7.2 The container should be plastic rather than glass to prevent loss due to breakage during transportation and handling.

8.0 PROCEDURE

8.1 PROCEDURE FOR SAMPLES

8.1.1 Use a measured aliquot of water sample. If the available sample volume is less than 500mL, or if a decreased aliquot size is required due to suspected coprecipitation of dissolved solids, dilute a reduced aliquot to 500mL with distilled water. No dilution is necessary for aliquot sizes greater than 500mL.

8.1.2 Prepare quality control (QC) samples per Section 10.

8.1.3 Add 5 drops of the diluted detergent.

8.1.4 Place the sample on a magnetic stirrer/hot plate and, while stirring, gently add 20mL of 1N sulfuric acid and boil for 10 minutes to flush carbon dioxide (from carbonates and bicarbonates) and radon from the sample.

8.1.5 Lower the hot plate temperature to below sample boiling, continue stirring, and add 1mL of barium carrier solution. Continue stirring for 30 minutes.

8.1.6 Add 1mL of bromocresol purple indicator solution, 1mL of iron carrier and 5mL of paper pulp/water reagent (aliquot taken while the paper pulp mixture is stirring). You may cut the end off of the pipet tip to facilitate pipetting the paper pulp if necessary.

8.1.7 Continue stirring and add 6M NH_4OH drop wise to the sample until there is a distinct color change (yellow to purple). Continue warming and stirring for 30 minutes.

8.1.8 Filter the sample through a glass fiber filter, rinsing all precipitate from the beaker to the filter. Wash the precipitate with 25mL of DI water.

8.1.9 Dry the filter in the drying oven and allow a minimum of 3 hours for the collected radon progeny to decay.

8.1.10 Three filter blanks, consisting of a glass fiber filter mounted on a flat planchet, are processed with the samples and used to determine the contribution to background and in determining the background correction to be applied to samples.

8.1.11 Count the filters for alpha activity on a calibrated low background gas flow proportional counter (GFPC).

8.1.12 Store samples in a desiccator if they are to be recounted at a later date. The Instrument Lab will ultimately dispose of the filters in the manner described in SOP 724.

8.2 PREPARATION OF CALIBRATION STANDARDS

8.2.1 Add at least 100pCi of NIST-traceable standard alpha-emitter (^{241}Am or other, as appropriate to meet DQOs), to a series of 500mL portions of DI water in separate beakers.

Add varying amounts of barium and iron carrier solutions (hold the volume of Fe carrier equal to that of the volume of Ba carrier), to produce final precipitate weights varying from 10-110mg.

Add 2.5mL conc. HNO_3 to each beaker and process according to the method.

Determine the background and decay corrected counting efficiency (cpm/dpm) for the alpha-emitter of each standard by taking these known additions through the procedure.

Prepare a curve of at least six standards to determine counting efficiency as a function of residue mass.

Plot mass of residue vs. measured efficiency to establish alpha attenuation correction factors for this method.

8.2.2 The normal mass-corrected efficiency is in the form of::

$$e * b * m^{a(x-x_0)}$$

where:

e = the individual zero-mass detector efficiency

x = the residual mass on the planchet in mg

x_0 = the average residual mass of the efficiency planchets

The mass attenuation curve used for gross alpha by co-precipitation is unable to incorporate a zero-mass point since a precipitate is necessary to the method. To facilitate reporting, in this case e equals the individual mid-mass detector efficiency and x_0 equals the mid-mass in mg.

9.0 CALCULATIONS

9.1 Total Propagated Uncertainty (TPU) is reported at the one sigma level.

9.2 The Prep uncertainty is 0.0564, based on one gross aliquoting, one quantitative transfer, one pipetting, one mass measurement and one volumetric measurement:

$$0.0564 = \sqrt{0.05^2 + 0.025^2 + 0.004^2 + 0.003^2 + 0.006^2}$$

9.3 Instrument uncertainty is assumed to be equivalent to that specified in SOP 708.

10.0 QUALITY CONTROL

Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames); consult applicable LIMS program specification.

10.1 One Laboratory Control Sample (LCS) is processed with each set of 20 or fewer samples. This is done by aliquoting 500mL of DI water made acidic to a pH less than 2 with concentrated nitric acid. The LCS is spiked with approximately 100dpm of ^{241}Am.

10.2 One Blank is processed with each set of 20 or fewer samples. This is done by aliquoting 500mL of DI water made acidic to a pH less than 2 with concentrated nitric acid.

10.3 One duplicate sample is prepared for each batch of ten samples.

10.4 One matrix spike analysis is performed per 20 samples. Matrix spikes are spiked at 5-10 times expected activity.

NOTE: Spikes are added *before* the sample receives any chemical treatment.

11.0 DEVIATIONS FROM METHOD

There are no significant deviations from Standard Method 7110C.

12.0 SAFETY HAZARDS AND WASTE

12.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.2 Gloves, safety glasses, and lab coats must be worn during the sample preparation part of this procedure.

12.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g. solvents and acids).

DOCUMENT REVISION HISTORY

9/11/06: No technical changes. Augmented LIMS program specification language (RESPONSIBILITIES). Added DOCUMENT REVISION HISTORY section. Other minor clerical corrections.

8/31/07: Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Section 7.1. Removed activity calculations and referenced SOP 708, Section 9. Added Notes to Section 10 that acceptance limits for quality control parameters may vary per client specifications, consult applicable LIMS program specification; also spikes are added *before* the sample receives any chemical treatment.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 791 REVISION 3

TITLE: PREPARATION OF SILICA GEL SAMPLES FOR TRITIUM ANALYSIS

FORMS: 302, 311

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/6/07
QUALITY ASSURANCE MANAGER _____ DATE 8/14/07
LABORATORY MANAGER _____ DATE 8/15/07

HISTORY: Rev0, 11/02/01; Rev1, 4/07/03; Rev2, 10/7/03; Re-released w/o revision 11/30/04 and 3/15/05 (format updated); Rev3, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the preparation of silica gel matrices for quantitative measurement of tritium by liquid scintillation analysis. This SOP was written specifically for the ESH-17 group at Los Alamos National Laboratory (LANL), but may be applicable to silica gel samples from other clients and sites.

2. SUMMARY

The contents of silica gel filter cartridges used to monitor environmental airborne tritium, are heated in a traditional distillation apparatus to capture the trapped water. The distillate is then analyzed by liquid scintillation counting (LSC, SOP 704) to quantify the tritium extracted from the sample. Water removal efficiencies are monitored by measuring the amount of water extracted from the sample and comparing this value to the field measurement of the corresponding pre-loaded and post-loaded silica gel weights.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst performing the method to notify the Instrument Lab Gas-Flow Proportional Counter analyst in advance of the number of samples arriving and the expected delivery date and time. This allows the analyst to schedule adequate instrument time to analyze the short-lived Ac-228 analyte.

3.2 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful completion of an unknown proficiency test sample.

3.3 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715

as well as the LIMS program specification related to the client, project, and test method being performed.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 This method addresses the preparation of silica gel that has been loaded with ambient water vapor. The presence of other volatile organic compounds has been shown to cause elevated luminescence in the sample/LSC cocktail mixture, which may interfere with the subsequent analysis by liquid scintillation counting. For this reason, silica gel samples are always counted in the LS6000. This instrument provides a lumex correction.

4.2 The target nuclide in this analysis is an isotope of hydrogen (^{3}H), usually bound to a water molecule. Addition of water, acid or any other materials containing significant quantities of hydrogen, and possibly tritium, can significantly alter the hydrogen and tritium concentrations in the sample and could potentially compromise sample integrity.

4.3 All glassware used for this procedure must be cleaned per Paragon SOP 720, using Radiacwash™ or similar detergent, triple-rinsed with DI water, and thoroughly dried in a 100-110°C oven. Distillation flasks should be thoroughly cleaned with aqua regia, as needed, to remove buildup of visible residues in the flasks.

4.4 When determining water removal efficiencies, the mass of water extracted is compared to the mass of water loaded onto the silica gel. In some cases, moisture native to the silica gel, which is not part of the ambient water vapor loaded onto the gel, may be co-distilled and interfere with the accurate determination of distillation efficiency.

4.5 When used for liquid scintillation counting, the scintillation vial is an optical surface. Therefore, any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation using the LSC instrument. All

markings and materials must be removed prior to analysis using alcohol and a lint-free lab wipe. ***All labeling must be done on the cap of the vial.***

4.6 The presence of visible discoloration in the distillate will act as an 'inner filter' in the sample/cocktail mixture. This effect, known as 'color quenching', is an interference to the detection of the scintillation. The quench indicating parameter or 'QIP' (usually H-number), should be monitored, and variations in quench that could correspond to a greater than 10% relative bias in efficiency (+/-15 H#'s), should be addressed by using standard additions to determine a sample specific efficiency. The correct procedure for performing standard additions is detailed in Paragon SOP 704.

4.7 The presence of particulate contaminant in the final distillate may interfere with the detection of the scintillation. This effect is known as 'physical quenching'. The symptoms, control limits, and corrective actions for physical quenching are identical to those discussed in Section 4.6 above.

4.8 The presence of chemical contaminants in the final distillate may inhibit scintillation. This effect is known as 'chemical quenching'. The symptoms, control limits, and corrective actions pertaining to chemical scintillation are identical to those mentioned in Section 4.6 above.

4.9 The presence of volatile beta- (or alpha-) emitting materials (e.g., low boiling organics, etc.), which could co-distill with water, are a positive interference to this method. The sample spectrum is monitored for evidence of higher energy species in the distillate (especially ^{14}C). When counts above the established control limits are observed in the higher energy analysis region, these counts could bias the tritium results, and a Non-Conformance Report (NCR; Form 313), must be initiated. If the tritium results are below the calculated MDC for that sample, or if the sample contains sufficient tritium such that the potential bias is not significant, a Quality Assurance Summary Sheet (QASS; Form 302) and appropriate narrative comments are sufficient.

5. APPARATUS AND MATERIALS

5.1 Scintillation vials, low-potassium glass, 20mL

5.2 VOA vials, 40mL

5.3 Glass bottle, amber, 125mL

5.4 Condenser, Pyrex™, #8946-24 or equivalent, 24/40 ground glass joints

5.5 Distillation neck, Pyrex™, #8946-24 or equivalent, 24/40 ground glass joints

5.6 Flask, round-bottom, Pyrex™ or equivalent, 250mL, 24/40 ground glass neck

5.7 Drying tube, polyethylene with desiccant

5.8 Heating mantle assembly, Lancor™, #01023 or equivalent, fits 250mL flasks

5.9 Variable output transformer, Staco™, #3PN1010 or equivalent

5.10 Infrared Thermometer, Raynger ST #267249, or equivalent

5.11 Small funnel

5.12 Pipette and disposable pipet tips, fixed, 1mL

5.13 Pipettor, adjustable, 1-5mL

5.14 Re-pipette dispenser and disposable pipet tips, adjustable, 1-20mL

5.15 Transfer pipettes, disposable, glass

5.16 Rigid tubing for vacuum, attached to condenser outlet

5.17 Specimen cups, plastic, disposable, with lid

5.18 Analytical balance, 0.0001g sensitivity

6. REAGENTS

6.1 Deionized (DI) water, obtainable from the laboratory's DI water system

6.2 Anhydrous calcium sulfate ($CaSO_4$), or indicating Drierite™

6.3 Liquid scintillation cocktail, Ultima-Gold™ LLT or equivalent brand (e.g., Packard)

6.4 Hydrochloric acid (HC1), 12N, concentrated. TLV = 5 ppm (ceiling). Irritant, corrosive

6.5 Nitric acid (HNO_3), 16N, concentrated. TLV = 2 ppm (TWA). Irritant, corrosive

6.6 Tritium-free water: Water from a deep well or other reagent water (e.g., distilled or deionized), that shows activity indistinguishable from the method background. At the time of publication of this SOP, an independent source of tritium-free water has not been located. As long as this remains the case, each analytical batch will be prepared with laboratory deionized water.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Environmental tritium is collected in a silica gel cartridge. The silica gel can be removed from the cartridge in the field and transferred to a separate container for shipment to the lab, or the loaded cartridge may be sent directly to the lab.

7.2 Tritium samples should not be chemically preserved.

7.3 Keep all sample containers tightly closed. If samples are to be stored for an extended period of time, refrigeration or freezing is recommended to prevent biological growth in the sample.

7.4 At the current time, there is no regulatory holding time for tritium preparation and analysis. Many sampling and analysis plans, however, apply a default holding

time of 180 days from collection for this analysis. If samples are analyzed more than 180 days after collection, this fact should be noted in the case narrative.

8. SILICA GEL DISTILLATION PROCEDURE

8.1 Note the number of functional distillation apparatti available, and gather the appropriate number of collection vessels to be used. The processing of the Quality Control (QC) samples described in Section 9 of this SOP, must also be provided for. Use a 20mL scintillation vial as the collection vessel for these QC samples.

8.2 Consult the moisture loading data provided by the client to determine which type of collection vessel should be used for each sample. For samples with less than 18mL of water loaded onto the silica gel, a 20mL scintillation vial may be used. For samples with greater than 18mL of water loaded, use a 40mL VOA vial. If the moisture loading data indicates that more than 35mL of water is loaded onto the silica gel, use a 125mL amber glass bottle as the collection vessel.

8.3 Label the cap of each collection vessel with a field or QC sample ID. Obtain a tare weight for each collection vessel with cap, using an analytical balance on which a daily calibration verification check has been performed (SOP 305). Record this capped empty collection vessel tare weight on the benchsheet.

8.4 Assuming that the silica gel has already been removed from the sampling cartridge, remove one silica gel sample per remaining available distillation apparatus from the sample storage area. Transfer the entire contents of each sample container into a labeled round bottom flask.

NOTE: If the entire sample does not fit into the flask, **stop immediately**. Tightly cover the flask and sample container with Parafilm, and notify the supervisor and project manager immediately, to receive directions on how to proceed.

8.5 If not already assembled, assemble the distillation apparatti. The heating mantle should be controlled with a variable output transformer. The round bottom flask should fit snugly in the mantle. The neck of the flask and the condenser should be supported with a ring-stand or similar apparatus. The round bottom flask should be fitted securely onto the condenser. The collection vessel (Step 8.1), should be placed snugly under the bottom of the condenser, and should be supported in a small disposable cup or similar apparatus to prevent spillage.

8.6 Fit a flask, containing sample, onto each distillation apparatus. Make sure that the ground glass joints fit tightly together.

8.7 Turn the heating mantle power on. The variable output transformer should be set to approximately 80%.

8.8 Allow the silica gel (or QC sample) to heat for a minimum of two hours. After two hours, use an infrared thermometer to check the surface temperature of the round bottom flask. *The each day of use check (SOP 210) must be performed before using the infrared thermometer.*

Take great care in aiming the thermometer to ensure an accurate reading of the flask below the level of the gel. Be sure not to measure the mantle or other apparatus. If the temperature reads below 200°C, additional heating time is required. Continue heating the sample, checking the temperature approximately every thirty minutes.

NOTE: The infrared thermometer is verified in-house, annually, per SOP 923. General procedures for operating the infrared thermometer are given in SOP 210.

8.9 When the temperature of the flask exceeds 200°C, the distillation is complete. Remove the collection vessel and cap tightly. Be sure that the collection vial is labeled properly with the sample ID number.

8.10 Weigh the vial containing the collected distillate and record this mass on the benchsheet. For field samples, this mass is used to determine the net weight of water recovered, for comparison with the moisture loading data provided by the client. If the water recovery is less than 90% of the expected value, continue heating the sample until the net weight of the distillate remains constant (i.e., ±2%) over a 60 minute interval. ***Do not turn the heating mantle off until this criterion is achieved.*** A QASS should be written for each sample that required additional distillation, to describe the situation and the corrective action taken.

8.11 Once the heating mantles are turned off, allow the silica gel to cool for approximately 60 minutes. When the flask is cool enough to handle, discard the gel into the sanitary trash.

8.12 Use a previously calibrated pipettor (SOP 321), to aliquot 5.0mL of distillate from the collection vial into a labeled, 20mL, glass scintillation vial. Record the aliquot of sample distillate used on the benchsheet.

8.13 If less than 5.0mL of distillate is available, tare a scintillation vial on an analytical balance, transfer the available distillate, Record the transferred distillate on the benchsheet and bring the distillate to the standard mass of 5.0 grams with tritium-free water. This brings the reduced sample volume to a standard counting geometry volume. If the distillate was collected in a 20mL glass scintillation vial, this same vial may be used for the actual analysis, without transferring the sample to a new vial.

8.14 Dispense 15.0mL Ultima Gold LLT™ scintillation cocktail into each scintillation vial, cap, and shake well.

8.15 Clean the outside of the scintillation vials with a lint-free wipe and alcohol to remove dust, smudges, and fingerprints.

8.16 Place the vials in a scintillation counting rack, and deliver the vials and benchsheet to the Instrument Lab for counting.

9. QUALITY CONTROL

9.1 CALIBRATIONS

9.1.1 Re-pipettor calibration: The re-pipette dispenser is checked monthly by dispensing a 10mL aliquot of scintillation cocktail into a 10mL graduated cylinder. The volume dispensed should be 10mL +/- 0.1mL. If not, adjust the dispenser and re-check. Record the calibration check in the pipette calibration logbook (Form. When scintillation cocktail is dispensed in Step 8.14 of this SOP, it is delivered as two 7.5mL aliquots.

9.1.2 Efficiency calibration: Single point efficiency calibrations should be performed in the same counting geometry as the samples, typically 5.0mL sample in 15.0mL cocktail. The specific calibration sequence is detailed in SOP 704.

9.1.3 Background calibration (calibration blanks): Unless the client specifically requests otherwise, the instrument background rate will be determined by preparing seven calibration blanks in the same counting geometry as the samples (i.e., 5mL of DI water with 15mL of Ultima Gold™ LLT scintillation cocktail added will be used). The calibration blanks will be counted under identical parameters as the samples, and the mean gross count rate will be used as the instrument background count rate for this method. This approach should be noted in the case narrative, and all pertinent raw data and calculations should be provided in the data package report. If requested by the client, the instrument background rate may be determined using the background calibration procedure described in SOP 704.

9.2 QC SAMPLE PREPARATION

9.2.1 Quality control samples are processed and results calculated in the same manner as the associated field samples.

9.2.2 Method Blank. One Method Blank is prepared per each batch of 20 or fewer samples. The method blank is prepared by distilling 10mL of DI water (distill 20mL of DI water if a laboratory control sample duplicate

is prepared for the sample set; this provides for volume consistency amongst the QC samples), without silica gel, as described in Section 8.

9.2.3 Blank Spike (also known as the Laboratory Control Sample, LCS). Prepare one Blank Spike (LCS) per batch of 20 or fewer samples. If there is insufficient field sample to prepare a client sample duplicate per Section 9.2.3 below, the laboratory control sample can be prepared in duplicate (i.e., create an LCSD).

Dilute approximately 2000 pCi ^{3}H with tritium-free water to a final volume of 10.0mL to prepare an LCS. If both an LCS and LCSD are to be prepared, dilute approximately 4000 pCi ^{3}H with tritium-free water to a final volume of 20.0mL.

Distill and prepare as described in Section 8.

9.2.4 Sample duplicates are prepared at a minimum frequency of two per batch of 20 samples or 10%, whichever is greater. The sample duplicate is prepared by aliquotting a second 5.0mL portion from the same distillate obtained for the sample (the total amount of sample distillate should exceed 10.3mL in order to accommodate the duplicate as well). If the volume of sample distillate is limited, note in a QASS and prepare an LCSD (as described in Section 9.2.2) instead.

10. CALCULATIONS

10.1 The sample activity, TPU, and minimum detection concentration calculations are provided in SOP 708, Calculations for Radioanalytical Results.

10.2 The tritium Prep Uncertainty, as shown below, is 0.007 based on one pipetting and one reagent addition:

$$0.007 = \sqrt{(0.004^2 + 0.006^2)}$$

11. DEVIATIONS FROM METHOD

This procedure is compliant with Method H-02, of the Eastern Environmental Radiation Facility (EERF) Procedures Manual.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Renew the anhydrous $CaSO_4$ desiccant approximately every analytical run, or as needed. Remove the drying tube and replace the spent $CaSO_4$ with fresh anhydrous $CaSO_4$.

12.1.2 Read the MSDSs prior to preparing standards or using any solvents or reagents.

12.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.4 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents) or when handling materials or equipment potentially contaminated with chemicals (e.g., samples).

12.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at a minimum with compound name; NFPA Health, Flammability, and Reactivity ratings; and date.

12.1.6 Care should be taken when working with the heating mantles and boiling water to prevent thermal burns.

12.1.7 Silica gel, when dry, can be a skin and respiratory irritant. All handling of the silica gel should be done inside a fume hood.

12.2 WASTE DISPOSAL

12.2.1 All empty radionuclide standard solutions are disposed of by rinsing the standard container a minimum of three times using tap water. The container must be surveyed prior to release for disposal. Please note that all labels and markings must be defaced or removed prior to disposal.

12.2.2 The tritium analytical process effluent from this method has been determined to not be hazardous in any way. Consequently, this material may be discharged into the Paragon wastewater treatment facility (i.e., down the drain with plenty of tap water). The solution will be neutralized prior to discharge, and the radionuclide concentration will be monitored to ensure compliance with Colorado Rules and Regulations, Radiation Control, Part 4.

12.2.3 Silica gel is non-hazardous and, after distillation, may be disposed of in the sanitary trash. The original sample containers may also be placed in the sanitary trash after rinsing the container and removing the client ID label and any other identifying marks.

12.2.4 Check with waste management staff for proper disposal of scintillation cocktail.

12.2.5 Vials of sample/cocktail mixture may be accumulated (intact) in a container provided by Waste Management Staff.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 792 REVISION 0

TITLE: **DETERMINATION OF TOTAL ALPHA-EMITTING RADIUM ISOTOPES IN ENVIRONMENTAL SAMPLES BY ALPHA SPECTROSCOPY**

FORMS: **631**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/3/07

LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, was DRAFT, first published 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) is applicable to the measurement of total soluble alpha emitting isotopes of radium, namely Ra-223, Ra-224, and Ra-226, in environmental samples.

2. SUMMARY

2.1 SAMPLE PREPARATION (MINERALIZATION / CONCENTRATION / DISSOLUTION)

2.1.1 **Aqueous Samples:** Barium-133 tracer is equilibrated with an aliquot of the sample. Aqueous samples are concentrated using cation exchange. The column eluate is taken to dryness and is redissolved in 0.095M HNO_3. Radium is separated from the concentrated sample as summarized in Section 2.2 below.

2.1.2 **Solid Samples:** A representative sub sample of the sample is dried and ground. Barium-133 is equilibrated in 1 gram of the ground sample. The sample may be muffled if significant organic material (e.g., humic soils or oily solids) is present. The sample is digested on a steam bath in concentrated HCL, HNO_3, and HF acids. The sample is taken to dryness and redissolved in concentrated HNO_3 and DI water. The sample is concentrated using cation exchange resin. The column eluate is taken to dryness and is redissolved in 0.095M HNO_3. Radium is separated from the concentrated sample as summarized in Section 2.2 below.

2.2 SEPARATION, PURIFICATION, AND MOUNTING OF THE RADIUM

Radium is separated from the nitric acid digestate/concentrate using Eichrom LN-Resin. The radium is co-precipitated with $BaSO_4$ and mounted onto a

polypropylene filter. The filter is mounted onto a planchet and submitted for alpha spectroscopy analysis, as described in SOP 714. To quantify Ra-224 directly, the alpha counting must start within 24 hours of barium sulfate precipitation. After alpha counting the filter is counted by gamma spectrometry to determine the Ba-133 concentration to establish the chemical recovery of the sample. The radiometric results are corrected for chemical yield on a sample-by-sample basis.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful completion of a proficiency evaluation test.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715, and the applicable LIMS program specification.

3.3 In the event that Ra-224 analysis is required , it is the responsibility of the technician performing this separation method to coordinate the delivery of samples with the instrument analyst to ensure that sufficient detector capacity is immediately available.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon’s standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who perform this procedure to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 The presence of significant native barium in the sample may cause interference by producing excessive precipitate in the final preparation steps. This will lead to degradation of spectral quality due to mass-attenuation of the alpha particle kinetic energy. In this case, a split of the separated (Ra + Ba) sample must be performed prior to micro-precipitation, in order to limit the total mass of $Ba(Ra)SO_4$ deposited on the filter.

4.2 Samples that contain very high concentrations of cation concentrations can overwhelm the capacity of the cation exchange column. This will cause a low chemical and radiometric recovery in the samples.

4.3 Samples that contain a significant concentration of sulfates may sequester the radium and barium as $Ba(Ra)SO_4$, making these analytes unavailable to the separation technique. This may result in a either a low chemical yield, with otherwise acceptable results, or an overall low bias in the final results.

5. APPARATUS AND MATERIALS

5.1 Disposable ion exchange columns: 15mL resin volume with attachable funnel to receive 2 L bottle. (Environmental Express part numbers R10204 and R10304 or equivalent.)

5.2 Disposable Bio-rad column (catalog #731-1553) or equivalent, with funnel.

5.3 Analytical balance with 0.0001g resolution, Mettler AE200 or equivalent.

5.4 Pipet tips

5.5 Graduated cylinder, 1L

5.6 50 mL polypropylene centrifuge tubes

5.7 2 L disposable plastic bottles

5.8 Repipettor, Eppendorf model 4780 or equivalent

5.9 pH paper

5.10 Eppendorf pipets or equivalent, variable volumes

5.11 Specimen cups, 250mL, or equivalent

5.12 Specimen cups 100mL or equivalent

5.13 Tongue depressors

5.14 Test tubes, 15mL, disposable, with caps

5.15 Beaker, 50, 100, 400, and 500mL

5.16 Plastic stir rods

5.17 Polypropylene filter, 0.1 micron, 25mm

5.18 Polysulfone funnel

5.19 Heat lamp

5.20 Desiccator

5.21 Metal wire, bent into a loop

5.22 Hot Water Bath, (90-100 °C)

5.23 Vacuum apparatus

5.24 Vacuum desiccator

5.25 0.45µ membrane filter

5.26 Stir bars, plastic

5.27 Erlenmeyer flask, 250mL

5.28 Blast burner, or equivalent

5.29 Tongs

5.30 Transfer pipets, plastic

5.31 Funnel, plastic, to fit in the Bio-rad column

5.32 Filter paper, Whatman 41

6. REAGENTS

NOTE: TLV and other hazard information may also be given here. Any chemical with a TLV below 50 ppm must be worked with in a laboratory fume hood. The absence of this information does not mean that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Deionized (DI) water, ASTM Type II.

6.2 NIST traceable ^{133}Ba spiking solution. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.3 NIST traceable ^{226}Ra spiking solution. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.4 Hydrofluoric acid (HF), 48.0-51.0 %, conc. TLV = 3 ppm (ceiling). Irritant, burns, bone, teeth, fluorosis.

6.5 Nitric acid, concentrated (16M). ACS grade. TLV = 2 ppm (TWA). Irritant, corrosive

6.6 Nitric acid, 8M: Cautiously add 500mL of concentrated nitric acid to 400mL of DI water. Dilute to 1 L. See 6.5 for TLV.

6.7 Nitric acid, 0.1M: Cautiously add 6.3mL of concentrated nitric acid to 900mL of DI water. Dilute to 1 L. See 6.5 for TLV.

6.8 Nitric acid, 0.095M: Cautiously add 6.0mL of concentrated nitric acid to 900mL of DI water. Dilute to 1 L using a class A 1 L volumetric flask. See 6.5 for TLV.

6.9 Hydrochloric acid, concentrated (12M). ACS grade. TLV = 5 ppm for conc. HCl (ceiling). Irritant, corrosive.

6.10 ICP Solution; 5% HNO_3/2.5% HCL for diluting solutions to be analyzed by ICP. Carefully add 50mL of concentrated HNO_3 and 25mL of concentrated HCL to 925mL of DI water. Mix thoroughly. See 6.5 and 6.9 for TLVs.

6.11 Cation exchange resin, AG50x8 (Eichrom or equivalent).

6.12 LN resin, Eichrom (particle size 50-100µm).

6.13 Silica sand, reagent grade.

6.14 Barium chloride, dihydrate ($BaCl_2 \bullet 2H_2O$), reagent grade. TLV = 0.5 mg/m^3 (TWA) as Barium.

6.15 Barium carrier, 0.75mg/mL: Dissolve 338 mg of barium chloride, dihydrate, in 200 mL DI water and dilute to 250 mL with DI water. See 6.14 for TLV.

6.16 Glacial Acetic Acid (CH_3COOH_2), 17.4N, concentrated: 99.8%, ACS reagent grade. TLV = 10 ppm (TWA). Irritant.

6.17 Acetic acid, 1:1: Add 500mL of glacial acetic acid to 400 mL DI water and dilute to 1 L. Shake to mix before use. See 6.16 for TLV.

6.18 Sodium sulfate, anhydrous, reagent grade.

6.19 Sodium sulfate, 20%: Dissolve 100g of anhydrous sodium sulfate in 460mL of DI water at room temperature with stirring and filter through 0.45µm filter. Collect filtrate and discard residue on the filter.

6.20 Sodium sulfate, 70%: Add 45mL of concentrated sulfuric acid slowly with continuous stirring to 180mL of water in a 500mL beaker. Add 104g of anhydrous sodium sulfate. Cover the beaker and stir until completely dissolved. See 6.21 for sulfuric acid TLV.

6.21 Sulfuric acid, concentrated (36M). ACS grade. TLV = 1 mg/m^3 (= 0.25 ppm)

(TWA). Irritant. Strong mists are considered a suspected human carcinogen.

6.22 Seeding suspension: Place 11.3mg of barium chloride, dihydrate, 10mL of the 70% sodium sulfate solution in a 250 mL Erlenmeyer flask. Evaporate the solution carefully over high heat (e.g. a blast burner) while swirling the solution continuously to prevent bumping until the barium sulfate has dissolved. Increase the heating and continue until most of the excess sulfuric acid has been expelled and a fusion is obtained. Cool the flask and add a solution of 50mL of 20% sodium sulfate solution and 25mL of DI water. Swirl to mix. **To be prepared fresh weekly.** (Old seeding suspension may cause a degradation of the alpha peak resolution. In old suspensions, recrystallization of the barium sulfate may occur that is significant enough to cause the original extremely finely divided barium sulfate to become more granular, which in turn sets the lattice for the precipitation.) See 6.14 and 6.20 for TLVs.

6.23 Methanol, reagent grade. TLV = 200 ppm.

6.24 Amyl acetate, reagent grade. TLV = 100 ppm as n-Amyl acetate.

6.25 Collodion, reagent grade.

6.26 Thin film solution: Add 1:1 ration of amyl acetate and collodion together. Mix well. Prepare fresh weekly. See 6.24 for TLV.

7. PROCEDURE

7.1 SOLID SAMPLES

7.1.1 Verify and record (on Form 631) the condition of the sample.

7.1.2 Weigh 1 gram of dried, pulverized soil into a permanently labeled 50 or 100mL glass beaker. Typical aliquot size is 1.0g but may be adjusted due to MDA or matrix interference considerations. Record the sample weight and beaker number on the benchsheet.

NOTE: If the samples do not require muffling (little to no organic material), aliquot into a 250mL specimen cup.

7.1.3 Prepare QC samples by placing an ashless filter paper in a permanently labeled 50 or 100mL glass beaker. If no muffling is required do not add filter paper, label a 250mL specimen cup instead.

NOTE: Spiking and tracing activity levels for solids, and in some cases liquids, may need to be significantly adjusted to allow for possible splitting of the prepared sample, before micro-precipitation. This may be necessary in samples with elevated native barium concentrations.

Unless otherwise directed, spike the LCS with 10-50 dpm of Ra-226. Activity levels may be adjusted after consulting with the alpha spectroscopist, and with approval from the Department Manager. Add spikes *before* chemically treating sample.

7.1.4 Add 1,000-5,000dpm of Ba-133 to all the samples. Activity levels may be adjusted after consulting with the gamma spectroscopist, and with approval from the department manager.

7.1.5 If muffling is not required proceed to Section 7.1.8, also adding 25mL of concentrated nitric acid. Otherwise proceed to Step 7.1.6.

7.1.6 Dry the beakers on a hotplate set at 2. Cover beakers with a watch glass and muffle at approximately 600˚C for at least 4 hours.

7.1.7 After muffling, allow the beaker to cool and transfer to a 250mL specimen cup with 25mL of concentrated nitric acid. Scraping with a plastic spatula may be necessary to remove all of the soil from the beaker.

7.1.8 Add 25mL of concentrated HCl and 25mL of concentrated HF. Cover the sample with a 100mL specimen cup and heat for 4 hours on a steambath.

7.1.9 Remove the 100mL specimen cup and take the sample to dryness. The 100mL specimen cups may be rinsed off with tap water and disposed of in the sanitary trash.

7.1.10 Once samples are dry, redissolve the residue in 10 mL of concentrated nitric acid and approximately 100mL of DI water. Leave on the steambath for 15 minutes to aid in the dissolution of the sample. Remove from steambath.

7.1.11 Remove a known aliquot for ICP analysis. Bring the sample to a known volume with DI water. Using the graduations on the specimen cup to determine the sample volume is acceptable. Record this volume on the bench sheet. Pipette 0.1mL, into a disposable test tube. Add 9.9mL ICP solution. Submit to the metals department for Ba analysis by ICP.

7.1.12 Proceed to Section 7.3 for concentration by cation exchange.

7.2 PROCEDURE FOR AQUEOUS SAMPLES

7.2.1 If, based on the expectation of matrix interferences, an ICP analysis of the native Ba concentration is indicated, perform Step 7.1.11 before proceeding.

7.2.2 Verify and record the pH of the sample on a liquid sample condition form per SOP 733.

7.2.3 Measure an aliquot in a graduated cylinder and place the aliquot in a labeled disposable 2 L bottle. Record the volume in mL on the benchsheet. Typical sample volume is 1 L. If sample volume is less than 1 L, note the volume on the benchsheet.

7.2.4 Prepare a blank and an LCS by aliquotting 1 L of DI water for both and tranfering to a labeled 2 L disposable bottle.

7.2.5 NOTE: Spiking and tracing activity levels for solids, and in some cases liquids, may need to be significantly adjusted to allow for possible splitting of the prepared sample, before micro-precipitation. This may be necessary in samples with elevated native barium concentrations.

Unless otherwise directed, spike the LCS with 10-50 dpm of Ra-226. Activity levels may be adjusted after consulting with the alpha spectroscopist, and with approval from the Department Manager.

7.2.6 Add 1,000-5,000 dpm of Ba-133 to each sample.

7.2.7 Proceed to Section 7.3 for concentration by cation exchange.

7.3 CONCENTRATION BY CATION EXCHANGE

7.3.1 Precondition a disposable ion exchange column by adding 1-2mL of methanol, just enough to pass through the frit at the orifice of the column, which is hydrophobic. Transfer cation exchange resin to the stem of the column as a slurry with DI water to at least the 7 cm mark. Place a layer of glass beads (approximately 1 cm) on top of the resin bed to hold the resin in place. Attach the funnel to the column (make certain that the column and funnel fit tightly), and precondition the column with 50mL of 0.1M HNO_3. Discard the conditioning solution into the Paragon wastewater treatment facility (down the laboratory sink followed by plenty of tap water).

7.3.2 Pass the sample through the column at a rate of about 1-2 mL/min. This is accomplished by inverting the 2 L bottle into the funnel that is attached to the top of the cation exchange column. Secure the 2 L bottle to a laboratory stand or support with a rubber band. The sample will feed automatically through the column. For solid samples pour the entire sample directly into the funnel.

7.3.3 After the sample has completely passed through the resin, rinse the column with 30 mL of 0.1M HNO_3.

7.3.4 Discard the feed and rinse solutions into the Paragon wastewater treatment facility (down the laboratory sink followed by plenty of tap water).

7.3.5 Elute Ra, Ba, and other cations with 100 mL of 8M HNO_3. Collect the solution in a labeled 250mL specimen cup and take to dryness on a steambath.

7.3.6 The used resin from the column is collected in a wide mouth jar labeled "Resin Waste" for disposal. When the container is full contact the Waste Management Officer for disposal instructions.

7.3.7 Dissolve the residue from Step 7.3.5 with 10mL of 0.095M HNO_3. If necessary, cover with a 100 mL specimen cup and heat on the steambath to aid in dissolution.

7.3.8 Proceed to Section 7.4 for purification by LN resin.

7.4 PURIFICATION BY LN RESIN

7.4.1 Prepare LN resin column: Use a Bio-rad column (catalog #731-1553) or equivalent and transfer the LN resin to the column as a slurry with DI water. Add resin up to approximately the 1.6 mark on the column. Place a layer of clean silica sand on top of resin bed to hold resin in place. Attach a funnel to the column.

7.4.2 Precondition the LN resin column by passing 5mL of 0.095M HNO_3 through the column.

7.4.3 Place a clean, labeled 250 mL specimen cup underneath each column.

NOTE: The following Steps 7.4.3 to 7.5.18 should be carried out without a break and as quickly as possible. Where ICP determination of native Ba concentrations is required, ensure that the ICP results are available and reviewed before proceeding.

7.4.4 Transfer the sample solution to the funnel of the column. Collect the eluate for Ra and Ba.

7.4.5 Rinse the 250mL specimen cup with 5mL of 0.095M HNO_3 and add to the column after the feed has passed through. Collect the eluate for Ra and Ba.

7.4.6 Rinse the column with 5mL of 0.095M HNO_3 and collect the eluate for Ra and Ba.

7.4.7 Repeat Step 7.4.5.

7.4.8 Place the specimen cups containing the Ra and Ba fraction on a steambath and evaporate to about 10mL. Cool solution to room temperature.

7.4.9 Transfer the solution to a 50mL centrifuge tube, rinsing the specimen cup with approximately 5mL of DI water.

NOTE: Where a gravimetric split of the sample may be necessary due to elevated native Ba concentrations, record the tare weight of any 50mL centrifuge tubes that will be used for splitting samples, before transferring the samples into the tubes.

7.4.10 For those reasons discussed in the "Interferences" section, the total mass of barium in the sample, including Ba carrier added, should not exceed 0.1mg. The following steps should be followed for soils, and potentially for waters, in which native Ba is suspected and for which ICP Ba analyses have been performed.

7.4.10.1 Carefully review of the native Ba concentrations, determined by ICP. Calculate a sample fraction, to be used in the micro-precipitation of the sample, that does not contain more than 0.1mg native barium.

7.4.10.2 Gravimetrically transfer the appropriate aliquot of the sample, as calculated in Section 7.4.10.1, to a clean, tared 50mL centrifuge tube.

7.4.10.3 When the entire fraction for analysis contains more than 0.05 mg native Ba, skip Section 7.5.1 and proceed directly to Step 7.5.2. If the entire fraction for analysis contains less than 0.05mg native Ba, proceed to Section 7.5.1.

7.5 MICROPRECIPITATION OF RADIUM AND BARIUM

7.5.1 Add 0.1mL of Ba carrier.

7.5.2 Add 6mL of 20% sodium sulfate solution. Immediately add 4 drops of 1:1 acetic acid solution and gently mix.

7.5.3 Add 0.1mL of seeding suspension, cap the sample and mix the solution gently.

7.5.4 Place the tube in an ice-water bath for at least 30 minutes.

7.5.5 Place a 25mm 0.1µ polypropylene filter on a filter apparatus with a polysulfone funnel.

7.5.6 Add approximately 5mL of methanol to the filter, applying vacuum and ensuring there is no leak along the sides. Add approximately 5mL of DI water to the filter.

7.5.7 Just as the DI water is about to pass all the way through, transfer the solution from Step 7.5.4 into the funnel.

7.5.8 Rinse the sample tube with 5mL of DI water and transfer into the funnel.

7.5.9 Rinse the sides of the funnel thoroughly with DI water.

7.5.10 Rinse the funnel with approximately 5mL of methanol.

7.5.11 Remove filter and attach to a stainless steel planchet using double sided tape.

7.5.12 Dry the filter under a heat lamp.

7.5.13 Place the filter into a desiccator and apply vacuum for 20 minutes. After 20 minutes, close the valve to the desiccator first, followed by the closer of the vacuum valve. At the desiccator, disconnect the hose that connects the desiccator to the vacuum line. Slowly open the desiccator valve in such a manner as to release the vacuum in the desiccator very slowly.

7.6 PREPARATION OF "THIN-FILM" COVERING TO PROTECT ALPHA DETECTORS

7.6.1 Add approximately 250mL of DI water to a 400mL beaker.

7.6.2 Place a metal wire loop into the DI water; making sure the entire loop is covered by the DI water. Bend the arm of the wire loop over the beaker to hold the loop in place.

7.6.3 Place 1 drop of the Thin film solution into the beaker. Allow 30 seconds for the thin film to cure, then remove and allow to dry.

7.6.4 Once dry, place thin film over the planchet. Push the wire loop down below the planchet to seal the thin film to the rim of the planchet and to break off the excess film material. If necessary, smooth the excess

under the planchet.

7.6.5 Repeat Steps 7.6.1 through 7.6.4 above until all samples have thin films placed over them.

7.6.6 Arrange the planchets in a petri dish and label the petri dish with the analyte, sample ID's and batch number. Submit the prepared samples and the updated benchsheet to the Counting Lab. Relinquish the samples to the Counting Lab in the ICOC. The Counting Lab will analyze and ultimately dispose of the planchet and disk in the manner described in SOP 714.

8. CALIBRATION

8.1 Prepare a set of three calibration samples by adding approximately 5,000 dpm Ba-133 and approximately 10,000 dpm Ra-226 activity to a labeled, empty 250mL specimen cup.

8.2 Take to dryness on a steambath.

8.3 Redissolve the residue in 10mL of 0.095M HNO_3.

8.4 Proceed to Section 7.4 and continue until Step 7.6.6.

9. CALCULATIONS

TPU FACTORS. As defined in SOP 708, the following one-sigma preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty:

9.1 Water samples require a preparation uncertainty factor of 0.0752. This factor is based on one gross aliquoting (sample homogeneity), one volumetric measurement, one tracer addition, and four quantitative transfers. See the following equation:

$$0.0752 = \sqrt{.05^2 + .006^2 + .025^2 + .025^2 + .025^2 + .025^2 + .025^2}$$

9.2 Soil samples require a preparation uncertainty factor of 0.0792. This factor is based on one gross aliquoting (sample homogeneity), two mass measurements, one tracer addition, and five quantitative transfers. See the following equation:

$$0.0792 = \sqrt{.05^2 + .003^2 + .003^2 + .025^2 + .025^2 + .025^2 + .025^2 + .025^2 + .025^2}$$

9.3 In practice, these values are substantially equivalent. For simplification in reporting, the larger factor of 0.0792 may be used for both matrices.

10. QUALITY CONTROL

Acceptance limits for quality control parameters may vary per client specifications (typically controlled via test code nicknames), consult applicable LIMS program specification.

10.1 A blank and laboratory control sample (blank spike, LCS) is run for each batch. Both are run at a 5% minimum frequency. Each is taken through the entire procedure as specified for the matrix.

10.2 The LCS (blank spike) is spiked with 10 - 50 dpm of Ra-226 standard solution using a calibrated pipet.

10.3 DI water is used as the matrix for the blank and blank spike of water samples. If soil samples are to be muffled, an ashless filter is used for the blank and blank spike. If soil samples do not need muffling, an empty 250mL specimen cup is used for the blank and blank spike.

10.4 Sample duplicates are run at a 10% minimum frequency. If enough sample is not provided to do duplicates, an LCS duplicate is prepared and analyzed.

11. DEVIATIONS

This method is adopted from the ASTM Draft Method, "Standard Test Method for Alpha-Emitting Radium Isotopes in Water". Paragon has adapted this method to accommodate soils and solids, including the ICP determination of native Ba to prevent mass-attenuation in analysis by alpha spectrometry.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 13.2 below.

12.2 Read the appropriate MSDSs before preparing standards or using any reagents.

12.3 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.4 Gloves, safety glasses and lab coats must be worn when working with any chemicals (e.g. standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals. Use care when handling strong acids (e.g. HNO_3, HCl, etc.). When diluting strong acids, always add acids to water, not water to acids.

12.5 All non-original containers used to hold reagents (e.g. wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) the date.

STANDARD OPERATING PROCEDURE 799 REVISION 3

TITLE: DETERMINATION OF RADON-222 IN WATER SAMPLES BY LIQUID SCINTILLATION COUNTING - SM METHOD 7500-Rn B AND ASTM METHOD D5072-92

FORMS: 631

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/31/06

QUALITY ASSURANCE MANAGER _____ DATE 8/31/06

LABORATORY MANAGER _____ DATE 8-31-06

HISTORY: Rev0, 3/14/00; Rev1, 4/26/02; Rev2, 9/22/03; Rev3, 9/1/06.

1. SCOPE AND APPLICATION

The methods specified are for Rn-222 (radon) in drinking water. This procedure has been developed for the analysis of radon in drinking water, groundwater and surface-water. Applications of this analytical procedure to matrices other than drinking water have not been studied; use caution in analyzing any such samples.

The Minimum Detectable Concentration (MDC) is estimated at <50pCi/L for a 50 minute count time assuming ~6cpm background (optimized counting window), ~3cpm/dpm efficiency, and 2-4 days decay between sampling and analysis.

This procedure is substantially compliant with Standard Methods for the Evaluation of Water and Wastewater Method 7500-Rn B and ASTM Method D5072-92.

2. SUMMARY

The sample is carefully transferred from a zero headspace 40mL VOA vial to a scintillation vial containing water-immiscible mineral-oil cocktail, taking precautions to minimize losses of Rn-222 in the water sample. The vial is capped and shaken. Radon partitions selectively into the mineral-oil scintillation cocktail. The sample is dark-adapted, and the short-lived Radon daughters are allowed to come to equilibrium. The samples are then counted in a Liquid Scintillation Counter (LSC) using a region of the energy spectrum optimal for radon alpha particles. Results are reported as pCi/L and decay corrected to the time and date of collection.

3. RESPONSIBILITIES

3.1 In the event that a sample containing headspace is received by the lab, it is the responsibility of the analyst to immediately notify the Project Manager (PM) for instructions.

3.2 It is the responsibility of the analyst to be familiar with the acceptance criteria for the QC samples and other quality indicating parameters, as specified in SOP 715 and also in any LIMS program specification related to the client, project, and test method being performed.

3.3 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.4 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review or in the performance of precision and accuracy tests, or by other suitable means.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 There are no known chemical interferences from species found in drinking water or from the dilute concentration of acid that may be present in the calibration standards.

4.2 Uranium, radium, or other radioactive elements may cause a positive bias, if present in quantities significantly greater than the radon. Thorium-228 or Uranium-235 daughters (Thorium-227 and shorter-lived progeny) in the samples will lead to the presence of Radon-220 or Radon-219 in the sample. The half-lives of these species is such that partitioning into the cocktail is minimal, thus interference with the Radon-222 measurement is routinely minimal.

4.3 Diffusion of radon is affected by temperature and pressure. Let samples equilibrate to room temperature before processing.

4.4 Some cocktails are quenched by atmospheric oxygen after opening. This effect has not been noted for the mineral-oil-based cocktail.

4.5 Precision and accuracy of the method are affected by the background in the energy window used for analysis. This procedure provides for optimization of the counting window to minimize the background in the measurement.

4.6 Radon has an affinity for some plastics used in sample containers. Use only glass sample containers or glass scintillation vials with Teflon or foil-lined caps.

5. APPARATUS AND MATERIALS

5.1 Pipettor, Precision® mechanical pipette, or syringe, 10mL. Calibration of pipette must be verified (SOP 321) before use.

5.2 Pipette tips, modified by cutting approximately 5mm from the tip to minimize turbulence during the sample transfer.

5.3 Scintillation cocktail dispenser, or pipette adjusted to deliver 10mL. Calibration of pipette must be verified (SOP 321) before use.

5.4 Scintillation vials, borosilicate glass, 23mL, with Teflon or foil-lined caps.

5.5 KimwipeS®

6. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that a substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.2 Scintillation cocktail, Dupont water-immiscible *High Efficiency Mineral Oil Cocktail*®, or other commercial equivalent

6.3 Water, radon-free demineralized or equivalent

6.4 Methanol, reagent grade. TLV = 200 ppm.

6.5 Radium-226 standard solutions, NIST-traceable, one source for calibration and a second source for check standards.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLD TIME

7.2 Sampling is the sole responsibility of the client. Guidance from the laboratory, however, is appropriate to help assure the integrity of results. The recommended sampling procedure is summarized in Appendix A of this SOP, and should be provided to clients requesting this test.

7.3 Radon-222 has a 3.823 day half-life. The USEPA has established a holding time of 4 days for this analysis. Sample analysis must be completed counting within 4 days of collection.

7.4 Sampling schedules must be pre-arranged and approved by the laboratory to ensure that adequate capacity is available to meet the hold time restriction of 4 days.

7.5 Samples are routinely collected from a non-aerated water source (distribution system or well, etc.) that has been allowed to flow for sufficient time so that the sample is representative of the water being sampled.

7.6 The time, date and time zone for sample collection must be accurately recorded and used for decay correction of sample results. Transport samples by overnight delivery to the laboratory in a cooler or other suitable insulated package to avoid large temperature changes and out-gassing of radon. Samples should be stored in a cooler.

8. PROCEDURE

8.2 PREPARATION OF CALIBRATION STANDARDS

8.2.1 Prepare an appropriate volume of radium-226 in water standard so that the final activity will deliver adequate response such that 10,000 net counts can be gathered in the analysis window within a reasonable count period.

8.2.2 Transfer 10mL diluted standard into a scintillation vial, to which 10mL of mineral oil cocktail has been added. Prepare at least three standards and three backgrounds using distilled or deionized water.

8.2.3 Set standards and background samples aside for ~25 days (99% ingrowth) to allow radon progeny to attain secular equilibrium with radium-226.

8.2.4 Determine optimal analytical window as outlined in Section 8.3 below.

8.2.5 After the ingrowth period, let the sample dark adapt for 3 hours and count for 50 minutes or other appropriate time period, ensuring that 10,000 net counts are gathered for each standard.

8.2.6 From pooled results, calculate a system calibration factor which reflects the system response in net cpm per dpm Rn-222, using the equation in Step 9.1.

8.3 SELECTING THE OPTIMAL WINDOW

8.3.1 Count a radon standard for 5 minutes or sufficient time to acquire several thousand counts or more in the alpha region, and generate a sample spectrum.

8.3.2 For greater clarity, use a log scale for the channel number or energy axis, if possible. The alpha activity region of interest (ROI) will be

obvious as one or two large peaks at the higher end of the energy spectrum. The lower peak is the doublet of radon-222 and polonium-218 and the higher peak is that of polonium-214. The optimal window is formed by extending the region by approximately 10 channels on each side of the alpha peaks. Use this window for subsequent calibration and analysis. The calibration factor (see 9.1) should be at least 6cpm/pCi with the background not exceeding 6cpm.

8.3.3 For counters not having a spectrum display, set the window initially wide-open and count for sufficient time to obtain several thousand counts. Adjust the energy window to a width of 5% of full scale at the upper end of the scale (95 to 100%) and determine the count rate in the region. Repeat counts at successively lower regions using the same 5% interval (90 to 95, 85 to 90, 80 to 85, etc.). Plot the count rate versus the midpoint of each interval and choose a ROI, which will be evident by one or two prominent peaks in the upper half of the energy scale. Background should be 6cpm or less and the conversion factor should be approximately 6cpm/pCi.

8.4 PREPARATION OF CALIBRATION BLANKS

Two pre-prepared calibration blanks are supplied in the instrument lab and are counted as the first and last samples in each count batch. The calibration blanks consist of 10mL mineral-oil-based cocktail mixed with 10mL of Rn-free water, and are prepared analogous to samples at a time separate from the preparation of a given batch. The calibration blanks are to be prepared from the same batch of cocktail as is used for samples and must be re-established for each new lot number of cocktail used. The average of the two calibration blanks (or a running mean of the calibration blanks if the test is run frequently enough that a representative population of calibration blanks may be assembled), is used in calculations to provide the value for background corrections.

8.5 PREPARATION OF SAMPLES

8.5.1 Include the following samples in each quality control (QC) batch (see Secion 10): the first three samples in each batch are a) Reagent Blank-1, b) LCS-1 (see Section 10.3 for preparation of the LCS), and c) Method Blank-1 (see Section 10.2 for preparation of the method blank), in that order. Up to 20 field samples then follow. The last three samples in each batch are the x) Method Blank-2, y) LCS-1-D1, and z) Reagent Blank-2, in that order.

8.5.2 Pre-label one scintillation vial (lid only) for each sample, replicate (see Section 10.4), and method blank to be analyzed.

8.5.3 Do not take the pH of the samples, they are assumed to be neutral. However, a sample condition form (Form 631) should still be used to note any abnormalities.

8.5.4 Using a calibrated repipettor, transfer 10mL of mineral-oil-based cocktail to each scintillation vial to be used for analysis.

8.5.5 If any bubbles are noted in any of the original sample vials available for each sample, note the discrepancy on the sample condition form (Form 631) and do not use the vial for analysis. If more than one vial contains bubbles, note the discrepancy on the benchsheet and only aliquot one sample. If all vials contain bubbles, aliquot the two with the smallest bubbles, note the discrepancy, and notify the PM regarding the discrepancy.

NOTE: Work carefully while performing sample transfers. Radon gas can be easily lost while sample vials are open and during the transfer process. Minimize the time that vials are open by removing the VOA vial cap one sample at a time and working quickly during sample transfer.

8.5.6 Prepare the first method blank as the first sample by transferring 10mL of radon-free distilled water to a VOA vial. Tightly cap the vial. Record the date and time of this preparation on the benchsheet.

8.5.7 Using a calibrated pipettor with a modified 10mL pipette tip (see 5.2), carefully withdraw a 10mL aliquot from the VOA vial for each sample. Avoid radon loss by taking extra care to avoid drawing bubbles into the pipette and by withdrawing slowly enough to minimize turbulence in the pipette tip. Also, avoid disturbing any sediment in the vial, so as not to transfer it to the scintillation vial. Carefully and quickly pipette the liquid under the surface of the mineral-oil cocktail to minimize radon losses during transfer. Cap the vial tightly immediately following completion of the transfer. If any problems are encountered during the transfer, discard the first sample and continue aliquotting using the backup vial.

8.5.8 Shake the samples for at least 30 seconds to facilitate extraction of the radon into the mineral oil.

8.5.9 Wipe the surface of each vial with a Kimwipe® and methanol to remove any residues on the surface of the vial.

8.5.10 Immediately submit the samples to the instrumentation lab for analysis.

8.5.11 Sample analysis must be completed within the 4-day hold-time. Count samples for a period of time that will allow achievement of the requested detection limits. The counting lab will ultimately dispose of the scintillation vials in the manner described in SOP 704.

9. CALCULATIONS

9.1 SYSTEM CALIBRATION FACTOR

$$EFF = \frac{S - B}{C \times V}$$

where:

EFF = efficiency, cpm/dpm.

S = average standard gross count rate, cpm.

B = average background gross count rate, cpm.

C = concentration of radium-226 standard, dpm/g, decay corrected to count date.

V = volume of standard used, g

9.2 TPU and MDC:

$$ACT = \frac{S - B}{CF \times D \times V \times 2.22}$$

$$CU = \frac{1.96 \times \sqrt{\frac{S}{T_S} + \frac{B}{T_B}}}{CF \times D \times V \times 2.22}$$

$$TPU = \sqrt{(CU)^2 + (ACT \times PU)^2 + (ACT \times IU)^2}$$

$$MDC = \frac{4.65 \times \sqrt{\frac{B}{T_S}} + \frac{2.71}{T_S}}{CF \times D \times V \times 2.22}$$

$$D = e^{-\lambda t}$$

$$l = ln2 / 3.823 \text{ days}$$

$$PU = 0.008 = \sqrt{0.006^2 + 0.006^2}$$

where:

ACT = Rn-222 activity in pCi/L decay corrected to the time and date of sampling.

CU = Counting uncertainty at the 2 sigma level, pCi/L.

TPU = Total Propagated Uncertainty (See SOP 743), pCi/L

MDC = Minimum Detectable Concentration, pCi/L.

V = volume of aliquot, L.

D = Decay correction factor from Sample collection to midpoint of count.

T_S = Sample count duration, min.

T_B = Background count duration, min.

t = elapsed time between time and date of collection and the midpoint of sample count, days.

PU = 0.008, based on one volumetric measurement and one repipetting of reagent, per SOP 743

IU = 0.056, based on a calibration with an in-house prepared calibration standard, per SOP 743

9.3 DATA REPORTING AND EVALUATION

9.3.1 The LCS sample consists of Rn-222 supported by Ra-226. For purposes of LCS and blank calculations, the sample date is entered as the start of the sample count.

9.3.2 All samples are decay corrected to the point of collection.

9.3.3 For consistency purposes, all times will be noted in Mountain time.

9.3.4 The LCS-Duplicate is used to evaluate precision.

9.3.5 Method blanks are batch QC samples and are used to evaluate the acceptability of data in a given QC batch. Reagent blanks are not QC samples, rather are used to calculate the background count rate for purposes of sample calculations.

9.3.6 Results are reported to the client for each replicate of the field sample. This data is not evaluated as a duplicate. Such evaluation is left to the client. It is important to note that failure to replicate may be indicative of problematic sampling in the field.

10. QUALITY CONTROL

10.2 Two method blanks are prepared for each batch of samples. The method blank consists of 10mL cocktail and 10mL of radon-free deionized water and is prepared as are samples.

10.3 Two pre-prepared calibration check standards (LCS) are supplied in the instrument lab and are counted as the second and next-to-last samples in each count batch. The calibration check samples consist of 10mL mineral-oil-based cocktail mixed with 10mL of Ra-226 standard solution at concentrations in the range of 5-50,000pCi/L, prepared analogous to samples. The calibration check samples are to be prepared from the same batch of cocktail as is used for samples and must be re-established for each new batch of cocktail used. These standards are allowed to come to secular equilibrium prior to use. The calibration samples are measured and evaluated against appropriate control limits for each batch of samples analyzed. These are reported as LCS1 and LCS1-D1 in association with sample results.

10.4 Sample replicates are run at 100% frequency, where sample volume is available. Due to limited sample availability, replicate results are reported and appropriately qualified. Repreparation of samples is generally not possible when replicate criteria are not met.

11. DEVIATIONS FROM METHOD

11.2 This procedure references ASTM Method D5072-92. The transfer is conducted with a pipette instead of the syringe noted in the method. This is consistent with Method 7500-Rn B, below.

11.3 This procedure references Standard Methods for the Evaluation of Water and Wastewater Method 7500-Rn B. The sample volume used is 10mL sample + 10mL of cocktail. This reflects the volumes used in USEPA Round Robin Testing. QC requirements prescribed in the SOP are comparable to those outlined in the Method, but have been modified to provide consistency with more procedures in place for liquid scintillation counting at Paragon.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.2 SAFETY AND HAZARDS

12.2.1 Read the appropriate MSDSs before preparing standards or using any reagents.

12.2.2 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

12.2.3 Gloves, safety glasses, and a lab coat must be worn when working with any chemicals (e.g., standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.2.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

12.2.5 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: 1) the compound name, 2) NFPA Health, Flammability and Reactivity ratings, and 3) date.

12.2.6 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.3 WASTE DISPOSAL
Wastes that are "corrosive only", are disposed of by discharging into the Paragon wastewater treatment facility. These materials that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity) may be neutralized in the waste treatment facility.

DOCUMENT REVISION HISTORY

9/1/06: LIMS program specifications referenced. DOCUMENT REVISION HISTORY section added. Form attached. Other clerical changes.

APPENDIX A

Recommended Sampling Procedure for Rn-222 by Liquid Scintillation

SAMPLE COLLECTION, PRESERVATION AND HANDLING

Sampling is the sole responsibility of the client. This or other equivalent sampling procedures should be followed carefully to ensure the integrity of sample results. The following information is based on the procedure provided in the 18th Edition of Standard Methods for the Evaluation of Water and Wastewater, Method 7500-Rn B.

Sampling schedules must be pre-arranged and approved by the laboratory to ensure adequate capacity is available to meet hold time requirement of analysis within 4 days of collection.
Samples are routinely collected from a non-aerated water source that has been allowed to flow for sufficient time so that a representative water sample is taken. The following procedure is designed to minimize the loss of radon from the sample during collection.

Equipment Needed:

Faucet connector or universal faucet adapter (where sample is being drawn from well or distribution system)

Plastic tubing for connector or adapter

VOA vials, borosilicate glass, 40mL, with Teflon-lined septum closure

Sample storage and shipping containers, insulated

Chain of Custody (COC) forms

Procedure

1. Place a clean 40mL VOA vial (with Teflon-lined septum closure) in a 300- to 600mL beaker, or other suitable container; attach delivery tube to faucet, and start the flow. Make sure that the delivery tube does not let bubbles enter the sample.
2. Fill the 40mL VOA vial to prevent its floating, then fill beaker until the vial is submerged.
3. Place the tip of the delivery tube about two thirds of the way into the vial and fill until approximately two or more vial volumes (50 to 100mL) have been displaced.
4. Carefully remove vial by hand or with a pair of 25cm (10in.) tweezers and cap the vial with a Teflon or foil-lined cap. Cap sample vials underwater, if possible.
5. Invert sample and check for air bubbles. If any bubbles are present, discard sample and repeat sampling procedure.
6. Sample results will be reported decay corrected to the date and time of collection, assuming the presence of unsupported Rn-222 activity in the samples. On the COC, note the date and exact time of sampling for each vial to the nearest minute. Include a reference to time zone (e.g., EDT or PST). The collection time is converted to Mountain Time (where appropriate) at the point of receipt to ensure that accurate decay corrections are performed for the samples.
7. Ensure that the sample is properly, clearly and unambiguously labeled. Append a fraction ID to the field sample ID for each of the three vials collected per sample (i.e., XXXXXX (1), XXXXXX (2) and XXXXXX (3)).
8. Repeat Steps 1-7 of this procedure two times to collect three vials for each sample.
9. Pack the samples on ice (4$\pm$2 °C) and ship overnight to the laboratory for analysis.

TITLE: **DIGESTION OF WATERS, SOILS AND WASTES FOR METALS ANALYSIS -- METHODS SW3005A, SW3010A, SW3050B, EPA 200.2, AND CLP SOW ILM03.0 & ILM04.0**

FORMS: **805, 824** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER Roy French DATE 11/5/07

QUALITY ASSURANCE MANAGER Deb Schantz DATE 11/4/07

LABORATORY MANAGER K Neal DATE 11/5/07

HISTORY: Rev0, 3/22/93; Rev1, PCN # 87, 1/18/94; Rev2, 4/9/96; Rev3, 11/18/96; Rev4, 10/07/99; Rev5, 3/07/01; Rev6, 11/10/01; Rev7, 3/02/02; Rev8, 4/29/02; Rev9, 12/04/02; Rev10, 4/23/04; Rev11, 1/31/05; Rev12, 7/26/05 and 3/13/06; Rev13, 11/4/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- Methods SW3005A, SW3010A, SW3050B, EPA 200.2, CLP SOW ILM03.0 and CLP SOW ILM04.0 – describe the digestion and preparation of liquid and solid samples prior to total or dissolved metals analysis.

2. SUMMARY OF METHOD

The purpose of these procedures is to extract metals from the native matrix and hold them in a form that is suitable for analysis by inductively coupled plasma atomic emission spectrometry (ICP-AES) or inductively coupled plasma mass spectrometry (ICP-MS). The extraction is accomplished by refluxing the acidified sample at a suitable temperature for a period of time or until the sample is reduced to a desired volume.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the workorder file indicates that the data are complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 In sample preparation, contamination is of prime concern. The work area, including bench top and fume hood should be periodically cleaned in order to eliminate environmental contamination.

4.2 The analyst should be cautioned that these digestion procedures might not be sufficiently vigorous to release all metals from complexed forms.

4.3 Waste samples can contain diverse matrix types, each of which may present its own analytical challenge. Spiked samples and any relevant standard reference material should be processed to aid in determining whether Method SW3050B is applicable to a given waste.

4.4 Chemical interferences are matrix dependent and cannot be documented prior to analysis. Interferences are discussed in the analytical SOPs.

5. APPARATUS AND MATERIALS

5.1 Hot plate or Steam bath, capable of maintaining a constant temperature of 95°C$\pm$5°C.

5.2 Beakers and lids, polypropylene, disposable, 100mL and 200mL capacity

5.3 Watch glasses (or equivalent), ribbed and non-ribbed

5.4 Balance, top loading, able to read to 0.1g

5.5 Membrane filter paper, cellulose acetate, 0.45µm, Corning, #431220 or equivalent

5.6 Glass fiber filter paper, 0.7µm, Whatman™ #1441 150 or equivalent

5.7 Buchner funnel and flask, or similar filtration device

5.8 Volumetric flasks of suitable size and accuracy

5.9 Volumetric pipets of suitable size and accuracy

5.10 Scissors

5.11 Autosampler tubes, polypropylene, 14mL

5.12 Ion exchange columns, disposable, graduated to 10cm (Environmental Express #R10204) or equivalent

6. REAGENTS

NOTE: Only trace metals grade acids may be used. Lot # must be verified by the Metals Department prior to the analysis of samples with any new acids. Each lot of acids must be certified (no metals detected at or above the RL).

6.1 Hydrochloric acid (HCl), concentrated, trace metals grade, JT Baker #9530-33 or equivalent. Also a diluted (1:1) hydrochloric acid solution.

6.2 Nitric acid (HNO_3), concentrated, trace metals grade, JT Baker #9598-34 or equivalent. Also a diluted (1:1) nitric acid solution.

6.3 Reagent water, deionized, obtained from Paragon's DI water system.

6.4 Hydrogen Peroxide (H_2O_2), 30%, Malinckrodt #5240 or equivalent.

6.5 Cation exchange resin, analytical grade, 50W x 8 (Eichrom or equivalent).

6.6 SPIKING SOLUTIONS
Prepared from purchased certified individual elemental standards or analyte mixes. ***Records of vendor-supplied certificates of analysis must be maintained by the Department.*** Undiluted stock solutions may be retained until the manufacturer's expiration date (at least one year), replaced sooner if degradation occurs. Diluted stock solutions may also be retained until the manufacturer's expiration date (at least one year), replaced sooner if degradation occurs.

All spiking solutions are prepared, documented, and stored in accordance with Paragon SOP 300. All spiking solutions are to be contained in fresh (previously unused) polypropylene bottles.

6.6.1 Spike Solution Z:

Element	*Concentration (µg/mL)*
Al, Ba, As, Se, Tl, Si	100
Fe, B, Mo	50
Sb, Co, Mn, Ni, V, Zn	25
Ti, Sn, Li, Sr, Pb	25
Be, Cd	2.5
Cr	10
Cu	12.5

6.6.2 Cation Spike Solution: Contains 2,000 µg/mL Ca, Mg, K, Na.

6.6.3 C Spike: Contains 10 µg/mL Ag.

6.6.4 CLPP-Spike-1:

Element	*Concentration* (µg/mL)
Al, Ba	2000
Fe	1000
Co, Mn, Ni, V, Zn	500
Cu	250
Cr	200
Ag, Be	50

6.6.5 CLPP-Spike-4:

Element	*Concentration* (µg/mL)
Sb	100
Cd, Tl	50
As	40
Pb	20
Se	10

6.6.6 Non-TAL Spike:

Element	*Concentration* (µg/mL)
Si	200
B, Mo	100
Li, Sr, Sn, Ti	50

NOTE: CLPP-Spike-1 & CLPP-Spike-4 are mixes prepared and purchased from a vendor. All other spiking solutions listed are prepared from commercially purchased single element stock standards.

6.6.7 Be Filter Spike:

Element	Concentration (ug/mL)
Be	1.0

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples for total or potentially dissolved metals analyses are collected in plastic or glass containers and must be chemically preserved with nitric acid to

pH<2. Typically, a 1L sample is collected. Samples for dissolved metals analyses should be filtered in the field prior to chemical preservation. Analysis of the sample cannot begin until it has been acidified for at least 24hrs.

7.3 Solid samples are collected in plastic or glass containers. Solid samples are not chemically preserved.

7.4 All samples, liquid or solid, should be maintained at 4±2°C. All samples, liquid or solid, must be prepared and analyzed within 180 days of collection.

8. PROCEDURE

8.1 METHOD SW3005A, 200.2 - DISSOLVED METALS PREPARATION (ICP-AES and ICP-MS)

8.1.1 Samples to be analyzed for dissolved (soluble) metals are to be filtered through a 0.45µm filter at the time of collection and the liquid phase is then acidified at the time of collection with nitric acid.

- If the samples have been filtered prior to entering the lab, check that the pH of the sample(s) is <2 and that there are no visible solids or precipitates in the sample container. If the pH of a sample if found to be >2, then concentrated nitric acid (trace metals grade) must be added and the sample held for a minimum of 24 hours until verified to be pH<2 (Form 824).
- Record on the LIMS tracking sheet that the samples were received filtered and preserved.
- If solids or precipitates are noticed in a sample that is filtered and preserved, consult Project Manager before continuing with the sample preparation.
- The samples are now ready for digestion (see Section 8.3, Method SW3005A).

8.1.2 If the samples have not been filtered or preserved before entering the lab, then they need to be filtered through a 0.45µm filter and preserved with concentrated nitric acid to a pH<2.

8.1.3 Prepare a blank, blank spike (Laboratory Control Sample, LCS) and sample duplicate and carry them through the preceding filtration and preservation Steps at a frequency of at least 1 per 20 samples of like matrix (see Section 9.0).

8.1.4 Aliquot about 100mL of filtered and preserved samples into properly labeled disposable beakers.

8.1.5 All steps must by recorded in the metals digestion logbook (Form 805)

and any pertinent comments regarding the samples recorded on the LIMS tracking sheet to be included with the workorder file.

8.1.6 The samples are now ready for digestion (see Section 8.3, Method SW3005A).

8.2 FINAL VOLUME ADJUSTMENT

8.2.1 Final volumes for the digestion procedures described in Sections 8.3 through 8.8 are adjusted by bringing the digestion beaker containing the digestate to a predetermined weight by adding reagent (double-deionized) water after the digestion is completed.

8.2.2 The predetermined weight for water samples is the total weight of the empty digestion beaker plus the weight of the desired final volume of digestate, recorded to the nearest 0.01 grams. The predetermined weight for soil samples is the total weight of the empty digestion beaker plus the weight of the soil aliquot plus the weight of the desired final volume of digestate, recorded to the nearest 0.01 grams.

8.2.3 The weight of the final volume of digestate depends on the acid content of the digestate. Hence, each digestion method results in digestates with slightly different densities because the acid concentrations are different.

8.2.4 The weight of the final volume of digestate for the digestion procedures described in Sections 8.3 through 8.8 has been determined by digesting method blanks and weighing the digestates after bringing to volume in a volumetric flask (see below, further details provided in Appendix A).

SOP Section	Method	Final Volume (mL)	Weight of Digestate (g)
8.3	SW3005A	50	51.18
8.4	SW3010 A	50	52.39
8.5	EPA 200.2	50	50.38
8.6	SW3050B	100	105.11
8.7	CLP Water	100	100.83
8.8	CLP Soil	200	206.95

8.2.5 If digestates are to be brought to a final volume not given above, the weight of the desired final volume of digestate should be determined by digesting a method blank and weighing the digestate after bringing to volume in the appropriate volumetric flask.

8.2.6 The empty weight of the disposable polypropylene beakers used for a

digestion must be determined prior to performing the digestion. The empty beaker weight for each lot of beakers is determined by weighing 10 beakers and calculating the average. The empty beaker weight data for each lot is recorded in the beaker weight logbook.

8.2.7 The formula used for the calculation of the predetermined weight is given below:

$$P = B + D + S$$

where:

P = Predetermined weight (Section 8.2.1 to 8.2.5)

B = Empty beaker weight (Section 8.2.6)

D = Weight of final volume of digestate (Sections 8.2.4 and 8.2.5)

S = Weight of soil aliquot (S = 0 for water samples)

8.2.8 The predetermined weight, empty beaker weight, weight of the final volume of digestate and the beaker Lot number are recorded on the digestion benchsheet (Form 805).

8.3 METHOD SW3005A - TOTAL RECOVERABLE METALS DIGESTION OF WATERS FOR ICP-AES AND ICP-MS ANALYSIS

8.3.1 For each sample in the batch, use a test strip to verify that the solution pH is <2. Record the measured pH on the benchsheet. If the pH of a sample is >2, then concentrated nitric acid (trace metals grade) must be added and the sample held for a minimum of 24hrs until verified to be pH<2 (Form 824).

8.3.2 Transfer a 50mL aliquot of preserved (pH<2), well-mixed sample to a beaker.

8.3.3 Add 1.0mL of concentrated nitric acid and 2.5mL of concentrated hydrochloric acid.

NOTE: When analyzing for Vanadium using ICP-MS, the 2.5mL of concentrated HCl is not used. Instead, a total of 4mLs of concentrated nitric is used to avoid interferences.

8.3.4 Cover the beaker with a ribbed watch glass and heat at 95±5°C ***without boiling*** until the volume has been reduced to about 10mL.

8.3.5 Remove the beaker from the heat and allow to cool.

8.3.6 Wash down the beaker walls and the watch glass with reagent water.

8.3.7 Filter the sample only if necessary.

8.3.8 Adjust the final volume to 50mL with reagent water (adjust to the predetermined weight as described in Section 8.2).

8.3.9 Prepare quality control (QC) samples as discussed in Section 9.0.

8.3.10 The metals digestion logbook (Form 805) is to be completed in full for each digestion batch of 20 or fewer samples.

8.4 METHOD SW3010A - TOTAL METALS DIGESTION OF WATERS FOR ICP-AES AND ICP-MS ANALYSIS

8.4.1 For each sample in the batch use a test strip to verify that the solution pH is <2. Record the measured pH on the benchsheet. If the pH of a sample is >2, then concentrated nitric acid (trace metals grade) must be added and the sample held for a minimum of 24hrs until verified to be pH<2 (Form 824).

8.4.2 Transfer a 50mL aliquot of preserved (pH<2), well mixed sample to a beaker.

8.4.3 Add 1.5mL of concentrated nitric acid and cover the beaker with a ribbed watch glass.

8.4.4 Heat the sample ***without boiling*** until the volume has been reduced to a low volume (about 5mL), ***making sure the sample doesn't go to dryness.***

8.4.5 Cool the sample and add another 1.5mL of concentrated nitric acid.

8.4.6 Heat the sample briefly until the volume has been reduced to a low volume (about 5mL), ***making sure the sample doesn't go to dryness***. If necessary, continue to repeat the addition of 1.5mL of concentrated nitric acid and heating until the digestion is complete (generally indicated when the digestate is light in color or does not change in appearance with continued refluxing).

8.4.7 Cool the sample and add 5mL of 1:1 Hydrochloric Acid. Heat the sample for about 15 minutes.

8.4.8 Cool the sample and wash down the beaker walls and watch glass with reagent water.

8.4.9 Filter the digestate only if necessary.

8.4.10 Adjust the final volume to 50mL with reagent water (adjust to the predetermined weight as described in Section 8.2).

8.4.11 This procedure is used for the digestion of TCLP extracts, initially using a 5mL sample aliquot of filtered TCLP leachate and following the steps stated above. The 50mL final volume results in a 1/10 dilution for TCLP leachates during the digestion procedure.

8.4.12 Prepare quality control (QC) samples as discussed in Section 9.0.

8.4.13 The metals digestion logbook (Form 805) is to be completed in full for each digestion batch of 20 of fewer samples.

8.5 METHOD 200.2 - TOTAL RECOVERABLE METALS DIGESTION OF WATERS FOR ICP-AES AND ICP-MS ANALYSIS

8.5.1 For each sample in the batch use a test strip to verify that the solution pH is <2. Record the measured pH on the benchsheet. If the pH of a sample is >2, then concentrated nitric acid (trace metals grade) must be added and the sample held for a minimum of 24hrs until verified to pH<2 (Form 824).

8.5.2 Transfer a 50mL aliquot of preserved (pH<2), well mixed sample to a beaker.

8.5.3 Add 2mL of 1:1 Nitric Acid and 1mL of 1:1 Hydrochloric Acid.

8.5.4 Cover the beaker with a ribbed watch glass and heat until the volume has been reduced to about 20mL.

8.5.5 Replace the ribbed watch glass with a non-ribbed watch glass and reflux the sample for about 30 minutes.

8.5.6 Cool and adjust the final volume to 50mL with reagent water (adjust to the predetermined target weight as described in Section 8.2).

8.5.7 Prepare quality control (QC) samples as discussed in Section 9.0.

8.5.8 The metals digestion logbook (Form 805) is to be completed in full for each digestion batch of twenty or fewer samples.

8.6 METHOD SW3050B - TOTAL DIGESTION OF WASTES, SEDIMENTS, SLUDGES, AND SOILS FOR ICP-AES AND ICP-MS ANALYSIS

8.6.1 Mix the sample by stirring with a disposable wooden spatula in order to obtain a representative aliquot. The aliquot should have a similar particle size distribution as the bulk sample (visually). For very heterogeneous or unusual matrices, consult the Department Manager and Project Manager. Document if special processing was required prior to taking an aliquot in the comments section of Form 805. Also,

record on the digestion benchsheet the texture (coarse, medium, fine) and color of the sample.

8.6.2 Weigh a 1-1.5g sample aliquot into a 200mL disposable polypropylene beaker. Record the aliquot size to 0.01g on the digestion benchsheet.

8.6.3 Add 10mL of 1:1 Nitric Acid, mix the slurry and cover with a ribbed watch glass.

8.6.4 Heat the sample to 95±5°C and reflux for 10 to 15 minutes without boiling.

8.6.5 Cool the sample and add 5mL of concentrated nitric acid. Replace the watch glass and reflux for about 30 minutes. If brown fumes are generated indicating oxidation of the sample by nitric acid, then repeat this Step (addition of nitric acid) until no brown fumes are given off. Heat sample at 95±5°C without boiling until the solution evaporates to approximately 5mL or if necessary continue heating at 95±5°C without boiling for a total of about 2hrs. The maximum two hours may be necessary for example if the sample matrix is not readily reduced. Maintain a covering of solution over the bottom of the vessel at all times.

8.6.6 Cool the sample and add 2mL of reagent water and 3mL of 30% hydrogen peroxide. Care must be taken to avoid loss of sample due to excessive effervescence.

8.6.7 Heat the sample until the effervescence subsides.

8.6.8 Cool the sample and continue to add 30% hydrogen peroxide in 1mL aliquots (up to 10mL) with heating until the effervescence is minimal or until the general sample appearance is unchanged. Do not add more than 10mL of 30% hydrogen peroxide. Continue heating without boiling at 95±5°C until the volume is reduced to approximately 5mL or if necessary continue heating at 95±5°C for a total of about two hours. The maximum two hours may be necessary for example if the sample matrix is not readily reduced. Maintain a covering of solution over the bottom of the beaker at all times.

8.6.9 Cool and add 10mL conc. HCl. Cover with watch glass.

8.6.10 Heat the sample for about 15 minutes at 95±5°C

8.6.11 Cool and bring to 100mL final volume with reagent water (adjust to the predetermined weight as described in Section 8.2).

8.6.12 Mix well and allow solids to settle. Filter the sample only if necessary.

8.6.13 Prepare quality control (QC) samples as discussed in Section 9.0.

8.6.14 The metals digestion logbook (Form 805) is to be completed in full for each digestion batch of 20 of fewer samples.

8.7 CLP ILM03.0 AND ILM04.0 - ACID DIGESTION FOR TOTAL METALS IN WATERS (ICP-AES AND ICP-MS)

8.7.1 For each sample in the batch use a test strip to verify that the solution pH is <2. Record the measured pH on the benchsheet. If the pH of a sample is >2, then concentrated nitric acid (trace metals grade) must be added and the sample held for a minimum of 24hrs until verified to be pH<2 (Form 824).

8.7.2 Shake the container and transfer 100mL of well-mixed sample to a 250mL beaker. The sample aliquot is measured gravimetrically (100±0.5g). Add 2mL of 1:1 nitric acid (trace metals grade) and 10mL 1:1 hydrochloric acid to the sample.

8.7.3 Cover with watch glass and heat on a steam bath for about 2 hours at 95±5°C or until sample volume is reduced to between 25 and 50mL, making certain sample does not boil.

8.7.4 Cool the sample and filter only if necessary.

8.7.5 Adjust sample volume to 100mL with reagent water (adjust to the predetermined target weight as described in Section 8.2).

8.7.6 Prepare quality control (QC) samples as discussed in Section 9.0.

8.7.7 The metals digestion logbook (Form 805) is to be completed in full for each digestion batch of 20 or fewer samples.

8.8 CLP ILM03.0 AND ILM04.0 - ACID DIGESTION FOR TOTAL METALS IN NON-AQUEOUS SAMPLES (ICP-AES AND ICP-MS)

8.8.1 Mix the sample by stirring with a disposable wooden spatula in order to obtain a representative aliquot. The aliquot should have a similar particle size distribution as the bulk sample (visually). For very heterogeneous or unusual matrices, consult the Department Manager and Project Manager. Document in the comments section of Form 805 if special processing prior to taking an aliquot was required. Record on the digestion benchsheets the texture (coarse, medium, fine) and color of the sample as well.

8.8.2 Weigh a 1-1.5g sample aliquot into a 200mL disposable polypropylene beaker. Record the aliquot size to 0.01g on the digestion benchsheet.

8.8.3 Add 10mL of 1:1 Nitric Acid, mix the slurry, and cover with a watch glass.

8.8.4 Heat the sample to 95±5°C and reflux for about 10 minutes without boiling.

8.8.5 Allow the sample to cool, add 5mL of concentrated nitric acid, replace the watch glass, and reflux for about 30 minutes. Maintain a covering solution over the bottom of the beaker and do not allow the volume to be reduced to less than 5mL.

8.8.6 Cool the sample and add 2mL of reagent water and 3mL of 30% hydrogen peroxide.

8.8.7 Heat the sample until effervescence subsides.

8.8.8 Cool the sample and continue to add 30% hydrogen peroxide in 1mL aliquots (up to 10mL) with heating until effervescence is minimal or until the general sample appearance is unchanged. Do not add more than 10mL of 30% hydrogen peroxide.

8.8.9 Add 5mL of 1:1 HCl and 10mL of reagent water; return the covered beaker to the hot plate and heat for an additional 10 minutes.

8.8.10 Cool the sample and filter only if necessary.

8.8.11 Dilute the sample to 100mL with reagent water.

8.8.12 The diluted sample has an approximate acid concentration of 2.5% (v/v) HCl and 5.0% (v/v) HNO_3. Dilute the digestate 1:1 (200mL final volume), to the predetermined weight with acidified water to maintain constant acid strength (as described in Section 8.2).

8.8.13 Prepare quality control (QC) samples as discussed in Section 9.0.

8.8.14 The metals digestion logbook (Form 805) is to be completed in full for each digestion batch of 20 or fewer samples.

8.9 SPECIAL DIGESTION OF AIR FILTERS FOR BERYLLIUM ANALYSIS

8.9.1 Rinse scissors with acetone and cut filters in half.

8.9.2 Place one half of filter in 100mL polypropylene beaker (archive the other half in case reanalysis is necessary).

8.9.3 Add 5mL conc. HNO_3 and 5mL conc. HCl.

8.9.4 Heat sample at 95±5°C until dry.

8.9.5 Remover beaker from heat and allow to cool.

8.9.6 Add 10mL of blank acid (5% HNO_3, 2.5% HCl) to beaker using a calibrated pipet.

8.9.7 Weigh beaker and record weight.

8.9.8 Heat sample at 95±5°C for about 15 minutes.

8.9.9 Remove beaker from heat and allow to cool.

8.9.10 Bring digestate to 10mL final volume gravimetrically by adding blank acid (5% HNO_3, 2.5% HCl) to bring beaker weight to the weight recorded in Step 8.9.7. Mix thoroughly.

8.9.11 Transfer the digestate from the 100mL beaker to a labeled 15mL polypropylene autosampler tube. Cap with parafilm.

8.9.12 Prepare quality control (QC) samples as discussed in Section 9.0.

8.9.13 Document information in the metals digestion logbook (Form 805) for each digestion batch of twenty or fewer samples.

8.10 SPECIAL CLEANUP PROCEDURE FOR ARSENIC AND SELENIUM ANALYSIS BY ICP-MS

The measurement of arsenic and selenium by ICP-MS is difficult in heavy matrices, mainly due to the presence of chloride and its associated interferences. To improve these measurements, the digestates are passed through a cation exchange column. This column should remove most calcium and sodium from the sample matrix and help reduce the Ca^{40} Cl^{35} interference on the monoisotopic As^{75} as well as reducing the suppression of signal usually seen with high concentrations of sodium.

8.10.1 Digestates to be analyzed for arsenic and/or selenium by ICP-MS should be diluted a minimum of ten-fold before being treated by the cation exchange column. This dilution is done to achieve a better match between sample matrix and standards and also to improve the effectiveness of the cation exchange column.

8.10.2 All digested samples and matrix quality control samples will be treated with the cation exchange procedure before analysis. In addition, the interference check standards (ICSA and ICSAB), which contain known

amounts of calcium and sodium plus analytes of interest, will be treated with the cation exchange procedure. These treated interference check standards should help demonstrate the effectiveness of the cation exchange procedure.

8.10.3 Create cation exchange columns that contain 4 to 5cm of resin. Fill an empty column (5.12) to between 8 and 10cm with slurry of ½ resin and ½ reagent water. This will yield a cation exchange column with a quantity of resin between 4 and 5cm.

8.10.4 Rinse each column with 10 to 20mL of reagent water.

8.10.5 Rinse each column with 10 to 20mL of the diluted digestate or interference check standard. Discard this volume to waste.

8.10.6 Pass at least 20mL of diluted digestate or interference check standard through the column and collect in a labeled, 100mL polypropylene container and cover. These solutions are now ready for analysis by ICP-MS.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of twenty (20) or less field samples of like matrix that is associated with one unique set of batch QC samples that have been processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS) and matrix spike and duplicate (MS/MSD). All QC samples must be carried through all stages of the sample preparation and measurement steps.

9.2 MB

Also referred to as a laboratory reagent blank (LRB) or Preparation Blank (PB). The MB consists of an aliquot of reagent water (or TCLP fluid) that has been digested and prepared in the same manner as the associated samples, and is run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. See determinative SOP for acceptance limits.

9.3 LCS

Referred to as a laboratory fortified blank (LFB) in Method 200.2, also referred to as a Blank Spike (BS). The LCS consists of an aliquot of reagent water, TCLP fluid, or a certified, commercially prepared, spiked solid that is digested and prepared in the same manner as the associated samples. The LCS is analyzed to measure the accuracy of the method. Guidance regarding the identity and amount of spike solution to be used is presented below:

Procedure / Method	Spiking Solution Used	Amount of Spike Used	Final Vol. Digestate
SW3005A / Dissolved Metals - ICAP	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
200.7 / Dissolved Metals - ICAP	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
SW3005A / Total Recoverable Metals - ICAP	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
SW3010A / Total Metals - ICAP	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
200.2 / Total Recoverable Metals - ICAP (Waters)	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
SW3050 / Soils for ICAP	Spike Solution Z C Spike Cation Spike	2.0mL 0.50mL 2.0mL	100mL
CLP 4.0 / for Solid	Solid LCS	1.0g	200mL
CLP 4.0 / for Waters	Spike Solution Z C Spike Cation Spike	2.0mL 0.50mL 2.0mL	100mL
Be Filter	Be Filter Spike Solution	0.05mL	10mL

NOTE: A commercially prepared solid LCS standard with established control limits is used at the client's request.

See determinative SOP for manner of calculation and acceptance limits.

9.4 MS/MSD

Sometimes referred to as a laboratory fortified matrix (LFM) sample. MS/MSDs consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection. One MS/MSD are analyzed with each batch of 20 or fewer field samples (SW846 and CLP); one MS/MSD is analyzed with each batch of 10 or fewer field samples for EPA Method 200.7. For TCLP leachates, an MS/MSD

set are run for each fluid type present per batch of 20 samples or less. Guidance regarding the identity and amount of spike solution to be used is presented below:

Procedure / Method	Spiking Solution Used	Amount of Spike Used	Final Vol. Digestate
SW3005A / Total Recoverable Metals - ICAP	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
SW3010A / Total Metals - ICAP	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
200.2 / Total Recoverable Metals - ICAP (Waters)	Spike Solution Z C Spike Cation Spike	1.0mL 0.25mL 1.0mL	50mL
SW3050 / Soils for ICAP	Spike Solution Z C Spike Cation Spike	2.0mL 0.50mL 2.0mL	100mL
CLP 4.0 / for Solid	CLP-SPK-1 CLP-SPK-4	0.20mL 0.20mL	200mL
CPL 4.0 / for Waters	CLP-SPK-1 CLP-SPK -4	0.10mL 0.10mL	100mL

NOTE: Spikes may vary per client's request.

See determinative SOP for manner of calculation and acceptance limits.

9.5 LABORATORY DUPLICATE

The laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. One duplicate is to be prepared per matrix for each sample batch. Quality control criteria for evaluating laboratory duplicates are presented in the analytical SOP.

10. DEVIATIONS FROM THE METHOD

This SOP meets the requirements of Methods SW3005A, SW3010A, SW3020A, SW3050B, EPA 200.2, CLP ILM03.0 and CLP ILM04.0. There are no known deviations from these methods.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) must be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The sample digestates shall be disposed of in the Aqueous Laboratory Waste.

11.2.2 Radioactive sample disposal - solid sample residues shall be disposed of in the Radioactive Soils & Solids container. Radioactive sample digestates shall be disposed of in the Radioactive Aqueous Lab Waste.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. ***Please note that all labels and markings must be defaced prior to disposal.***

DOCUMENT REVISION HISTORY

7/26/05: Added LIMS Program Specification directive in RESPONSIBILITIES.

4/10/06: Added DOCUMENT REVISION HISTORY.

11/4/07: Revamped Section 7. Added that sample must be acidified to pH<2 for a minimum of 24hrs before analysis may begin (Federal Register, 3/26/07, Volume 72, Number 57). Likewise changed '16' to 24hrs Sections 8.1.1; 8.3.1; 8.4.1; 8.5.1; 8.7.1. Also updated Form 824 and replaced logbook pages, trained analyst). Updated QC Section 9 to make it more consistent with PAR format (Definition of Batch 9.1; Blanks 9.2, etc.). Updated attached Forms.

Appendix A

The weight of the final volume of digestate for each digestion procedure was determined by digesting 5 method blanks and weighing the digestates after bringing to volume in a volumetric flask. The method blanks were placed in a variety of positions on the steam bath. Results for each digestion method are tabulated below.

Weight of digestate in grams.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references -- Method EPA 200.7 -- is used to determine the concentration of total or dissolved metals in aqueous samples. Analytes are viewed axially, providing detection limits for many analytes similar to those that may be achieved using Graphite Furnace Atomic Absorption (GFAA) analysis.

The following elements are routinely determined using this method:

Aluminum (Al)	Antimony (Sb)	Arsenic (As)	Barium (Ba)	Beryllium (Be)
Cadmium Cd)	Calcium (Ca)	Chromium (Cr)	Cobalt (Co)	Copper (Cu)
Iron (Fe)	Lead (Pb)	Lithium (Li)	Magnesium (Mg)	Manganese (Mn)
Molybdenum (Mo)	Nickel (Ni)	Phosphorous (P)	Potassium (K)	Selenium (Se)
Silicon (Si)	Silver (Ag)	Sodium (Na)	Strontium (Sr)	Thallium (Tl)
Tin (Sn)	Titanium (Ti)	Uranium (U)	Vanadium (V)	Zinc (Zn)

2. SUMMARY OF METHOD

Samples are digested and prepared prior to analysis in accordance with Method EPA 200.7, per SOP 806. Filtered liquid samples, liquid samples containing low solids, or leachates may also be analyzed by direct aspiration into the ICAP instrument (i.e., without prior digestion). A computer-controlled Inductively Coupled Argon Plasma (ICAP) Trace Analyzer is used to accomplish the analyses.

Samples or sample digestates are aspirated into the ICAP instrument, into a high temperature argon plasma stream. Radio frequencies are generated to induce excitation of the plasma stream that causes constituent elements contained in the sample to emit light at characteristic wavelengths. A grating spectrometer is used to disperse the resulting spectra. The light emissions are received by a photomultiplier tube, which in turn transmits a signal to the data acquisition system. The software of the data acquisition system interprets the signal by comparing it to a previously calibrated standard curve. The data are then further manipulated in the reporting process to incorporate such factors as dilution, etc.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 SPECTRAL INTERFERENCES

Potential spectral interferences include the following:

4.1.1 Overlap of a spectral line from another element at the analytical or background measurement wavelengths. Spectral overlap may be compensated for by computer-correcting the raw data after monitoring and measuring the interfering element (see Section 8.8 for a description of this correction).

4.1.2 Unresolved overlap of molecular band spectra.

4.1.3 Background contribution from continuum or recombination phenomena.

4.1.4 Stray light from the line emission of high concentration elements. Background contribution and stray light may usually be compensated for by a background correction adjacent to the analyte line.

4.2 PHYSICAL INTERFERENCES

Effects associated with the sample nebulization and transport processes are considered physical interferences. Changes in viscosity and surface tension may cause significant inaccuracies, especially in samples containing high dissolved solids or high acid concentrations. If physical interferences are present, they must be reduced by diluting the samples.

4.3 CHEMICAL INTERFERENCES

Molecular compound formation, ionization effects, and solute vaporization effects are chemical interferences. The most significant potential interference in the Trace ICAP instrument is ionization effects caused by varying levels of easily ionized elements in samples and standards. The ionization effects can be reduced by adding a constant amount of an easily ionized element (such as lithium) as an "ionization buffer" to all solutions. The lithium is added using a peristaltic pump that delivers a constant flow of lithium solution to the sample delivery tubing through a "T" connector.

5. APPARATUS AND MATERIALS

5.1 Autosampler: Thermo Jarrell Ash Model AS300 or equivalent

5.2 ICAP: An argon plasma trace analyzer (e.g., Thermo Jarrell Ash ICAP 61E Trace Analyzer), set to simultaneous operating conditions and containing the following:

- an axially mounted torch
- an R.F. (radio frequency) generator; set at 27.12MHz, 2kW (i.e., an inductively coupled argon plasma excitation source)
- holographic grating, 2400 grooves/nm, blazed at 500nm
- a 0.75m Rowland Circle spectrometer (polychromator) or equivalent, with a Paschen-Runge mount and capable of accepting up to 63 channels

- an automated instrument control and data acquisition system (i.e., personal computer or equivalent) capable of providing various (i.e., background, interelemental) corrections
- Thermospec™ version 6.20 or higher or ICAP Manager™ version 6.10 or higher software, or equivalent

5.3 Volumetric flasks, various sizes, of suitable precision and accuracy

5.4 Volumetric pipets, fixed or adjustable, verified per SOP 321

6. REAGENTS – Only trace metals grade solvents shall be used!!

6.1 Hydrochloric acid (HCl), concentrated, JT Baker #9530-33 or equivalent

6.2 Nitric acid (HNO_3), concentrated, JT Baker #9598-34 or equivalent

6.3 Reagent water, deionized (DI) water obtained from the laboratory's DI water system (SOP 319)

6.4 Liquid Argon, 99.99% pure

6.5 STANDARDS

6.5.1 All standard solutions are prepared, documented, and stored in accordance with Paragon SOP 300. All standard solutions are to be contained in fresh (previously unused) polypropylene bottles.

6.5.2 Detailed documentation of all standards associated with each ICAP acquisition (analytical sequence) is recorded in the Header Information of the ICAP software, and included with the associated raw data. This documentation includes the stock and intermediate standard identification numbers, dilutions performed to create the working standards, and the resulting concentrations of the working standards. (Further details pertaining to header information is provided in Section 8.4).

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are collected in plastic or glass containers, and must be chemically preserved with nitric acid to pH<2. Samples for dissolved metals analyses should be filtered in the field prior to chemical preservation. If samples are not preserved in the field, they may be acidified by the laboratory upon receipt, but must be held in their original container for a minimum of 16 hours before transfer or analysis of the sample.

7.3 Samples must be maintained at 4±2°C, and must be prepared and analyzed within 180 days of collection.

8. PROCEDURE

8.1 TYPICAL OPERATING CONDITIONS

Torch Gas:	High Flow
Auxiliary Gas:	Low
Nebulizer Gas:	25 PSI
RF Power:	1150 W
Pump Rate:	125 rpm
Sample Tubing:	Orange/Orange
Rinse Tubing:	Red/Red

8.2 The instrument is calibrated each day, by analyzing and processing multi-point calibration curves for each element quantitated. Second order (quadratic) calibration equations with at least 5 points are used to fit the calibration data and to determine concentration results.

8.3 The typical autosampler analytical sequence is listed below along with brief descriptions of each solution. Refer to attached quality control (QC) Table at end of SOP for performance criteria:

Autosampler Run Number	***Solution Name***	***Description***
1	Mix A	Reanalysis of the highest calibration standard for Mix A elements. Processed as a sample.
2	Mix B	Reanalysis of the highest calibration standard for Mix B elements. Processed as a sample.
3	Mix C	Reanalysis of the highest calibration standard for Mix C elements. Processed as a sample.
4	ICV	Initial Calibration Verification check standard for all elements (second source).
5	ICB	Initial Calibration Blank. Must be run following the multi-point calibration and before any samples are analyzed.
6	ICSA	Interference Check Solution A (contains high concentrations of Ca, Mg, Al, Fe).
7	ICSAB	Interference Check Solution B (contains high concentrations of Ca, Mg, Al, Fe and low concentrations of other elements).
8	CRI	Low concentration test solution containing analyte concentrations near the reporting limit; analysis of this solution is not described in Method 6010B. Run for informational purposes only, Paragon does not control on CRI recovery, unless required by client LIMS program specification.

Autosampler Run Number	*Solution Name*	*Description*
9	CCV	Continuing Calibration Verification check standard for all elements (second source).
10	CCB	Continuing Calibration Blank. Must follow CCV analyses.
11 thru 20	Samples	Additional analytical samples. Analytical samples include all samples analyzed on the instrument except ICV, ICB, CCV and CCB. The CRI, ICSA and ICSAB, along with all samples in the sequence and any dilutions, post-spikes (see Section 8.6.4), laboratory and matrix spikes, duplicates, serial dilutions and method/ preparation blanks, are all considered to be analytical samples. The sequence is closed out with the following solutions: CRI, ICSA, ICSAB (analyzed at the end of each analytical sequence, and every eight hours if the analytical sequence is longer than eight hours), followed by CCV, CCB.
21	CCV	Continuing Calibration Verification check standard for all elements (second source).
22	CCB	Continuing Calibration Blank, must follow CCV analyses.
Repeat (11 through 22); the sequence continues with CCV and CCB analyzed after every 10 analytical samples.		

8.4 After the analytical sequence is complete, a "header and summary" section is produced which includes:

- Standard information including standard identifications, expiration dates, elements and concentrations, and preparation procedures
- Acid lot numbers
- Pipet identification numbers
- Dilution information and preparation procedures
- Analytical spike information and preparation procedures
- Daily and monthly maintenance items performed. (Maintenance is further discussed in Section 8.10).
- Summary page with analytical sequence and elements of interest

8.5 At the completion of the sequence, the instrument is shut down as follows:

8.5.1 Disconnect pump tubing.

8.5.2 Lower "purge optics" gas flow to approximately 1L/min.

8.5.3 Exit the software.

8.6 PREPARATION AND EVALUATION OF QUALITY CONTROL (QC) SAMPLES

8.6.1 Calibration Blank (STD-Blank): An aliquot of reagent water is acidified in the same manner as the sample digestates. This calibration blank is used as a component in establishing the calibration curve and is also analyzed repeatedly throughout the analytical sequence as the Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB). To be acceptable, the calibration blank cannot contain any analyte above the analyte reporting limit (or as otherwise specified in the applicable LIMS program specification). Refer to Section 10.1 for further discussion.

8.6.2 Method Blank (MB): Referred to as a reagent blank in Method 200.7 (40 CFR). One MB is prepared per batch of 20 or less field samples. The method blank consists of an aliquot of reagent water that has been digested and prepared in the same manner as the associated samples. To be acceptable, the method blank cannot contain any analyte above the analyte reporting limit (or as otherwise specified in the applicable LIMS program specification). Method blank results are also acceptable if sample concentrations are greater than 10 times the concentration found in the method blank. Refer to Section 10.5 for further discussion.

8.6.3 Sample Duplicate: One sample duplicate is prepared per batch of 10 or less field samples. The control limit for duplicate precision is that the relative percent difference (RPD) must be ≤20%. RPD is calculated as shown below:

$$\text{RPD} = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

The results are flagged if duplicate precision is greater than 20% RPD. Refer to Section 10.6 for further discussion.

8.6.4 Matrix Spike (MS) and Matrix Spike Duplicate (MSD): One MS and MSD are prepared per batch of 10 or less field samples. MS and MSD samples consist of additional aliquots of a particular field sample that are spiked, digested and prepared in the same manner as the associated samples.

Matrix spike samples are evaluated in terms of recovery, calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right) (100)$$

Matrix spike recovery is not evaluated if the analyte concentration in the unspiked sample is greater than 4 times the spike level. The quality control limit for matrix spike recovery is 70 to 130%. The control limit for MS/MSD precision is that the RPD must be ≤20%. RPD for the MS/MSD is calculated the same as for the Sample Duplicate (see Section 8.6.3 above). Results are flagged if MS/MSD recovery or precision results are outside control limits.

A post digestion spike analytical spike (i.e., sample aliquot is spiked after digestion) should be performed when matrix spike recovery is outside the control limit. If recovery of the post digestion analytical spike is not within 90-110%, the result is flagged indicating that matrix interference is suspected. Refer to Section 10.8 for further discussion.

8.6.5 Laboratory Control Sample (LCS): One laboratory control sample is prepared per batch of 20 or less field samples. The LCS is a water sample with known analyte concentrations that is digested and prepared in the same manner as the associated samples. LCSs are evaluated in terms of recovery (%R), calculated as follows:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right) (100)$$

The control limits for LCS recovery are 85-115%. All samples associated with a failed LCS must be redigested and reanalyzed. Refer to Section 10.9 for further discussion.

8.6.6 Serial Dilution Sample: A 1:5 serial dilution of an additional sample digestate is prepared per 20 field samples of like matrix that are processed as a unit. If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test should agree within ±10 % of the undiluted results. Sample analyte results failing this test should be flagged indicating the existence of matrix interferences. Refer to Section 10.10 for further discussion.

8.7 LINEAR RANGE

The element concentrations in the Mix A and Mix B High Standards define the upper end of the analytical range. Samples whose concentrations exceed the calibration range must be diluted to bring their concentrations within the known calibration range of the instrument.

8.8 INTERELEMENT SPECTRAL INTERFERENCE CORRECTIONS

Interelement spectral interferences are determined by analyzing a solution that contains a high concentration of a potentially interfering element and observing the "apparent" concentration arising from the solution in other element channels. Interelement interference correction factors are calculated from these observations. *For example*: a 500ppm Al solution produces an apparent Pb concentration of 0.15ppm. The interelement correction factor K is calculated as follows:

$$K = \frac{Apparent\ Conc.\ in\ ppm}{Conc.\ of\ Interfering\ element\ in\ ppm}$$

In this example, K = 0.15 / 500 = 0.00030.

The interelement correction factor K is the amount of interference produced by 1ppm of the interfering element on the element being interfered with. Interference correction factors are used by the ICAP software to calculate corrected concentrations using the following equations:

$$Corrected\,Conc.(ppm) = Uncorrected\,Conc.(ppm) - \left(K * Conc.of\ Interfering\,Element(ppm)\right)$$

High concentrations of elements (such as Fe and Al in solid digestates) are the most likely sources of significant spectral interferences. The ICSA and ICSAB are analyzed at the beginning and end of each analytical sequence to verify that the spectral interferences arising from Al, Fe, Ca, and Mg are being corrected properly.

An interelement interference study is conducted every six months by analyzing single element solutions of each analyte at high concentrations. The study is used to verify or update interelement interference correction factors. Because the instrument is a direct reading polychromator with fixed detectors, interelement interference correction factors usually remain quite constant.

8.9 In addition to the electronic run information provided by the instrument's output (analyst, date, time, sample ID, etc.), a hardcopy Run Log is maintained as an internal Departmental record of instrument throughput. Standard intensities for selected elements are noted as comments, these recordings are used to verify that operating conditions remain the same. If a variation or trend is noticed in intensity readings, the cause should be determined and corrected if necessary.

8.10 REGULAR MAINTENANCE ITEMS

The following items should be checked prior to each run to ensure the instrument is in good working order.

- check argon level; order more as needed
- check printer, paper supply and ribbon; replace as needed
- check filters on rear of instrument and vacuum monthly
- check water level in drain bottle and empty if necessary
- check pump tubing -- replace when necessary
- check that the previous day's work is properly recorded and processed

There is a section in the raw data header information where the Regular Maintenance items may be initialed as completed.

8.11 MAINTENANCE LOG

A maintenance logbook is used to record all information concerning instrument maintenance that is not covered by the daily and monthly maintenance items described previously. This logbook is used to document all repairs and the symptoms of the problems.

9. QUALITY CONTROL

9.1 Various quality control indicators are discussed in Sections 8.3 and 8.6.

9.2 A method detection limit (MDL) study consisting of the analysis of a minimum of seven replicate aliquots of target analytes at concentration levels 3-5 times the anticipated detection limit, shall be performed as needed, and at a minimum, annually.

9.3 Instrument detection limits (IDLs) reflect instrument capability and are determined per CLP protocol. These studies are performed quarterly.

10. METHOD MODIFICATIONS

10.1 Section 12.1.1 of EPA Method 200.7 (40 CFR) recommends that the results for calibration blanks "should be within 2 standard deviations of the meal *(sic)* value." The intent of this statement is most likely that calibration blanks should be within ±2 standard deviations of the 'mean' value. Paragon follows a different criteria for calibration blanks than the one recommended. Paragon's criteria require that the calibration blank results be less than the reporting limit (ICB, CCB).

Method 200.7 (40 CFR) does not define the data set to be used for determining the control limits. Paragon notes that several factors could significantly affect data used for calculation of control limits. Some examples include: different acid lot numbers; instrumentation changes (nebulizer, torch); the number of data points used; and the frequency of updating the control limits. A significant problem with the recommendation given in Section 12.1.1, is that a control limit of ±2 standard deviations of the mean value could allow blank results to be higher

than the reporting limit. Paragon's criteria for evaluating calibration blanks are clearly defined and allow for straightforward data review and validation.

10.2 Section 12.1.2 of EPA Method 200.7 (40 CFR) recommends that results for the interference check sample "should fall within the established control limits of 1.5 times the standard deviation of the mean value." A control limit of 1.5 times the standard deviation of the mean value shows that the interelement spectral interference correction routines are operating reproducibly, but this control limit does not provide assurance that the corrections are accurate. Paragon analyzes 2 interference check samples (named ICSA and ICSAB) rather than one interference check sample as described in Method 200.7 (40 CFR). These solutions are analyzed at the beginning, end, and periodically throughout an analytical sequence. The ICSA solution contains Ca, Mg, Al and Fe at the upper analytical range concentration and no other analytes. Ca, Mg, Al and Fe are the elements most likely to cause significant spectral interferences in environmental samples. The control limits used by Paragon for the ICSA results require that no analyte concentrations (other than Ca, Mg, Al and Fe) may exceed the absolute value of 2 times the reporting limit. The ICSAB solution contains Ca, Mg, Al and Fe at the upper analytical range concentration and the other analytes at low concentrations. The control limits used by Paragon for the ICSAB results requires all analyte recoveries to be within ±20% of the known concentrations. The analysis of the ICSA and ICSAB solutions verifies that the spectral interference correction routines are functioning at concentrations near the reporting limit and also at concentrations above the reporting limit. Paragon control limits for the ICSA and ICSAB solutions are clearly defined and allow for straightforward data review and validation.

10.3 Paragon analyzes a CRI solution at the beginning and end of each sequence. This CRI solution provides assurance that the instrument sensitivity is adequate to support the reporting limit. Method 200.7 (40 CFR) does not describe the analysis of a low level test solution as part of an analytical sequence.

10.4 Section 12.1.1 in EPA Method 200.7 (40 CFR) states: "Analyze and *(sic)* appropriate instrument check standard at a frequency of 10%". This is assumed to mean that an appropriate instrument check standard should be analyzed. The control limit given in Method 200.7 (40 CFR) is ±5% of the true value. This control limit has been found to be too stringent to allow for the routine analysis of samples with widely varying matrix constituents. Instrumental drift is caused by samples containing high levels of dissolved constituents, which perturb the nebulizer, and changes in ambient temperature. Paragon's control limit for CCVs is ±10% of the true value. The ±10% control limit is also given in EPA Method 200.7 (EPA 600). The ±10% control limit provides adequate assurance that instrumental drift has not significantly affected quantitation.

10.5 Section 11.1 of Method 200.7 (40 CFR) recommends, "reagent blanks should be

subtracted from all samples". No criteria are given in Method 200.7 (40 CFR) defining the maximum allowable analyte concentration in reagent blanks. Paragon does not subtract method blank results from samples. If reagent (method) blank results are either above the reporting limit or are greater than 1/10 the concentration found in samples, then all associated samples are re-digested and re-analyzed.

10.6 EPA Method 200.7 (40 CFR) does not describe the preparation and evaluation of duplicate samples. Paragon performs duplicate analyses at a frequency of 10% to provide a measure of the precision of the analytical results.

10.7 Method 200.7 (40 CFR) does not discuss the preparation and evaluation of digested matrix spike and matrix spike duplicate samples. Paragon prepares and analyzes matrix spike and matrix spike duplicate samples at a frequency of 10%.

10.8 Section 5.2.2 of Method 200.7 (40 CFR) recommends that a spike addition test should be performed whenever a new or unusual matrix is encountered. It is assumed that the spike addition is performed on a digested sample (i.e., a post digestion analytical spike) because it is discussed in the same section (5.2) as the serial dilution test. It is not likely that a commercial laboratory will be able to determine if a matrix is new or unusual. Therefore, Paragon uses matrix spike recovery results in each preparation batch to evaluate matrix interferences. The matrix spike recovery control limits (70-130%) are taken from Method 200.7 (EPA 600). If matrix spike recovery is outside the control limit, then a post digestion spike is prepared and analyzed. Paragon uses the 90-110% control limit for post digestion spike recovery recommended by Method 200.7 (40 CFR).

10.9 Method 200.7 (40 CFR) does not describe the preparation and evaluation of a digested laboratory control sample (LCS). Paragon analyzes a LCS with each sample batch to provide assurance that the digestion and analysis is in control. Paragon's LCS recovery limit is 85-115%, which is taken from Method 200.7 (EPA 600).

10.10 Section 5.2 of Method 200.7 (40 CFR) recommends that serial dilution results should agree within $\pm$5% of the original determination. The amount that the sample should be diluted for the test is not defined. The difference between undiluted and diluted results usually becomes larger as the level of dilution increases. A $\pm$5% criterion seems too stringent for samples with widely varying levels of constituents. Paragon flags data if the serial dilution (5 fold dilution) results do not agree within ±10% of the original determination. The ±10% criterion is also suggested by Method 200.7 (EPA 600).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire

extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The sample digestates shall be disposed of in the Aqueous Laboratory Waste.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. ***Note that all labels and markings must be defaced prior to disposal.***

DOCUMENT REVISION HISTORY

11/20/06: SOP was updated to apply to newly acquired second trace ICAP instrument as well. Abbreviation 'ICP' was updated to 'ICAP' throughout. Element list verified, updated and presented in tabular form, Section 1. LIMS program specification reference augmented, Section 3.3. Simplified standards discussion, Section 6.5, and included reference to information contained in software header. Reorganized Section 7 and added comment that if acidified by laboratory, sample must be held in

original container for at least 16hrs prior to processing. Typical Operating Conditions added, Section 8.1. QC information taken out of analytical sequence Table (Section 8.3); QC Table at end of SOP referenced instead. References to LIMS program specification requirements added to QC Table where appropriate, MDL Study information added to Table. DOCUMENT REVISION HISTORY Section added.

Analytical Method: EPA 200.7	**Parameter**: ICAP Metals		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration, using, at minimum, 4 standards and a blank	Daily	Correlation coefficient for all analytes >0.995	Correct problem and repeat initial calibration
Reanalysis of Mix-A, Mix-B and Mix C calibration standards as samples	Immediately after calibration	All analytes within ±5% of expected value	Correct problem then repeat initial calibration
ICV (Initial Calibration Verification) check standard (second source); at or below midpoint	Daily after initiation calibration	All analytes within ±5% of expected value	Correct problem then repeat initial calibration
ICB (Initial Calibration Blank)	Immediately following ICV	Absolute value of result for each analyte < reporting limit (or as specified in the applicable LIMS program specification)	Correct problem then re-analyze ICB
CCV (Continuing Calibration Verification) check standard; concentration of analytes must be different from the ICV	After every 10 samples and at the end of the analytical sequence	All analytes within ±10% of expected value Note: (where compliance samples are analyzed for regulatory reporting purposes, a ±5% CCV must be maintained).	Repeat calibration and reanalyze all samples since last successful CCV
CCB (Continuing Calibration Blank)	Immediately after every CCV	Absolute value of result for each analyte < reporting limit (or as specified in the applicable LIMS program specification)	Correct problem then analyze CCB and previous 10 samples
ICSA (Interference Check Solution A)	At the beginning and the end of an analytical run	All analytes within ±20% of expected value	Terminate analysis, correct problem, reanalyze ICSA, reanalyze all affected samples
ICSAB (Interference Check Solution B)	At the beginning and the end of an analytical run	All analytes within ±20% of expected value	Terminate analysis, correct problem, reanalyze ICSAB, reanalyze all affected samples
MB (Method blank)	One MB per batch of 20 or fewer field samples	Absolute value of result for each analyte < reporting limit (or as specified in the applicable LIMS program specification)	Correct problem then reprep and analyze MB and all samples processed with the associated MB

Analytical Method: EPA 200.7	**Parameter**: ICAP Metals		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
LCS (Laboratory Control Sample)	One LCS per batch of 20 or fewer field samples	Recovery limit 85-115% for each analyte	Correct problem then reanalyze. If still out, reprep and reanalyze the LCS and all samples in the affected batch
Sample Duplicate	One sample duplicate per batch of 10 or fewer field samples	For each analyte RPD ≤20%	Flag results if RPD >20%.
MS/MSD (Matrix Spike/Matrix Spike Duplicate)	One MS/MSD pair per batch of 10 or fewer field samples	Recovery limit 70-130% for each analyte, not calculated if analyte conc >4X the spike level. For each analyte RPD ≤20%	Flag results if MS/MSD recovery or precision results are outside control limits, perform post digestion analytical spike as applicable
Post Digestion Spike	Performed when MS/MSD recovery is outside ± 30% (unless analyte conc > 4X the spike level)	Recovery limit 90-110% for each analyte	Flag results if post spike recovery or precision results are outside control limits
Serial Dilution sample analysis	Performed on one sample per batch of 20 or fewer field samples, where analyte concentrations exceed 50X IDL	Results should agree within ±10% of undiluted results	Flag results if outside criteria
Method Detection Limit (MDL) Study	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level ≤ to that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

TITLE: PREPARATION AND DETERMINATION OF MERCURY BY COLD VAPOR ATOMIC ABSORPTION SPECTROSCOPY -- METHODS SW7470A, SW7471A, EPA 245.1, ILMO3.0, ILMO4.0

FORM NUMBERS: 808, 824

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/13/07

QUALITY ASSURANCE MANAGER _____ DATE 8/11/07

LABORATORY MANAGER _____ DATE 8-13-07

HISTORY: Rev0, 3/18/93; Rev1, PCN #84, 1/17/94; Rev2, PCN #262, 9/26/94; Rev3, 1/13/95; Rev4, 3/31/96; Rev5, 5/7/97; Rev6, 3/1/99; Rev7, 3/7/01; Rev8, 3/2/02; Rev9, 3/28/03; Rev10, 2/25/04; Rev11, 2/1/05; Rev12, 7/26/05; Rev13, 4/10/06; Rev14, 8/11/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the digestion procedures and instrument analysis of all matrices for mercury.

2. SUMMARY

Waters and TCLP leachates analyzed by methods SW7470A, EPA 245.1, CLP ILMO3.0, CLP ILMO4.0 are digested using the same basic procedure. A weighed portion of sample is digested using acids, potassium permanganate and potassium persulfate for liquid samples and soil CLP samples. Aqua regia and potassium permanganate are used for digesting SW7471A soil samples. After digestion, and the addition of hydroxlyamine sulfate, the digestate is analyzed using a cold vapor mercury atomic absorption spectrometer (CVAA). The mercury (Hg) is reduced to the elemental state by the addition of stannous chloride. The mercury vapor passes through a cell in the light path of an atomic absorption lamp that emits light at 253.7nm. The 253.7nm light is absorbed in proportion to the concentration of Hg atoms in the cell. The absorbance is measured as a function of mercury concentration by running a series of standards with each batch of samples. The typical reporting limits for this method are 0.0002mg/L and 0.0006mg/Kg.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate and interpret acceptable

results utilizing these methods. This demonstration may come in the form of Supervisory/training review, performance of precision and accuracy tests, or the successful analysis of an unknown proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Possible interference from sulfide is eliminated by the addition of potassium permanganate. Concentrations as high as 20mg/L or 20mg/kg of sulfide as sodium sulfide do not interfere with the recovery of added inorganic mercury from reagent water.

4.2 Copper has also been reported to interfere, however, copper concentrations as high as 10mg/L or 10mg/kg had no effect on recovery of mercury from spiked samples.

4.3 Samples that contain relatively high amounts of chlorides or oxidizable organic material require additional permanganate (as much as 25mL in a 100mL final volume) because, during the oxidation step, chlorides are converted to free chlorine, which also absorbs radiation at 253.7nm. Care must be taken to ensure that free chlorine is absent before the mercury is reduced and swept into the cell. This may be accomplished by using an excess of hydroxylamine sulfate reagent (25mL).

4.4 Certain volatile organic materials that absorb at this wavelength may also cause interference. A preliminary run without reagents should determine if this type of interference is present.

4.5 Low level mercury sample preparation, digestion, and analysis may be subject to environmental contamination if performed in areas with high ambient backgrounds where mercury was previously employed as an analytical reagent in analyses such as total Kjeldahl nitrogen (TKN) or chemical oxygen demand (COD).

5. APPARATUS AND MATERIALS

5.1 Mercury analyzer, automated, CETAC M-6000A, or equivalent

5.2 Mercury vapor lamp, electro-optically regulated, low pressure, high frequency, thermally stabilized

5.3 Nafion drying cartridge and mercury trap ($KMnO_4$), CETAC SP5894 or equivalent

5.4 Hot plate or water bath -- capable of maintaining a temperature of 95±5°C

5.5 Thermometer -- for monitoring hot plate or water bath temperature. **Use only a mercury-free type of thermometer.**

5.6 Beakers, polypropylene, disposable, 250mL - - used for soils

5.7 Centrifuge tubes with caps, disposable, 50mL - - used for liquids

5.8 pH test strips, low range, acidic – capable of testing solutions < pH2

5.9 Pipette(s), adjustable, 0.01-5.0mL

5.10 Laboratory balance -- capable of weighing to 0.01g

5.11 Test tubes, 16X100mm

5.12 Spatulas, wooden, disposable

5.13 Boiling chips, Teflon™, ChemWare PTFE Chips, VWR Cat. No. 26397-103 or equivalent

6. REAGENTS

NOTE: Only trace metals grade acids may be used. The lot # must be verified by the Metals Department prior to the preparation/analysis of samples with any new acids. Each lot of acid must be certified (no metals detected at or above the MDL).

6.1 Reagent water/deionized (DI) water, interference free

6.2 Liquid argon, 99.99% pure

6.3 Sulfuric acid (H_2SO_4), concentrated, EMD SX1247-2 or equivalent

6.4 Nitric acid (HNO_3), concentrated, JT Baker 9598-34 or equivalent

6.5 Hydrochloric acid (HCl), concentrated, JT Baker 9530-33 or equivalent

6.6 Stannous chloride solution (10% w/v): CCI 5515AL or equivalent. Dissolve a ratio of 25g stannous chloride with 25mL HCl up to a 250mL final volume with reagent water for a final concentration of 10%.

6.7 Sodium chloride - hydroxylamine sulfate solution (12% w/v): EMD SX0420-5 and GFS Chemicals 144 or equivalents. Dissolve a ratio of 12g sodium chloride

and 12g hydroxylamine sulfate in reagent water and dilute to 100mL for a final concentration of 12%.

6.8 Potassium permanganate, mercury-free (5% solution w/v): JT Baker 3227-01 or equivalent. Dissolve a ratio of 5g potassium permanganate in 100mL of reagent water for a final concentration of 5%.

6.9 Potassium persulfate (5% solution w/v): JT Baker 3238-01 or equivalent. Dissolve a ratio of 5g potassium persulfate in 100mL of reagent water for a final concentration of 5%.

6.10 Aqua regia: 3 parts concentrated HCl to 1 part concentrated HNO_3. *Made immediately before using.*

6.11 Mercury stock solution; 1000ug/mL: Purchased from two separate sources.

6.12 Intermediate mercury standards, 10ug/mL: **Two** standards are made, one using the primary source mercury stock solution, and the second using the secondary source mercury stock solution. Use 10% HNO_3 to dilute 1mL mercury stock solution to a final volume of 100mL.

6.13 Spiking solutions (working standards):

6.13.1 Spiking Solution A (100ug/L Hg): This solution is *made fresh daily* by diluting the first source 10ug/mL intermediate mercury standard 1:100 with DI water.

6.13.2 Spiking Solution B (100ug/L Hg): This solution is *made fresh daily* by diluting the second source 10ug/mL intermediate mercury standard 1:100 with DI water.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Use sample containers obtained from the vendor pre-washed with detergents, acids, and reagent water. Plastic and glass containers are both suitable.

7.3 Aqueous samples must be acidified to a pH<2 with HNO_3. Typically, a 1L sample is collected. Analysis of the sample cannot begin until it has been acidified for at least 24hrs. The maximum holding time for an aqueous sample is 28 days from collection.

7.4 Non-aqueous samples are not chemically preserved, but are required to be refrigerated at $4\pm2^{o}C$ until analyzed. Typically, 200g of solid or waste is collected.

8. PROCEDURE

8.1 DIGESTION LOGBOOK

8.1.1 Two types of digestion logbooks are used, one for liquid samples and another for soil or solid samples. The most recent iteration of the

mercury benchsheet (Form 808) is to be used. At the time of digestion, the analyst should complete the header and footer information prompted in the digestion logbook (e.g., digestion date, method, digestion analyst, etc.)

8.1.2 Standard/Verification information -- The information needed to prepare the standard curve is pre-printed in the digestion logbook. The concentrations of these calibration standards are: 0, 0.2, 0.5, 1.0, 2.0 and 5.0ppb.

Also pre-printed in the digestion/analysis logbook are the ICV (initial calibration verification), ICB (initial calibration blank), CCV (continuing calibration verification), CCB (continuing calibration blank), and the CRA (low level check standard). Note that a calibration verification and blank must bracket every ten analytical samples (i.e., any sample except a CCV or CCB), and that a CCV and CCB must also be run to closeout the analytical sequence.

IPC -- For method 245.1, an initial performance check (IPC) solution is analyzed immediately following calibration. The IPC solution should be prepared from the same source used for the calibration standards. The IPC concentration should be near the midpoint of the calibration range. The percent recovery of the IPC must be 95-105% before sample analysis can begin.

8.1.3 Sample/Digestate information -- A 'Preparation Batch' is created in LIMS that lists the specific client samples to be digested, and well as the associated QC samples (Blanks, Blank Spikes, Laboratory Control Samples, Duplicates, Matrix Spikes and Matrix Spike Duplicates) that are digested for analysis. A Serial Dilution QC sample is also analyzed per batch, but this sample is not digested.

8.1.4 Additional documentation -- Reagent lots, support equipment ID, etc. are also recorded in the digestion/analysis logbook.

8.2 SAMPLE PREPARATION AND DIGESTION (Soils, Solids, and Wastes)

8.2.1 Label 250mL disposable polypropylene beakers with solution IDs as prepared in the digestion logbook.

8.2.2 Mix the sample by stirring with a disposable wooden spatula in order to obtain a representative aliquot. The aliquot should have a similar particle size distribution as the bulk sample. For very heterogeneous or unusual matrices, consult the Department Manager and Project Manager. If special processing prior to taking an aliquot was required, document in the comments section of the benchsheet. Record the texture (coarse, medium, fine) and color of the sample on the digestion benchsheet as well.

8.2.3 For SW7471A digestions, weigh approximately a 0.60g aliquot of sample into the appropriately labeled beaker. For CLP digestions, weigh approximately a 0.20g aliquot of sample into the appropriately labeled beaker. Record the aliquot size on the digestion benchsheet to the nearest 0.01g.

8.2.4 For soil/solid digestions, the method blank is prepared by digesting approximately 0.60g of Teflon™ chips for method SW7471A, or 0.20g of Teflon™ chips for CLP methods. Record the weight to the nearest 0.01g on the laboratory benchsheet.

8.2.5 For SW7471A digestions, the Laboratory Control Sample (LCS) is approximately 0.60g of Teflon™ boiling chips (record on benchsheet to nearest 0.01g) with a known amount of spike added. For CLP digestions, the LCS is a beaker containing approximately 0.20g of a vendor-supplied soil standard (the certified values and acceptance criteria for these soil standards are based on lot numbers and supplied by the vendor). Both types of LCSs are treated identically to the samples throughout the digestion procedure.

8.2.6 Spike the standards, check standards and matrix spike samples as described in the digestion logbook (Spike Solution and Volume).

8.2.7 Serial Dilution Sample: A 1:5 serial dilution of an additional sample digestate is prepared per 20 field samples of like matrix that are processed as a unit. If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test should agree within ±10 % of the undiluted results. Sample analyte results failing this test should be flagged indicating the existence of matrix interferences.

8.2.8 For SW7471A digestions, add 5.0mL of Aqua regia to each beaker. For CLP digestions, add 2.5mL concentrated nitric acid and 5mL concentrated sulfuric acid to each beaker. Place beakers in the pre-heated water bath for 2 minutes. Remove the beakers and cool to room temperature.

8.2.9 Add 50.0mL of DI water.

8.2.10 For SW7471A digestions, add 15mL of 5% potassium permanganate solution. For CLP digestions, add 8mL of 5% potassium persulfate solution and 15mL 5% potassium permanganate solution.

8.2.11 Loosely cover the beakers with polypropylene lids and mix well. Return the beakers to the water bath for 30 minutes. Remove the beakers and allow to cool.

8.2.12 Add 6mL of 12% sodium chloride hydroxylamine sulfate solution. Mix well until the color from the potassium permanganate has disappeared. Bring all standards and samples to 100mL with DI water. The samples are now ready for analysis.

8.3 SAMPLE PREPARATION AND DIGESTION (Aqueous Samples)

8.3.1 Label 50mL disposable centrifuge tubes with solution ID's as noted in the prepared digestion logbook.

8.3.2 For each sample in the batch, use a test strip to verify that the solution pH is <2. Record the result of the pH test on the benchsheet (Form 824). **If the pH of a sample is found to be >2, concentrated nitric acid (trace metals grade) must be added and the sample held *in its original container* for a minimum of *24 hours* until verified to be pH<2.**

8.3.3 Transfer a well mixed 20g aliquot (or smaller aliquot diluted to 20mL with DI water) into the appropriately labeled tube. TCLP leachates are usually digested at a ten-fold dilution (2.0mL of leachate and 18.0mL of deionized water). Transfer the required amount of DI water, as described in the digestion logbook, into the appropriately labeled tubes for standards and quality control (QC) samples.

8.3.4 For aqueous digestions, the method blank (MB) is prepared by digesting an aliquot of reagent water.

8.3.5 A 1:5 serial dilution of an additional sample digestate is prepared per 20 field samples of like matrix that are processed as a unit. If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test should agree within ±10 % of the undiluted results. Sample analyte results failing this test should be flagged indicating the existence of matrix interferences.

8.3.6 Spike the standards, check standards and matrix spike samples as described in the digestion logbook (Spike Solution and Volume).

8.3.7 Add 1.0mL of concentrated sulfuric acid to each tube.

8.3.8 Add 0.5mL of concentrated nitric acid to each tube.

8.3.9 Add 3.0mL of 5% potassium permanganate solution to each tube.

8.3.10 Add 1.6mL of 5% potassium persulfate solution to each tube.

8.3.11 Cap the tubes tightly and mix well making sure the purple color persists for at least 15 minutes. If necessary, add equal amounts of permanganate solution to all tubes in the batch until the color persists for at least 15 minutes, or re-aliquot the sample at a dilution, or re-aliquot the sample and put in a separate batch.

8.3.12 Heat the tubes in a pre-heated (95±2°C) water bath for 2 hours. Remove the tubes from the water bath and allow to cool.

8.3.13 Add 1.2mL of 12% sodium chloride hydroxylamine sulfate solution to each tube. Mix well until the color from the potassium permanganate has disappeared. The samples are now ready for analysis and should be analyzed within 24 hours of the addition of the hydroxylamine sulfate.

8.4 MERCURY ANALYSIS (using CETAC M-6000A automated mercury analyzer)

8.4.1 Complete the digestion logbook by filling in the analytical filename, date analyzed and analyst information.

8.4.2 <u>Preparing the System</u>

- Turn on the mercury lamp and auto sampler (behind the instrument) and allow to warm up for at least 10 minutes (if in stand by mode). The mercury lamp is equipped with an oven to keep it at a constant temperature of 70^{o}C. If the system has been completely shut down, the instrument requires a warm up time of 90 minutes.
- Open the mercury software by clicking on the icon and open the appropriate worksheet.
- Stannous chloride is added using a peristaltic pump that delivers a constant flow of a 10% stannous chloride solution to the sample delivery tubing through a “T” connector. Clamp the pump tubing and turn the pump on. The pump line should be in 10% stannous chloride solution and the rinse tank should be filled with 1% hydrochloric acid and 1% nitric acid solution. Allow flow through all lines for about fifteen minutes before running the analytical sequence.
- Next, lower the autosampler tip. This is done by going to the “Instrument” option, and then going to “M6000 Controls”. Then pick the “Autosampler” tab, and click the “Park” button.
- Turn the gas on at the main tank.

- Change the peristaltic pump tubing and Nafion drying cartridge as needed.

8.4.3 Software Set-up

Double click the shortcut icon on the computer desktop, then choose the worksheets. This will bring you to the instrument operating area. Choose the labels tab and type in samples (as they appear in the logbook).

8.4.4 Calibrating the System

- Make sure that the six standards (five concentrations and a blank) have been loaded into the standards rack.
- A calibration is pre-programmed into the system. Click on the read button, choose "Read Standard" and then choose "Std. 5". Click "Start" (the autosampler will go to std. 5 and give a signal and peak reading. This is to make sure the system is operating correctly). After you have checked the instrument, run the calibration curve.
- Calibration results are automatically stored, and displayed at the bottom right of the screen.
- Determination of acceptable calibration curve -- An r^2 value greater than 0.995 is acceptable. If the curve is acceptable, begin running samples.
- If the curve is not acceptable, click on the stop button. Try running the calibration sequence again and check to be certain the solutions have been mixed well. At times the instrument requires a second calibration sequence to allow for warm up time. The analytical batch must be re-digested if an acceptable calibration curve cannot be obtained.

8.4.5 Running Samples

- After the field and QC samples are loaded into their designated tubes and the racks are placed on the autosampler, the instrument can begin running samples. Note that the instrument usually starts to read samples immediately after calibration, unless the analyst stops it due to a failed calibration curve.
- ICV -- Analyze an initial calibration verification (ICV) after an acceptable calibration. This is a second source check standard. Analyze an ICB immediately following. The ICV concentration must be different from the CCV. Either the ICV or CCV must be at a concentration below the midpoint of the

calibration curve. For SW-846 methods and EPA 245.1, the ICV recovery must be within 90-110%. For CLP methods, the ICV must be within 80-120%. Cause of failure must be determined and corrected and the instrument recalibrated.

- CRA -- Analyze this reporting limit standard after the ICB. The results of this standard analysis are not formally assessed, unless otherwise directed in the applicable LIMS program specification. The purpose of this standard analysis is simply to verify the analyte reporting limit.
- CCV -- Analyze a continuing calibration verification (CCV) after every ten analytical samples. An analytical sample is every solution analyzed on the instrument except ICV/CCV or ICB/CCB. A CCV is also analyzed after the last analytical sample. Percent recovery of the CCV must be 80-120% of the true value (SW-846 methods and CLP methods). If samples are being analyzed by method 245.1, percent recovery of the CCV must by 90-110%. Cause of failure must be determined and corrected. Samples following the last acceptable CCV must be reanalyzed. All samples must be bracketed by satisfactory CCVs.
- The autosampler will follow the run log you entered under the "Labels" tab, this will be the order in which the samples are analyzed. The instrument will store the data in the folder (the data are stored by date and output sequence).

8.4.6 Shutdown Procedures

- After the sample run is complete, pull up the autosampler tip and change the pump tubing from stannous chloride over to 10% nitric acid, and then deionized water. Let both run for approximately 5 minutes.
- Shut the mercury lamp off.
- When the pump has run DI water for 5 minutes, remove all lines so that air is pumped through the system for 5 minutes. Turn pump switch off and unclamp tubing.
- Turn the gas off at the main tank.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

An analysis batch is defined as a group of twenty (20) or less field samples of like matrix that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike and duplicate (MS/MSD), and serial dilution sample.

All QC samples must be carried through all stages of the sample preparation and measurement steps.

9.2 BLANKS

Method blanks (MBs) are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. The blank concentration found must be less than the analyte reporting limit, or as otherwise specified in the applicable LIMS program specification.
TCLP leachates have associated blanks that are carried through the tumbling process with designated samples. These blanks are analyzed as though they are samples. Calculated results for these blanks must be less than the reporting limit, or as otherwise specified in the applicable LIMS program specification.

ICB -- Analyze an initial calibration blank (ICB) after the ICV. The calculated result of the ICB must be less than the reporting limit, or as otherwise specified in the applicable LIMS program specification. CCB -- Analyze a continuing calibration blank after every CCV. The calculated result of the CCB must be less than the reporting limit, or as otherwise specified in the applicable LIMS program specification.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. One laboratory control sample (LCS) is analyzed with each batch of 20 or fewer field samples. Percent recovery of the LCS must be 80-120% unless solid LCS is used in which case a range will be given by the vendor. If samples are being analyzed by EPA 245.1, percent recovery of the LCS must be 85-115%. Samples associated with a failed LCS must be re-digested and reanalyzed. Other limits may apply, consult applicable LIMS program specification.

Blank spikes (LCSs) are prepared for TCLP leachate samples using the blanks that were carried through the tumbling process. Two different fluids (determined by pH of the sample) may be used for TCLP extraction. These fluids are termed Fluid #1 and Fluid #2. One TCLP blank spike is analyzed for each fluid type present per batch of 20 samples or less.

9.4 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Matrix spikes (MS/MSDs) consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection. One MS/MSD are analyzed with each batch of 20 or fewer field samples (SW846 and CLP). One MS/MSD is analyzed with each batch of 10 or fewer field samples for EPA method 245.1. For TCLP leachates, an MS/MSD set are run for each fluid type present per batch of 20 samples or less.

Analyte recovery for matrix spikes is calculated as shown below:

$$\text{MS \% Recovery} = \frac{(C_{found} - C_{native})}{C_{added}} \text{ X } 100$$

where:

C_{found}	=	analyte concentration found in the spiked sample
C_{native}	=	native analyte concentration found in the unspiked sample
C_{added}	=	spike added analyte concentration

The MSD is analyzed as a measure of the precision of the analytical results generated as is expressed as Relative Percent Difference (RPD):

$$\text{RPD} = \frac{| \text{Result}_x - \text{Result}_{Dup} |}{(\text{Result}_x + \text{Result}_{Dup}) / 2} \text{ X } 100$$

For SW-846 methods, the recovery for the matrix spiked analytes should be within $\pm$20% of the expected value. For CLP methods, the recovery of the matrix spiked analytes should be within $\pm$25% of the expected value. For EPA 245.1, the recovery of the matrix spiked analytes should be within $\pm$30% of the expected value. Other limits may apply, consult applicable LIMS program specification.

The RPD between the matrix spike and the matrix spike duplicate (all methods) should be <20, unless otherwise specified in the applicable LIMS program specification.

9.5 SAMPLE DUPLICATE

One sample duplicate (Duplicate) is analyzed with each batch of 20 or fewer field samples (SW846). One sample duplicate is analyzed with each batch of 10 or fewer field samples (EPA 245.1). The RPD between the sample and duplicate (all methods) should be <20.

9.6 SERIAL DILUTION

To assist in the assessment of possible matrix interferences, a 1:5 serial dilution of an additional sample digestate is prepared per 20 field samples of like matrix that are processed as a unit. If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test should agree within ±10 % of the undiluted results, or as otherwise specified in the applicable LIMS program specification. Sample analyte results failing this test should be flagged indicating the existence of matrix interferences.

9.7 A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study shall be performed as needed (i.e., whenever there is a significant change in operator, background, or instrument response) and at a minimum, every 6 months.

10. DEVIATIONS FROM METHODS

This SOP meets the requirements of methods SW846 7470A/7471A, EPA 245.1 and CLP ILMO3.0/ILMO4.0. The laboratory performs one known deviation from method SW7471A as follows: instead of weighing out three 0.20g aliquots of soil for triplicate analysis, the laboratory weighs out approximately 0.60g for a single analysis to ensure a representative sample.

11. SAFETY, HAZARDS, AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) must be labeled at a minimum with compound name, NFPA Health, Flammability, Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The sample digestates shall be disposed of in the Aqueous Laboratory Waste (otherwise known as the CLE Waste stream)..

11.2.2 Radioactive sample disposal – solid sample residues shall be disposed of in the Radioactive Soils & Solids container. Rad sample digestates

shall be disposed of in the Radioactive Aqueous Lab Waste.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/26/05: Added reference Program Specification directive in "Responsibilities".

4/10/06: Added DOCUMENT REVISION HISTORY.

8/11/07: Changed sample must be acidified to pH<2 *for a minimum of 24hrs* before analysis may begin (Federal Register, 3/26/07, Volume 72, Number 57) to Sections 7.3 and 8.3.2 (also updated Form 824 and replaced logbook pages, trained analyst). Clarified (Sections 8.1.2, 8.4.4, QC Table) that a blank is included as a calibration point. Updated Paragon practice (Sections 8.1.3, 8.2.7, 8.3.5, 9 and QC Table) to include analysis of a five-fold serial dilution with every batch of samples analyzed (re-trained analyst). Revamped QC Section 9 (9.1 calibration curve statement removed, belongs in PROCEDURE text; IPC discussion moved to 8.1.2; ICV and CCV discussion moved to 8.4.5). Further updated QC Section 9 to make it more consistent with PAR format (Definition of Batch 9.1; Blanks 9.2, etc.). Added LIMS program specification references throughout QC Section 9 and QC Table.

Analytical Method: SW 7470A/7471A; EPA 245.1; CLP ILMO3.0/ILMO4.0	**Parameter:** Mercury		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point (plus blank)	Daily at on-set of analyses or when corrective action for CCV failure does not resolve calibration verification non-compliance	Correlation coefficient (r^2) for linear regression must be $\geq$ 0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze calibration standards. If quality control acceptance criterion still not met, analyses cannot proceed; a new suite of calibration standards must be prepared and analyzed. Analyses cannot proceed until an acceptable initial calibration curve is generated.
Initial Performance Check (IPC) Standard; first source (run for Method 245.1 only)	Immediately following initial calibration	Results must agree within $\pm$5% of expected value	If QC criterion not met, analyze again. If IPC still fails, IPC and initial calibration standards must be re-digested and reanalyzed.
Independent Calibration Verification (ICV); second source; run at a concentration at or below the midpoint of the calibration curve	Once after each initial calibration	Response must agree within $\pm$10% of initial calibration for SW7470A/7471A and EPA 245.1; response must agree within $\pm$20% for CLP 3.0/4.0	If QC criterion not met, analyze again. If ICV still fails, ICV and initial calibration standards must be redigested and reanalyzed.
Blanks: Preparation (Method), Initial and Continuing Calibration Blank (ICB and CCB)	ICB run following the ICV One method blank per matrix type processed and analyzed per batch of twenty or less environmental samples processed. CCB run following the CCV to bracket a set of 10 analyses and to close a run sequence	Blank value must be less than reporting limit (RL), or as otherwise specified in LIMS program specification	If QC criterion not met for ICB, locate and correct problem; repeat initial calibration. If QC criterion not met for method blank, the method blank and all associated samples must be redigested and reanalyzed. If QC criterion not met for CCB, locate and correct the problem; all samples analyzed since last acceptable CCB must be reanalyzed.

Analytical Method: SW 7470A/7471A; EPA 245.1; CLP ILMO3.0/ILMO4.0	**Parameter:** Mercury		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
CRA Standard -- Low-Level Reporting Limit Standard run for CLP 3.0/4.0 only	Run immediately following the ICB	No acceptance criteria applicable	No corrective actions required.
Continuing Calibration Verification (CCV); may be first or second source; run at a concentration at or below the midpoint of the calibration curve	Run to bracket a set of 10 analyses, and to end any run sequence (must be followed by a CCB analysis)	Response must agree within ±20% of expected value (SW7470A/7471A and CLP3.0/4.0); response must agree within ±10% (EPA 245.1).	Check for calculation errors. If no calculation errors are found, analyze again. If CCV still fails, evaluate/correct instrument malfunctions; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after last acceptable CCV must be reanalyzed.
Laboratory Control Sample (LCS)	One prepared and analyzed per matrix type per batch of 20 or less field samples	Recovery must be within ±15% of expected value (EPA 245.1). For SW7470A and CLP 3.0/4.0, recovery for aqueous LCS must agree within ±20% of expected value. For SW7471A, the recovery for the solid matrix LCS must agree within ±20% of expected value. For CLP 3.0/4.0 solid matrix, vendor-supplied QC limits apply. Other client-specified criteria may apply, consult applicable LIMS program specification.	Check for documentable errors (e.g., calculations and spike preparation) If no computation errors are found, all associated field and quality control samples must be redigested and analyzed.
Matrix Spike (MS)	One prepared and analyzed per matrix type per batch of 20 or less field samples for SW7470A/ 7471A and CLP 3.0/4.0 One prepared and analyzed per matrix type per batch of 10 or less field samples for Method 245.1	For SW7470A/7471A, recovery should agree within ±20% of expected value. For CLP 3.0/4.0 recovery should agree within ±25% of expected value. For EPA 245.1, recovery must agree within ±30% of expected value. Other client-specified criteria may apply, consult applicable	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative and flag results appropriately.

Analytical Method: SW 7470A/7471A; EPA 245.1; CLP ILMO3.0/ILMO4.0	**Parameter:** Mercury		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
		LIMS program specification.	
Matrix Spike Duplicate (MSD)	One prepared and analyzed per matrix type per batch of 20 or less field samples for SW7470A/ 7471A and CLP 3.0/4.0 One prepared and analyzed per matrix type per batch of 10 or less field samples for EPA 245.1	(See MS recovery criteria above). RPD should be < = 20. Other client-specified criteria may apply, consult applicable LIMS program specification.	Check for documentable errors (e.g., calculations and spike preparation) If no errors are found, then sample matrix effects are the most likely cause. Note in narrative and flag results appropriately.
Laboratory Duplicate	One prepared and analyzed per matrix type per batch of 20 or less field samples for SW7470A/ 7471A and CLP 3.0/4.0 One prepared and analyzed per matrix type per batch of 10 or less field samples for EPA 245.1	RPD should be less than or equal to 20. Other client-specified criteria may apply, consult applicable LIMS program specification.	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample heterogeneity is the most likely cause. Note in narrative and flag results appropriately.
Serial Dilution Test (1:5 dilution), analyzed to assist in the assessment of possible matrix interferences	One prepared and analyzed per matrix type per batch of 20 or less field samples	If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test should agree within ±10 % of the undiluted results, or as otherwise specified in the applicable LIMS program specification	Sample analyte results failing this test should be flagged indicating the existence of matrix interferences.
Method Detection Limit (MDL) Study; run at an analyte concentration lower than the reporting limit (RL)	As needed; at minimum annually	Must yield a positive result < than the analyte reporting limit (RL).	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).

LABORATORY MANAGER [signature] DATE 8/13/07

HISTORY: Rev0, 8/26/2002; Rev1, 3/6/04; Rev2, 5/20/04; Rev3, 8/23/04; Rev4, 7/26/05 and 3/13/06; Rev5, 4/10/06; Rev6, 8/11/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- EPA 200.8 and SW6020A-- are used to determine the concentration of total or dissolved elements in prepared liquid and solid samples. This SOP is applicable to a large number of elements in waters and wastes after appropriate sample preparation steps are taken. Instrument detection limits (IDLs), sensitivities, and linear ranges for these elements will vary with the matrices and operating conditions. Reporting limits in relatively simple matrices will generally be below 0.1µg/L. Less sensitive elements (such as As and Se) and desensitised major elements may have reporting limits of 1.0µg/L or higher.

2. SUMMARY

This SOP describes the multi-element determination of trace elements by Inductively Coupled Plasma - Mass Spectrometry (ICP-MS). Sample material in solution is introduced by pneumatic nebulization into a radiofrequency plasma where energy transfer processes cause desolvation, atomization and ionization. The ions are extracted from the plasma through a differentially pumped vacuum interface into a hexapole-based radiofrequency lens (collision cell). Reaction gases such as helium and hydrogen are introduced into the collision cell to facilitate ion beam focusing and minimization of molecular ion interferences. The ions are then introduced into a mass spectrometer where they are sorted according to their mass-to-charge ratios (m/z) and quantified with a detector. Interferences relating to the technique must be recognized and corrected. Such corrections must include compensation for isobaric elemental interferences and interferences from polyatomic ions derived from the plasma gas, reagents or sample matrix. Instrumental drift as well as suppressions or enhancements of instrument response caused by sample matrix must be corrected for by the use of internal standards.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Paragon uses custom Program Specifications which are directives and controls programmed into LIMS that govern the acquisition and reporting of project data. It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification prior to initiating handling of samples or data.

3.3 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Isobaric elemental interferences occur when isotopes of different elements form singly or doubly charged ions of the same nominal mass-to-charge ratio, and which cannot be resolved by the mass spectrometer (e.g., Mo98 and Ru98). A data system must be used to evaluate and correct for these interferences when they are present. Corrections for isobaric interferences may be made by measuring the intensity (response) due to the interfering element at another isotope and using its natural abundance ratios to correct for its presence at the analytical mass of interest. Care should be taken that the isotope measured for correction purposes does not suffer from overlap with other isotopes that may be present in the sample.

4.2 Abundance sensitivity is a property defining the degree to which the wings of a mass peak contribute to adjacent masses. The abundance sensitivity is affected by ion energy and quadrupole operating pressure. Wing overlap interference may occur when a small ion peak is being measured adjacent to a large one. The

potential for these interferences should be recognized and the spectrometer resolution adjusted to minimize them.

4.3 Isobaric molecular interferences are caused by ions consisting of more than one atom or charge which have the same nominal mass-to-charge ratio as the isotope of interest, and which cannot be resolved by the mass spectrometer (e.g., ArCl, ClO, Nitrogen dimer, oxygen dimer, oxide species, double charged species, etc.). These ions are commonly formed in the plasma or interface system from support gases or sample components. Predictions about the type of molecular interferences may be made using knowledge about the sample matrix. Molecular interferences can often be corrected for in the same manner as isobaric interferences, i.e., measuring the intensity present at another isotope and using isotope ratios to calculate the amount of the interfering species. For example, corrections for interferences of Ar_40Cl_{35} on As at mass 75 may be made by measuring the intensity of ArCl present at mass 77 (Ar_40Cl_{37}) and converting to the apparent intensity of ArCl at mass 75 by using the isotope ratio of Cl_{37} to Cl_{35}. Corrections for these interferences may be made based on the natural isotope ratios of the molecular ion (as described above) or by measuring the interference that occurs when the interferent is present.

4.4 Physical interferences are associated with the physical processes that govern the transport of the sample into the plasma, sample conversion processes in the plasma, and the transmission of ions through the plasma-mass spectrometer interface. These interferences may result in differences between instrument responses for the sample and the calibration standards. Physical interferences may occur in the transfer of solution to the nebulizer (e.g., viscosity effects), at the point of aerosol formation and transport to the plasma (e.g., surface tension), or during the excitation and ionization processes within the plasma itself. High levels of dissolved solids in the sample may contribute to deposits of material on the extraction and/or skimmer cones. Deposits can reduce the effective diameter of the orifices and therefore ion transmission. Dissolved solid levels not exceeding 0.2% (w/v) have been recommended to reduce such effects. Internal standardization may be effectively used to compensate for many physical interference effects. Internal standards ideally should have similar analytical behavior to the elements being determined.

4.5 Memory interferences result when isotopes of elements in a previous sample contribute to the signals measured in a new sample. Memory effects, or carryover, can result from sample deposition on the sampler and skimmer cones, as well as from the build up of sample material in the plasma torch and spray chamber. The site where these effects occur is dependent on the element and can be minimized by flushing the system with a rinse blank between samples. The possibility of memory interferences should be recognized within an analytical run and suitable rinse times should be used to reduce them.

5. APPARATUS AND MATERIALS

5.1 Micromass Platform inductively coupled plasma mass spectrometer (ICP-MS) or equivalent. System must be capable of providing resolution, less than or equal to 0.75amu at 5% peak height from 6-253amu and must be equipped with a data system that allows corrections for isobaric interferences and the application of the internal standard technique.

5.2 Autosampler, Cetac ASX-510 or equivalent

5.3 Radiofrequency generator compliant with FCC regulations

5.4 A variable speed peristaltic pump is required for solution delivery to the nebulizer

5.5 A mass flow controller on the nebulizer gas supply is required

5.6 Volumetric flasks of suitable precision and accuracy

5.7 Volumetric pipets of suitable precision and accuracy

6. REAGENTS

6.1 Hydrochloric Acid (HCl), concentrated, trace metals grade

6.2 Nitric Acid (HNO_3), concentrated, trace metals grade

6.3 Reagent water

6.4 Liquid Argon, 99.999% pure or better

6.5 Helium, high purity, 99.999% or better

6.6 Hydrogen, high purity, 99.999% or better

6.7 STANDARDS

NOTE: All standard solutions are prepared, documented, and stored in accordance with SOP 300. All standard solutions are to be contained in fresh (previously unused) polypropylene bottles.

6.7.1 Individual Elemental Standards, 10,000µg/mL or 1,000µg/mL: First source, purchased as certified solutions of 99.99% purity or greater. Element stocks should be checked for the presence of impurities that might influence the accuracy of the standard. Records of vendor supplied certificates of analysis must be maintained. Shelf life = Manufacturer's date of expiration; replaced sooner if degradation occurs.

6.7.2 Intermediate Standard Solutions (single- or multi-element): Made by the dilution of vendor purchased individual elemental standards. Care must be taken in the preparation of multi-element standards that the elements are compatible and stable. Freshly prepared solutions should be transferred to acid cleaned bottles for storage and monitored periodically for stability.

6.7.3 Calibration Standards: Prepared by diluting the individual elemental standards or the intermediate standard solutions to levels appropriate to the operating range of the instrument, using reagent water, for example, containing 1% HNO_3 and 1% HCl. Dilutions should be made with a diluent that best matches the acid strength in the samples, digestates, or their dilutions. Calibration standards should be prepared at a minimum of three concentrations, one of which should be at the reporting limit.

Example of calibration standards for U:

- 10PPB: Made daily by diluting 0.1mL of a multi-element intermediate containing 1ppm each of U to a 10mL final volume.
- 2PPB: Made daily by diluting 2mL of the 10PPB calibration standard to a 10mL final volume.
- 1PPB: Made daily by diluting 1mL of the 10PPB calibration standard to a 10mL final volume.
- 0.01PPB: Made daily by diluting 0.1mL of the 1PPB calibration standard to a 10mL final volume.

6.7.4 ICSA (Interference Check Standard-A): Made daily by diluting 0.1mL of ICSA stock solution (vendor purchased) up to a 10mL final volume. The ICSA working solution contains the following elements and concentrations:

Element	*Concentration (ppm)*
Ca	30
Fe, Na	25
C	20
Al, K, Mg, P, S	10
Mo, Ti	0.2

6.7.5 ICSAB (Interference Check Standard-AB): Made daily by diluting 0.1mL of ICSA Stock solution (vendor purchased) and 2.0mL of the high calibration standard up to a 10mL final volume. The ICSAB working solution contains the following elements and concentrations:

Element	*Concentration (ppm)*
Cl	212.15
Ca	30
Fe, Na	25

C	20
Al, K, Mg, P, S	10
Mo, Ti	0.2
Cd, Pb	0.01
As, Se	0.004
Ag, Sb, U	0.002
Tl	0.0001

6.7.6 ICV (**second source** Initial Calibration Verification Standard): Made daily by diluting 0.05mL of a second source intermediate (dilution from a second source stock) up to a 10mL final volume. The ICV working solution contains elements of interest with concentrations near the midpoint of the linear range and at a concentration other than that used for instrument calibration.

6.7.7 CCV (**first source** Continuing Calibration Verification Standard): Made daily by dilution of intermediate or calibration standard solutions. The concentrations for each element found in the CCV should be at or near the mid-point of the calibration curve.

6.7.8 CRI (**first source**, low level, reporting limit check standard): This solution will be the same concentration as the lowest calibration standard. Analysis of this solution will be a "read-back" of the low calibration standard.

6.8 Internal Standard Solutions: An internal standard intermediate containing 2ppm Be and 0.5ppm each of Rh, In, Bi, Ga, and Pt is made by diluting 0.2mL of Be (1,000ppm individual element standard) and 0.05mL each of Rh, In, Bi, Ga, Pt (1,000ppm individual element standards) up to a 100mL final volume. This intermediate is added to all standards and samples in the same proportion of 1:100. Most often this dilution is performed by adding 0.05mL of the internal standard intermediate to 5mL of sample or standard. The final concentrations of internal standards in working solutions or samples is approximately 20ppb Be and 5ppb each Rh, In, Bi, Ga, Pt.

6.9 Mass Spectrometer Tuning Solution: Consists of a solution containing elements representing all of the mass regions of interest. A vendor purchased stock (containing for example, 10mg/L of Be, Bi, Ce, Co, In, Mg, Ni, Pb and U) is diluted 1000X. The concentration of these elements in the working solution is 10ppb. Concentration of the tuning solution is not critical as the tuning solution is used to verify that the resolution and mass calibration of the instrument are within the required specifications. This solution is also used to verify that the instrument has reached thermal stability.

6.10 BLANKS

6.10.1 Calibration blank: Consists of, for example, 1% (v/v) nitric acid and 1% (v/v) hydrochloric acid in reagent water. This blank is the diluent used in preparing the calibration standards, and should match (as close as possible) the strength in the samples, digestates, or their dilutions.

6.10.2 Method blank: Contains all the reagents in the same volumes as used in processing the samples. The method blank must be carried through the same entire preparation scheme as the samples, including digestion.

6.10.3 Rinse blank: Consists of 1% (v/v) nitric acid and 1% (v/v) hydrochloric acid in reagent grade water.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are collected in plastic or glass containers and must be chemically preserved with nitric acid to a pH<2. The acidified sample must remain in its original container for a minimum of 24hrs before analyses can begin. Samples for dissolved metals analyses should be filtered in the field prior to chemical preservation. Unfiltered samples must be maintained at 4±2°C. Aqueous metals samples must be prepared and analyzed within 180 days of collection.

7.3 Solid samples are collected in plastic or glass containers. Solid samples are not chemically preserved and must be maintained at 4±2°C. Solid metals samples must be prepared and anlayzed within 180 days of collection.

8. PROCEDURE

8.1 INSTRUMENT START-UP

Verify that the cooling water for the instrument is flowing. Make sure that all gas supplies are connected and switched on. Make sure that the ventilation system is running. The MassLynx™ software will check the instrument communications, including any peripheral devices before commands can be issued. Open the tune page and establish a plasma following the manufacturer's instructions. An automatic start-up procedure has also been programmed into the software. Allow a period of not less than 30 minutes for the instrument to warm up.

8.2 Tune the instrument following the manufacturer's instructions. Instrument parameters are controlled from the tune page in the software. Optimize the instrument’s sensitivity, stability, oxide levels, etc., by aspirating the tuning solution and adjusting, if necessary, any parameters. Some of these parameters include: torch position in the X, Y, and Z axis, various gas flow rates, cone voltages, etc.

8.3 PRECALIBRATION ROUTINE

Follow the pre-calibration routine below before completing the calibration of the instrument:

8.3.1 Instrument stability is demonstrated by running the tuning solution ten times with resulting standard deviations of absolute signals for all analytes of less than 10% (Reference 12.3). Data from this stability test is included with the daily raw data.

NOTE: To meet the requirements of Section 10.2.2 of EPA Method 200.8, the tuning solution shall be run a minimum of five times with resulting standard deviations of absolute signals for all analytes of less than 5%, when analyzing wastewater samples for State of California compliance monitoring,

8.3.2 Conduct mass calibration and resolution checks using the scan produced from the final replicate in the stability test described above. Resolution at low mass is indicated by magnesium isotopes 24, 25, 26. Resolution at high mass is indicated by lead isotopes 206, 207, 208. Adjust mass calibration if it has shifted by more than 0.1amu from unit mass. Adjust the spectrometer resolution, if needed, to produce a peak width <0.9amu full width at 10% peak height (SW6020A). Data showing these criteria were met are included with the data package upon client request.

NOTE: To meet the requirements of Section 10.2.1 of EPA Method 200.8, the spectrometer resolution, shall be adjusted, if needed, to produce a peak width less than 0.75amu at 5% peak height, when analyzing wastewater samples for State of California compliance monitoring.

8.4 INTERNAL STANDARDIZATION

Internal standardization must be used in all analyses to correct for instrument drift and physical interferences. For full range mass scans, a minimum of three internal standards shall be used. Generally, an internal standard should be no more than 50amu removed from the analyte. Internal standards shall be present in all samples, standards, and blanks at identical levels. This is achieved by directly adding an aliquot of the internal standard intermediate to each sample, standard, and blank. The concentration of the internal standard should be sufficiently high for good precision and to minimize the possibility of correction errors if the internal standard is naturally present in the sample. Internal standards should be added to samples, standards, and blanks in a similar manner, in order for dilution effects to be disregarded. Internal Standard performance information is available

in Level 4 data packages (see Compound Summary Report; value of '1' in PPB column signifies 100% internal standard recovery).

8.5 CALIBRATION

Before initial calibration, set up proper instrument software routines for quantitative analysis. Calibrate the instrument for the analytes of interest for the selected isotopes using the calibration blank and at least three calibration standards according to the manufacturer's recommended procedures. Flush the system with the rinse blank for at least 30 seconds between each standard solution and sample. Use the average of multiple integrations for both standardization and sample analysis. All masses that could affect data quality should be monitored to determine potential effects from matrix components on the analyte peaks. These masses should be monitored either simultaneously in a separate scan or at the same time quantification occurs.

8.6 ANALYTICAL SEQUENCE

The typical autosampler analytical sequence after the initial calibration is listed below along with brief descriptions of each solution. See also Section 9 and the QC Summary Table for further details.

8.6.1 High Standard Read Back: Reanalysis of the highest calibration standard and processed as a sample. Results must be within 95-105% of the known concentration. This concentration also establishes the upper linear range of the instrument.

8.6.2 ICV: Initial calibration verification check standard (second source). Results must be within 90-110% of the expected concentration. Cause of failure must be determined and corrected and the instrument recalibrated.

8.6.3 ICB: Initial calibration blank. Analyzed immediately after the ICV. The absolute value of the blank results must be less than the analyte reporting limit, or as specified in the applicable LIMS program specification. Demonstrates that the analytical system is free from interferences and is in control.

8.6.4 CRI: Low level (reporting limit) check standard. Unless otherwise specified by LIMS program specification, run for informational purposes only. Paragon does not typically control on CRI recovery.

8.6.5 ICSA: Interference check standard A. Contains high concentrations of possible interfering elements. Analyzed at the beginning of an analytical sequence or once every 12 hours, whichever is more frequent. Analyzed to verify the magnitude of elemental and molecular-ion isobaric interferences and the accuracy of any

corrections made. Results for this check standard analysis should not contain analyte concentrations (i.e., analytes susceptible to interference) above twice the analyte reporting limit (2X MDL per DOD), consult applicable LIMS program specification.

8.6.6 ICSAB: Interference check standard B. Contains all elements in the ICSA. In addition, contains low concentrations of the elements of interest. Analyzed at the beginning of an analytical sequence or once every 12 hours, whichever is more frequent. Analyzed to verify the magnitude of elemental and molecular-ion isobaric interferences and the accuracy of any corrections made. Results for this check standard analysis should be within 80-120% of the expected concentrations for the elements of interest.

8.6.7 SAMPLES: Additional analytical samples include all samples analyzed on the instrument except ICV, ICB, CCV and CCB. The CRI, ICSA and ICSAB along with all samples in the sequence and any dilutions, post-spikes, laboratory and matrix spikes, duplicates, serial dilutions and method/preparation blanks are all considered to be analytical samples.

8.6.8 CCV: Continuing calibration check standard (first source). A CCV is analyzed at a frequency of 10% or every two hours whichever is more frequent. The CCV is also analyzed after the last analytical sample. Results must be within 90-110% of the expected concentration. Cause of the failure must be determined and corrected and the instrument recalibrated. Samples following the last acceptable CCV must be reanalyzed.

8.6.9 CCB: Continuing calibration blank. Must follow CCV analyses. The absolute value of the blank results cannot exceed the analyte reporting limit, or as specified in the applicable LIMS program specification. Demonstrates that the analytical system is free from interferences and is in control.

The sequence continues with CCV and CCB analyzed after every 10 analytical samples and at the conclusion of the sequence.

8.7 After the analytical sequence is complete, a "header and summary" section is produced which includes:

- standard information including standard identifications, expiration dates, elements and concentrations, and preparation procedures
- acid lot numbers
- pipet identification numbers

- dilution information and preparation procedures
- analytical spike information and preparation procedures
- daily and monthly maintenance items performed
- summary page with analytical sequence and elements of interest

8.8 In addition to the electronic run information provided by the instrument's output, a hardcopy Run Log is maintained as an internal Departmental record of instrument throughput.

8.9 REGULAR MAINTENANCE ITEMS
Check the following items prior to each run to ensure the instrument is in good working order:

- argon, hydrogen and helium levels; order more as needed
- printer and paper supply
- water in recirculating coolers -- fill as necessary
- pump tubing -- replace when necessary
- empty the drain containers
- tune instrument per manufacturer's procedures
- perform ten minute stability test (include results with data package)
- check / clean torch and cones for deposits
- check / clean nebulizer and spray chamber
- check / fill vacuum pump oil

There is a section in the raw data header information where the Regular Maintenance items may be initialled as completed.

8.10 MAINTENANCE LOG
A maintenance logbook is used to record all information concerning instrument maintenance that is not covered by the daily and monthly maintenance items described above. This logbook is used to document all repairs and the symptoms of the problems.

9. QUALITY CONTROL

The quality control requirements for analyses by ICP-MS consist of an initial demonstration of laboratory capability, and the periodic analysis of laboratory reagent blanks, fortified blanks and calibration solutions as a continuing check on performance. In addition to this Section, various quality control samples and acceptance criteria are discussed in Section 8.6 and in the QC Table at the end of this SOP.

9.1 A method detection limit (MDL) study consisting of the analysis of a minimum of seven replicate aliquots of target analytes at concentration levels 3-5 times the anticipated detection limit, shall be performed as needed and at a minimum, annually.

9.2 Instrument detection limits (IDLs) reflect instrument capability and are determined per CLP protocol. These studies are performed quarterly.

9.3 Tune Standard: The tune standard shall be prepared in the same acid matrix as the calibration standards and analyzed at least five times consecutively. If the peak width at 10% peak height is not <0.9amu, the mass calibration is not within 0.1amu, or the percent relative standard deviation (%RSD) of the absolute signals of the analytes exceeds 5% (discussed in Section 8.3.1), the analysis shall be terminated, the problem corrected, and the instrument re-tuned. All sample results reported must be associated with an instrument tune that meets these requirements

9.4 Method Blank (MB): One method blank is prepared per batch of 20 or less field samples. The method blank consists of an aliquot of reagent water that has been digested and prepared in the same manner as the associated samples.

For drinking water matrix samples analyzed for regulatory compliance purposes, values in the method blank cannot exceed 2.2 times the analyte MDL. If this criterion is not met, fresh aliquots of the samples must be prepared and analyzed again for the affected analytes after the source of contamination has been corrected and acceptable method blank values have been obtained.

For non-drinking water matrix sample analyses, the method blank cannot contain any analyte above the analyte reporting limit, or as specified in the applicable LIMS program specification. Method blank results are also acceptable if sample concentrations are greater than 10 times the concentration found in the method blank.

9.5 Laboratory Control Sample (LCS): One laboratory control sample is prepared per batch of 20 or less field samples. The LCS is a water sample with known analyte concentrations that is digested and prepared in the same manner as the associated samples. The control limits for LCS recovery are 80-120%, or as otherwise specified in the applicable LIMS program specification. All samples associated with a failed LCS must be redigested and reanalyzed.

9.6 Sample Duplicate: One sample duplicate must be prepared per batch of 20 or less field samples. The control limit for duplicate precision is that the relative percent difference (RPD) must be ≤20%, or as otherwise specified in the applicable LIMS program specification. RPD is calculated as shown below:

$$RPD\ (\%) = \frac{(Result_x - Result_{dup})}{(Result_x + Result_{dup}) / 2} \quad X \quad 100$$

The results are flagged if the RPD exceeds 20%.

9.8 Matrix Spike (MS) and Matrix Spike Duplicate (MSD): One MS and MSD are prepared per batch of 20 or less field samples. MS and MSD samples consist of additional aliquots of a particular field sample that are spiked, digested and prepared in the same manner as the associated samples. Matrix spike samples are evaluated in terms of recovery, calculated as follows:

$$\%R = \frac{(Conc_{Found} - Conc_{Sample})}{Conc_{Target}} \quad X \quad 100$$

where:

$Conc_{Found}$ = analyte concentration found in the MS or MSD sample

$Conc_{Sample}$ = analyte concentration found in the field sample

$Conc_{Target}$ = target (anticipated) analyte concentration based on amount spiked

Matrix spike recovery is not evaluated if the analyte concentration in the unspiked sample is greater than 4 times the spike level. The quality control limit for matrix spike recovery is 75-125%, and the control limit for MS/MSD precision is that the RPD must be $\leq$20%, unless otherwise specified in the applicable LIMS program specification. RPD for the MS/MSD is calculated the same as for the Sample Duplicate (see Section 9.6 above). Results are flagged if MS/MSD recovery or precision results are outside of control limits. A post digestion spike analytical spike (i.e., sample aliquot spiked after digestion) should be performed when matrix spike recovery is outside the control limits. If recovery of the post digestion analytical spike is not within 75-125% (or other specified limits), the result is flagged indicating that matrix interference is suspected.

9.9 Serial Dilution Sample: A 1:5 serial dilution of an additional sample digestate is prepared per 20 field samples of like matrix that are processed as a unit. If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test should agree within ±10 % of the undiluted results. Other client-specified control limits may apply, consult applicable LIMS program specification. Sample analyte results failing this test should be flagged indicating the existence of matrix interferences.

9.10 Linear Range: After the initial calibration, the highest calibration standard is reanalyzed and processed as a sample. Results must be within 95-105% of the known concentration. The element concentration in the highest calibration

standard defines the upper end of the analytical range. Samples whose concentrations exceed the calibration range must be diluted to bring their concentrations within the known calibration range of the instrument.

9.11 Internal Standard Responses: The responses from the internal standards should be monitored throughout the analytical sequence. Ratios of the internal standards responses against each other should also be monitored routinely. This information may be used to detect potential problems caused by mass dependent drift, errors incurred in adding the internal standards or increases in the concentrations of individual internal standards caused by background contributions from the sample.

For drinking water samples analyzed for regulatory compliance purposes, the absolute response of any one internal standard must not deviate more than 60-125% of the original response in the calibration blank. For non-drinking water matrix sample analyses, the absolute response of any one internal standard must not fall below 30% of the intensity of that internal standard in the initial calibration blank (Paragon evaluates against the zero standard), *or as specified in the applicable Program Specification.* If deviations greater than these are observed, flush the instrument with the rinse blank and monitor the responses in the calibration blank (CCB). If the responses of the internal standards in the calibration blank (CCB) are within limits, dilution and reanalysis of the sample is required. If the response of the internal standards in the calibration blank (CCB) is outside the control limits, terminate the analysis and determine the cause of the drift. Possible causes of drift may be a partially blocked sampling cone or a change in the tuning condition of the instrument.

10. DEVIATIONS FROM METHOD

10.1 There is variability between the two methods referenced by this SOP regarding the preparation and analysis of interference check standards (ICSA and ICSAB); interference check standards are not discussed in Method EPA 200.8 at all. Hence, in this SOP, the ICSA and ICSAB standards are prepared according to the specifications of Method 6020A, with the exception that the solution concentration of all the constituents is ten fold less, in accordance with the sensitivity characteristics of the ICP-MS instrument used at Paragon.

10.2 Method 200.8 states that the blanks need to be <2.2X the analyte MDL. SW6020A states that blanks must be less than 3X the current IDL for each element. For non-drinking water matrix sample analyses, Paragon's criteria requires the blank results (ICB, CCB, MB) to be less than the reporting limit, unless superceded by criterion specified in the applicable Program Specification.

10.3 Section 9.4.5 of Method 200.8 stipulates control limits of 60-125% for internal standard response, Sections 4.4 and 9.3 of SW6020A discuss internal standards response in terms of suppression (below 30%) due to physical interferences.

Unless otherwise directed by LIMS Program Specification, Paragon observes SW6020A guidance for evaluating internal standards performance as it has been Paragon's experience that the data and performance of quality control samples are not impacted when internal standard response is enhanced (i.e., above 100%).

10.4 Section 9.3.4 of Method 200.8 provides for ±15% CCV criteria. In concurrence with SW6020A, Paragon follows the more stringent CCV criteria of ±10%.

10.5 Section 9.4.2 of Method 200.8 provides for ±30% matrix spiked recovery. In concurrence with SW6020A, Paragon follows the more stringent matrix spiked recovery criteria of ±25%.

10.6 Both Methods 6020A and 200.8 calculate IDLs based on the analysis of reagent blank solution. Paragon uses a solution containing low levels of analytes for calculating IDLs.

10.7 SW6020A requires dilution of samples when post spike criteria is not met. Paragon's policy is to flag results and narrate if post spike criteria is not met.

10.8 SW6020A requires reanalysis of samples that fail duplicate precision criteria. Paragon's policy is to flag results and narrate if duplicate precision criteria is not met.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

11.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with

compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.6 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The sample digestates shall be disposed of in the Aqueous Laboratory Waste.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/26/05: Added reference Program Specification directive in "Responsibilities".

4/10/06: Clarified mass calibration and resolution criteria per the referenced methods, Paragon's standard practices, and other client specifications that may be applicable. Likewise clarified blank and internal standard criteria, as well as evaluation of CRI Standard response. Added DOCUMENT REVISION HISTORY.

8/11/07: Updated Section 7.3 to indicate minimum 24hr hold following acidification (instead of 16hrs) per Federal Register, 3/26/07, Volume 72, Number 57. Included LIMS program specification reference to ICSA discussion (Section 8.6.5, QC Table).

Analytical Methods: EPA 200.8, SW6020A	**Parameter**: ICP-MS Elements		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	**Frequency**	**Acceptance Criteria**	**Corrective Action**
Tune Standard; analyzed at least 5 times consecutively	Daily before the initial calibration	Peak width <0.9amu at 10% peak height, mass calibration within 0.1amu and %RSD of replicates <5% (unless otherwise noted in Program Specification)	Correct problem and repeat tune standard routine.
Initial Calibration; uses at least 3 standards and a blank	Daily	Correlation coefficient (r^2) for all analytes >0.995	Correct problem and repeat initial calibration.
Reanalysis of high calibration standard as a sample	Immediately after calibration	All analytes within ±5% of expected value	Correct problem then repeat initial calibration.
Initial Calibration. Verification (ICV); second source	Daily after initiation calibration	All analytes within ±10% of expected value	Correct problem then repeat initial calibration.
Initial Calibration Blank (ICB)	Immediately following ICV	Absolute value of result for each analyte <reporting limit (RL), or as specified in applicable LIMS program specification	Correct problem then repeat initial calibration.
Continuing Calibration Verification (CCV); conc. of analytes must be different from the ICV	After every 10 samples and at the end of the analytical sequence	All analytes within ±10% of expected value	Repeat calibration and reanalyze all samples since last successful CCV.
Continuing Calibration Blank (CCB)	Immediately after every CCV	Absolute value of result for each analyte <RL, or as specified in applicable LIMS program specification	Correct problem then analyze CCB and previous 10 samples
CRI (reporting limit check) Standard	Run immediately following the ICV/ICB	Paragon does not typically control on CRI Standard response. However, if so specified by LIMS program specification, Paragon will observe the following performance criteria: recovery within 50-150% for Sb, Pb and Tl; recovery within 70-130% for all other analytes.	Reanalyze failed analytes. If still outside of control limits, halt analyses, correct problem and recalibrate. Analyses may not proceed until an acceptable CRI Standard has been analyzed.

Analytical Methods: EPA 200.8, SW6020A	**Parameter**: ICP-MS Elements		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	**Frequency**	**Acceptance Criteria**	**Corrective Action**
ICSA (Interference Check Solution A) and ICSAB (Interference Check Solution B)	At the beginning of an analytical run or every 12 hours whichever is more frequent	All analytes of interest should be within ±20% of expected value. Should not contain non-spiked analytes at concentrations above twice the analyte RL, or as otherwise specified in the applicable LIMS program specification	No directives are given in the referenced methods for this QC check. The limits indicated in this Table are used as Paragon guidelines; no corrective actions are taken on an analytical batch basis.
Method blank (MB)	One MB per batch of 20 or fewer field samples	For drinking water compliance samples, blank values must be <2.2 times the analyte MDL For non-drinking water matrix sample analyses, absolute values in MB <analyte RL, or as specified in applicable LIMS program specification	Correct problem then reprep and analyze MB and all samples processed with the contaminated blank.
Laboratory Control Sample (LCS)	One LCS per batch of 20 or fewer field samples	For drinking water compliance samples, analyte recoveries must be within ±15% of expected values. For non-drinking water matrix sample analyses, analyte recoveries must be within 80-120% of expected values for each analyte Other client-specified criteria may apply, consult applicable LIMS program specification	Correct problem then reanalyze. If still out reprep and reanalyze the LCS and all samples in the affected batch.
Sample Duplicate (DUP)	One sample duplicate per batch of 20 or fewer field samples	For each analyte RPD ≤20%, or as otherwise specified in applicable LIMS program specification	Flag results if RPD > 20%.
Matrix Spike/Matrix Spike Duplicate MS/MSD	One MS/MSD pair per batch of 20 or	Recovery limit 75-125% for each analyte, not	Flag results if MS/MSD recovery or precision results are outside

Analytical Methods: EPA 200.8, SW6020A	**Parameter**: ICP-MS Elements		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	**Frequency**	**Acceptance Criteria**	**Corrective Action**
(MS/MSD)	fewer field samples	calculated if analyte conc > 4X the spike level. For each analyte RPD ≤20% Other client-specified criteria may apply, consult applicable LIMS program specification	control limits, perform post digestion analytical spike.
Post digestion analytical spike	Performed when MS/MSD recovery is outside ± 25% (unless analyte conc > 4X the spike level)	Recovery limit 75-125% for each analyte, or as specified in applicable LIMS program specification	Flag results if post spike recovery or precision results are outside control limits.
Internal standard responses	Monitored throughout the analytical run	For drinking water compliance samples, response of internal standard in sample must be within 60-125% of response in initial calibration blank For non-drinking water matrix sample analyses, response of internal standard for samples must be >30% of the original response in the calibration blank, or as specified in the applicable LIMS program specification *	Dilute samples until internal standard response is within criteria.
Serial Dilution	Performed on one sample per batch of 20 or fewer field samples	Results should agree within ±10% of undiluted results if analyte concentrations are sufficiently high (at least 50X the IDL)	Flag results if outside criteria.
Method Detection Limit (MDL) Study; run per method requirements and at an analyte concentration near the minimum detection capabilities of the method	As needed and, at minimum, annually	Positive result < analyte RL	Determine the reason for failure and correct problem with system; then repeat study for analytes that did not meet criteria. If MDL study still not acceptable, discuss with Department and QA Managers, RL may be adjusted, if necessary.

* Note that per DOE client specification,
IS response not to exceed 155%.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 834 REVISION 7

TITLE: **DETERMINATION OF METALS BY INDUCTIVELY COUPLED PLASMA EMISSION SPECTROSCOPY – METHOD SW6010B (TRACE ICAP)**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/13/07

QUALITY ASSURANCE MANAGER _____ DATE 8/11/07

LABORATORY MANAGER _____ DATE 8-13-07

HISTORY: Rev0; 1/24/02; Rev1, 4/3/02; Rev2, 4/7/03; Rev3, 5/12/04; Rev4, 2/1/5; Rev5, 7/26/05; Rev6, 11/20/06; Rev7, 8/11/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references -- Method SW6010B (trace ICAP) -- is used to determine the concentration of total or dissolved metals in prepared liquid and solid samples. Analytes are viewed axially, providing detection limits for many analytes similar to that which can be achieved using Graphite Furnace Atomic Absorption (GFAA) analysis.

The following elements are routinely determined using this method:

Aluminum (Al)	Antimony (Sb)	Arsenic (As)	Barium (Ba)	Beryllium (Be)
Cadmium (Cd)	Calcium (Ca)	Chromium (Cr)	Cobalt (Co)	Copper (Cu)
Iron (Fe)	Lead (Pb)	Lithium (Li)	Magnesium (Mg)	Manganese (Mn)
Molybdenum (Mo)	Nickel (Ni)	Phosphorous (P)	Potassium (K)	Selenium (Se)
Silicon (Si)	Silver (Ag)	Sodium (Na)	Strontium (Sr)	Thallium (Tl)
Tin (Sn)	Titanium (Ti)	Uranium (U)	Vanadium (V)	Zinc (Zn)

2. SUMMARY OF METHOD

Sample digestates are prepared prior to analysis (SOP 806) per EPA Methods SW3005A or SW3010A (liquid samples) or SW3050B (solid samples). Filtered liquid samples, liquid samples containing low solids, or leachates may also be analyzed by direct aspiration into the ICAP instrument (i.e., without prior digestion). A computer-controlled Inductively Coupled Argon Plasma (ICAP) trace analyzer is used to

accomplish the analyses.

Samples or sample digestates are aspirated into the ICAP instrument, into a high temperature argon plasma stream. Radio frequencies are generated to induce excitation of the plasma stream that causes constituent elements contained in the sample to emit light at characteristic wavelengths. A grating spectrometer is used to disperse the resulting spectra. The light emissions are received by a photomultiplier tube, which in turn transmits a signal to the data acquisition system. The software of the data acquisition system interprets the signal by comparing it to a previously calibrated standard curve. The data are then further manipulated in the reporting process to incorporate such factors as dilution and percent solids (i.e., dry weight adjustment).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 SPECTRAL INTERFERENCES

Potential spectral interferences include the following:

4.1.1 Overlap of a spectral line from another element at the analytical or background measurement wavelengths. Spectral overlap may be compensated for by computer-correcting the raw data after monitoring and measuring the interfering element (see Section 8.8 for a description of this correction).

4.1.2 Unresolved overlap of molecular band spectra.

4.1.3 Background contribution from continuum or recombination phenomena.

4.1.4 Stray light from the line emission of high concentration elements. Background contribution and stray light may usually be compensated for by a background correction adjacent to the analyte line.

4.2 PHYSICAL INTERFERENCES

Effects associated with the sample nebulization and transport processes are considered physical interferences. Changes in viscosity and surface tension may cause significant inaccuracies, especially in samples containing high dissolved solids or high acid concentrations. If physical interferences are present, then they must be reduced by diluting the samples.

4.3 CHEMICAL INTERFERENCES

Molecular compound formation, ionization effects, and solute vaporization effects are chemical interferences. The most significant potential interference in the Trace ICAP instrument is ionization effects caused by varying levels of easily ionized elements in samples and standards. ~~The ionization effects can be reduced by adding a constant amount of an easily ionized element (such as lithium) as an "ionization buffer" to all solutions. The lithium is added using a peristaltic pump that delivers a constant flow of lithium solution to the sample delivery tubing through a "T" connector.~~ **Stricken from SOP 8/16/07 because it is not Paragon's practice to add this buffer. DAS**

5. APPARATUS AND MATERIALS

5.1 Autosampler: Thermo Jarrell Ash Model AS300 or equivalent.

5.2 ICAP: An argon plasma trace analyzer (e.g., Thermo Jarrell Ash ICAP 61E Trace Analyzer), set to simultaneous operating conditions and containing the following:

- an axially mounted torch
- an R.F. (radio frequency) generator; set at 27.12MHz, 2kW (i.e., an inductively coupled argon plasma excitation source)
- holographic grating, 2400grooves/nm, blazed at 500nm
- a 0.75m Rowland Circle spectrometer (polychromator) or equivalent, with

a Paschen-Runge mount and capable of accepting up to 63 channels

- an automated instrument control and data acquisition system (i.e., personal computer or equivalent), capable of providing various (e.g., background, interelemental) corrections
- Thermospec™ version 6.20 or higher or ICAP Manager™ version 6.10 or higher software, or equivalent

5.3 Volumetric flasks, various sizes, of suitable precision and accuracy

5.4 Volumetric pipets, fixed or adjustable, verified per SOP 321

5.5 Chemware™ PFTE Chips, VWR #26397-103 or equivalent

6. REAGENTS – Only trace metals grade solvents shall be used!!

6.1 Hydrochloric Acid (HCl), concentrated, JT Baker #9530-33 or equivalent

6.2 Nitric Acid (HNO_3), concentrated, JT Baker #9598-34 or equivalent

6.3 Reagent water, deionized (DI) water obtained from the laboratory's DI water system (SOP 319)

6.4 Liquid Argon, 99.99% pure

6.5 STANDARDS

6.5.1 All standard solutions are prepared, documented, and stored in accordance with Paragon SOP 300. All standard solutions are to be contained in fresh (previously unused) polypropylene bottles.

6.5.2 Detailed documentation of all standards associated with each ICAP acquisition (analytical sequence) is recorded in the Header Information of the ICAP software and included with the associated raw data. This documentation includes the stock and intermediate standard identification numbers, dilutions performed to create the working standards and the resulting concentrations of the working standards. (Further details pertaining to header information is provided in Section 8.4).

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 All samples (liquid, solid) are collected in plastic or glass containers, must be maintained at 4±2°C, and must be prepared and analyzed within 180 days of collection.

7.3 Liquid samples must be chemically preserved with nitric acid to pH<2. Samples for dissolved metals analyses should be filtered in the field prior to chemical preservation. If samples are not preserved in the field, they may be acidified by the laboratory upon receipt, but must be held in their original container for a

minimum of 24 hours before transfer or analysis of the sample.

8. PROCEDURE

8.1 TYPICAL OPERATING CONDITIONS

~~Torch Gas: High Flow~~
~~Auxiliary Gas: Low~~
~~Nebulizer Gas: 25 PSI~~
~~RF Power: 1150 W~~
~~Pump Rate: 125 rpm~~
~~Sample Tubing: Orange/Orange~~
~~Rinse Tubing: Red/Red~~

Details stricken from SOP 8/16/07 because PAR now has more than one Trace ICP instrument and the settings are not exactly the same. It should be noted that the instrument software maintains an electronic file of the established instrument settings. DAS

8.2 The instrument is calibrated each day, by analyzing and processing multi-point calibration curves for each element quantitated. Second order (quadratic) calibration equations with at least 5 points are used to fit the calibration data and to determine concentration results.

8.3 The typical autosampler analytical sequence is listed below along with brief descriptions of each solution. Refer to attached quality control (QC) Table at end of SOP for performance criteria:

Autosampler Run Number	***Solution Name***	***Description***
1	Mix A	Reanalysis of the highest calibration standard for Mix A elements. Processed as a sample.
2	Mix B	Reanalysis of the highest calibration standard for Mix B elements. Processed as a sample.
3	Mix C	Reanalysis of the highest calibration standard for Mix C elements. Processed as a sample.
4	ICV	Initial Calibration Verification check standard for all elements (second source).
5	ICB	Initial Calibration Blank. Must be run following the multi-point calibration and before any samples are analyzed.
6	ICSA	Interference Check Solution A (contains high concentrations of Ca, Mg, Al, Fe).
7	ICSAB	Interference Check Solution B (contains high concentrations of Ca, Mg, Al, Fe and low concentrations of other elements).
8	CRI	Low concentration test solution containing analyte concentrations near the reporting limit; analysis of this solution is not described in Method 6010B. Run for informational purposes only, Paragon does not control on CRI recovery,

Analysis of this standard typically precedes analysis of the ICSA. DAS 8/16/07

Autosampler Run Number	*Solution Name*	*Description*
		unless required by client LIMS program specification.
9	CCV	Continuing Calibration Verification check standard for all elements (second source).
10	CCB	Continuing Calibration Blank. Must follow CCV analyses.
11 thru 20	Samples	Additional analytical samples. Analytical samples include all samples analyzed on the instrument except ICV, ICB, CCV and CCB. The CRI, ICSA and ICSAB, along with all samples in the sequence and any dilutions, post-spikes (see Section 8.6.4), laboratory and matrix spikes, duplicates, serial dilutions and method/ preparation blanks, are all considered to be analytical samples. The sequence is closed out with the following solutions: CRI, ICSA, ICSAB (analyzed at the end of each analytical sequence, and every eight hours if the analytical sequence is longer than eight hours), followed by CCV, CCB.
21	CCV	Continuing Calibration Verification check standard for all elements (second source).
22	CCB	Continuing Calibration Blank, must follow CCV analyses.
Repeat (11 through 22); the sequence continues with CCV and CCB analyzed after every 10 analytical samples.		

8.4 After the analytical sequence is complete, a "header and summary" section is produced which includes:

- Standard information including standard identifications, expiration dates, elements and concentrations, and preparation procedures
- Acid lot numbers
- Pipet identification numbers
- Dilution information and preparation procedures
- Analytical spike information and preparation procedures
- Daily and monthly maintenance items performed. (Maintenance is further discussed in Section 8.10).
- Summary page with analytical sequence and elements of interest

8.5 At the completion of the sequence, the instrument is shut down as follows:

8.5.1 Disconnect pump tubing.

~~8.5.2 Lower "purge optics" gas flow to approximately 1L/min.~~ **Stricken from SOP 8/16/07 DAS.**

8.5.3 Exit the software.

8.6 PREPARATION AND EVALUATION OF QUALITY CONTROL (QC) SAMPLES

8.6.1 Calibration Blank (STD-Blank). An aliquot of reagent water is acidified in the same manner as the sample digestates. This calibration blank is used as a component in establishing the calibration curve and is also analyzed repeatedly throughout the analytical sequence as the Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB). To be acceptable, the calibration blank cannot contain any analyte above the analyte-reporting limit, or greater than that prescribed in the applicable LIMS program specification. Refer to Section 10.1 for further discussion.

8.6.2 Method Blank (MB). Required by Method 6010B. One MB is prepared per 20 field samples of like matrix that are processed as a unit. The method blank consists of an aliquot of reagent water, TCLP fluid or PFTE chips that has been digested and prepared in the same manner as the associated samples. To be acceptable, the method blank cannot contain any analyte above the analyte reporting limit, or greater than that prescribed in the applicable LIMS program specification. Method blank results are also acceptable if sample concentrations are greater than 10 times the concentration found in the method blank. Refer to Section 10.1 for further discussion.

8.6.3 Sample Duplicate: One sample duplicate is prepared per batch of 20 or less field samples. The control limit for duplicate precision is that the relative percent difference (RPD) must be ≤20% or as otherwise specified in the applicable LIMS program specification. RPD is calculated as shown below:

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

The results are flagged if duplicate precision is greater than 20% RPD.

8.6.4 Matrix Spike (MS) and Matrix Spike Duplicate (MSD): One MS and one MSD are prepared per batch of 20 or less field samples. MS and MSD samples consist of additional aliquots of a particular field sample that are spiked, digested and prepared in the same manner as the associated samples.

Matrix spike samples are evaluated in terms of recovery, calculated

thusly:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right) (100)$$

Matrix spike recovery is not evaluated if the analyte concentration in the unspiked sample is greater than 4 times the spike level. The quality control limits for matrix spike recovery are 80 to 120%. The control limit for MS/MSD precision is that the RPD must be ≤20%. RPD for the MS/MSD is calculated the same as for the Sample Duplicate is shown in Section 8.6.3 above. Results are flagged if MS/MSD recovery or precision results are outside control limits.

A post digestion spike analytical spike (i.e., sample aliquot is spiked after digestion) should be performed when matrix spike recovery is outside the control limit. If recovery of the post digestion analytical spike is not within 75-125%, the result is flagged indicating that matrix interference is suspected.

8.6.5 Laboratory Control Sample (LCS): One laboratory control sample is prepared per 20 field samples of like matrix that are processed as a unit. LCSs for water batches are prepared by spiking known concentrations of analytes into reagent water. LCSs for TCLP leachate batches are prepared by spiking the appropriate TCLP leaching fluid (fluid #1, fluid #2). Client-specific requirements determine the LCS to be used for solid digestion batches. Solid LCSs are either prepared by spiking onto 1.0g of PFTE chips, or by use of a commercially prepared soil matrix reference material.

LCSs are evaluated in terms of recovery:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right) (100)$$

Per Method 6010B, the control limits for LCS recovery are 80-120%. If a commercial certified reference material was used, the manufacturer's control limits as stipulated apply. Consult applicable LIMS specification for other client-specified criteria. All samples associated with a failed LCS must be redigested and reanalyzed.

8.6.6 Serial Dilution Sample: A 1:5 serial dilution of an additional sample digestate is prepared per 20 field samples of like matrix that are processed as a unit. If analyte concentrations are sufficiently high (at least 50X the instrument detection limit), the results of the dilution test

should agree within ±10 % of the undiluted results, or as otherwise specified in the applicable LIMS program specification. Sample analyte results failing this test should be flagged indicating the existence of matrix interferences.

8.7 LINEAR RANGE

The element concentrations in the Mix A and Mix B High Standards define the upper end of the analytical range. Samples whose concentrations exceed the calibration range must be diluted to bring their concentrations within the known calibration range of the instrument.

8.8 INTERELEMENT SPECTRAL INTERFERENCE CORRECTIONS

Interelement spectral interferences are determined by analyzing a solution (Interference Check Standard A, ICSA) that contains a high concentration of a potentially interfering element and observing the "apparent" concentration arising from the solution in other element channels. Interelement interference correction factors are calculated from these observations. *For example*: a 500ppm Al solution produces an apparent Pb concentration of 0.15ppm. The interelement correction factor K is calculated as follows:

$$K = \frac{Apparent\ Conc.\ in\ ppm}{Conc.\ of\ Interfering\ element\ in\ ppm}$$

In this example, K = 0.15 / 500 = 0.00030.

The interelement correction factor K is the amount of interference produced by 1ppm of the interfering element on the element being interfered with. Interference correction factors are used by the software to calculate corrected concentrations using the following equations:

Corrected Conc. (ppm) = Uncorrected Conc. (ppm) – [K * Conc. Of Interfering Element (ppm)]

High concentrations of elements (such as Fe and Al in solid digestates) are the most likely sources of significant spectral interferences. Interference Check Standard B contains all elements in the ICSA, and in addition, low concentrations of the elements of interest. Results for these check standards should be within 80-120% of the expected concentrations for the elements of interest. Concentrations of non-spiked analytes should not exceed twice the RL, or as otherwise specified in the applicable LIMS program specification. The ICSA and ICSAB are analyzed at the beginning and end of each analytical sequence, or once every 12 hours, whichever is more frequent, to verify that the spectral interferences arising from Al, Fe, Ca, and Mg are being corrected properly.

An interelement interference study is conducted every six months or after a

significant instrument change by analyzing single element solutions of each analyte at high concentrations. The study is used to verify or update interelement interference correction factors. Because the instrument is a direct reading polychromator with fixed detectors, interelement interference correction factors usually remain quite constant.

Due to software improvements, hardcopy record no longer maintained. 8/16/07 DAS

8.9 ~~In addition to the electronic run information provided by the instrument's output (analyst, date, time, sample ID, etc.), a hardcopy Run Log is maintained as an internal Departmental record of instrument throughput. Standard intensities for selected elements are noted as comments, these recordings are used to verify that operating conditions remain the same. If a variation or trend is noticed in intensity readings, the cause should be determined and corrected if necessary.~~

8.10 REGULAR MAINTENANCE ITEMS

The following items should be checked prior to each run to ensure the instrument is in good working order.

- check argon level; reorder as needed
- check printer, paper supply and ribbon; replace as needed
- check filters on rear of instrument and vacuum monthly
- check water level in drain bottle and empty if necessary
- check pump tubing -- replace necessary
- check that the previous day's work is properly recorded and processed

There is a section in the raw data header information where the Regular Maintenance items may be initialed as completed.

8.11 MAINTENANCE LOG

A maintenance logbook is used to record all information concerning instrument maintenance that is not covered by the daily and monthly maintenance items described above. This logbook is used to document all repairs and the symptoms of the problems

8. QUALITY CONTROL

9.1 Various quality control indicators are discussed in Sections 8.3 and 8.6.

9.2 A method detection limit (MDL) study consisting of the analysis of a minimum of seven replicate aliquots of target analytes at concentration levels 3-5 times the anticipated detection limit, shall be performed as needed, and at a minimum, annually.

9.3 Instrument detection limits (IDLs) reflect instrument capability and are determined per CLP protocol. These studies are performed quarterly.

10. METHOD MODIFICATIONS

10.1 The calibration blank acceptance limit used by Paragon is different from the acceptance limit given in Method SW6010B (Section 8.6.1.3). Paragon requires that calibration blank results must be less than the reporting limit. Method SW6010B (Sec. 8.6.1.3) states: "The results of the calibration blank are to agree within three times the IDL. If not, repeat the analysis two more times and average the results. If the average is not within three standard deviations of the background mean, terminate the analysis, correct the problem, recalibrate, and reanalyze the previous 10 samples." The calibration blank acceptance limits given in Method SW6010B are not clearly defined. Two types of acceptance limits are described in Method SW6010B -- one based on an IDL, the other on a background mean. Method SW6010B does not give guidance on how the IDL is measured or how 3 times the standard deviation of the background mean is determined. Paragon also notes that Draft Update Method SW6010C uses entirely different criteria for evaluating Calibration Blanks than Method SW6010B. Method SW6010C requires that Continuing Calibration Blanks must "not contain target analytes above 2-3 times the MDL for the curve to be valid." Additionally, Method SW6010C requires that the "absolute value of the results of the calibration blank should be less than the value of the MDL check sample for each analyte or less than the level of acceptable contamination specified in the approved quality assurance project plan." Given the somewhat ambiguous and cumbersome guidance stated in Method SW6010, Paragon's criteria for evaluating Calibration Blanks will continue to be the Report Limit unless specific client or regulatory needs demand otherwise. These specific client or regulatory needs are communicated to the laboratory via LIMS program specifications, which relate criteria that supercede Paragon's default performance criteria. The calibration blank acceptance limit based on the reporting limit is clearly defined thereby allowing straightforward data validation and also providing adequate assurance that instrument calibration is in control. Please note that although Paragon's default for addressing Calibration Blanks is the reporting limit, Paragon can employ use of a client-specific LIMS program specification to govern the processing of client data as requested by the client.

10.2 Method SW6010B (Section 5.7) states, "The CCV should be prepared in the same acid using the same standards used for calibration...". This SOP describes preparing the CCV from a source different from the source used for the calibration standards. CCVs prepared from a second source are equivalent to CCVs prepared from the first source for providing assurance that instrument calibration is in control.

10.3 Method SW6010B (Section 7) discusses instrument calibration by the use of a first order (linear) calibration curve. As provided for in Section 7.2.5 of Method SW6010B, Paragon employs a second order (quadratic) calibration curve with typically five points for *all* trace metals analytes, based on historical experience

that this type of calibration curve (quadratic) provides a better fit of the calibration data.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) must be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The sample digestates shall be disposed of in the Aqueous Laboratory Waste.

11.2.2 Radioactive sample disposal - solid sample residues shall be disposed of in the Radioactive Soils & Solids container. Radioactive sample digestates shall be disposed of in the Radioactive Aqueous Lab Waste.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. ***Please note that all labels and markings must be defaced prior to disposal.***

DOCUMENT REVISION HISTORY

7/26/05: LIMS program specification references added.

11/20/06: SOP was updated to apply to newly acquired second trace ICAP instrument as well. Abbreviation 'ICP' was updated to 'ICAP' throughout. Element list verified, updated and presented in tabular form, Section 1. LIMS program specification reference augmented, Section 3.3. Simplified standards discussion, Section 6.5, and included reference to information contained in software header. Reorganized Section 7 and added comment that if acidified by laboratory, sample must be held in original container for at least 16hrs prior to processing. Typical Operating Conditions added, Section 8.1. QC information taken out of analytical sequence Table (Section 8.3); QC Table at end of SOP referenced instead. References to LIMS program specification requirements added to QC Table where appropriate, MDL Study information added to Table. DOCUMENT REVISION HISTORY Section added.

8/11/07: Updated Section 7.3 to indicate minimum 24hr hold following acidification (instead of 16hrs) per Federal Register, 3/26/07, Volume 72, Number 57. Augmented ICSA/B and interelement correction discussion Section 8.8 and included LIMS program specification references (QC Table also).

Analytical Method: SW 6010B	**Parameter:** ICAP Metals		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Actions
Initial Calibration using 4 standards and a blank	Daily	Correlation coefficient (r^2) for all analytes $\geq$0.995	Correct problem and repeat initial calibration.
Reanalysis of Mix-A, Mix-B and Mix C cal standards as samples	Immediately after calibration	All analytes within ±5% of expected value	Correct problem then repeat initial calibration
ICV (Initial Calibration Verification) check std (second source); at or below midpoint	Daily after initial calibration	All analytes within ±10% of expected value	Correct problem then repeat initial calibration
ICB (Initial Calibration Blank)	Immediately following ICV	Absolute value of result for each analyte < reporting limit, or as specified in applicable LIMS program specification	Correct problem then re-analyze ICB
CCV (Continuing Calibration Verification) check std; concentration of analytes must be different from ICV	After every 10 samples and at the end of the analytical sequence	All analytes within ±10% of expected value	Repeat calibration and reanalyze all samples since last successful CCV
CCB (Continuing Calibration Blank)	Immediately after every CCV	Absolute value of result for each analyte < reporting limit, or as specified in applicable LIMS program specification	Correct problem then analyze CCB and previous 10 samples
ICSA (Interference Check Solution A) and ICSAB (Interference Check Solution B)	At the beginning and the end of an analytical run or once every 12 hours, whichever is more frequent	All analytes within ±20% of expected value. Concentrations of non-spiked analytes should not exceed twice the RL, or as otherwise specified in the applicable LIMS program specification.	Terminate analysis, correct problem, reanalyze ICSA, reanalyze all affected samples
MB (Method blank)	One MB per batch of 20 or fewer field samples	Absolute value of result for each analyte < reporting limit, or as specified in applicable LIMS program specification	Correct problem then reprep and analyze MB and all samples processed with the contaminated blank

Analytical Method: SW 6010B	**Parameter:** ICAP Metals		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Actions
LCS (Laboratory Control Sample)	One LCS per batch of 20 or fewer field samples	For spiked LCS all analytes within ±20% of expected value For commercially prepared solids use vendor's QC limits See applicable LIMS program specification for client-specified limits	Correct problem then reanalyze. If still out reprep and reanalyze the LCS and all samples in the affected batch
Sample Duplicate	One sample duplicate per batch of 20 or fewer field samples	For each analyte RPD ≤20%, or as otherwise specified in the applicable LIMS program specification	Flag results if RPD > 20%
MS/MSD (Matrix Spike/Matrix Spike Duplicate)	One MS/MSD pair per batch of 20 or fewer field samples	Recovery limit 80-120% for each analyte, not calculated if analyte concentration > 4X the spike level. For each analyte RPD ≤20% Other limits may apply, consult applicable LIMS program specification	Flag results if MS/MSD recovery or precision results are outside control limits, perform post digestion analytical spike
Post digestion analytical spike	Performed when MS/MSD recovery is outside ±20% (unless analyte concentration > 4X the spike level)	Recovery limit 75-125% for each analyte, or as otherwise specified in the applicable LIMS program specification	Flag results if post spike recovery or precision results are outside control limits
Serial Dilution	Performed on one sample per batch of 20 or fewer field samples	Results should agree within ±10% of undiluted results if analyte concentrations are sufficiently high (at least 50X the IDL), or as otherwise specified in the applicable LIMS program specification	Flag results if outside criteria
Method Detection Limit (MDL) Study	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level ≤ to that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and

STANDARD OPERATING PROCEDURE 901 REVISION 7

TITLE: VERIFYING WEIGHTS

FORMS: 315 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2/27/07

QUALITY ASSURANCE MANAGER _____ DATE 2/27/07

LABORATORY MANAGER _____ DATE 2/27/07

HISTORY: Rev0, SOP 324, 10/15/93; Rev1, SOP 324, 4/9/96; Rev2, SOP 324, 1/10/00; Rev3, SOP 324, 4/19/02; Rev4, SOP 901, 1/02/03; Rev5, 4/3/04; Rev6, 7/20/05; Rev7, 2/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the in-house procedures used to verify weights that are used for laboratory balance calibration verifications. ~~Laboratory weights less than or equal to 100g are categorized as ASTM Class 5 (OIML Class M_1). Weights greater than 100g are categorized as ASTM Class 6 (OIML Class M_2).~~ Quality Assurance (QA) Department staff or a delegate performs in-house weight verifications annually by verifying ~~them~~ the laboratory weights against Class S (ASTM Class ~~2~~ 1 or) ~~Master~~ weights that are NIST-traceable and certified annually by a qualified vendor. Note that it is Paragon's policy that weights lower than 20mg cannot be appropriately verified in-house, needed weights less than 20mg (e.g., 2mg) are sent outside for vendor certification.

Laboratory weights are classified as OIML Class F2, which is most comparable to NBS Class P / ASTM Class 4.

2. SUMMARY

All laboratory weights are identified with a unique number. The QA Department maintains a database Table of all weights and their locations. Weights/weight sets used for daily operations are located strategically throughout the laboratory. Additional weights are stored in reserve by the QA Department. Only weights that have been currently verified may be used for laboratory operations. All weights are stored in protective containers when not in use. Upon successful verification, a sticker, indicating the following information is placed on the container:

- weight(s)' identity
- date the verification is valid through
- initials of the individual who verified the weight
- date the verification was performed

Acceptance criteria derived from American Standard Test Methods (ASTM) and International Organization of Legal Metrology (OIML) tolerances, along with balance capabilities, are used to accept or reject the tested weight. Rejected weights are removed from service immediately. Unverified weights stored in reserve by the QA Department

are labeled **"**DO NOT USE - NOT VERIFIED***."*** Records of both vendor certifications and in-house verifications are maintained by the QA Department.

3. RESPONSIBILITIES

3.1 The QA Department is responsible for maintaining an inventory of suitable Master and laboratory weights. Currently Paragon's weight inventory is managed via a database Table maintained by the QA Department. The QA Department shall coordinate the annual vendor-certification of weight Masters and other needed weights that cannot be appropriately verified in-house. The QA Department is responsible for the content of this SOP and for maintaining all weight certification and verification records.

3.2 It is the responsibility of the Technician verifying the laboratory weights to perform these procedures according to this SOP and to thoroughly complete all required documentation.

3.3 It is the responsibility of all laboratory personnel to handle and store laboratory weights properly and to report any concerns or anomalies promptly to the QA Department.

4. INTERFERENCES

4.1 Make sure the balances used for testing are stable and level and that the balance pan is clean. Use a Kimwipe™ or brush to clean the pan as needed. As applicable, the pan's surrounding chamber should also be free of debris. In the event of a spill, consult the operating manual if more thorough cleaning is required.

4.2 Drafts can cause the balance to drift and produce unstable readouts. Draft shields either integral to or external to the balance must be used where needed.

4.3 Use gloves, a Kimwipe™, or some other barrier (e.g., tweezers) when handling the weights. Do not handle the weights with bare hands. The weights must be clean and free from all deposits. If the weights must be cleaned, use acetone or another suitable solvent and a Kimwipe™. Make sure the weights have air-dried completely before using them.

4.4 A balance's total capacity is usually incorporated in the model designation. For example, an AE104 balance has a total operational capacity of 104 grams. ***Know the limits of the balance being used. Never attempt to weigh anything whose mass exceeds the balance's capacity.***

5. APPARATUS AND MATERIALS

5.1 The most sensitive balance capable of handling the mass to be loaded must be used to verify the test weights. The balance's certification by an outside vendor must be current (refer to balance's calibration sticker, good through one year from

date of certification).

5.2 NBS Class S (ASTM Class 1 or 2) Master weights with current certification (valid within ~~one-year~~ 5 years of vendor calibration).

5.3 ~~ASTM Class 5 (OIML Class M_1) and ASTM Class 6 (OIML Class M_2)~~ OIML Class F2 (NBS Class P; ASTM Class 4) laboratory weights to be verified, and a database printout of all weights.

5.4 Blank verification stickers (obtainable from the QA Department), scissors, clear tape.

6. PROCEDURE

6.1 Record all test data on Form 315. Form 315 must be completely filled-out with regard to all information requested (e.g., balance number, serial number of weight, etc.).

6.2 Select a suitable balance to use for testing (see 5.1 above). *Weight verifications are customarily performed in the Ra/Sr Lab, using balance #13 for lower mass weights, and balance #21 for larger mass weights.* If not already on, power the balance on. Make sure that the balance pan is clean, and that the daily verification (SOP 305) has been performed on all balances used for verification. Make sure all weights used (Master, laboratory) are clean.

6.3 ESTABLISH WEIGHT MASTER AND BALANCE PERFORMANCE
Choose a certified Master weight per each order of magnitude of mass to be weighed on the balance (e.g., 100g, 10g, 1g, 100mg, 20mg). Tare the balance. Carefully place and weigh each Master weight, allowing the balance reading to stabilize before recording the reading. Re-tare the balance between each order of magnitude change in mass loading. Confirm that the Master weights are within the acceptance limits for its nominal value as listed on Form 315.

6.4 TEST AND VERIFY LABORATORY WEIGHTS

NOTE: ~~Where necessary, previously verified weights may be used to supplement Master weights in order to achieve the total mass loading needed~~. The balance's upper and lower limit of performance verified must bracket the largest and smallest laboratory weights tested.

6.4.1 Tare the balance. Place and weigh each laboratory test weight, record the observed value. Retare the balance between each order of magnitude change in mass loading.

NOTE: Duplicate weights in the same set will usually be distinguished with a period stamped next to the nominal value.

6.4.2 Calculate and record the difference between the test weight and Master weight, where available, or the test weight yielded and its nominal value. Confirm that the difference falls within the acceptance limits listed on Form 315.

If a laboratory weight is demonstrated to perform within acceptance limits, then the weight has been successfully verified. Place a sticker on the weight's case indicating the weight's identity, the date the verification is valid through, the initials of the person who verified the weight, and the date verified.

6.4.3 Re-clean and re-test any weight that fails. If a weight fails twice, it must be removed from service immediately (this weight will be discarded or stored in the QA Department after clearly labeling "DO NOT USE"; status information for this weight will be subsequently updated in the database).

Obtain a replacement weight from the QA Department and test as described above. Place the replacement weight in service after successful testing is completed. Annotate Form 315, and the database printout as applicable. Submit all data collected to the QA Department.

6.5 The QA Manager or designee will update the weight database Table as necessary, and will ensure that any weights stored in reserve and not tested are clearly labeled "DO NOT USE - NOT VERIFIED".

7. SAFETY AND HAZARDS

7.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

7.2 Safety glasses, a lab coat, and gloves must be worn at all times when working in the laboratory.

7.3 Food and drink are prohibited in all lab areas.

8. REFERENCES

8.1 Annual Book of ASTM Standards, Volume 14.02, Standard E617-97, 2002.

8.2 International Organization of Legal Metrology (OIML), Specification R111 -- Weights of Classes E_1, E_2, F_1, F_2, M_1, M_2 and M_3, 2004.

DOCUMENT REVISION HISTORY

2/27/07: Removed LIMS Program Specification text from RESPONSIBILITIES because it's not applicable. Under PROCEDURE, the balance(s) used for verification must pass the daily calibration verification check, but it is not necessary to perform this check using the Master weight set; text was updated/corrected accordingly. Additionally, some organizational changes were made to PROCEDURES for clarity. DOCUMENT REVISION HISTORY Section added.

Form 315r14.doc (7/7/08) ***Paragon Analytics***

WEIGHT VERIFICATION FORM

Master Weights NBS Class S (1000g - 20g ASTM Class 1; 10g - 20mg ASTM Class 2), most comparable to OIML Class E2, vendor certified every 5 years: **#31945** (15 piece set), good through 4/15/2012 **#08-711912-2** (200g), good through 5/14/2013 **#04-51936** (500g), good through 5/12/2013 **#08-711912** (1000g), good through 5/14/2013 **#08-711912-1** (1000g), good through 5/14/2013

Note that based on limit of capability, Paragon does not verify any weight smaller than 20mg in-house.
2mg weights, used for Oil & Grease determinations, are vendor certified annually (see QA Department records).

STANDARD OPERATING PROCEDURE 923 REVISION 8

TITLE: VERIFICATION OF THERMOMETERS

FORMS: 304 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER Deb Schenk DATE 2/28/07

QUALITY ASSURANCE MANAGER Deb Schenk DATE 2/28/07

LABORATORY MANAGER [signature] DATE 3-1-07

HISTORY: SOP 312, Rev0, 8/05/92; SOP 312, Rev1, PCN #81, 1/12/94; SOP 312, PCN #523, Rev2, 9/05/95; SOP 923, Rev0, 9/08/95; SOP 923, Rev1, 4/02/97; SOP 923, Rev2, 8/15/99; Rev3, 3/01/00; Rev4, 4/17/02; Rev5, 4/3/04; Rev6, 7/20/05; Rev7, 9/11/06; Rev8, 3/1/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) outlines the process for the annual standardization of laboratory thermometers (liquid-in-glass, electronic, infrared) to a thermometer traceable to the National Institute of Standards (NIST).

2. SUMMARY

All laboratory thermometers are identified with a unique number. Only thermometers that have been currently verified may be used for laboratory operations (***exception***: the electronic thermocouple used by the Radiochemistry Department to independently estimate the performance temperature of muffle furnaces -- a non-critical measurement).

Laboratory (test) thermometers and a current, independently certified, Master (reference) thermometer are placed together in applicable (i.e., relevant to the thermometer's use) test environments. After the thermometers and temperature have stabilized, readings are taken and recorded (Form 304). With the exception of the infrared (IR) temperature device used by the Radiochemistry Department (non-critical measurement conducted), the difference between the test and reference thermometer must not exceed ±1°C in order for the test thermometer to be accepted. The acceptance limits for the Radiochemistry Department IR temperature device is ±10°C

If the test thermometer cannot perform within the established acceptance limits, the thermometer is removed from service. At the conclusion of the standardization effort, verification tags, indicating the thermometer's serial number, the date the standardization is valid through, the initials of the test technician, and the date the standardization was performed, are applied to each thermometer successfully verified (***exception***: in some cases, the temperature of the unit the thermometer is assigned to chars the sticker, making it friable and unreadable; in these cases, the verification sticker is placed directly on the unit). Records of both Master vendor certifications and in-house verifications are maintained by the Quality Assurance (QA) Department.

3. RESPONSIBILITIES

3.1 The laboratory staff is charged with coordinating with the QA Department to ensure that all thermometers in use have been verified, and that the thermometer in use at each location, has the same identification number as indicated in the daily temperature logbook for that location. It is the responsibility of all laboratory personnel to handle the thermometers properly and to report any concerns or anomalies promptly to the QA Department, so that appropriate corrective action may be taken.

3.2 The QA Department shall coordinate the annual certification of thermometer Masters by a NIST-approved vendor prior to the annual in-house verification effort. The QA Department will also coordinate the standardization of all laboratory thermometers in use annually. The QA Department is responsible for the content of this SOP, for maintaining a suitable inventory of laboratory thermometers and batteries, and for maintaining all thermometer certification and verification records.

3.3 It is the responsibility of the Technician verifying the thermometers to perform these procedures according to this SOP and to thoroughly complete all required documentation.

4. INTERFERENCES

When standardizing thermometers, it is important to ensure that the temperature of the test environment and any material the thermometer or probe is immersed in has stabilized before readings are obtained.

5. APPARATUS AND MATERIALS

5.1 ***Freezer Environment.*** Choose an operating laboratory freezer with space sufficient to accommodate the Master and laboratory test thermometers.

5.2 ***Ambient Environment.*** Choose an area with sufficient benchtop space to accommodate the Master and laboratory test thermometers, and that is not susceptible to drafts.

5.3 ***Oven Environment.*** Choose an operating laboratory oven (or ovens) maintained at a suitable test temperature with space sufficient to accommodate the Master and laboratory test thermometers. Coordinate use of the oven(s) for thermometer verification purposes, with the Department so as not to impact production.

5.4 ***Master (Reference) thermometers*** -- must be currently certified by an independent calibration service using NIST reference standards. *Note that these thermometers are maintained by the QA Department with restricted access, these thermometers are to be used for verification purposes only, and are not to be used by laboratory staff for general purposes.*

5.5 ***Test thermometers*** -- laboratory thermometers currently in use, and those held in reserve by the QA Department for replacement.

5.6 Blank verification stickers (obtainable from the QA Department), scissors, clear tape.

5.7 A 'Thermometers' database Table printout.

6. PROCEDURE

6.1 OVERVIEW

The thermometers shall be tested under conditions applicable to their use. Note that the particular thermometer assigned to an application, takes into consideration the method requirements (e.g., range, graduations, etc.) for that thermometer's performance. Only thermometers meeting method criteria may be used.

Where possible, the standardization of thermometers at *two* test points is desirable (not possible with short range thermometers).

- Electronic min/max thermometers used to monitor cooling units or ambient conditions shall be tested under freezer and ambient conditions.
- Sample receiving infrared temperature devices (IR guns) shall be tested under refrigerator conditions, and the Radiochemistry IR gun shall be tested using oven conditions.
- General use thermometers shall be tested under both ambient and oven conditions.

6.2 GENERAL PROCEDURES

- The standardization effort should be conducted at such a time and in such a manner that the impact to the laboratory is minimized.
- It is easiest to gather one type of thermometer (e.g., min/max, short range oven, general use) at a time for testing. Collect laboratory thermometers in use, as well as those held in reserve by the QA Department for replacement.
- Use the thermometer database printout to ensure that all thermometers are collected. **Verify the thermometer identity at its location upon collection, and annotate the database printout as necessary.**
- Wipe thermometer (or probe) clean before testing, and visually inspect unit for damage (e.g., readability of etchings, integrity of liquid column, etc.). Replace unreadable thermometers (i.e., substitute an appropriate replacement thermometer for testing; dispose of unreadable

thermometer appropriately; annotate database printout with change; *remember to replace thermometer logbook with one that indicates updated thermometer identity!*).

If necessary, reconstitution of a thermometer's liquid column can be attempted per manufacturer's instructions (see QA Department for information). Otherwise, the thermometer must be properly disposed (see Section 7 below).

- Where the test thermometer or probe is immersed in liquid, the Master thermometer should also be immersed in the same (or equivalent) material.
- It is important to ensure that the temperature of the test environment and any material the thermometer or probe is immersed in, has stabilized before readings are obtained. *Tip*: it may be easiest to set-up the test and allow the thermometers to equilibrate overnight.
- The process of obtaining readings may destabilize the test environment, necessitating the readings to be taken in small batches. Similarly, it may be necessary to reposition the Master thermometer to nearer proximity to selected test thermometers, in order to obtain accurate readings in smaller batches.

6.2.1 Conduct one or two-point environment tests, as applicable for the thermometer type, as described in OVERVIEW and below.

6.2.2 Neatly record all test data on Form 304 (forward the benchsheets to the QA Department when completed).

6.2.3 Place a current verification label (thermometer number, date verification is valid through, technician's initials, and date of verification) on each successfully verified thermometer (or assigned unit, where necessary) before placing the thermometer back into service (or reserve storage). Cover the verification sticker with a piece of clear tape to help preserve the sticker. **For thermometers placed back into service, check again that the right thermometer is returned to the designated location, and that the associated logbook indicates the correct thermometer identity.**

6.2.4 The QA Manager or designee will update the thermometer database Table as necessary, and will ensure that any thermometers stored in reserve and *not* tested are labeled "DO NOT USE - NOT VERIFIED". The QA Manager or designee will also update any laboratory logbooks as necessary due to replaced thermometers.

6.3 FREEZER ENVIRONMENT TEST

6.3.1 Clear space in a suitable freezer unit so that the Master and all test thermometers and probes can be held securely without disturbance for the duration of the test. *Tip*: It has been determined that the electronic min/max probes are interchangeable. Therefore, it is not necessary to keep the probes matched to particular electronic min/max units. For ease in reading then, the attachment ends of the probes can be left external to the cooling unit so that rapid readings may be acquired by connecting a min/max thermometer unit sequentially through the probe attachments.

6.3.2 Place the thermometers/probes in the freezer unit, allowing space around each container. Let the thermometers stabilize (i.e., 0°C change over 3 minutes). If not equilibrated overnight, check the environment temperature initially after 1 or more hours, then repeat in 20-minute intervals until stable readings of the thermometers can be obtained.

6.3.3 After the thermometers/probes have stabilized, record the temperature readings of the reference thermometer and all test thermometers to the nearest degree (Form 304).

6.3.4 Evaluate each test reading to determine the acceptability of the thermometer. The test thermometer must agree within $\pm$1°C of the reference thermometer.

If the test reading does not meet acceptance limits, reposition the thermometers and retest. If still unacceptable, the test thermometer must be removed from service and replaced with a successfully verified thermometer. See the QA Department for a suitable replacement thermometer. The QA Manager will initiate appropriate corrective action, as needed.

6.4 IR TEMPERATURE DEVICES

6.4.1 ***Sample Receiving IR Guns.*** First, successfully verify the min/max thermometer assigned to cooling unit RU#20. Document the current temperature reading of this thermometer as the reference temperature (Form 304).

Use the one-liter amber water check bottle stored in RU#20 to conduct the verification of each Sample Receiving IR gun as follows:

- Hold the bottle away from your body and down toward the floor.
- Point the IR gun at the center of the bottle and hold the gun tip about 1-2 inches from the bottle's surface.

- Depress the gun's trigger and obtain a temperature reading of the water check bottle. Record this reading as the test temperature.
- Compare the test temperature to the reference temperature. The IR gun reading must agree within ±1°C of the reference temperature to be successfully verified.

6.4.2 ***Radiochemistry IR Gun.*** *Tip*: It is easiest to conduct this verification in the LLRP lab, however, any laboratory oven may be used as the test environment.

- First, successfully verify the thermometer assigned to the laboratory oven.
- Obtain a current temperature of the laboratory oven and document as the reference temperature (Form 304).
- Because a heavy-duty PyrexTM beaker is generally used to contain the laboratory sand the oven thermometer is held in, reading the surface of this beaker will yield results that are biased low (the glass used in this type of beaker is formulated to retard heat conduction). Consequently, it is important to use the actual type of glassware (e.g., condensers, glass joints) that is dried in this oven to conduct this test.

  Quickly point the IR gun at the center of several pieces of glassware, depressing the trigger and noting the readings obtained. Work quickly to avoid the oven temperature dropping due to the open oven door. Record the average reading on Form 304.
- Compare the test temperature to the reference temperature. The IR gun reading must agree within ±10°C to be successfully verified.

  NOTE: The acceptance limits for the Radiochemistry IR gun are greater than that applied to other thermometers because this particular device is not used for critical measurements. Note also that the verification acceptance limits for the Radiochemistry IR gun are half the criteria allowable for the established daily use check.

6.4.3 If any IR temperature device does not successfully verify, consult with the QA Manager. The device may need to be removed from service and an alternative provided. The QA Manager will initiate appropriate corrective action, as needed.

6.5 AMBIENT ENVIRONMENT TEST

Conduct the Steps described for the FREEZER ENVIRONMENT TEST, using a suitable benchtop area without drafts, as the test environment.

6.6 OVEN ENVIRONMENT TEST

Conduct the Steps described for the FREEZER ENVIRONMENT TEST, using a suitable laboratory oven(s) as the test environment. *Tip*: it is helpful to place the Master and test thermometers in containers of silica sand or Drierite™ and allow them to equilibrate overnight. Also, testing of probe stem thermometers may require that a water bath high temperature test be conducted in lieu of the oven environment test, so that the entire probe stem thermometer is not incubated (oven incubation of the entire probe stem thermometer may effect the thermometer's liquid crystal display, preventing readings from being obtained).

7. CORRECTIVE MEASURES

For the most part, malfunctioning thermometers are noted during routine temperature checks and are addressed as discussed in SOPs 320, 326 and 663. However, with the annual verification effort, some thermometers may be selected for replacement based on diminished readability (accuracy not impaired, no impact to data), still others may simply not test successfully. These thermometers must be replaced as discussed above. In cases where the thermometer has not tested successfully, usually the thermometer performs just outside the ±1°C control criterion and impact to data is not likely, in rarer instances, a break in the thermometer's liquid column might not have been noticed. In all instances, however, the occurrence must be further investigated (QA and Departmental participants), and professional judgment applied as to the nature and extent of the corrective action that should be taken. Corrective actions may include retraining, and notification to clients where deemed appropriate.

8. SAFETY, HAZARDS AND WASTE DISPOSAL

8.1 SAFETY AND HAZARDS

8.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

8.1.2 Safety glasses, a lab coat, and gloves must be worn at all times when working in the laboratory.

8.1.3 Food and drink are prohibited in all lab areas.

8.2 WASTE DISPOSAL

Thermometers that are broken or are rendered unusable due to damage are to be immediately removed from service and transferred to Waste Disposal personnel. The unusable or broken (spirit-filled) thermometers must be placed in containers that can be safely sealed to contain the broken pieces and thermometer contents.

Notify the QA Department immediately so that the unusable thermometer can be noted and a replacement thermometer provided.

NOTE: Mercury-filled thermometers can only be handled for cleanup and disposal by the laboratory Health & Safety Manager or designee. ***Under no circumstances are other laboratory personnel to handle or dispose of these mercury-containing materials.***

DOCUMENT REVISION HISTORY

9/11/06: Added RAD IR gun to exception from ±1°C quality control criteria in Summary text. Expanded equipment text for Master thermometer to note that Masters are not for general use. In OVERVIEW, added statement that only thermometers that meet method requirements for that application may be used. Added CORRECTIVE MEASURES section to PROCEDURE. Added DOCUMENT REVISION HISTORY.

3/1/07: Indicated in SUMMARY and Step 6.2.3 that in certain instances, the verification sticker may be placed directly on the unit the thermometer is assigned to. Minor text clarifications/format corrections throughout. For maximum interchangeability, non-high temperature min/max thermometers shall be tested under freezer and ambient conditions (brackets potential range of use); text pertaining to refrigerator test environment removed.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 926 REVISION 8

TITLE: REVIEW, REVISION, DISTRIBUTION AND ARCHIVING OF CONTROLLED DOCUMENTS

FORMS: 059, various laboratory benchsheets

APPROVED BY:

TECHNICAL MANAGER _____ DATE 6/9/06

QUALITY ASSURANCE MANAGER _____ DATE 6/9/06

LABORATORY MANAGER _____ DATE 6-9-06

HISTORY: Rev0, 7/08/93; Rev1, PCN #4, 8/26/93; Rev2, PCN #551, 10/18/95; Rev3, 7/15/99; Rev4, 10/15/01; Rev5, 3/2/02; Rev6, 4/17/02; Rev7, 4/3/04; Rev8, 6/8/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes Paragon's requirements for reviewing, revising, distributing and archiving controlled documents. Examples of controlled documents include -- SOPs, laboratory logbook forms, and Paragon plan guidance documents, such as the Laboratory Quality Assurance Plan (LQAP), Chemical Hygiene Plan (CHP), Emergency and Contingency Plan (ECP), Radiation Protection Plan (RPP) and Waste Management Plan (WMP). Non-conformance reports (NCRs) are also controlled documents, however, processes governing NCRs are detailed separately in SOP 928.

Documents that are controlled contain a revision number that is incremented with each iteration (i.e., change in content and issuance). Controlled documents may be electronic images that are posted to designated 'read only' network directories. A hardcopy controlled document original is identifiable by its printing on controlled (i.e. red-stamped) paper.

Laboratory logbooks, and the controlled forms that are used to create them, are managed by the Quality Assurance (QA) Department. The QA Department is responsible for assigning a unique identifier, and for creating and distributing requested logbooks. SOPs and Paragon plan documents are published by the QA Department through use of the SOP and Training Records database application.

The QA Department is responsible for ensuring that laboratory logbooks are made only from the most current benchsheet form. The QA Department is also responsible for ensuring that only the most current iteration of SOPs and Paragon plan documents are posted to the designated network directory. This is verifiable by any laboratory staff by comparing the network postings to the Table of Contents report of the SOP and Training Records database.

The intent of controlling documents and their distribution is to ensure that everyone who needs it, has a copy of the document, and that all recipients have the proper and most current information with which to work. Controlled distribution ensures that all

employees are following the same procedures, and helps to document when changes to procedures became effective. Controlled documents are issued and archived by the QA Department.

2. SUMMARY

With the exception of NCRs and laboratory logbook forms, a primary author is assigned to all controlled documents. The primary author is responsible for the content of the document, although actual revision and distribution of the document is accomplished by QA Department staff. Anyone may suggest a change or correction to a controlled document, the primary author is responsible for evaluating the suggestion and deciding whether or not it should be incorporated into the document. Controlled documents are reviewed for revision and distribution according to an established schedule that is determined by management staff. The primary author is responsible for adhering to the established schedule. Laboratory staff are responsible for reading the controlled document (if assigned) in a timely manner (i.e., within ~~10 work-days~~ of it's release), and for promptly implementing any procedural changes that are relayed in the document. This timely reading and implementation helps to establish when changes became effective. Department Managers are responsible for ensuring that all of the required controlled documents are assigned to each individual within their Departments, and for enforcing their timely reading. The QA Department maintains reading compliance records.

14 calendar days (3/9/09 DAS)

3. RESPONSIBILITIES

3.1 It is the responsibility of every employee to work *only* from approved versions of controlled documents. This means that employees may *not* refer to documents that have been hand-corrected as a means of updating the procedure, without properly processing the revision through the processes described in this SOP. Any employee may suggest a change or correction to a controlled document by submitting the request to the primary author. Each employee is responsible for reading the controlled documents assigned to them in a timely manner, and for signing the required reading compliance documentation.

3.2 Primary authors are designated by appropriate management staff. The content of the document is the primary author's responsibility, and it is the responsibility of the primary author to provide approved revisions to the QA Department for processing, according to schedule. The Department and QA Managers and the Laboratory Director are responsible for establishing the controlled document review and revision schedule.

3.3 It is the responsibility of every Department Manager to ensure that staff has adequate access to controlled documents, and to ensure that only the proper documents are referenced to accomplish the work. The Department Manager is also responsible for ensuring that all of the required controlled documents are assigned to each individual within their Department, and for enforcing their timely reading and submission of required reading compliance documentation to the QA Department.

3.4 It is the responsibility of the QA Department to process and distribute controlled documents in a timely fashion. The QA Department is responsible for maintaining an archive of controlled document versions. QA Department staff are responsible for providing oversight to the controlled document process, and for enforcing reading compliance. The QA Department maintains records of controlled document distribution and reading compliance. The QA Department maintains an archive of laboratory logbook form versions, manages a database for issuing laboratory logbooks, and is responsible for creating and distributing requested logbooks. Further details regarding laboratory logbooks are provided in SOP 303. Archiving of laboratory logbooks and other laboratory records is discussed in SOP 069.

, including review requirements, (3/9/09 DAS)

4. PROCEDURE

4.1 GENERAL REQUIREMENTS

4.1.1 Each individual's reading list (managed and accessible through Paragon's SOP and Training Records database) is determined by that individual's Supervisor, who must ensure that the reading list is current and appropriate. The SOP and Training Records database automatically updates the version of the assigned reading each time new version is released.

14 calendar days (3/9/09 DAS)

4.1.2 Each individual is responsible for reading all items on their reading list in a timely manner (i.e., annually; within ~~10 work days~~ of release for new/revised publications). Everyone has access to printing their reading list from the SOP and Training Records database (your Supervisor can show you how). The individual must inform their Supervisor that items have been read. Typically this is accomplished by providing an annotated reading list (i.e., read dates filled-in by hand by the individual) to the Supervisor, who in turn promptly enters the information into the SOP and Training Records database. Compliance with reading requirements appears as read dates shown for items on the reading list in the database. The SOP and Training Records database automatically archives off read dates that are greater than 1 year. Blank spaces on the reading list indicate items that are not compliant (i.e., have not been read within requirements).

4.1.3 Only current, approved versions of controlled documents may be used or referenced to accomplish work.

4.1.4 Anyone can suggest changes or corrections to controlled documents by submitting the request to the document's primary author. Primary authors are indicated on the Table of Contents report available from the SOP and Training Records database.

4.1.5 Review and revision of controlled documents is to occur according to a prescribed schedule, that is determined by management.

Although an overall biennial publication schedule is maintained, revision comments received are addressed as promptly as practicable. (3/9/09 DAS)

4.1.6 The version of the controlled document must be incremented with each publication that contains changes in content.

4.1.7 Controlled documents are distributed per a distribution list, that is derived from information contained in the SOP and Training Records database. Upon request, certain clients and agencies may be part of the document's distribution list. Typically, controlled documents are distributed by posting the image to the network in a designated 'read only' directory, and by issuing document release notifications that are produced from the SOP and Training Records database. The returned, signed document release notifications are maintained by the QA Department as reading compliance records. Past iterations of the document are maintained by the QA Department in archives.

4.1.8 Paragon does not typically issue addendums to documents between publications. Addendums may be issued only by the QA Department and must be distributed in the same manner as the associated primary document. The signature and date of the QA Manager and Laboratory Director must be present on the addendum.

4.2 PRIMARY AUTHORS

4.2.1 The primary author is a person knowledgeable about the processes described in the document and is designated by appropriate management staff.

The Quality Assurance Manager is the primary author for the LQAP. The Health & Safety Manager/Radiation Safety Officer is the primary author for the CHP, ECP and RPP. The Facilities Manager/Waste Coordinator is the primary author for the WMP.

annually (3/9/09 DAS)

4.2.2 The primary author is responsible for the document's content and must review the document for revision ~~according to schedule~~. The primary author must ensure that the document is compliant with referenced methods or guidance, and that the document reflects actual Paragon practices.

The primary author must review suggested changes and corrections and must incorporate the suggestions into the document as applicable. Typically some suggested changes and corrections are prompted by internal or external audit Findings. An audit Findings Table is available to everyone in LIMS. This Table can be sorted by status and SOP to find all OPEN Findings pertinent to the SOP in consideration.

Reviewed documents and their approved revisions are submitted to the QA Department for processing and distribution.

4.3 SOPS AND PLANS

4.3.1 To facilitate future revision, the QA Department makes electronic working copies of SOPs and Plans available to primary authors by posting them in restricted network directories each time a new version is released. The primary author can use this working copy to evaluate, manage and/or track suggested changes or corrections that are submitted to them.

When the revised document is ready to be published, the QA Department is notified by e-mail or through the SOP and Training Records database and the working copy is further processed for distribution.

- The QA Department is similarly notified when a document has been reviewed and it is determined that it can be re-released without revision.

- The QA Department is similarly notified when it is determined that a document can be retired (i.e., removed from active service).

More than one existing SOP can be consolidated into a single document at the discretion of the primary author, Department Manager and QA Manager.

If it is determined that a new SOP must be created, the primary author or Department Manager must obtain an SOP number from the QA Department.

'Operator Aids' are quick references, intended to be posted on a wall for easy viewing, that exist as an appendix of some SOPs. The Operator Aid is reviewed along with the main portion of the SOP per each review/revision cycle. Examples of Operator Aids include two Dishwasher's aids (one associated with SOP 334, the other with SOP 720), which are posted proximate to each laboratory sink that is used to clean glassware in the stable chemistry and radiochemistry laboratory areas, respectively. Another Operator Aid is the Preservations reference that is used in the Sample Receiving Department when bottle kits are made per SOP 205. The Operator Aids are posted in protective plastic sleeves, and are replaced with each distribution of the associated SOP.

4.3.2 Upon receiving notification from the primary author, the QA Department will further process the document in a timely manner.

- Revisions are reviewed for content changes; the QA Manager resolves any questions or issues that arise with the primary author.

- The format of the document (e.g., general, version number, history, etc.) is updated as needed.

- A hardcopy of the finalized document is provided to the primary author and Laboratory Director for review and signature; the Quality Assurance Manager also signs the document before it is published. With regard to the LQAP, Department Managers must additionally review and sign the master document before it can be published.

- The document is published through the SOP and Training Records database, notifications of release are distributed for returned signature attestation of reading compliance within ~~10 work-days~~ 14 calendar days (3/9/09 DAS) of release (the due date for return of these attestations is marked on the QA Manager's calendar so that compliance can be enforced), the network image for the document is replaced, where applicable, Operator Aids are replaced, and an appropriate working copy of the document is made available in the restricted primary author directory. The QA Department maintains distribution and reading compliance records.

4.3.3 Controlled documents that are printed out for reference or review are only valid for 30 calendar days from the date printed. An embedded document header identifies the document, and directs the person printing the document to write-in the date printed, and to discard the printout within 30 days. (3/9/09 DAS)

4.4 LABORATORY LOGBOOK FORMS

4.4.1 When distributed, custom spiral-bound laboratory logbooks contain a colored sheet (Logbook Reminder, Form 059), placed near the end of the logbook, that the user tears out and submits to the QA Department when that sheet is reached. This sheet contains information necessary to create a replacement logbook. The user may indicate changes that need to be made to the laboratory logbook form by writing comments on this sheet or by submitting a mark-up of a logbook page as an attachment.

4.4.2 A library of laboratory logbook forms is maintained in a restricted directory by the Quality Assurance Department. If changes to a form have been requested and are acceptable, the QA Manager works from the most current electronic version of the form to make the requested changes, but uses the 'Save As' command to create a new electronic file, advancing the version number of the filename by a value of '1' (e.g., edited Form 635r3.doc would be 'Saved As' Form 635r4.doc).

4.4.3 Further details about the issuance of laboratory logbooks can be found in SOP 303.

5. REFERENCES

This SOP describes an in-house procedure developed by Paragon. The requirements established herein are compliant with various quality assurance guidance documents, such as the most current versions of the National Environmental Laboratory Accreditation Conference (NELAC) Standard, the Department of Energy (DOE) Quality

Systems for Analytical Services (QSAS) document, and the Department of Defense (DoD) Quality Systems Manual (QSM) for Environmental Laboratories.

DOCUMENT REVISON HISTORY

6/8/06: Content completely restructured; text detail added; discussion of Operator Aids added; 'References' Section enhanced; 'Document Revision History' Section added; Forms incorporated as part of the SOP.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 928 REVISION 8

TITLE: NON-CONFORMANCES AND CORRECTIVE ACTIONS

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3/7/08

QUALITY ASSURANCE MANAGER _____ DATE 3/6/08

LABORATORY MANAGER _____ DATE 3-7-08

HISTORY: Rev0, 12/6/93; Rev1, PCN #553, 10/18/95; Rev2, 2/27/98; Rev3, 11/20/98; Rev4, 11/20/01; Rev5, 3/2/02; Rev6, 4/6/03; Rev7, 6/8/06; Rev8, 3/6/08.

1. SCOPE AND APPLICATION

A non-conformance is any instance (i.e., deviation, equipment failure, or laboratory error) that results in an established acceptance limit, policy or client-specified criteria not being met. Corrective actions are those measures taken to correct or mitigate the non-conformance, along with the steps taken to prevent the incident from happening again.

Examples of non-conforming events include, but are not limited to:

- tracer recovery exceeded laboratory-derived acceptance limits;
- continuing calibration verification (CCV) results not within method-defined control limits;
- performance parameter (e.g., lumex, negative activity, etc.) exceeded established Paragon limits;
- client criteria (e.g., LCS, DER, etc.), differs from Paragon Standard criteria and client criteria was not met;
- glassware broke and sample was lost;
- sample was erroneously double-spiked with surrogate;
- wrong date of collection was entered upon sample login;
- current IDLs were not presented in the electronic data deliverable (EDD).

Examples of corrective/preventive actions include, but are not limited to:

- further analyses were performed on both a traced and untraced fraction of a reduced aliquot of sample
- sample was resubmitted for preparation and analysis;
- a sample cleanup was performed;
- document in narrative, matrix contribution is the most likely cause;
- LIMS program specification was updated to clarify client requirement
- matter was discussed with staff and retraining was provided

Non-conformances are reported (documented) through the laboratory's LIMS interface (LIMS\ Laboratory\NCR Menu). The series of tabs that comprise the LIMS interface mimic the sections contained in the former hardcopy report (Form 313) that was previously circulated. Use of the hardcopy NCR Forms has been discontinued, as the LIMS interface yields a sequential, uniquely-identified, Controlled report that takes its place. Additional new features are also provided for via the current LIMS NCR interface. The NCR process also serves to initiate corrective action. NCRs are also used to address client inquiries, and to investigate Performance Test (PT) sample failures. The specific corrective measures taken are contingent upon the type and extent of the incident, and are coordinated by the laboratory Department and applicable Project Manager(s), and the QA Department. It is Paragon's policy to complete corrective action within the assigned date, which is not to exceed 21 calendar days. Note that exceptions may be applied where prudent, at the QA Manager's discretion (*example*: root cause is thought to be instrument malfunction, instrument is sent off-site for refurbishment and retained by vendor for 3 weeks, instrument must be re-installed and re-calibrated before corrective action can be complete, hence, corrective action cannot be completed within established 21 calendar days policy).

This standard operating procedure (SOP) provides an overview of Paragon's NCR/corrective action processes. Further details pertaining to these topics are contained in the Paragon NCR User's Guide (posted to the network, for internal use only), and Section 11 of the Laboratory Quality Assurance Plan (LQAP).

2. SUMMARY

Like before, NCRs are available to all laboratory staff and *anyone* who notices an error or discrepancy that results in the failure to meet an established limit, policy or client-specified criteria, is responsible for initiating an NCR in a timely manner (i.e., when the problem is noted). The general NCR process flows from the initiator, through their immediate Supervisor and/or Department Manager, to the Project Manager (discussions with the client, and between the PM and DPM occur as necessary), and finally to the Quality Assurance Manager. Authorized signatures (PM, DPM, QA) are required at various steps. Signature authority can be delegated as needed to cover key staff outages.

Paragon maintains a full-disclosure environment with regard to internal communications and dialogue with our clients. Non-conformance reporting facilitates these communications and is essential in helping to identify issues as early in our processes as possible, thus enhancing operational efficiency and the ability to provide outstanding customer service. NCRs also provide a means of identifying trends, giving us the ability to correct deficiencies in training, and insights into improving our processes and product.

3. RESPONSIBILITIES

3.1 It is important, and is everyone involved's responsibility, to initiate and complete NCRs in a timely manner. Rapid determination and application of needed corrective

measures may be necessary to meet sample hold times, client deadlines, etc.

3.2 It is the responsibility of all personnel who work with samples to document any discrepancies (non-conformances) that occur with sample handling.

Chemists who prepare samples for analysis must document any problems noted during preparation. Refer to LQAP for details regarding use of Quality Assurance Summary Sheets (QASS) and initiation of NCRs.

Analyst's are responsible for monitoring the proper functioning of the analytical system prior to, during and following sample analysis, and for documenting any problems that are noted.

3.3 The Project Manager (PM), with assistance from the Department Manager (DPM) as necessary, is responsible for assessing the severity of the non-conformance and its impact on project requirements. If client contact is necessary to determine appropriate corrective action, the PM contacts the client and documents it in the NCR interface. The specific corrective measures to be taken are also recorded in the NCR interface.

The Department Manager is responsible for ensuring that the corrective measures applied were completed, and that overall, NCRs are initiated and completed when necessary.

PM and DPM signatures are required in various places via the NCR interface to track the flow of the correction and to attest that the measures taken were appropriate and complete.

3.4 The Quality Assurance (QA) Department is responsible for providing final approval of each NCR and oversight of the entire NCR process. The QA Department provides monthly NCR feedback to Management staff. Archives of hardcopy NCRs are maintained in QA Department files. Documents generated through the NCR interface are maintained (archived) through established electronic backup and archiving protocols.

3.5 Reporting Group staff are responsible for ensuring that completed NCRs are included in laboratory data package reports, as applicable.

4. PROCEDURE

4.1 Whoever notices an error or discrepancy that results in the failure to meet an established limit, policy or client-specified criteria, is responsible for initiating an NCR in a timely manner (i.e., when the problem is noted).

4.2 The steps for initiating and processing NCRs are generally the same regardless of whether the NCR is used to document a non-conformance, to research a client inquiry, or to request a corrective action investigation (see Section 4.6). NCRs used to document non-conformances are typically initiated by laboratory staff; an

NCR used to research a client inquiry is typically initiated by the Project Manager; an NCR used to request corrective action investigation (e.g., resolution of an internal audit Finding, investigation of a PT result failure, etc.) is typically initiated by the QA Department.

4.3 Refer to the Paragon NCR User's Guide for instructions on interacting with the LIMS NCR interface. The NCR interface contains various controls and lockdown features. Contact the QA Department should any information need to be edited. If, after initiating an NCR, it is subsequently determined that the NCR was not needed, contact the QA Department so that the NCR can be properly voided.

The Project Manager, at his or her discretion, may or may not contact the client to discuss options based on the nature of the non-conformance. Means for documenting client contact are provided for in the NCR interface.

The NCR is considered to be complete when all final approval signatures (PM, DPM, QA, or designees) are in place.

4.4 The Reporting Group discusses any anomalies described on the NCR in the data package narrative, and includes a copy of the NCR in the data package report (as applicable for the level of the data deliverable generated).

4.5 The QA Department tracks NCRs as they are finalized, so that systematic problems or trends can be readily identified and responded to promptly. The QA Manager, at his or her discretion, may initiate corrective action investigation for recurrent events (see 4.6 below). On a monthly basis, the QA Department summarizes the NCR occurrences and distributes this summary, along with additional comments, to key laboratory staff for their further consideration.

4.6 Formal corrective action requests (i.e., additional efforts that are mandated that are beyond the scope of NCRs), are managed through a different LIMS interface, namely the LIMS Audit Finding Table (LIMS\Quality Assurance\Audit Findings). All laboratory staff have read access to this Table, the QA Department manages the Table's contents. The LIMS AF Table is also used to manage corrective actions requests associated with external audits.

Each formal corrective action is assigned a unique identifier. The QA Department uses a sequential identifier of "CA-yymm###" to designate corrective actions that are initiated internally. Internal corrective action requests are issued at the QA Department's discretion, and may be used to investigate and resolve trends, internal audit Findings, PT sample result failures, etc.

All corrective actions must be resolved in the most timely manner practicable. Corrective actions associated with NCRs are typically completed within turnaround time requirements for the data. In general, corrective actions are to be

completed within 21 calendar days or less as assigned. Exceptions or extensions may be granted at the QA Department's discretion, contingent upon the particular incident's circumstances.

The QA Department is responsible for maintaining supporting documentation pertaining to corrective action investigations and outcomes; this information is archived on the network.

5. REFERENCES

This SOP describes an in-house procedure developed by Paragon. The requirements established herein are compliant with various quality assurance guidance documents, such as the most current versions of the National Environmental Laboratory Accreditation Conference (NELAC) Standard, the Department of Energy (DOE) Quality Systems for Analytical Services (QSAS) document, and the Department of Defense (DoD) Quality Systems Manual (QSM) for Environmental Laboratories.

DOCUMENT REVISION HISTORY

6/8/06: Completely reformatted; 'Responsibilities' Section enhanced; greater detail added; management aspects of NCR use and evaluation included; scope broadened to include corrective action and audit Finding management; 'References' Section enhanced; 'Document Revision History' added, Forms incorporated as part of SOP.

3/6/08: Complete re-write as NCRs are now electronic in LIMS. Updated Title. Removed Forms, which are no longer applicable.

Must Discard 30 Days from _____ (date printed)

See amendment, Section 3.2 (i.e., internal auditor qualifications). 3/9/09 DAS

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 937 REVISION 7

TITLE: INTERNAL AUDITS

FORMS: 168, 169 (use most current iterations)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 6/9/06
QUALITY ASSURANCE MANAGER _____ DATE _____
LABORATORY MANAGER _____ DATE 6-9-06

HISTORY: Rev0, PCN #513, 8/1/95; Rev1, 9/22/97; Rev2, 8/10/99; Rev3, 10/8/01; Rev4, 4/17/02; Rev5, 9/9/03; Rev6, 4/24/04; Rev7, 6/8/06.

1. SCOPE AND APPLICATION

An audit is a formal assessment of a procedure or product that documents the evaluation of that procedure or product against relevant guidelines and requirements. Audits help to ensure that good laboratory practices are being observed and serve as a management tool for evaluating the appropriateness of quality assurance policies. This Standard Operating Procedure (SOP) describes how Paragon conducts its internal audits. Consult Chapter 12 of the Laboratory Quality Assurance Plan (LQAP) for similar information regarding external audits and Performance Test (PT) study evaluations.

2. SUMMARY

Near to the beginning of each calendar year, the Quality Assurance (QA) Manager creates an audit schedule. The annual audit schedule is designed to touch upon all laboratory Departments at least once, and to evaluate critical elements of laboratory and quality systems. Note, however, that the Facilities and Waste Department and the Health & Safety Department are responsible for determining and managing their own internal assessments per their applicable quality and regulatory requirements.

Qualified personnel prepare for, conduct and document each internal audit. Corrective actions are determined and applied as necessary. Follow-up is performed and documented as applicable. Senior Departmental staff and management are made aware of audit outcomes.

The QA Department maintains archives of internal audit records.

3. RESPONSIBILITIES

3.1 The QA Department is responsible for developing the annual internal audit schedule, managing the internal audit program, approving individuals as qualified to conduct internal audits, evaluating and enforcing corrective actions, distributing audit reports to appropriate personnel, and maintaining an archive of internal audit records.

3.2 The designated internal auditor shall be a person who possesses previous knowledge or experience in the area being audited, or who has been trained in the concepts of the area being audited. As a Laboratory Director or QAM designee, the internal auditor is empowered with the same authority/autonomy as that defined for QA Dept. staff, and shall have unlimited access to all laboratory areas. It may be appropriate, however, in some instances (such as IS Dept. evaluations), for the unfettered accesses to be given by proxy. The internal auditor shall conduct themselves, at all times, professionally, exercising courtesy and respect. 3/9/09 DAS

3.3 Department Managers and laboratory staff are responsible for supporting the internal audit program (e.g., being available, cooperating, fully disclosing, etc.), for determining the root cause of any noted non-compliances, effectively implementing corrective actions, and where applicable, submitting required corrective action documentation to the QA Department.

3.4 The Laboratory Director is responsible for providing adequate resources for conducting the internal audit program and for applying agreed-upon corrective measures where necessary.

4. PROCEDURE

4.1 GENERAL INFORMATION

4.1.1 The QA Manager establishes an annual audit schedule near to the beginning of each calendar year and assigns designations for each internal audit. Internal audits are typically identified as 'IAyymmdd'.

4.1.2 Internal audits are conducted by QA staff or qualified designees as determined by the QA Manager. Where possible it is desirable that the auditor be independent of the area being audited.

4.1.3 Technical method audits are performed for the Departmental audits. This type of audit is called a 'performance audit'. Elements evaluated during technical method audits typically include:

- compliance with method requirements;
- performance of actual practices per procedures stated in the SOP;
- performance and documentation of instrument maintenance;
- proper preparation, storage, use and documentation of standards;
- appropriate documentation via benchsheet, logbook and/or Laboratory Information Management System (LIMS) entries;
- initiation of Non-Conformance Reports (NCRs), where applicable;
- proper performance and documentation of data review;
- review of method data package deliverables, including aspects of data integrity.

Specific processes are evaluated during a 'systems audit'. Examples of laboratory system audits that are conducted annually include:

- electronic practices;
- project instructions and program specifications;
- sample receiving, handling and chain-of-custody;
- prescreening;
- compliance with Paragon's Standards Database;

- logbook records and reviews; and
- operations and manager's meetings.

Quality systems elements evaluated annually include:

- SOP review and revision;
- SOP reading compliance;
- Demonstrations of Capability (DOC) and other training records;
- internal audit program status (includes the annual Quality Systems Audit-QSA, the Annual Managerial Review-AMR and PT study performance);
- certifications;
- Non-conformance Reports (NCRs), corrective actions and audit Findings response;
- Method Detection Limits (MDLs);
- Quality Control (QC) limits;
- records and archiving;
- master and support equipment; and
- client interface.

Overall, Paragon performs approximately 13 internal audits annually, additional audits may be performed as needed (e.g., corrective action, per client request, as requested by laboratory management, etc.). The internal audit system is designed such that the compilation of all individual audits serve together as the QSA and AMR.

4.2 PRE-AUDIT ACTIVITIES

4.2.1 Before the audit, the auditor identifies the scope, intent, and expected duration of the audit to the Department Manager and any other appropriate laboratory staff, and coordinates the time the audit is to be conducted.

4.2.2 The auditor prepares an audit questionnaire (a Form 169 equivalent is used to conduct the audit, as this document also serves as the audit report; Form 168 is used to document and report the QSA). The questionnaire is developed from reading applicable documents such as the SOP, LQAP and/or client quality plans or contracts, and the Paragon Program Specification, as applicable.

4.3 AUDIT CONDUCT AND REPORTING

Internal audits are conducted in a professional manner, in the most efficient and effective way possible:

- keep on track, have a respectful and conversational demeanor.

- perform the audit through interview, observation and investigation; conduct the audit using the prepared questionnaire as a guide.
- ask focused but open questions (i.e., do not reveal the desired answer by the manner in which you ask the question); record responses on the audit questionnaire.
- if information given raises a question or possible concern, continue to explore the topic (i.e., it is not necessary or appropriate to stick strictly to the prepared questionnaire).
- a Finding is a non-compliance that requires correction, an Observation is food for thought. Discuss Findings and Observations with participants as they occur, as well as possible corrective actions or improvements.

  Corrective actions may be taken when an item is noted or an appropriate corrective action plan may be discussed. The possible effects the corrective actions may have on any in-process work or product already released to the client must be considered. The QA Manager and Laboratory Director will determine the need for and pursue client notification as deemed necessary. Where warranted, clients will be contacted in the most timely manner practicable.

  Be sure to document these topics discussed on the audit guide.
- give the auditee the chance to provide any other information they feel is pertinent.
- add summary auditor comments to the questionnaire as applicable and indicate on the audit guide whether or not follow-up is necessary.
- have participants initial the audit questionnaire.
- promptly debrief the area Supervisor; the area Supervisor is responsible for providing clarification as needed.
- attach notes or indicate references used to conduct the audit; submit the internal audit documentation to the QA Manager.

The QA Manager:

- in a timely manner, reviews the completed audit questionnaire and further discusses corrective actions with the Department Manager and Laboratory Director as necessary.

  Content and time frame (contingent upon extent of Finding, typically within 12 business days) for corrective action implementation are defined, as well as parties responsible for implementing the corrective action.
- Additional notes are made on the audit questionnaire/report and the information for the Finding is entered into the LIMS audit database for all parties to reference and follow further. The date for follow-up is marked on the QA Manager's calendar as well.

- A copy of the audit report is distributed to the Department Manager and Laboratory Director and is archived on the network.
- It is the joint responsibility of the QA Manager (or designee) and Department Manager (or designee) to ensure that agreed upon corrective measures were applied and are effective and to 'close-out' (i.e., deem the audit concerns as fully satisfied) the audit. Additional documentation is provided to the QA Department where necessary and added to the network archives. The information contained in the LIMS audit database must also be updated accordingly.

4.4 ANNUAL QUALITY SYSTEMS AUDIT (QSA)

Results of individual internal audits are compiled to comprise the annual QSA, which is a lab-wide review of conformance to Paragon's quality system. The QSA shall be conducted, managed and reported according to the procedures described in this SOP. PT study results and status of external audit responses are also highlighted in the QSA.

4.5 ANNUAL MANAGERIAL REVIEW (AMR)

A lab-wide Managerial Review shall be performed annually to asses operational effectiveness in terms of meeting Paragon's business goals. The AMR serves as a tool for evaluating and tracking potential improvements to laboratory facilities, services, processes, etc.

The AMR is performed by a designee under the direction of the Laboratory Director. The general techniques of scoping, assessment interview, reporting and follow-up outlined in this SOP shall be used to conduct the AMR. Interview of the Laboratory Director may be an integral component of the AMR.

Inputs to the AMR may include, but are not limited to:

- a snapshot summary of product generated (i.e., number of samples analyzed and the types of analyses performed);
- various business assessment reports (e.g., TAT, on- time delivery);
- output from the annual QSA (i.e., problem areas identified);
- interview of laboratory staff; and
- presentation of items discussed during strategic planning sessions and/or Manager's meetings.

The contents of the AMR are considered to be confidential. A confidential footer must appear as a component of the AMR report.

5. REFERENCES

This SOP describes in-house procedures developed by Paragon. The requirements established herein are compliant with various quality assurance guidance documents, such as the most current versions of the National Environmental Laboratory Accreditation Conference (NELAC) Standard, the Department of Energy (DOE) Quality

Systems for Analytical Services (QSAS) document, and the Department of Defense (DoD) Quality Systems Manual (QSM) for Environmental Laboratories.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 939 REVISION 3

TITLE: MANUAL RE-INTEGRATION POLICY AND PROCEDURES

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-14-07

QUALITY ASSURANCE MANAGER _____ DATE 11/12/07

LABORATORY MANAGER _____ DATE 11-14-07

HISTORY: Rev0, 9/10/01; Rev1, 4/8/03; Rev2, 3/13/06; Rev3, 11/12/07.

1. SCOPE AND APPLICATION

The intent of this standard operating procedure (SOP) is to define Paragon's policy and procedures for manual re-integrations of peaks integrated and stored by chromatography software systems. This SOP describes acceptable re-integration practices that will ensure consistently integrated and defensible data. This SOP is intended to ensure that Paragon achieves requirements set forth by Good Automated Laboratory Practices (GALP).

The policies and procedures described in this SOP are applicable to all data collected, processed, reported, and stored by a chromatography software system (e.g., gas chromatography, liquid chromatography, mass spectrometry, ion chromatography).

2. SUMMARY

Paragon's analysts optimize peak integration parameters to ensure that standard and sample responses are integrated correctly and consistently. Field samples and high-level standards may not be detected and integrated as consistently by the software systems. Although **Paragon's policy is to perform minimal re-integration,** in cases where the software has incorrectly identified or quantified a peak, it is necessary to re-integrate that peak.

All peaks that are integrated by a software system are reviewed by Paragon's analysts, reviewers, and/or Department Managers. The intent of reviewing the data system's integration is to ensure that:

- each peak has been identified correctly by the chromatography system (i.e., each qualitative identification is accurate); and
- each peak has been integrated correctly by the chromatography system (i.e., quantitative integration/calculation is correct).

If an analyst judges (and subsequent reviewers concur) that a peak has been misidentified and/or improperly integrated, then it is appropriate to overrule the data system's determination and manually re-integrate a peak, thereby adding or subtracting area from the

peak. **All manual re-integrations must be performed consistently throughout a given analytical process, and documented properly by the analyst and reviewers.**

3. RESPONSIBILITIES

3.1 The analyst who generates the raw data has the primary responsibility for the correctness and completeness of the data. It is the responsibility of the analyst to perform any manual re-integrations according to the policies outlined in this SOP and to complete all documentation during for review.

3.2 The analyst and reviewer are responsible for the generation and compilation of the data. These employees must ensure that all manual re-integrations are acceptable and properly documented. Any improper manual re-integrations must be corrected immediately and discussed with the analyst and Department Manager.

3.3 It is the responsibility of all personnel who perform data review to document any anomalies, out-of control events, or non-compliant events associated with the analysis of the samples. The reviewer must ensure that all manual re-integrations are properly documented.

3.4 The Department Manager is required to provide adequate training on the use of the data system and documentation requirements associated with manual re-integration. The Department Manager is also required to provide adequate training on the requirements set forth in this SOP and is responsible for monitoring manual re-integration practices.

4. PROCEDURE

4.1 There are many valid reasons to manually re-integrate a peak and this SOP does not address all possible situations. The following are examples of acceptable reasons to manually re-integrate a peak:

4.1.1 The data system has mis-identified a peak within a prescribed retention time window. An example is given in Figure 4.1.1a. The smaller peak identified and integrated by the data system is further from the center of the retention time window than the larger peak. If no retention time shifts were observed within the analytical run, then the peak closer to the center of the retention time window is the correct identification. In this case, the analyst shall reassign the qualitative identification of the peak as shown in Figure 4.1.1b.

4.1.2 The data system has integrated a peak incorrectly. Non-Gaussian peaks often cause inappropriate integrations and the analyst shall correct such over-integrations or under-integrations. A “tailing peak” is an example of a non-Gaussian peak that may be integrated incorrectly. An example is given in Figure 4.1.2a and 4.1.2c, which shows examples of pyridine and

benzoic acid integrated incorrectly. In this case, the analyst shall reassign the endpoint at the end of the peaks (see Figures 4.1.2b and 4.1.2d).

Excess column loading and detector saturation/shutdown are other examples of conditions that may result in non-Gaussian peaks.

4.1.3 The data system has interpreted an electronic spike as the baseline. This situation is encountered in end-to-end integration techniques used to quantify standards and samples for petroleum hydrocarbons (e.g., GRO, DRO). An example is given in Figure 4.1.3a, which shows a misinterpretation of the baseline by the data system as a result of an electronic spike. In this case, the analyst shall reassign the baseline to eliminate area as shown in Figure 4.1.3b.

4.1.4 The data system has mis-identified isomeric pairs. Examples of adjacent peaks that may require re-integration include: 1,3-dichlorobenzene and 1,4-dichlorobenzene; benzo(b)fluoranthene and benzo(k)fluoranthene; chrysene and benzo(a)anthracene. An example is given in Figure 4.1.4a, which shows incorrect identification of an isomeric pair. In this case, the analyst shall reassign the baseline as shown in Figure 4.1.4b.

4.1.5 A manual re-integration shall be performed if the intent is to ensure consistency between calibration standards and samples at similar concentrations. That is, if one manually re-integrates a standard, then the sample(s) shall be re-integrated in a similar fashion. In most cases, a data system will properly integrate a standard (in which matrix effect is not a factor) if the peak recognition algorithms have been optimized in the method file. Integration of a field sample may be complicated by co-extractives that cause the data system to treat a peak in a field sample differently from the same peak in a calibration standard.

4.2 The following are several **unacceptable** reasons to manually re-integrate a peak:

4.2.1 Manual re-integrations shall **not** be performed if the analyst doesn't "like the looks" of the data system's integration and believes that he or she can achieve a better-looking peak via manual re-integration. A peak should not be manually re-integrated for subjective, artistic reasons. If the re-integration will not change the area of the peak by more than 2-5%, then the re-integration should not be performed. In such marginal cases, it is preferable -- and more defensible -- to allow the data system to determine the integration.

4.2.2 Manual re-integrations shall **not** be performed in order to achieve initial or continuing calibration criteria. For example, removing area from a properly integrated peak in a continuing calibration verification (CCV)

standard with the intent of achieving the percent difference criterion is prohibited ("peak shaving"). Similarly, adding area to a properly integrated peak in an initial calibration verification (ICV) standard with the intent of achieving the percent difference criterion is prohibited ("peak enhancement").

Manual re-integrations shall **not** be performed in order to achieve established control limits for surrogates, internal standards, or spiking compounds. For example, removing area from a properly integrated internal standard with the intent of meeting the 50-200% criterion is prohibited ("peak shaving"). Similarly, adding area to a properly integrated surrogate compound with the intent of meeting a lower control limit is prohibited ("peak enhancement").

4.2.3 Manual re-integrations shall **not** be performed in order to verify tuning compounds. It is prohibited to circumvent the autotune checking function in the Enviroquant® software. The software chooses the apex of the tuning compound and one scan on either side of the apex. The autotune checking software also performs a background subtraction.

4.2.4 Manual re-integrations shall **not** be performed in order to achieve a quantitation of a target compound that is below the reporting limit (RL) or method detection limit (MDL).

4.2.5 Manual re-integrations shall **not** be performed in order to compensate for column degradation or instrument maintenance problems.

4.2.6 **Note that Paragon supports and enforces a zero tolerance policy for unacceptable manual re-integrations.**

4.3 The following documentation shall be provided for every peak that is manually re-integrated:

4.3.1 A printout of the data system's original integration and the analyst's manual re-integration along with the mass spectra. These printouts are known as "before" and "after" spectra. The intent of including both in the data package is to demonstrate the result of the manual re-integration. The "after" spectra printout shall be signed and dated by the analyst.

NOTE: As part of Paragon's data review process (SOP 052), a second reviewer's initials are documented on the associated data's review checklist. This data review checklist in not normally included in the client data package report.

4.3.2 The "after" spectra shall be annotated with the custom stamp provided to the laboratory.

4.3.3 The manual re-integration shall be identified on the raw data quantitation report. Most software systems append a qualifier flag ("m") that makes manual re-integrations apparent to all reviewers of the data. If the software system does not have the ability to append a flag, then the analyst must annotate the quantitation report with a flag that indicates manual re-integration.

4.3.4 The case narrative shall state how a data validator may locate manual re-integrations if they have been performed.

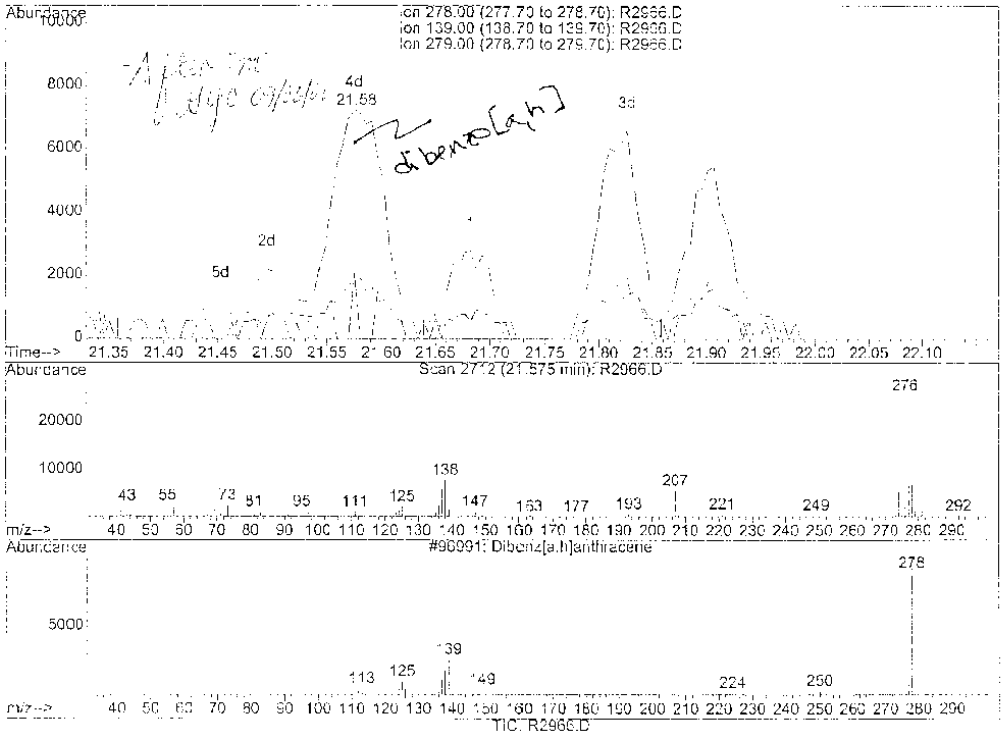
Quantitation Report (Qedit) FIGURE 4.1.4(b)

Data File : C:\HPCHEM\1\DATA\090501\R2966.D Vial: 13
Acq On : 5 Sep 2001 10:42 pm Operator: gcheng SOP
Sample : 0108214-11 Inst : HPSV-3
Misc : SOIL 8270PAH Multiplr: 1.00
MS Integration Params: RTEINT.P
Quant Time: Sep 6 11:49 2001 Quant Results File: temp.res

Method : C:\HPCHEM\1\METHODS\090501P3.M (RTE Integrator)
Title : GC-MS Semivolatiles SOP no. 506
Last Update : Thu Sep 06 10:59:48 2001
Response via : Multiple Level Calibration



(24) Dibenzo[a,h]anthracene (TV)

21.58min 2.89ng/uL m

response 24489

Ion	Exp%	Act%
278.00	100	100
139.00	20.30	5.37#
279.00	23.50	9.79#
0.00	0.00	0.00

MANUAL RE-INTEGRATION

- ☐ missed peak assignment
- ☒ assigned incorrect name to peak
- ☐ over-integrated peak's area
- ☐ under-integrated peak's area
- ☐ other _____

initials WA date 09.01.2001
