13.1.9 If you are running a heated procedure, set the heat controller temperature to the required setting by pressing the "on" button. To

adjust the temperature, press the "up" and "down" buttons. Press the "on" button again to lock in the setting.

NOTE: ***Be sure to turn the heat controller off at the end of the run!***

13.1.10 Prepare the appropriate working standards and place them in the sampler in order of decreasing concentrations. Complete filling of the sampler tray using the prepared samples to be analyzed.

13.1.11 After flushing the lines with deionized water, place the reagent lines into the proper reagent solutions and begin pumping reagent through the system.

NOTE: ***Some chemistries require a certain sequence in which reagents are introduced. Check the Lachat's operator's manual.***

13.1.12 If running a chemistry that requires a column, place the column ***on-line*** at this time by first turning the pump speed to the lowest setting, then placing the column switch to the "on-line" position. Turn the pump speed back to the required setting of 35rpm slowly, avoiding the introduction of any air bubbles.

13.1.13 Allow the reagents to be pumped through the entire system for at least 3-5 minutes.

13.1.14 Set up the computer as described in Section 13.2. Once the computer is set up, the system is ready to be started to begin calibration and data collection. Refer to the specific analyte procedure Sections of this SOP.

13.1.15 System shut down procedures are addressed in SOP Section 18.0.

13.2 COMPUTER SET UP PROCEDURE

13.2.1 From the Program Manager in Windows, double click on the "Lachat Instruments" icon. Then double click on the "Omnion FIA" icon. Click "OK" in the Omnion data system window.

NOTE: The sample probe will return to the wash reservoir and the injection valves will open and close.

13.2.2 Type your user name and password then click "OK". Click on the "Flow Injection Analysis" icon. If a username and password has not been assigned, have the System Manager assign one, or refer to the installation section of the *QuickChem 8000 Continuum Series*

Automated Ion Analyzer Omnion FIA Software Installation and Tutorial manual.

13.2.3 Load the method for the analyte(s) you want to run. From the menu bar, click on "File", then "Open Method". The path for Channel 1 is c:\Omnion\methods\method_temp\noxtemp.met. A new "Method" is created for each analysis each day of use. Each day's data are stored in an analyte subdirectory named for the year, using a mmdd format (e.g., c:\Omnion\methods\nox\2004\0412nox.met). This method pathway refers to NO_3^--N + NO_2^--N run on 04/12/2004.

NOTE: For native nitrite (only) analysis, substitute NO2 for NOX in all pathways. Example: c:\Omnion\methods\no2\2004\ 0412no2.met).

13.2.4 Load the master trays for the analyte(s) you want to run. From the "File" option on the menu bar, click on "Open Tray". Select the appropriate tray. The path for the default tray is c:\Omnion\trays\traytemp\noxtemp.tra. Each day's analysis data are stored in a subdirectory named for the year using a mmdd format (e.g., c:\Omnion\trays\2004\0412nox.tra). Fill in the sample identifications and dilution factors and save the tray by clicking "File", then "Save Tray As".

13.2.5 Check the calibration curve information by clicking on the "Review" icon, or pull down the "Method" menu and click on "Review Analyte Calibration Curve". If calibration curve data appears, clear the previous data by pulling down the "Method" menu and clicking on "Calibration Clear".

NOTE: You must clear the previous calibration curve before analyzing calibration standards.

13.3 MANIFOLD CLEANING PROCEDURE

If the baseline drifts, peaks are too wide, or other problems with precision arise, clean the manifold by the following procedure:

13.3.1 Place all reagent lines in deionized water and pump 2-5 minutes to clear the lines of all residual reagents.

13.3.2 Place the reagent lines and carrier in 1M hydrochloric acid (i.e., 82.6mL concentrated HCl brought to a final volume of liter using DI water). Allow the pump to run for several minutes to flush and clean the lines.

13.3.3 Place all the flushed lines in deionized water and pump until the HCl is thoroughly washed out.

13.4 Reattach all the reagent lines and resume pumping the reagents.

Note that the manifold cleaning procedure should be done with the column off-line or not attached.

14. PROCEDURE FOR DETERMINING NITRATE PLUS NITRITE

NOTE: When particulate matter is present, the sample must be filtered prior to the analyses. The sample may be centrifuged in place of filtration.

14.1 Prepare the calibration standards as described in Sections 7.0.

It should be noted that only the NO_3^--N standards and an NO_2^--N column check standard are used in the determination of nitrate + nitrite (see sequence below). This is done so that the standards are processed in the same manner as the samples (i.e., NO_3^--N content is reduced to NO_2^--N via the cadmium reduction column).

14.2 Prepare the samples as described in Sections 10.0 (aqueous leachates) or 11.0 (aqueous samples).

14.3 Fill the autosampler tubes with the appropriate standards and samples (including QC); load the auto sampler as described in Step 13.1.10 and per the run sequence depicted below:

Stage the autosampler per the following run sequence:

(1) 2.00mg/L NO_3^--N calibration standard
(2) 1.00mg/L NO_3^--N calibration standard
(3) 0.50mg/L NO_3^--N calibration standard
(4) 0.20mg/L NO_3^--N calibration standard
(5) 0.10mg/L NO_3^--N calibration standard
(6) 0.05mg/L NO_3^--N calibration standard
(7) 0.01mg/L NO_3^--N calibration standard
(8) 0.00mg/L NO_3^--N calibration standard
(9) 1.00mg/L NO_2^--N column check
(10) ICV (second source). Results must agree within ±10% of known value.
(11) ICB (Initial Calibration Blank, aqueous matrix Method Blank). *See also note below.* Any analyte concentration found must be less than the analyte reporting limit.
(12) Preparation (Method) Blank. Any analyte concentration found must be less than the analyte reporting limit.
(13) Laboratory Control Sample (LCS)

(14-21) maximum of 8 Field Samples (including MS/MSD)
(22) CCV (prepared like the 1.0mg/L calibration standard). Results must agree within ±10% of known value.
(23) CCB (DI water). Any analyte concentration found must be less than the analyte reporting limit.
(24-33) maximum of 10 Field Samples
(34) CCV
(35) CCB
(36) repeat Steps 24 through 35

NOTES: *It is often helpful to refer to your tray as a guide to ensure proper placement of standards and samples in the auto sampler.*

No more than ten samples (including QC) may be analyzed between the ICV/ICB and first CCV/CCB.

No more than ten samples (including QC) may be analyzed between CCV/CCB sets.

A CCV/CCB set must be analyzed to close-out the run sequence.

14.4 Complete the proper instrument set up as described in Steps 13.1.11 through 13.1.14.

14.5 Make sure the method and tray pathways are correctly set up and that the previous calibration information has been cleared as described in Section 13.2.

14.6 Start the run by clicking on the "Run Tray" icon. Click "Catalogue". Save the run data catalogue in the proper path using a mmdd format (i.e., c:\Omnion\data\nox\2004\0412nox.fdt). Click "Run" to begin the analysis process.

NOTE: The analysis may be paused or stopped in the middle of the run by clicking on the "Stop" icon. You can add samples or sample dilutions to your run by clicking on the "Tray" window and typing them in at the end of your saved tray. Save the updated information by first clicking "File", then "Save Tray". Restart the run by clicking "Resume". If you edit your tray by deleting standards or samples, you must "Save Tray As" by using the original file name with a "b" ("c", "d", etc.) added; example: 0412noxb.tra. Restart the analysis by renaming the data file in the same manner; example: 0412noxb.fdt.

15. PROCEDURE FOR DETERMINING NITRITE (ONLY) CONTENT

Prepare samples as described previous in Sections 10.0 or 11.0. To analyze for nitrite (only) content, use the same determination steps described in Section 14.0 above, with the following exceptions:

- Only the nitrite calibration standards (Section 8.0), and only the NO_2^--N QC samples (i.e., LCS and MS/MSD; Sections 10.0 and 11.0) need to be loaded into the autosampler (Step 13.1.10). *See run sequence below.*

- Aqueous field samples and the aqueous extracts of solid field samples analyzed for nitrite (only) do not require pH adjustment.

- The analyzer's cadmium column switch is placed in the "off-line" position for this analysis. The cadmium column is not used in nitrite determination.

- The pathway and naming convention used for the method is c:\Omnion\ methods\no2\2004\0412no2.met (substitute proper date, mmdd, for 0412).

  The pathway and naming convention used for the tray is c:\Omnion\trays\ 2004\0412no2.tra (substitute proper date, mmdd, for 0412).

  The pathway and naming convention used for the run data file is c:\Omnion\ data\no2\2004\0412no2.fdt (substitute proper date, mmdd, for 0412).

- <u>Stage the autosampler per the following run sequence:</u>

  (1) 0.50mg/L NO_2^--N calibration standard
  (2) 0.20mg/L NO_2^--N calibration standard
  (3) 0.10mg/L NO_2^--N calibration standard
  (4) 0.05mg/L NO_2^--N calibration standard
  (5) 0.02mg/L NO_2^--N calibration standard
  (6) 0.01mg/L NO_2^--N calibration standard
  (7) 0.00mg/L NO_2^--N calibration standard
  (8) ICV (second source). Results must agree within ±10% of known value.
  (9) ICB (Initial Calibration Blank, aqueous matrix Method Blank). *See also note below.* Any analyte concentration found must be less than the analyte reporting limit.
  (10) Preparation (Method) Blank. Any analyte concentration found must be less than the analyte reporting limit.
  (11) Laboratory Control Sample (LCS)
  (12-19) maximum of 8 Field Samples (including MS/MSD)
  (20) CCV (prepared like the 0.25mg/L calibration standard). Results must agree within ±10% of known value.
  (21) CCB (aqueous matrix method blank, DI water or KCl solution). Any analyte concentration found must be less than the analyte reporting limit.
  (22-31) maximum of 10 Field Samples
  (32) CCV
  (33) CCB
  (34) repeat Steps 22 through 33

NOTES: *It is often helpful to refer to your tray as a guide to ensure proper placement of standards and samples in the auto sampler.*

No more than ten samples (including QC) may be analyzed between the ICV/ICB and first CCV/CCB.

No more than ten samples (including QC) may be analyzed between CCV/CCB sets.

A CCV/CCB set must be analyzed to close-out the run sequence.

16. PROCEDURE FOR DETERMINING NITRATE (ONLY) CONTENT

Nitrate (only) is determined by subtracting the nitrite (only) sample results from the combined Nitrate + Nitrite sample results. An Excel spreadsheet is used to conduct all nitrate sample calculations. Refer to SOP Section 19.0.

17. REPORTING RESULTS

After the analysis is complete, print a copy of the following analyzer reports (access proper menu, "Open", "Print") and copy data to a data disk (access proper menu, "Import" and save to drive A:\, to be transferred to the LIMS:

- Tray Table(s) with any written comments and handwritten date and initials of analyst.
- Run Time Report(s); must be hand dated and initialed by the analyst.
- Import data (as txt. File) to be transferred i:\oprtns\wtchm\limsdata.

Results are calculated as described in SOP Section 19.

18. SYSTEM SHUT DOWN PROCEDURE

NOTE: ***Some methods require certain reagents to be removed last. Check the Lachat's operator's manual.***

18.1 If applicable, turn the pump setting down then switch the column to the "off-line" position.

18.2 Turn the heat down.

18.3 Remove the reagent lines from each reagent and place into deionized water. Turn the pump setting up so that the DI water is pumped through. Continue to run the system and allow the transmission lines to rinse for 5-10 minutes. ***This is a critical step in preventive maintenance of the manifolds.*** Then, allow the lines to suck air briefly to remove any liquid.

18.4 Release the cartridge tension on the transmission line to the sipper bath and remove the line from the deionized water. Turn the heat controller off (if required).

18.5 Make sure the appropriate files are saved, then exit and log off from the current Omnion session. Exit Windows and shut down the computer.

18.6 Remove the reagent transmission lines from the deionized water and allow all liquid to be pumped out of the manifold by pumping air through the lines.

18.7 Turn off the pump, auto sampler and manifold unit by switching off the power strip.

18.8 Release the pump tube cartridges tension completely to avoid the tubing from becoming crushed.

18.9 To remove the manifold, follow the Lachat set up procedure (Section 13.1) ***in reverse order***, starting with Step 13.1.8.

19. CALCULATIONS

19.1 Excel spreadsheets are used to verify spike information and calculate nitrate results by difference. The pathways for each Excel spreadsheet template are as follows:

Nitrate + nitrite, Nitrite, (aqueous and soil samples), spike verification information: i:\oprtns\wtchm\nox\template\noxautowver.xls.

Nitrate, calculation by difference:
i:\oprtns\wtchm\no3\template\no3temp.xls.

Call up each Excel spreadsheet template you need to use and rename it in the year's subdirectory using the identity of the mmdd (without the year reference) in the batch as a naming convention.

Example: i:\oprtns\wtchm\nox\2002\1211nox.xls.

19.2 The standard curve is plotted by the Lachat and is imported, along with all run data, to LIMS. Linear regression analysis of the standard curve yields a coefficient of determination (r^2) value. For the standard curve to be accepted, the r^2 value must be $\geq$ 0.995.

19.3 Applicable sample adjustments (i.e., dilutions, % solids) are made in LIMS and final sample analyte concentrations are quantitated. LIMS also calculates QC sample % recoveries and RPD values.

The representative sample calculation for NO_3^--N + NO_2^--N in soil samples is as follows:

$$\text{Concentration (mg/L)} = \frac{A \bullet D \bullet V}{W_{dry}}$$

where:

A = mg/L NO_3^--N + NO_2^--N (calculated from the sample peak area using the standard curve equation)

D = Dilution factor (if applicable)

V = Extract volume (mL); (40mL if this SOP is followed without deviation)

W_{dry} = Dry weight (g) of soil extracted (see equation below)

$$W_{dry} = \frac{W_{moist} \bullet \% \text{ solids}}{100}$$

where:

W_{moist} = moist weight of soil extracted

20. QUALITY CONTROL

20.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and are processed together as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike and duplicate (MS/MSD). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

20.2 METHOD BLANKS

Method blanks (MB) are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the MB consists of 5mL DI water or 4.0g clean sand. Any analyte concentration found in the blank must be less than the analyte reporting limit.

20.3 LABORATORY CONTROL SAMPLE

The Laboratory Control Sample (LCS) is analyzed to measure the accuracy of the method. A known amount of analyte is spiked into an aliquot of representative clean matrix and analyzed. For this method, 5mL DI water (representative of aqueous samples) and 4.0g clean sand (representative of solid samples) were used as the clean matrices.

LCS results obtained are compared to results expected using the equation presented below:

$$\text{Percent Recovery (\%R)} = \frac{\text{Concentration}_{Found}}{\text{Concentration}_{Expected}} \times 100$$

where:

$Conc_{Found}$ = analyte concentration found in the LCS

$Conc_{Expected}$ = anticipated analyte concentration based on known amount spiked

To be acceptable, LCS recovery must be between 90% and 110% (aqueous matrix) and 85% and 115% (soil matrix) of the expected concentration.

20.4 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Matrix spikes (MS) consist of representative field samples into which known concentrations of target analyte(s) are spiked. MSs are analyzed as a means of determining the effect of matrix on target analyte detection.

The matrix spike is prepared in duplicate (MSD) to serve as a laboratory duplicate, which is analyzed to measure the precision of the analysis.

Analyte recovery for the MS/MSD is calculated as shown below:

$$\%R = \frac{Concentration_{Found} - Concentration_{Sample}}{Concentration_{Target}} \times 100$$

where:

$Conc_{Found}$ = analyte concentration found in the MS or MSD
$Conc_{Sample}$ = analyte concentration found in the native field sample
$Conc_{Target}$ = analyte concentration anticipated based on known amount spiked

The advisory quality control limits for MS/MSD recovery are set at 75-125%.

Precision is evaluated as the Relative Percent Difference (RPD) between the sample and its duplicate. RPD is calculated as shown below:

$$RPD\ (\%) = \frac{|Result_x - Result_{Dup}|}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

The RPD should be $\leq$20 to be accepted.

20.5 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study should be performed as needed and at a minimum, every 6 months.

20.6 LINEAR CALIBRATION RANGE STUDY

A linear calibration range (LCR) study must be performed at minimum, every six months, or whenever there is a significant change in operator, background or instrument response. The study must consist of a blank and a minimum of three standards. The range of the linearity study is broader than that defined as the linear calibration range, since the purpose of the linearity study is to verify the

instrument's overall capabilities. All verification data must agree within ±10% of expected values.

21. DEVIATIONS FROM METHOD

21.1 Section 6.5 of Method 353.2 provides for treated distilled water for the preparation of samples, standards and reagents. Paragon uses deionized (DI) water generated by the in-house laboratory deionization system. It has been demonstrated, through the analysis of MDL studies and PT samples that Paragon's DI water is free of NO_3^--N and NO_2^--N and meets ASTM Type I and II standards. Therefore, no additional treatment is applied.

21.2 SM 4500-NO_3^- I reagent citations, Section 6 of Method 353.2, and QuickChem Method 10-107-04-1-C all provide for the preservation of NO_3^--N and NO_2^--N stock standards with chloroform. Paragon closely monitors the performance of and assigned shelf lives of the 1000 mg/L nitrate (NO_3^--N) and nitrite (NO_2^--N) stock standards and does not preserve these standards with chloroform.

21.3 Section 6.9 of Method 353.2 discusses the creation and use of a wash solution. Because the type of automated flow injection analyzer used by Paragon provides a constant flow of reagents through the system, the use of a separate wash solution is not required.

21.4 The amount of EDTA used in the creation of the ammonium chloride/EDTA buffer solution presented in Section 6.10 of Method 353.2 (0.1g) differs from that presented in the reagent citations of SM4500-$NO3^-$ I (1.0g). Paragon uses an approximate median amount of 1.0g, because this amount is cited in the manufacturer's method, QuickChem Method 10-107-04-1-C.

The recipe for the ammonium chloride/EDTA buffer solution presented in Section 6.10 of Method 353.2 mentions the addition of 1/2mL "Brij-35" (available from Technicon Corporation) to the ammonium chloride/EDTA buffer solution. The addition of this material is not provided for in SM4500-$NO3^-$ I or in the manufacturer's method. Paragon does not add this material the ammonium chloride/EDTA buffer solution.

21.5 Section 6.0 of Method 353.2 provides for the use of KNO_2 in the creation of the nitrite standards. Paragon uses $NaNO_2$ to make the nitrite standards as provided for in Section 3g of SM4500-NO3- I.

21.6 Paragon uses a 200mg/L intermediate nitrite solution rather than the 100mg/L intermediate nitrite solution described in Method 353.2 (Section 6.0).

21.7 Section 10 of this SOP describes a solid preparation procedure. Paragon notes that Method EPA 353.2 is applicable to the measurement of nitrate/nitrite in surface and saline waters, and domestic and industrial wastes (Section 1.1).

21.8 Section 7.1 of Method 353.2, and QuickChem Method 10-107-04-1-C all provide for the adjustment of sample pH with Ammonium Hydroxide and Hydrochloric Acid. Paragon uses 10N Sodium Hydroxide and the actual preserved sample to adjust the pH. If samples are drinking water samples analyzed for compliance monitoring, then concentrated ammonium hydroxide (NH_4OH) will be used as the pH-adjusting reagent.

22. SAFETY, HAZARDS AND WASTE DISPOSAL

22.1 SAFETY HAZARDS

22.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

22.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

22.1.3 Wear gloves, safety glasses, and lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

22.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids)

22.1.5 All flammable compounds must be kept away from ignition sources.

22.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

22.1.7 Food and drink are prohibited in all lab areas.

22.2 WASTE DISPOSAL

22.2.1 Solid filtrate residues and any other solid residues shall be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

22.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

22.2.3 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Health and Safety Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

7/6/06: Added reference Program Specification directive in "Responsibilities".

4/10/06: Updated Excel spreadsheet references to LIMS. Added DOCUMENT REVISION HISTORY.

7/20/08: Minor clerical corrections and procedural clarifications. Use of 0.2% copper sulfate solution added to REAGENTS and PROCEDURE. Use of leur-lock syringe to flush column rather than putting column under vacuum changed Section 12.

Analytical Method: EPA 353.2, SM 4500-NO_3 I	**Parameter:** Nitrate, Nitrate plus Nitrite, and Nitrite in water and soil		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point	As needed (i.e., at on-set of analyses or repeated when continuing calibration does not meet criteria)	Coefficient of determination (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); second source; at or below midpoint	Once after each initial calibration	Response must agree within $\pm$10% of initial calibration	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Blanks: Method Blank (MB), Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	The MB may be run initially as part of the calibration curve, the ICB is run following the calibration curve. CCBs are run following the CCV (after every ten samples), and to close an analytical run sequence	NO_2^--N / NO_3^--N content of the blank must be < RL	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Laboratory Control Sample (LCS)	One LCS must be run per 20 environmental samples of similar matrix	Results must agree within $\pm$10% of expected values for aqueous sample analyses; within ±15% for solid matrix extract analyses	Check all calculations. If no computation errors are found, prepare a fresh LCS and analyze. If criteria are still not met, system must be recalibrated and all samples run since the last acceptable LCS must be reanalyzed.
Continuing Calibration Verification (CCV); at or below midpoint; first source	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis)	Response must agree within $\pm$10% of initial calibration	Check that calculations and preparation are correct, evaluate/ correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Matrix Spike (MS)	One per batch of $\leq$20 field samples of similar matrix	Recoveries should meet advisory limits of ±25% of the expected values; client-specified criteria may apply	Compare with LCS results and check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (laboratory) Duplicate	One per batch of $\leq$ 20 field samples of similar matrix	(See MS recovery criteria above). RPD advisory limit is $\leq$20; client-specified criteria may apply	(See MS recovery criteria above). For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.

Analytical Method: EPA 353.2, SM 4500-NO_3 I	**Parameter:** Nitrate, Nitrate plus Nitrite, and Nitrite in water and soil		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	As needed; at minimum every 6 months.	Positive result < the analyte reporting limit (RL).	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).
LCR Study	As needed, at minimum every 6 months.	All verification data must agree within ±10% of expected values.	Determine the reason for failure and fix problem with the system. Repeat the LCR study. If criteria still not met, discuss with QA Manager.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1128 REVISION 9

TITLE: DETERMINATION OF SPECIFIC CONDUCTANCE – METHODS EPA 120.1, SW9050A AND SM2510B

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11/6/07

QUALITY ASSURANCE MANAGER _____ DATE 11/6/07

LABORATORY MANAGER _____ DATE 11-6-07

HISTORY: **SOP 643:** Rev0, 2/12/92; Rev1, 6/30/92; Rev2, 2/16/95; PCN# 357; Rev3, 3/15/96; Rev4, 10/7/99. **SOP 1128:** Rev5, 4/29/02; Rev6, 2/10/03; Rev7, 4/16/04, re-released w/o revision 3/29/05; Rev8, 7/23/05, re-released w/o revision 8/15/07; Rev9, 11/6/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the measurement of specific conductance of drinking, ground, surface, and saline waters and domestic and industrial aqueous wastes. This SOP is based on Methods EPA 120.1, SW9050A and SM2510B. This SOP also includes adapted procedures for determining specific conductance of solid matrix samples (via conductivity determination of aqueous leachates).

2. SUMMARY

Conductivity is a numerical expression of the ability of an aqueous solution to carry an electrical current. Conductivity is measured using a Wheatstone bridge apparatus (a component of the conductivity meter). The ability of the solution to carry an electrical current is dependent on the presence of ions, their total concentrations, mobility, valence, relative concentrations, and on the temperature at the time of measurement. Solutions containing compounds that dissociate well are good conductors.

The specific conductance of a sample is measured in µmhos/cm using a conductivity meter equipped with a dip type conductivity cell. The measurements are made at 25±2°C. Results are reported at 25°C.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to the SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate and interpret acceptable

results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency evaluation test.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Temperature will affect specific conductance results due to the change in mobility of charged ions with changes in temperature. For most accurate results, the temperature of the calibrating standard and samples should be the same and as close to 25°C as possible. In order to provide an acceptable controlled measurement temperature, the calibration standards and samples are placed in a water bath maintained at 25±2°C for at least 1 hour and until just before analysis. Record the temperatures of the standards and samples on the bench sheet based on the actual water bath temperature.

4.2 A clean conductivity cell is critical to ensure accurate measurement of specific conductance. The specific conductance cell can become coated with oil and other materials. It is essential that the cell be thoroughly rinsed and, if necessary, cleaned between samples. A chromic-sulfuric acid cleaning mixture is used for cleaning; see manufacturer's instructions.

4.3 The electrodes of the conductivity cell are coated with platinum black. If the coating appears to be wearing or flaking off the electrodes, the cell should be cleaned and the electrodes re-platinized. Section 2c of Method SM2510B details the re-platinizing procedure.

5. APPARATUS and MATERIALS

5.1 Fisher Model Accumet 50 combination pH/conductivity meter or equivalent

5.2 Conductivity cell, YSI dip type, Model 3440, constructed from Pyrex™ glass with platinum electrodes or equivalent

5.3 Water bath maintained at 25±2°C

5.4 Centrifuge tubes, polypropylene, 50mL and 250mL, with caps

5.5 Wash bottle (filled with DI water to rinse cell between sample analyses)

5.6 Pipet, plastic, disposable

5.7 TCLP tumbler for soil preparation

6. REAGENTS

6.1 Deionized (DI) water with a conductivity less than 1µmho/cm.

6.2 Standard Potassium Chloride (KCl), 0.01M: First source. Dissolve 0.7456g anhydrous KCl in deionized water and bring to 1000mL final volume. This solution has a specific conductance of 1,413µmho/cm (1.413mmho/cm) at 25°C. *Shelf Life = 1 year.*

6.3 Standard Potassium Chloride, 0.005M: Second source. Dissolve 0.3728g anhydrous KCl in deionized water and bring to 1000mL final volume. This solution has a specific conductance of 718µmho/cm. *Shelf Life = 1 year.*

7. SAMPLE COLLECTION, HANDLING, PRESERVATION, AND HOLDING TIME

7.1 All samples should be collected according to an approved sampling plan.

7.2 Sample containers must be prewashed and thoroughly rinsed (certified clean containers may be used). Both plastic and glass containers are suitable.

7.3 The determination of conductivity is ideally a field measurement. Referenced laboratory methods state that conductivity should be analyzed within 24 hours, and if analysis within this time frame is not possible, samples should be filtered through a 0.45-micron filter and stored at 4±2°C. Paragon strives to analyze all conductivity samples as soon as possible, but allows for up to 4 days after receipt. Prior notification and/or special arrangements for Saturday sample receipt and analysis are encouraged between the client and the laboratory. However, the intention of the 4-day window is to accommodate the scenario of Friday sample collection, followed by login and release of the sample to the laboratory for analysis the following Monday, with the laboratory performing the analysis within 1 day of internal receipt. See also Section 10.1.

8. PROCEDURE

8.1 INSTRUMENT CALIBRATION

8.1.1 Connect the conductivity probe and turn the conductivity meter on. On the keypad of the conductivity meter, press “conductivity” to set the meter to conductivity mode.

8.1.2 Pour a portion of 0.01M Standard KCl solution into a centrifuge tube to use for cell preparation purposes. Use a plastic disposable transfer pipet to rinse the conductivity cell with the aliquotted 0.01M Standard

KCl solution. Use several small volumes, totaling about 5mL. Collect the wash solution in a waste beaker.

8.1.3 Immerse the conductivity cell in 45mL of 0.01M KCl standard, in order to fully submerge the probe's inlet holes when 50mL centrifuge tubes are used. Dip the electrode a few times to properly wet the cell and remove air bubbles. Allow the electrode to soak in 0.01M KCl solution until the displayed reading stabilizes.

8.1.4 The measurement of conductivity is temperature sensitive. In order to maintain consistent solution temperatures (and to obviate the need to apply temperature correction factors), Paragon uses a water bath maintained at 25±2°C.

Invoke the electronic spreadsheet (I:\Oprtns\ WTCHM\Specific Cond\template\spctemp.xls), and 'Save As' the current date. Record the temperature of the water bath to the nearest 0.5°C on the spreadsheet.

8.1.5 Remove the conductivity cell from the soak solution and rinse with DI water. Obtain an aliquot of 0.01M KCl solution that has been equilibrated in the water bath. Rinse the conductivity cell with several small volumes of solution; immerse the conductivity cell in the remaining solution. Press, "standardize" on the meter's keypad.

8.1.6 Set cell constant equal to "1 cm^{-1}" and press, "enter".

8.1.7 Note the conductivity value. This is the "displayed conductivity value". **The displayed conductivity value should be 1.41±0.14mmho/cm.**

NOTE: The instrument displays conductivity readings in milli-Siemens/cm (mS/cm) for conductivities greater than 1mS/cm. Siemens/cm units are the same as mho/cm units. For conductivities less than 1mS/cm, the display will show results in micro-Siemens/cm (µS/cm). 1mho/cm is equal to 1000mmho/cm units. 1mmho/cm is equal to 1000µmho/cm. *Be careful to use the correct units for the numerical value recorded.*

8.1.8 Use the following equation to calculate the actual cell constant:

$$\text{Cell Constant} = \frac{1.41\ \text{mmho/cm}}{\text{"displayed conductivity value" (mmho/cm)}}.$$

The cell constant value should be close to "1".

8.1.9 After calculating the cell constant, press, "standardize" on the keypad of the meter and enter the calculated result.

8.1.10 The instrument is now calibrated.

8.2 AQUEOUS EXTRACTION OF SOLID SAMPLES

8.2.1 Weigh a representative 10.0g aliquot of moist sample into a labeled 250mL disposable polypropylene centrifuge tube.

8.2.2 Select one sample representative of the batch and prepare a second 10.0g aliquot of moist sample to serve as the laboratory duplicate.

8.2.3 To all of the above add 100mL DI water.

8.2.4 Cap centrifuge tubes and shake for 1 hour on the TCLP tumbler.

8.2.5 Centrifuge for about 15min @ 3500rpm.

8.3 SAMPLE PREPARATION FOR ANALYSIS

8.3.1 Pour approximately 45mL of aqueous sample or extract into a labeled, dedicated, clean 50mL polypropylene centrifuge tube. Select one aqueous field sample per every ten field samples and prepare a duplicate aliquot for analysis.

8.3.2 Prepare the Initial Calibration Verification (ICV) standard from a ***second source standard*** by pouring an approximate 45mL aliquot of 0.005M Standard Potassium Chloride solution into a labeled polypropylene centrifuge tube.

8.3.3 Prepare the Continuing Calibration Verification (CCV) standard from a ***first source standard*** by pouring an approximate 45mL aliquot of 0.01M Standard Potassium Chloride solution into a labeled polypropylene centrifuge tube.

8.3.4 Place the centrifuge tubes in the water bath (at 25±2°C) and allow the solution temperatures to equilibrate (approximately 1 hour).

8.4 SAMPLE ANALYSIS

8.4.1 Record the temperature of the water bath to the nearest 0.5°C on the spreadsheet. Remove the conductivity cell from its soak solution and rinse thoroughly with deionized water.

8.4.2 Obtain the ICV from the water bath. Use a disposable pipet to rinse the conductivity cell with several small volumes of solution. Immerse the

conductivity cell in the remainder of this solution. Dip the electrode a few times to properly wet the cell and remove bubbles. The solution should completely cover the electrode.

8.4.3 Allow the reading to become stable. Record the stabilized conductivity reading (µmhos/cm) on the laboratory bench sheet template to 3 significant figures.

NOTES: Do not remove samples from the water bath until **just before** analysis in order to maintain proper temperature.

The ICV must be successfully analyzed before sample analyses can begin. The result must be 718±72µmho/cm. If the result is not within these limits, a problem exists and must be corrected before analyzing samples.

8.4.4 Clean the conductivity probe with deionized water between samples and repeat the techniques above until all samples have been analyzed. A CCV must be analyzed after every 10 samples and to close out the analysis sequence. The CCV result must be **1.41±0.14mmho/cm**. If the CCV result is outside these limits, a problem exists. When the problem has been corrected, restandardize the instrument and reanalyze all affected samples (i.e., samples that are not bracketed by passing calibration verifications). **Return the CCV to the water bath following each reading to maintain its temperature at 25±2°C.**

9. QUALITY CONTROL

A duplicate sample is analyzed per every 10 field samples as a measurement of analytical precision. Precision is expressed as the Relative Percent Difference (RPD) between a sample and its duplicate (see calculation below):

$$\text{RPD (\%)} = \frac{|\text{Result}_x - \text{Result}_{Dup}|}{\frac{(\text{Result}_x + \text{Result}_{Dup})}{2}} \times 100$$

The RPD should be $\leq$15% to be accepted.

10. DEVIATIONS FROM METHOD

10.1 Section 4.2 of Method EPA 120.1 states that analysis should be performed within 24 hours of collection. If not, samples should be filtered and stored at 4±2°C. Section 6.3 of Method SW9050A states that aqueous samples should be stored at 4±2°C and analyzed within 28 days. It is Paragon's policy to perform the analysis immediately upon receipt if the sample is received within 24 hours after sampling. If this is not possible, the laboratory will perform the analysis as soon as possible after receipt (sample stored at 4±2°C), but within four days of receipt.

Because Paragon analyzes the sample as soon as possible, samples are not filtered prior to storage.

10.2 Methods SW9050A and SM2510B reference use of a thermometer graduated to 0.1°C and directs that conductivity measurements be made and recorded to 0.1°C. Method EPA 120.1 stipulates the use of a thermometer graduated to 0.5°C and directs that 2% of the reading be added for each degree below 25°C and that 2% of the reading be subtracted for each degree above 25°C. Paragon equilibrates all standards and samples in a water bath maintained at 25±2°C. Because of the uniformity with which standards and samples are treated within prescribed temperature control limits, Paragon does not apply temperature correction factors to the analysis results. Based on the directives contained in Method EPA 120.1, maximum error is ±1% of the conductivity reading obtained.

10.3 Section 5.2 of Method SW9050A states that suitable conductivity water should be generated by passing distilled water through a mixed-bed deionizer and discarding the first 1,000mL. Conductivity should be less than 1µS/cm. It should be noted that deionized (DI) water available from the Paragon's deionized water system taps generates DI water of quality that meets or exceeds this criterion. Details regarding Paragon's DI water system and its monitoring can be found in SOP 319.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, Reactivity ratings and date opened.

11.2 WASTE DISPOSAL

11.2.1 The aqueous samples shall be disposed of in the Aqueous Laboratory Waste.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

3/29/05: Updated format.

7/23/05: Program specification language added.

8/15/07: Added DOCUMENT REVISION HISTORY Section.

11/6/07: Expanded Section 7.3 discussion and referenced Section 10.1 as well.

Analytical Method: E 120.1; SW 9050A; SM 2510B	**Parameter:** Specific Conductance		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Calibration: Conductivity meter standardized per manufacturer's instruction	Daily; each day of use.	0.01 M Standard KCl used for standardization; displayed conductivity value must read 1.41 0.14mmho/cm.	If targeted conductivity value not displayed; check meter settings and connections and condition of the conductivity cell. Check temperature of standardization solution and reanalyze. If problem not corrected, prepare fresh KCl standard (oven conditioning of KCl salt may be required prior to preparation) and repeat standardization.
Initial Calibration Verification (ICV); second source	Daily; each day of use. Run following standardization and before any samples are analyzed.	Results for the ICV must agree within ±10 % of the 718µmho/cm expected (true) value (646 - 790µmho/cm).	If ICV criterion not met, check for preparatory error (remake if necessary) and conductivity cell function; reanalyze. If ICV criterion still not met, restandardize meter.
Continuing Calibration Verification (CCV); first source	Run to bracket each set of 10 environmental samples processed and to closeout the analytical sequence.	Results for the CCV must agree within ±10 % of the 1.41mmho/cm expected (true) value (1.27-1.55mmho/cm).	If CCV criterion not met, check for preparatory error (remake if necessary) and conductivity cell function; reanalyze. All samples run since the last acceptable CCV must also be reanalyzed.
Laboratory Duplicate (DUP)	One per set of ≤10 field samples.	RPD must be ≤15%.	Check all calculations for errors. If no errors are found, discuss with Department/Project/QA Managers.

STANDARD OPERATING PROCEDURE 1129 REVISION 6

TITLE: **DETERMINATION OF AMMONIA USING AN AUTOMATED PHENOLATE PROCEDURE -- METHODS EPA 350.1, SM4500 NH_3-N H AND QUIKCHEM METHOD 10-107-06-1-C**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11/6/07

QUALITY ASSURANCE MANAGER _____ DATE 11/6/07

LABORATORY MANAGER _____ DATE 11-6-07

HISTORY: Rev0, 4/29/02; Rev1, 12/13/02; Rev2, 2/10/03; Rev3, 3/6/03; Rev4, 3/29/05; Rev5, 7/26/05; Rev6, 11/6/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) references EPA Method 350.1, Standard Method (SM) 4500 NH_3-N H, and Quikchem Method 10-107-06-1-C for the determination of ammonia as nitrogen (NH_3-N) in drinking, ground and surface waters, domestic and industrial wastes, and solid samples.

2. SUMMARY

This procedure is based on the Berthelot reaction and uses a Lachat Quikchem auto flow injection analyzer procedure. Ammonium (NH^{4+}) present in the sample or extract reacts with alkaline phenol and then with sodium hypochlorite to form indophenol blue. Sodium nitroprusside (sodium nitroferricyanide) is added to enhance color development. The absorbance of the reaction product is measured at 630nm, and is directly proportional to the original ammonium concentration. Test values are reported as NH_3-N.

To analyze solid matrix samples, first an aqueous sample extract is created by extracting an aliquot of solid sample with 2M potassium chloride (KCl) solution (1:10 ratio), and shaking on a TCLP-type rotary tumbler. The exchangeable NH^{4+} cations contained in the sample aliquot are displaced from the soil by the high concentration of K^+ cations available in the extraction solution. The ammonium displaced to the extract is then determined with the auto analyzer.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of

Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Calcium and magnesium ions may precipitate if present in sufficient concentrations. EDTA solution is added to the prepared sample in-line in order to prevent this problem.

4.2 Excessive color, turbidity and certain organic species may interfere. Turbidity is removed by manual filtration through a 0.45µm pore diameter membrane filter. Sample color may be corrected for by running the samples through the manifold without color formation. A corrected absorbance reading is then obtained by subtracting the initial absorbance (without color formation) from the final absorbance reading to obtain a corrected absorbance reading. Paragon does not routinely correct for color.

4.3 Standard procedures recommend acidifying samples to be analyzed for ammonia as nitrogen to pH < 2 for preservation. Samples that are over-acidified with sulfuric acid preservative will cause a negative response within the peak area during analysis. To overcome this, EDTA buffer is added to all prepared samples as part of the analysis process.

5. APPARATUS AND MATERIALS

5.1 Flow injection analysis equipment designed to deliver and mix/react sample and reagents in the required order and ratios. Lachat Quikchem 8000, or equivalent, equipped with the following:

- Autosampler
- Disposable autosampler tubes
- Multi-channel peristaltic pump
- heating unit
- Instrument manifold
- Spectrophotometric detector with 630nm filter in place
- Data system (Windows 3.1 and Ominion software version 1.4), or equivalents

5.2 volumetric dispensers, Eppendorf™ or equivalent, capable of dispensing 0.01-5.0mL

5.3 TCLP-type mechanical tumbler, capable of 1 hour soil extraction by agitation

5.4 centrifuge, capable of sustaining 3500rpm

5.5 centrifuge tubes with caps, disposable, 50mL

5.6 volumetric flasks, various sizes, Class A

5.7 magnetic stir bars, Teflon coated

5.8 magnetic stir plate, capable of variable speed control

5.9 analytical balance, capable of weighing to 0.0001g

5.10 Corning pH meter, Model 320 or equivalent, and appropriate buffer solutions for calibration. Capable of a two-point calibration.

5.11 syringe, with 0.45µm filter disk

6. REAGENTS

NOTES: To prevent bubble formation, degas all solutions, *except those noted*, with helium (He). Use He at 140kPa (20lb/in^2) applied through a helium degassing tube (Lachat Part 50100, or equivalent). Bubble He vigorously through the solution for one minute.

Only ACS grade or better chemicals and reagents may be used. Unless otherwise noted, reagents may be stored in polypropylene containers.

6.1 Deionized (DI) water. Obtained from the laboratory DI water system.

6.2 Ottawa sand. EMD, SX0075-3 or equivalent. *Shelf life = indefinite.*

6.3 Sodium Phenolate Solution: In a 500mL volumetric flask, dissolve 44mL of 88 % liquefied phenol or 41g of crystalline phenol (C_6H_5OH) in approximately 300mL of DI water. While stirring, *slowly* add 16g sodium hydroxide (NaOH). Cool. When cool, dilute to 500mL with DI water. Cap tightly and gently invert several times to mix. *Do not degas this reagent. Shelf Life = 1 year.*

CAUTION: Wear gloves. Phenol causes severe burns and is rapidly absorbed into the body through the skin.

6.4 Sodium Hypochlorite (NaOCl) Solution: In a 200mL volumetric flask, dilute 100g Regular Clorox bleach (5.25% sodium hypochlorite, can be purchased a local store) to the mark with degassed DI water. Cap and invert several times to mix. *Shelf Life = 1 year.*

6.5 EDTA Buffer, 5%: JT Baker, L693-07 or equivalent. In a 1L volumetric flask, dissolve 50.0g of disodium ethylenediamine tetraacetate ($C_{10}H_{14}Na_2O_8 \bullet 2H_2O$) and 11.0g of sodium hydroxide (NaOH) in about 900mL of degassed DI water. Dilute to 1L with degassed DI water. Cap and gently invert several times to mix. *Shelf Life = 1 year.*

6.6 Sodium Nitroprusside (Sodium Nitroferricyanide) Solution, 0.35%: Mallinckrodt, 7828-02 or equivalent. In a 1L volumetric flask containing a small amount of degassed DI water, dissolve 3.50g sodium nitroprusside (sodium nitroferricyanide; $[Na_3Fe(CN)_5NO \bullet 2H_2O]$) and dilute to 1L with degassed DI water. *Store in amber glass and refrigerate. Shelf Life = 1 year.*

6.7 Potassium Chloride (KCl) Solution, 2M: JT Baker, 3052-01 or equivalent. Dissolve 235g potassium chloride (KCl) in 1500mL DI water. *Do not degas this solution. Shelf Life = 1 year.*

6.8 Sodium Hydroxide Solution, 10N: JT Baker, 3722-07 or equivalent. Dissolve 160.0g Sodium Hydroxide (NaOH) to a final volume of 400mL using DI water. Not degassed. *Shelf life = 1 year.*

7. STANDARDS -- DO NOT degas standards.

7.1 Ammonia as N Stock Solutions, 1000mg/L NH_3 as N, 1st and 2nd sources: GFS Chemicals, Item No. 645 or equivalent. Purchased from different commercial vendors or created in-house by dissolving 3.821g ammonium chloride (NH_4Cl) salt (the two measures of ammonium chloride salt must be obtained from two different lot numbers) in DI water and diluting to 1L with DI water. *Store in a polypropylene bottle; refrigerate. Shelf Life = 1 year.*

7.2 Ammonia as N Intermediate Standard Solutions, 50mg/L NH_3 as N, 1st and 2nd sources: Made from diluting 5.0mL 1st and 2nd source ammonia as N stock solutions to 100mL using DI water and 100mL volumetric flasks. Cap and invert several times to mix. The working calibration standards and the continuing calibration verification standard (CCV) are made from the 1st source ammonia as N intermediate standard solution; the initial calibration verification standard (ICV) and the laboratory control sample (LCS) are made from the 2nd source ammonia as N intermediate standard solution. *Store in polypropylene bottles; refrigerate. Shelf Life = 3 months.*

7.3 Ammonia as N Calibration Standards (per Table below): Made in-house on each day of calibration by dilution of the 50mg/L intermediate ammonia as N standard, 1st source, with DI water. The final volume for all calibration standards is 5.0mL.

Pipet 5.0mL DI water into a clean auto sampler tube to prepare each calibration standard. Before pipetting the appropriate aliquot of intermediate standard into the tube, first remove an equivalent volume of water from the auto sampler tube, using the pipet, so that the final volume contained in the autosampler tube is 5.0mL.

VOLUME OF 50mg/L Ammonia as N INTERMEDIATE STANDARD SOLUTION, 1st SOURCE (mL)	CONCENTRATION OF FINAL CALIBRATION SOLUTION (mg/L NH_3 as N)
0.00	0.00
0.01	0.10
0.02	0.20
0.05	0.50
0.10	1.00
0.20	2.00
0.50	5.00

7.4 Initial Calibration Verification (ICV) Standard, 1.00mg/L: Use 0.10mL of 50mg/L Ammonia as N Intermediate Standard Solution, *2nd source*, to create 5.0mL of ICV standard in DI water.

7.5 Continuing Calibration Verification (CCV) Standard, 2.00mg/L: Use 0.20mL of 50mg/L Ammonia as N Intermediate Standard Solution, *1st source*, to create 5.0mL of CCV standard in DI water.

8. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

8.1 Samples must be collected according to an approved sampling plan.

8.2 Water samples must be acidified with Sulfuric Acid (H_2SO_4) to pH <2 at the time of collection. The acidified samples should be kept chilled (4±2°C) until analysis. Properly preserved water samples must be analyzed within 28 days of collection.

8.3 There are no chemical preservation considerations or holding time requirements for solid sample matrices. Soil samples should be chilled (4±2°C) until analysis.

9. AQUEOUS EXTRACTION OF SOLID SAMPLES AND ASSOCIATED QUALITY CONTROL (QC) SAMPLE PREPARATION

9.1 Weigh a representative 4.0g aliquot of moist sample into a labeled 50mL disposable polypropylene centrifuge tube.

9.2 Prepare a Method Blank (MB) by weighing 4.0g clean Ottawa sand into a labeled 50mL disposable polypropylene centrifuge tube. One method blank must be prepared for each batch of twenty (or fewer) solid matrix environmental samples processed together as a unit. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. An MB should also be prepared and analyzed each time there is a change in reagents.

9.3 Prepare a Laboratory Control Sample (LCS) by weighing 4.0g clean silica sand into a labeled 50mL disposable polypropylene centrifuge tube. Add 0.08mL of 1000mg/L Ammonia as N Stock Standard Solution (or 1.6mL of 50mg/L Ammonia as N solution), *2nd source*. One LCS should be prepared for each batch of twenty (or fewer) solid matrix environmental samples processed together as a unit. The Laboratory Control Sample (LCS) is analyzed to measure the accuracy of the method. The concentration of the LCS is expected to be 2.00mg/L.

9.4 Prepare a Matrix Spike (MS), Matrix Spike Duplicate (MSD) set as follows: Select a representative sample of the batch. To two 4.0g representative moist aliquots of selected sample, add 0.04mL of 1000mg/L Ammonia as N Stock Standard Solution (or 0.8mL of 50mg/L Ammonia as N solution), *1st source.* Matrix spiked samples are analyzed as a means of determining the effect of matrix on target analyte detection. The matrix spiked sample is prepared in duplicate to serve as a laboratory duplicate, which is analyzed to measure the precision of the analysis. One MS/MSD set should be prepared for each batch of twenty (or fewer) solid matrix environmental samples processed together as a unit. The concentration of the MS and MSD is expected to be 1.00mg/L.

9.5 To all of the above add 40.0mL 2M KCl solution.

9.6 Cap the prepared sample aliquots and shake for 1 hour on the TCLP tumbler.

9.7 Centrifuge the aqueous extracts for about 15 minutes at 3500rpm.

10. AQUEOUS FIELD SAMPLE, ASSOCIATED AQUEOUS QUALITY CONTROL (QC) SAMPLE, AND AQUEOUS EXTRACT PREPARATION FOR ANALYSIS

10.1 The reference methods discuss pH adjustment to between 5 and 9 for acid-preserved samples. This is only necessary in cases where the addition of EDTA buffer is not capable of producing adequate pH adjustment. Should pH adjustment be required, follow the Steps below:

10.1.1 Place approximately 20mL of aqueous sample into a disposable centrifuge tube containing a stir bar.

10.1.2 Place a previously calibrated pH probe into the sample aliquot and adjust the pH using 10N NaOH until the pH is between 5-9. If the pH

exceeds 9, add the original preserved sample drop wise to bring the pH back down into range.

10.2 Aliquot 5.0mL of each aqueous sample or previously prepared solid sample extract (including associated QC samples) into a designated auto sampler tube. If the aqueous sample or extract contains suspended solids, filter through a 0.45µm pore-diameter membrane filter.

10.3 Prepare the aqueous Method Blank (MB) by aliquoting 5.0mL of DI water into an auto sampler tube. One method blank must be prepared for each batch of twenty (or fewer) aqueous matrix environmental samples processed together as a unit. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. An MB should also be prepared and analyzed each time there is a change in reagents.

10.4 Prepare the aqueous Laboratory Control Samples (LCS) similar to the ICV standard by using 0.10mL of 50mg/L Ammonia as N Intermediate Standard Solution, *2nd source*, to create 5.0mL of LCS in DI water. One LCS must be prepared for each batch of twenty (or fewer) aqueous matrix environmental samples processed together as a unit. The LCS is analyzed to measure the accuracy of the method. The concentration of the LCS is expected to be 1.00mg/L.

10.5 Prepare a Matrix Spike (MS), Matrix Spike Duplicate (MSD) set as follows: Select a representative sample of the batch. To two 5.0mL representative aliquots of selected sample, add 0.10mL of 50mg/L Ammonia as N Intermediate Standard Solution, *1st source*. One MS/MSD set should be prepared for each batch of twenty (or fewer) aqueous matrix environmental samples processed together as a unit. Matrix spiked samples are analyzed as a means of determining the effect of matrix on target analyte detection; the matrix spiked sample is prepared in duplicate to serve as a laboratory duplicate, which is analyzed to measure the precision of the analysis. The concentration of the MS and MSD is expected to be 1.00mg/L.

11. GENERAL LACHAT OPERATION AND MAINTENANCE PROCEDURES

11.1 LACHAT INSTRUMENT SET UP

11.1.1 Turn on power to auto sampler, pump and the sample processing module by switching on the power strip. Turn on the computer.

NOTE: The auto sampler will automatically perform an operation check by lifting the probe out of the rinse reservoir and advancing the sample cartridges by one position. The sample processing module will open and shut each of the two valves, the LED of the heater control will display the current temperature of the block, and the lamp will come on.

11.1.2 Install the proper manifold for the analysis to be conducted (e.g., ammonia nitrogen analysis).

11.1.3 Place the appropriate interference filter into the upper slot of the detector.

11.1.4 Connect the "sample loop" to ports one and four of the injection valve.

11.1.5 Connect the "carrier" line to port two of the injection valve.

11.1.6 Place the manifold on to the sample processing module and connect the "to manifold" line to port three of the injection valve.

11.1.7 Connect the heating unit tubing to the manifold (if necessary).

11.1.8 Insert each pump tube into a pump tube cartridge and place on the pump. Adjust the tension levers to maximum tension. **Be sure that the pump tubes are seated correctly in the cartridges. This will prevent pinching of the tubes, which may restrict flow.**

NOTE: When preparing for any analysis that requires a column, make sure the column is in the **off-line** position at this time.

11.1.9 This is a heated procedure. Set the heat controller temperature to the required setting, 60°C, by pressing the "on" button. To adjust the temperature, press the "up" and "down" buttons. Press the "on" button again to lock in the setting.

NOTE: Be sure to turn the heat controller off at the end of the run!

11.1.10 Prepare the calibration standards (Section 7.0) and place them in the auto sampler in order of decreasing concentrations. Complete filling the sampler tray using the prepared samples to be analyzed.

11.1.11 After flushing the lines with deionized water, place the reagent lines into the proper reagent solutions and begin pumping reagent through the system.

NOTE: Some chemistries require a certain sequence in which reagents are introduced. Check the LACHAT operator's manual.

11.1.12 This chemistry does not require use of a column.

11.1.13 Allow the reagents to be pumped through the entire system for at least 3-5 minutes.

11.1.14 Set up the computer as described in Section 11.2 below. Once the computer is set up, the system is ready to be started to begin calibration and data collection. *Note that system shut down procedures are addressed in Section 14.*

11.2 COMPUTER SET UP PROCEDURE

11.2.1 From the Program Manager in Windows, double click on the "Lachat Instruments" icon. Then double click on the "Omnion FIA" icon. Click "OK" in the Omnion data system window.

NOTE: The sample probe will return to the wash reservoir and the injection valves will open and close.

11.2.2 Type your user name and password then click "OK". Click on the "Flow Injection Analysis" icon. If a user name and password has not been assigned, have the System Manager assign one, or refer to the installation section of the *Quickchem 8000 Continuum Series Automated Ion Analyzer Omnion FIA Software Installation and Tutorial* manual.

11.2.3 Load the method for the analyte(s) you want to run. From the menu bar, click on "File", then "Open Method". The path for Channel 2 is c:\Omnion\methods\methodtemp\nh3temp2.met. A new "Method" is created for each analysis each day of use. Each day's data are stored in an analyte subdirectory named for the year, using a mmdd format (e.g., c:\Omnion\methods\nh3\2004\1128nh.met). This method pathway refers to ammonia nitrogen run on 11/28/2004.

11.2.4 Load the master trays for the analyte(s) you want to run. From the "File" option on the menu bar, click on "Open Tray". Select the appropriate tray. The path for the default tray is c:\Omnion\trays\traytemp\nh3temp.tra. Fill in the sample identifications and dilution factor and save the tray by clicking "File", then "Save Tray As".

Each day's analysis data are stored in a subdirectory named for the year using a mmdd format (e.g., c:\Omnion\trays\nh3\2004\1128nh.tra).

11.2.5 Check the calibration curve information by clicking on the "Review" icon, or pull down the "Method" menu and click on "Review Analyte Calibration Curve". If calibration curve data appears, clear the previous data by pulling down the "Method" menu and clicking on "Calibration Clear".

NOTE: You must clear the previous calibration curve before analyzing calibration standards.

11.3 MANIFOLD CLEANING PROCEDURE
If the baseline drifts, peaks are too wide, or other problems with precision arise, clean the manifold by the following procedure:

11.3.1 Place all reagent lines in deionized water and pump 2-5 minutes to clear the lines of all residual reagents.

11.3.2 Place the reagent lines and carrier in 1M hydrochloric acid (i.e., 82.6mL concentrated HCl brought to a final volume of 1L using DI water). Allow the pump to run for several minutes to flush and clean the lines.

11.3.3 Place all the flushed lines in deionized water and pump until the HCl is thoroughly washed out.

11.3.4 Reattach all the reagent lines and resume pumping the reagents.

12. PROCEDURE

NOTE: When particulate matter is present, the sample must be filtered prior to analyses. The sample may be centrifuged in place of filtration.

12.1 Prepare the calibration standards as described in Section 7. Set heat to 60°C on the Lachat analyzer.

12.2 Prepare the samples as described in Sections 9 and 10.

12.3 Fill the autosampler tubes with the appropriate standards and samples (including QC); load the auto sampler as described in Step 11.1. and per the run sequence depicted below:

(1) 5.00mg/L NH_3-N calibration standard
(2) 2.00mg/L NH_3-N calibration standard
(3) 1.00mg/L NH_3-N calibration standard
(4) 0.50mg/L NH_3-N calibration standard
(5) 0.20mg/L NH_3-N calibration standard
(6) 0.10mg/L NH_3-N calibration standard
(7) 0.00mg/L NH_3-N calibration standard
(8) ICV (second source)
(9) ICB (Initial Calibration Blank)

(10) Method Blank (MB)

(11) Laboratory Control Sample (LCS)

(12) maximum of 8 Field Samples (including MS/MSD)

(22) CCV (Section 7.)

(23) CCB (DI water blank)

(24) maximum of 10 Field Samples

(34) CCV

(35) CCB

(36) repeat steps 10 through 22

NOTES: It is often helpful to refer to your tray as a guide to ensure proper placement of standards and samples in the auto sampler.

No more than ten samples (including QC) may be analyzed between the ICV/ICB and first CCV/CCB.

No more than ten samples (including QC) may be analyzed between CCV/CCB sets.

A CCV/CCB set must be analyzed to close-out the run sequence.

See QC Table for QC sample acceptance limits.

12.4 Complete the proper instrument set up as described in Steps 11.1.11 through 11.1.14.

12.5 Make sure the method and tray pathways are correctly set up and that the previous calibration information has been cleared as described in Section 11.2.

12.6 Start the run by clicking on the "Run Tray" icon. Click "Catalogue". Save the run data catalogue in the proper path using a mmdd format (i.e., c:\Omnion\data\nh3\2004\1128nh.fdt). Click "Run" to begin the analysis process.

NOTE: The analysis may be paused or stopped in the middle of the run by clicking on the "Stop" icon. You can add samples or sample dilutions to your run by clicking on the "Tray" window and typing them in at the end of your saved tray. Save the updated information by first clicking "File", then "Save Tray". Restart the run by clicking "Resume". If you edit your tray by deleting standards or samples, you must "Save Tray As" by using the original file name with a "b" ("c", "d", etc.) added; example: 1128nhb.tra. Restart the analysis by renaming the data file in the same manner; example: 1128nhb.fdt.

13. CALCULATIONS AND REPORTING RESULTS

13.1 After the analysis is complete, print a copy of the following analyzer reports (access proper menu, "Open", "Print"), and deliver them to the Reporting Group:

- Tray Table(s) with any written comments and handwritten date and initials of analyst.
- Run Time Report(s); must be hand dated and initialed by the analyst.
- Custom Report(s) with just header information.

13.2 The analyzer data is directed to a designated network directory from which the Reporting Group imports it into LIMS. All sample calculations are performed in LIMS.

13.2.1 Sample quantitation is accomplished using a standard curve, which is generated by plotting the peak areas of the processed standards against their known concentrations. The linear regression analysis of the standard curve must yield a correlation coefficient (r^2) value $\geq$0.995 to be acceptable.

13.2.2 The representative sample calculation for NH3 as N in soil samples is as follows:

$$\text{Concentration (mg/L)} = \frac{A \bullet D \bullet V}{W_{dry}}$$

where:

A = mg/L NH_3 as N (calculated from the sample peak area using the standard curve equation)

D = Dilution factor (if applicable)

V = Extract volume (mL); (100 mL if this SOP is followed without deviation)

W_{dry} = Dry weight (g) of soil extracted (see equation below)

$$W_{dry} = \frac{W_{moist} \bullet \%\ solids}{100}$$

where:

W_{moist} = moist weight of soil extracted

13.2.3 Note that sample results are adjusted for dilutions and/or % solids, as applicable.

13.2.4 Percent recoveries and RPD values for QC sample analyses are also calculated (see Section 15 for further details).

14. SYSTEM SHUT DOWN PROCEDURE

NOTE: Some methods require certain reagents to be removed last. Check the LACHAT operator's manual.

14.1 Make sure the appropriate files are saved, then exit and log off from the current Omnion session. Exit Windows and shut down the computer.

14.2 If applicable, turn the pump setting down then switch the column to the "off-line" position.

14.3 Remove the reagent lines from each reagent and place into deionized water. Turn the pump setting up so that the DI water is pumped through. Continue to run the system and allow the transmission lines to rinse for 5-10 minutes. ***This is a critical step in preventive maintenance of the manifolds.***

14.4 Release the cartridge tension on the transmission line to the sipper bath and remove the line from the deionized water. Turn the heat controller off (if required).

14.5 Remove the reagent transmission lines from the deionized water and allow all liquid to be pumped out of the manifold by pumping air through the lines.

14.6 Turn off the pump, auto sampler and manifold unit by switching off the power strip.

14.7 Release the pump tube cartridges tension completely to avoid the tubing from becoming crushed.

14.8 To remove the manifold, follow the Lachat set up procedure (Section 11.1) in reverse order, starting with Step 11.1.8.

15. QUALITY CONTROL

Various types of quality control (QC) samples such as method blank (MB), laboratory control sample (LCS) and matrix spike/matrix spike duplicate (MS/MSD) are discussed previously in Sections 9 and 10. Acceptance criteria for these samples are shown in the QC Check Summary Table presented at the end of this SOP.

15.1 LABORATORY CONTROL SAMPLE

LCS results obtained are compared to results expected using the equation presented below:

$$\text{Percent Recovery (\%R)} = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Expected}}} \times 100$$

where:

$Conc_{Found}$ = analyte concentration found in the LCS

$Conc_{Expected}$ = anticipated analyte concentration based on known amount spiked

15.2 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Analyte recovery for the MS/MSD is calculated as shown below:

$$\%R = \frac{Concentration_{Found} - Concentration_{Sample}}{Concentration_{Target}} \times 100$$

where:

$Conc_{Found}$ = analyte concentration found in the MS or MSD

$Conc_{Sample}$ = analyte concentration found in the native field sample

$Conc_{Target}$ = analyte concentration anticipated based on known amount spiked

Precision is evaluated as the Relative Percent Difference (RPD) between the sample and it's duplicate. RPD is calculated as shown below:

$$RPD\ (\%) = \frac{|Result_x - Result_{Dup}|}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

15.3 LINEARITY STUDY

A linear calibration range (LCR) study must be performed at minimum, every six months, or whenever there is a significant change in operator, background or instrument response. The study must consist of a blank and a minimum of three standards. The range of the linearity study is broader than that defined as the linear calibration range, since the purpose of the linearity study is to verify the instrument's overall capabilities. All verification data must agree within ±10% of expected values.

15.4 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study shall be performed as needed and at a minimum, every six months.

16. DEVIATIONS FROM METHODS

16.1 Section 6.1 of Method 350.1 and Section 3a of Method SM4500-NH_3 H state that all solutions must be made in ammonia-free water and discusses the use of treated distilled water. Paragon uses deionized (DI) water generated by the in-house laboratory deionization system. It has been demonstrated, through the analysis of MDL studies, PT samples, etc., that Paragon's DI water is ammonia-free and meets ASTM Type I and II standards.

16.2 Section 6.4 of Method 350.1 states that due to the instability of the sodium hypochlorite solution, storage over an extended period should be avoided. It is Paragon's policy to store this solution up to one year. Successful analysis of PT samples has indicated no negative impact from this practice.

16.3 Both Methods 350.1 and SM4500-NH_3 H refer to use of a wash water solution. Because the type of automated flow injection analyzer used by Paragon provides a constant flow of reagents through the system, the use of a separate wash water solution is not required.

16.4 Section 6.6 of Method 350.1 and Section 3f of Method SM4500-NH_3 H directs the creation of a 0.05% sodium nitroprusside reagent (0.5g sodium nitroprusside to 1L using DI water). Paragon creates a 7 times stronger solution by dissolving 3.5g sodium nitroprusside in 1L of DI water. Sodium nitroprusside reagent is used in this procedure to intensify color development.

Section 7.1 of Method 350.1 and Section 1b of Method SM4500-NH_3 H state that the color intensity is pH dependent and recommends that standards should also be acidified in cases where acid-preserved samples are analyzed. Paragon does not acidify the standard solutions. Instead, Paragon uses a strong basic EDTA buffer to unify the pH of samples and standards as part of the analysis process. Further, this buffered pH adjustment reduces the interferences caused by over-acidified samples.

16.5 Paragon dilutes stock standards and creates calibration standards in concentrations that differ from those described in Section 6.0 of Method 350.1 and referenced in Method SM4500-NH_3 H. Both Methods 350.1 and SM4500-NH_3 H cite approximately 0.01 to 2.0mg/L NH_3 as N as the Method's operational range; Paragon standards bracket a range of approximately 0.10 to 5.0mg/L NH_3 as N.

16.6 Section 9 of this SOP describes a solid preparation procedure. Paragon notes that Method EPA 350.1 is applicable to the determination of ammonia in drinking, surface and saline waters, domestic and industrial wastes (Section 1.1).

17. SAFETY, HAZARDS AND WASTE DISPOSAL

17.1 SAFETY AND HAZARDS

17.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

17.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

17.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples),

handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

17.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

17.1.5 All flammable compounds must be kept away from ignition sources.

17.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name; NFPA Health, Flammability, and Reactivity ratings, and date.

17.1.7 Food and drink are prohibited in all lab areas.

17.2 WASTE DISPOSAL

17.2.1 Solid filtrate residues and any other solid residues shall be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

17.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

17.2.3 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Compliance Officer will address the disposition of these samples.

DOCUMENT REVISION HISTORY

7/26/05: Program Specification references added.

11/6/07: It is not necessary to 'matrix match' calibration standards and QC samples (not required in any referenced method, comparison of QC samples shows it's not warranted). Consequently, all matrix-matching text (i.e., 2M KCl for solids calibration, QC) was removed. Updated EDTA Buffer NaOH strength, Section 6.5, and pH adjustment discussion Section 10. Clerical corrections throughout. Revamped and combined CALCULATIONS and REPORTING RESULTS Sections 13, 15 (updated from spreadsheets to LIMS). Added DOCUMENT REVISION HISTORY section.

Analytical Method: EPA 350.1; SM4500-NH_3 H	**Parameter:** Ammonia-Nitrogen		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point (plus blank)	As needed (i.e., at on-set of analyses or repeated when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); second source; at or below midpoint	Once after each initial calibration	Response must agree within $\pm$10% of expected value	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Blanks: Method Blank (MB), Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	The MB may be run initially as part of the calibration curve; the ICB is run following the calibration curve. CCBs are run following the CCV (after every ten samples), and to close an analytical run sequence	Ammonia-nitrogen content of the blank must not exceed analyte reporting limit (RL)	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Laboratory Control Sample (LCS)	Matrix specific. One LCS must be prepared and analyzed per $\leq$20 environmental samples of similar matrix	Results must agree within $\pm$10% of expected values for aqueous sample analyses; within $\pm$15% for solid matrix extract analyses, or as otherwise specified in the applicable LIMS program specification	Check all calculations. If no computation errors are found, prepare a fresh LCS and analyze. If criteria are still not met, system must be recalibrated and all samples associated with the failed LCS must be reanalyzed.
Continuing Calibration Verification (CCV); first source; at or below midpoint	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis)	Response must agree within $\pm$10% of expected value	Check that calculations and preparation are correct, evaluate/ correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must also be reanalyzed.
Matrix Spike (MS)	One per batch of $\leq$20 field samples of similar matrix	Recoveries should meet advisory limits of $\pm$25% of the expected values; client-specified criteria may apply	Compare with LCS results and check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (laboratory) Duplicate	One per batch of $\leq$ 20 field samples of similar matrix	(See MS recovery criteria above). RPD advisory limit is $\leq$ 20; client-specified criteria may apply	(See MS recovery criteria above). For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.

Analytical Method: EPA 350.1; SM4500-NH_3 H	**Parameter:** Ammonia-Nitrogen		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Linearity check; minimum of three standards and a blank; run to verify the range of capability of the instrument	At minimum every six months; whenever a significant change in operator, background, or instrument response occurs	All verification data results must agree within ±10% of expected values	Evaluate/correct instrument malfunction; reanalyze until acceptable results are generated.
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	At minimum every six months; whenever a significant change in operator, background, or instrument response occurs	Positive result < the analyte reporting limit (RL).	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1130 REVISION 5

TITLE: **DETERMINATION OF NITROGEN, NITRITE (AS NO_2^--N) IN WATER AND SOIL BY COLORIMETRIC SPECTROPHOTOMETRIC DETERMINATION -- EPA METHOD 354.1 AND STANDARD METHOD SM4500-NO_2 B**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER Steve Wolfman DATE 7/21/08

QUALITY ASSURANCE MANAGER Dot Schenk DATE 7/20/08

LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: NEW, 8/12/02; Rev1, 12/11/02; Rev2, 2/13/04 and 12/15/04 (re-released without revision); Rev3, 7/26/05; Rev4, 4/10/06; Rev5, 7/20/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) references USEPA Method 354.1 and Standard Method (SM) 4500-NO_2 B for the determination of native nitrite content in environmental water samples. Soil samples may also be analyzed using these methods following rotary tumbler extraction with deionized water.

2. SUMMARY

To determine native nitrite (NO_2^--N) content, an aliquot of an unpreserved sample or extract is developed using a color reagent. The resultant color is read using a UV spectrophotometer. Values are reported as NO_2^--N.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the ability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of a proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any

errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 This colorimetric procedure requires an optically clear sample. Sample color that absorbs at approximately 543nm interferes with the colorimetric determination. This interference may be corrected by diluting the sample or by analyzing an aliquot of sample without the addition of color reagent (an initial absorbance reading can thus be obtained). The sample's corrected absorbance reading is then calculated by subtracting the initial absorbance reading from the final absorbance reading to obtain a corrected absorbance reading.

Since nitrite is found in a soluble form, the sample should be pre-filtered through a 0.45μm pore diameter membrane filter.

4.2 There are very few known interferences at concentrations less than 1,000 times that of the nitrite, however, the presence of strong oxidants or reductants in the samples will readily affect the nitrite concentrations. High alkalinity (> 600mg/L) will give low results due to a shift in pH.

5. APPARATUS AND MATERIALS

5.1 UV/VIS Spectrophotometer, Sequoia - Turner Model 340, or equivalent. Capable of absorbance measurements at 543nm

5.2 Spectrophotometer cuvettes, optical glass, 1" diameter (path length) and 150mm tall. VWR Cat No. 22366-006, No. 33-17-82 or equivalent

5.3 Analytical balance, 0.0001g sensitivity, verified per SOP 305

5.4 Syringe, outfitted with a 0.45μm filter disk

5.5 Volumetric dispensers, Eppendorf™ or equivalent, capable of dispensing 0.01-10.0mL, operated per SOP 321 requirements

5.6 TCLP-type mechanical tumbler, capable of 1 hour soil extraction by agitation

5.7 Centrifuge, capable of sustaining approximately 3500rpm

5.8 Centrifuge tubes, disposable, 50mL volume

5.9 Vortex mixer

5.10 Volumetric flasks, various sizes, Class A

5.11 pH paper, suitable of determining pH 6

6. REAGENTS

NOTE: Only ACS grade or better chemicals and reagents may be used. Reagents and solutions may be stored in either plastic or glass containers.

6.1 Deionized (DI) Water

6.2 Hydrochloric Acid (HCl) Solution: Slowly and cautiously add a measured volume of concentrated HCl to two equal volumes of DI water (1:3 dilution). *Shelf life = 1 year.*

6.3 Color reagent: To 250mL degassed DI water, add 50mL concentrated Phosphoric Acid (H_3PO_4) and 20.0g sulfanilamide. After dissolving the sulfanilamide completely, add 1.0g N-(1-naphthyl)-ethylenediamine dihydrochloride. Mix to dissolve, then dilute to 500mL with degassed deionized water. *Store refrigerated in an amber container. Shelf life = 6 months.*

6.4 Ottawa sand. *Keep container sealed tightly. No special storage or shelf life considerations.*

6.5 Sodium Nitrite ($NaNO_2$), reagent grade: First and second sources purchased from separate vendors. Used to create the first and second source NO_2^--N Stock Solutions. *Shelf life = 5 years. Oven dry for about 1hr then cool in desiccator before use.*

7. NITRITE CALIBRATION STANDARDS

7.1 Nitrite (NO_2^--N) Stock Solutions, 1000mg/L: Created from $NaNO_2$ reagent grade salts, first and second sources. Used to create the first and second source NO_2^--N 20mg/L Intermediate Standards. Dissolve 0.4925g of $NaNO_2$ salt in 100mL DI water. Store at 4±2°C. *Shelf life = 1 month.*

7.2 Nitrite (NO_2^--N) Intermediate Standard, 200ppm (first source): Made by diluting 20.0mL of the first-source 1000mg/L NO_2^--N Stock Solution to a final volume of 100mL with DI water. This "First Source" Intermediate Standard is used to prepare the daily calibration standards and the continuing calibration verification (CCV) standards. Store at 4±2°C. *Shelf Life = 1 month.*

7.3 Nitrite (NO_2^--N) Intermediate Standard, 200ppm (second source): Made by diluting 20.0mL of the second-source 1000mg/L NO_2^--N Stock Solution to a final volume of 100mL with DI water. This second source intermediate standard is

used to prepare the initial calibration verification (ICV) standard and the Laboratory Control Sample (LCS) standard, which are identical. Store at 4±2°C. *Shelf Life = 1 month.*

7.4 NO_2^--N Calibration Standards (per Table below): Made in-house each day of use by dilution of the first source 200ppm NO_2^--N Intermediate Standard.

Note that DI water is used as the diluent to prepare calibration standards for aqueous sample analyses. The final volume of for all calibration standards is 20mL.

CONCENTRATION OF INITIAL SOLUTION (ppm)	VOLUME OF INITIAL STANDARD USED (mL)	CONCENTRATION OF FINAL SOLUTION (ppm)	FINAL VOLUME OF SOLUTION (mL)
200	0.050	0.50	20
200	0.020	0.20	20
200	0.010	0.10	20
200	0.010	0.05	40
0.05	8.0	0.02	20
0.05	4.0	0.01	20
0	0.0	0.0	20

7.5 Initial Calibration Verification Standard (ICV), 0.10ppm: Made in-house each day of use by diluting 0.01mL of the "second source" NO_2^--N Stock Solution (1000ppm) to 100mL, using DI water or 0.010mL of 200ppm second source standard into 20mL DI water.

7.6 Continuing Calibration Verification Standard (CCV), 0.20ppm: Made in-house each day of use by diluting 0.02mL of the "first source" 200ppm NO_2^--N intermediate standard to 20mL using DI water.

8. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

8.1 All samples should be collected according to an approved sampling plan.

8.2 Sampling and storage of samples in glass bottles or in plastic bottles is permissible. Samples should be kept cool at 4±2°C.

8.3 For nitrite (NO_2^--N) analysis, aqueous samples must be analyzed within 48 hours after collection. There is no promulgated holding time for soil samples.

9. AQUEOUS EXTRACTION OF SOLID SAMPLES AND ASSOCIATED QC SAMPLE PREPARATION

9.1 Weigh 4.0g moist samples into a 50mL disposable polypropylene centrifuge tube.

9.2 Method Blank: Weigh 4.0g clean Ottawa sand into a 50mL disposable polypropylene centrifuge tube.

9.3 Prepare NO_2^--N Laboratory Control Sample (LCS) as follows: Weigh 4.0g clean silica sand into a 50mL disposable polypropylene centrifuge tube. Spike with 0.02mL of 200mg/L NO_2^--N intermediate standard (second source). Creates a 0.1mg/L LCS extract.

9.4 Prepare NO_2^--N Matrix Spike (MS), Matrix Spike Duplicate (MSD) samples as follows: For one of the samples in the batch, spike two duplicate 4.0g aliquots with 0.02mL of 200mg/L NO_2^--N intermediate standard (first source). Creates a 0.1mg/L MS/MSD sample.

9.5 To all of the above, add 40.0mL DI water.

9.6 Shake samples for 1 hour on the TCLP tumbler.

9.7 Centrifuge for about 15min @ 3500rpm.

10. PREPARATION OF AQUEOUS FIELD AND ASSOCIATED QC SAMPLES

10.1 Place a 20mL aliquot of sample into a clean spectrophotometer cuvette. If the sample is colored or turbid, treat as described in Section 4.1.

10.2 Place 20mL of DI water into a clean spectrophotometer cuvette to serve as the aqueous Method Blank.

10.3 Prepare NO_2^--N Laboratory Control Sample (LCS) as follows: Place 20mL of the aqueous ICV Solution (see Section 7.4) into a clean spectrophotometer cuvette. Used as the 0.1mg/L (second source) LCS standard or 0.010mL of 200ppm second source standard to 20mL DI water.

10.4 Prepare NO_2^--N Matrix Spike (MS), Matrix Spike Duplicate (MSD) samples as follows: For one of the samples in the batch, spike two duplicate 20mL aliquots with 0.01mL of 200mg/L NO_2^--N intermediate standard (first source). Creates a 0.1mg/L MS/MSD.

11. PROCEDURE FOR DETERMINING NITRITE CONTENT

NOTE: If the sample has a pH greater than 10 or total alkalinity in excess of 600mg/L, adjust to approximately pH 6 with 1:3 HCl, otherwise, there is no pH adjustment for NO_2^--N analysis.

11.1 COLOR DEVELOPMENT

11.1.1 Aliquots of standards, aqueous sample or solid sample extract are developed colorimetrically and read using a UV spectrophotometer.

11.1.2 Prepare calibration standards, solid sample extracts and aqueous samples as discussed previously. All aliquots are to be contained in optically-matched cuvettes.

11.1.3 Add 0.480mL of color reagent to each cuvette. Mix each using the vortex mixer.

11.1.4 Allow color to develop for at least 10 minutes (absorbance must be read within 2 hours).

11.2 ESTABLISHING THE CALIBRATION CURVE

11.2.1 Read each calibration standard at 543nm using the UV spectrophotometer. Record each reading in the LIMS interface spreadsheet.

11.2.2 Using LIMS, compute a linear regression for the calibration standard absorbance readings. The correlation coefficient (r^2) must be $\geq$0.995.

11.2.3 After an acceptable calibration curve has been established, analyze the second source check standard (ICV). The ICV result must agree within $\pm$10% of the known value when quantitated using the initial calibration.

11.2.4 Analyze an Initial Calibration Blank (ICB) following the ICV standard. The ICB must be free of analyte concentration above the analyte reporting limit. Sample analyses cannot proceed until an acceptable calibration curve has been verified and an acceptable ICB has been generated.

11.3 ANALYZING SAMPLES

11.3.1 The absorbance of each sample/extract is read at 543nm. Begin sample analysis with the batch Method Blank (MB), followed by the LCS. The MB must be free of analyte concentration above the analyte reporting limit, and the LCS must generate results within ±10% of the expected value for aqueous sample analysis, and within ±20% of the expected value for solid sample extracts analysis. Sample analyses cannot continue unless these acceptance criteria are met.

11.3.2 Begin analyzing the prepared samples (including the batch MS and MSD). A continuing calibration verification (CCV) standard must be analyzed after every tenth cuvette reading. The CCV analysis must yield results within ±10% of the initial calibration. If this criterion is not met, reanalyze the CCV (make sure calculations and preparation is correct). If the CCV still fails, analyses must be halted and a new calibration curve must be generated. All samples analyzed after the last acceptable CCV must be reanalyzed.

11.3.3 The analysis of a continuing calibration blank (CCB) must follow CCV analysis. The CCB must not yield results greater than the analyte reporting limit.

NOTE: The CCV/CCB combination must be analyzed after every ten environmental matrix samples, and to close any analytical run sequence.

12. QUALITY CONTROL (QC) SAMPLES

12.1 DEFINITION OF ANALYSIS BATCH

An analysis batch is defined as a group of twenty (20) or less field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike, and matrix spike duplicate (MS/MSD). All QC samples must be carried through all stages of the sample preparation and measurement steps.

12.2 BLANKS

Method blanks (MBs) are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Initial Calibration Blanks (ICBs) and Continuing Calibration Blanks (CCBs) are run to demonstrate that the analytical system remains free of artifacts and carryover. All blanks must be free of positive analyte results greater than the analyte reporting limit.

12.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. The results obtained are compared to results expected. To be acceptable, the LCS recovery must be between 90% and 110% of the expected concentration for aqueous sample analyses, and between 80% and 120% of the expected concentration for solid matrix extract analyses.

LCS results obtained are compared to results expected using the equation presented below:

$$\text{Percent Recovery (\%R)} = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Expected}}} \times 100$$

where:

$\text{Conc}_{\text{Found}}$ = analyte concentration found in the LCS

$\text{Conc}_{\text{Expected}}$ = anticipated analyte concentration based on known amount spiked

12.4 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Matrix spikes (MS/MSD) consist of field samples into which known concentrations of target analytes are added and analyzed as a means of determining the effect of matrix on target analyte detection. The matrix spike

duplicate (MSD) serves as a laboratory duplicate analysis. Analyte recovery for the MS/MSD pair is calculated as shown below:

$$\%R = \frac{Concentration_{Found} - Concentration_{Sample}}{Concentration_{Target}} \times 100$$

where:

$Conc_{Found}$ = analyte concentration found in the MS or MSD sample
$Conc_{Sample}$ = analyte concentration found in the field sample
$Conc_{Target}$ = target (anticipated) analyte concentration based on amount spiked

The advisory quality control limits in water and soil for MS/MSD recovery are set at 75-125%. Some clients may specify particular MS/MSD control limits.

The laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. For this procedure in water and soil, the Relative Percent Difference (RPD) between a sample and its duplicate should not be greater than 20%. RPD is calculated as shown below:

$$RPD\ (\%) = \frac{|\ Result_x - Result_{Dup}\ |}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

Advisory acceptance criteria for all spikes and duplicates should be met. If MS/MSD recovery or RPD criteria are not met, check calculations, spike preparation, and freshness of the standard used for spiking. Narrate if sample matrix interference is suspected as the cause of the MS/MSD advisory criteria not being met.

12.5 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study should be performed as needed and at minimum, annually.

13. DEVIATIONS FROM THE METHODS

13.1 Section 6.1 of Method 354.1 cites the use of distilled water for preparing all reagents and standards. Paragon uses laboratory-generated deionized (DI) water, which is equivalent to distilled water. The DI water system is monitored daily and meets ASTM Type I and II standards.

13.2 The reagent recipe as given differs between Section 6.2 of Method 354.1 and Section 3b of SM4500-NO_2 B for the creation of the color reagent. Paragon uses phosphoric acid (not HCl) based on the reagent recipe cited in SM4500-NO_2 B. However, Paragon creates a stronger color reagent than that described by using twice the ratioed amount of sulfanilamide and N-(1-naphthyl)-ethylenediamine

dihydrochloride. Additionally, though not described in either referenced method, Paragon degasses the DI water used to create this reagent. Per SM4500-NO_2 B, Paragon does not add sodium acetate as a buffer to the color reagent.

13.3 Per Section 3e of SM4500-NO_2 B, Paragon creates a stronger nitrite stock solution at a concentration of 1000mg/L, not 100mg/L as described in Section 6.3 of Method 354.1. SM 4500-NO_3^- I reagent citations, and Section 6.3 of Method 354.1 call for the preservation of nitrite stock standards with chloroform. Paragon closely monitors the performance of and assigned shelf life of the nitrite stock solution and does not preserve this standard with chloroform. Paragon does not standardize this reagent by titration.

Also, the concentration of Paragon's nitrite intermediate standard solution (200mg/L) is stronger than the nitrite standard solutions described in the referenced methods. However, the range of subsequent nitrite calibration standards used by Paragon (0.01–0.50mg/L) falls within the applicable analytical range cited by both methods.

13.4 Paragon uses a 20mL aliquot of standard or sample (or extract) for color development instead of the 50mL aliquot described in Section 7 of Method 354.1 and Section 4b of SM4500-NO2 B. Also, Paragon uses approximately half the ratioed amount of color reagent cited by the methods. Per SM4500-NO2 B, absorbance is read at 543nm (540nm cited in Method 354.1).

13.5 Section 9 of this SOP describes a solid preparation procedure. Paragon notes that Method EPA 354.1 is applicable to the measurement of nitrite in drinking, surface and saline waters, and domestic and industrial wastes (Section 1.1).

14. SAFETY, HAZARDS AND WASTE DISPOSAL

14.1 SAFETY AND HAZARDS

14.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

14.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

14.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area..

14.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

14.1.5 All flammable compounds must be kept away from ignition sources.

14.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

14.1.7 Food and drink are prohibited in all lab areas.

14.2 WASTE DISPOSAL

14.2.1 Solid filtrate residues and any other solid residues shall be disposed of in satellite the Contaminated Soils and Solids Waste collection vessel.

14.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

14.2.3 Certain clients may require that the samples and residues from their analyses be returned. The Waste Compliance Officer addresses these sample returns.

DOCUMENT REVISION HISTORY

7/26/05: Added reference Program Specification directive in "Responsibilities".

4/10/06: Added as item 13.4 of "Deviations" that Paragon does not add chloroform as a preservative to nitrite stock solutions. Added DOCUMENT REVISION HISTORY.

7/20/08: Minor clerical corrections and procedural clarifications. Added 'oven-dry' to sodium nitrite reagent 6.5. Updated Standard Method reference 15.1 from 17th to 20th edition.

Analytical Method: EPA 354.1, SM\4500-NO2 B	**Parameter:** Nitrite in water and soil		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point (plus blank); first source	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); second source	Once after each initial calibration	Response must agree within $\pm$10% of initial calibration	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Blanks: Method Blank (MB), Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	The MB may be run initially as part of the calibration curve, the ICB is run following the calibration curve. CCBs are run following the CCV (after every ten samples), and to close an analytical run sequence	NO_2^--N content of the blank must not exceed analyte reporting limit (RL)	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Laboratory Control Sample (LCS)	One LCS must be run per 20 environmental samples	Results must agree within $\pm$10% of expected values for aqueous sample analyses; within $\pm$ 20% for solid matrix extract analyses	Check all calculations. If no computation errors are found, prepare a fresh LCS and analyze. If criteria are still not met, system must be recalibrated and all samples run since the last acceptable LCS must be reanalyzed.
Continuing Calibration Verification (CCV); first source	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis)	Response must agree within $\pm$10% of initial calibration	Check that calculations and preparation are correct, evaluate/ correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Matrix Spike (MS)	One per batch of $\leq$20 field samples	Recoveries should meet advisory limits of $\pm$25% of the expected values; client-specified criteria may apply	Compare with LCS results and check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (laboratory) Duplicate	One per batch of $\leq$20 field samples	(See MS recovery criteria above). RPD advisory limit is $\leq$20; client-specified criteria may apply	(See MS recovery criteria above). For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	As needed; at minimum annually	Positive result < the analyte reporting limit (RL)	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1132 REVISION 3

TITLE: SEDIMENT LOAD

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2/6/07

QUALITY ASSURANCE MANAGER _____ DATE 2/6/07

LABORATORY MANAGER _____ DATE 2-9-07

HISTORY: Was DRAFT, Rev0, 10/2/03; Rev1, 2/25/04 and 3/29/05 (format updated); Rev2, 7/26/05 (Program Spec. reference added); Rev3, 2/2/07.
re-release w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes procedures for the separation of the aqueous phase and the sediment phase of a sample in order to determine the sediment load of the sample. This procedure may be performed as a stand-alone determination, or as a physical preparation prior to subsequent analytical preparation and testing.

2. SUMMARY

A measured volume of an aqueous sample containing sediments is separated into solid and liquid phases. Separation techniques may consist of centrifuging and decanting, filtration, and/or drying. The solid phase is weighed after separation, and Sediment Load is calculated and reported as mg/L. The separated phases may then be subjected to analytical testing, as requested.

3. RESPONSIBILITIES

3.1 The Paragon Project Manager is responsible for providing project instruction as needed.

3.2 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review.

3.3 Analysts must demonstrate the capability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard

criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the processing of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Filter congestion can occur during filtration, which increases separation time. If sediment levels visually look high, use a different method of separation or use multiple, staged filters, if appropriate.

5. APPARATUS AND MATERIALS

5.1 wash bottle

5.2 centrifuge, capable of 3500rpm

5.3 centrifuge tubes with caps, disposable, 250mL

5.4 graduated cylinders, 100-1000mL

5.5 peristaltic pump, and inert tubing dedicated to only one sample

5.6 filter capsules, 0.45µm, Pall/Gelman #12176, or Aqua Prep 600, or other equivalent; alternatively, glass fiber filters, 47mm, Gelman A/E or Whatman Grade 934AH

5.7 filter funnel assembly (e.g., funnel, glass-fritted filter base, funnel clamp, vacuum source, 1L vacuum flask)

5.8 polypropylene containers, 250mL-4L

5.9 weighing pans, aluminum

5.10 top loading balance, 0.01g sensitivity

5.11 analytical balance, 0.0001g sensitivity

5.12 drying oven, set at ~100°C

5.13 drying oven, set to maintain 103-105°C

5.14 desiccator, with color indicating desiccant

5.15 forceps and/or heat resistant oven gloves

5.16 vortex mixer

5.17 sample containers with caps, various sizes and materials

6. REAGENTS

Deionized (DI) water, obtainable from the laboratory's deionized water system

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples should be collected according to an approved sampling plan.

7.2 Sampling and storage of samples in plastic bottles, such as polyethylene or cube containers, is permissible. **Note that, as applicable, the container requirements of subsequent analytical methods must be met.**

7.3 **Samples should not be chemically preserved prior to sediment load determination. If required by a requested subsequent analytical method, appropriate chemical preservative may be added after sediment load determination is made.**

7.4 There is no maximum holding time allowance established for sediment load determination. However, if the sample is to be analytically tested subsequently, sediment load determination must be conducted within the analytical method's maximum holding time allowance.

8. PROCEDURE

8.1 SEPARATION OF AQUEOUS PHASE AND SEDIMENT PHASE

NOTE: The entire contents of a particular container must be used if possible. Subsampling a container can introduce significant bias, due to rapid settling.

- Due to client requirements (i.e., further analyses on separate phases), sediment state (settled vs mixed, dried vs undried) and sediment levels, the separation techniques used in sediment load determination can vary. This SOP addresses the most stringent methods - full separation with siphoning, centrifuging, and/or filtering. **The analyst must consult project instructions and the associated LIMS program specification for project-specific direction.**
- Any or all separation techniques may be applicable to a set of client samples. Be sure to document on the network spreadsheet, and in the data package narrative, what steps were required for the separation of the samples, as well as any extra steps taken to complete the separation.
- When the separation is complete, the separated phases are given a new Paragon sample ID. Hazard labels are applied, if necessary, and the

samples are returned to the appropriate storage area.

NOTE: It is important to maintain the separated phases in a condition such that they may be analyzed for any requested analysis.

8.2 SETTLED SOLIDS

8.2.1 If left undisturbed, some samples will separate into two phases with the sediment on the bottom and a clear aqueous layer on the top. Pour or siphon (with peristaltic pump and dedicated tubing) the clear aqueous phase from the sample container, **without disturbing or transferring any of the settled solid phase**, into an appropriately sized graduated cylinder. **Leave some liquid in the original container for mixing.** Measure the volume and record in the network spreadsheet.

8.2.2 Next, transfer the measured aqueous phase into a clean container of appropriate size. Label the container with the sample ID and "Aqueous Phase", and place it in proper storage.

8.2.3 The remaining liquid with sediment in the original container can now be processed. Mix the sediment and remaining liquid by swirling the container. Be sure that all solids are loosened and then…

8.2.3.1 …pour directly into an appropriate sized graduated cylinder. Measure the volume and record in the network spreadsheet. Next, quantitatively transfer the material to a **labeled, pre-weighed glass container with cap**. Use a wash bottle filled with DI water to rinse the sides of the graduated cylinder and the original sample container to remove any remaining sediment, adding the rinse directly into the pre-weighed glass container with cap.

8.2.3.2 **OR**, …pour directly into a **pre-weighed 250mL disposable centrifuge tube with cap**, and separate by means of centrifuging. Decant the aqueous phase into another **labeled, pre-weighed 250mL disposable centrifuge tube with cap**. Then, quantitatively transfer the sediment phase to a **labeled, pre-weighed glass container with cap**. Use a wash bottle filled with DI water to rinse the sides of the sample container to remove any remaining sediment, adding the rinse directly into the pre-weighed glass container with cap.

NOTE: The aqueous and sediment phase measurements added together become the sample's "Total Volume" in mLs.

8.2.4 DRYING SOLID MATERIALS

8.2.4.1 Dry the sediment phase (Step 8.2.3) by placing the labeled glass container(s) in a drying oven set at ~100°C. Let the sediment phase sit in the oven overnight to evaporate off all remaining liquid.

8.2.4.2 Move the sediment container(s) to a drying oven set to maintain 103-105°C and allow the sediment to bake for at least one hour.

8.2.4.3 Remove the sediment container(s) from the oven and store in a desiccator until cooled to room temperature.

8.2.4.4 Weigh the glass container (and cap); record weight in the network spreadsheet.

8.2.4.5 Repeat Steps 8.2.4.2 to 8.2.4.4 (drying, cooling, weighing) until a consistent weight is achieved (i.e., difference between weighing is ≤4%, or when the weight change is less than ±0.5mg).

8.2.5 Calculate sediment load (Section 8.5) using the last weight recorded.

8.3 SUSPENDED SEDIMENT

If the sample contains a large amount of suspended sediment that will not settle out, the entire sample must be serially centrifuged.

8.3.1 Pour the sample (or aliquot thereof) into an appropriate-sized graduated cylinder, measure and record the volume on the network spreadsheet.

8.3.2 Transfer an aliquot of sample into a 250mL centrifuge tube.

NOTE: If wet weight is required, pre-weigh the tube (and cap) and record.

8.3.3 Place the tube in the centrifuge and spin for ~15 minutes at 3500rpm.

8.3.4 Decant the top aqueous phase into a clean, labeled (sample ID and "Aqueous Phase") appropriate-sized container.

8.3.5 Repeat Steps 8.3.1 to 8.3.4, recording measurements and adding aliquots to the same tube and decanting to the same aqueous phase container, until the entire sample is centrifuged. **DO NOT pour off any of the settled solid phase!** Put the container of aqueous phase in proper storage.

8.3.6 Next, the sediment phase of the sample can be addressed. Dislodge the sediments in the centrifuge tube by carefully squirting with DI water, cap, then vortex. Quantitatively transfer the contents of the centrifuge tube, using DI water to rinse the sides of the tube, to a **labeled, pre-weighed glass container with cap**.

8.3.7 Dry the solid materials per Section 8.2.4 above.

8.3.8 Calculate sediment load (Section 8.5) using the last weight recorded.

8.4 LOW SEDIMENT LEVELS

If sediment levels are visually low, the entire sample can be filtered through a pre-washed, pre-weighed glass fiber filter.

8.4.1 FILTER PRE-TREATMENT

Begin by assembling the filtration apparatus (vacuum source, vacuum flask, filter base, funnel and clamp). Pre-wash filter by placing it on the filter assembly and passing 100mL of DI water through it (discard rinsate). Move the rinsed filter to labeled aluminum weighing dish, and place the dish with filter in an oven set to maintain 103-105°C, for approximately 1hr. Remove the dish with filter from the oven and place in a desiccator to cool to room temperature. Weigh the dish with filter using an analytical balance, record weight.

8.4.2 Select a pre-treated filter (Step 8.4.1) and center it in the funnel. Turn on the vacuum. Pre-wet the filter using a small amount of DI water to ensure a good seal.

8.4.3 Label a suitable container with sample ID and "Aqueous Phase", and use the container as a sample-specific collection flask.

8.4.4 Measure a volume of sample into a clean graduated cylinder; record on network spreadsheet. Pour the sample volume through the filter, and collect in the labeled container (Step 8.4.3). Repeat until all the sample has been filtered and collected. Then cap and place the filtered aqueous portion of the sample in proper storage.

NOTE: All measurements added together become the sample's "Total Volume" in mLs.

Multiple filters may be required if filtration rate slows or stops due to congestion.

The filter(s) and contents must be retained (i.e., each filter must be carefully returned to it's labeled aluminum weighing dish).

8.4.5 Next, the sediment portion of the sample that was captured by the filter(s) can be addressed. Place the filter and dish into a drying oven set to maintain 103-105°C, for at least 1hr. Remove the filter and dish from the oven and place in a desiccator until cooled to room temperature. Weigh the filter and dish and record on the network spreadsheet.

8.4.6 Repeat drying, cooling and weighing, as described in Step 8.4.5 above, until a consistent weight is achieved (i.e., difference between weightings is ≤4%, or when the weight change is less than ±0.5mg).

8.4.7 Calculate sediment load (Section 8.5) using the last weight recorded.

8.5 CALCULATIONS

$$\text{Sediment Load (mg/L)} = (C_{residue} - C_{empty}) * 1000 / (V_{sample} /1000)$$

where:

$C_{residue}$ = Weight of container with dry residue (g)
C_{empty} = Weight of empty container (g)
V_{sample} = Measured volume of sample (mL)

9. QUALITY CONTROL

No method blank, duplicate or spiked samples are applicable to this procedure.

10. DEVIATIONS FROM METHOD

This procedure was developed at Paragon, based on client need, and is not based on any published method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Manager will address the disposition of these samples.

12. REFERENCES

None.

DOCUMENT REVISION HISTORY

2/2/07: Updated LIMS program spec. language. Added DI water to REAGENTS. Augmented Section 7, pertaining to preservation and hold time. Reformatted PROCEDURES, added minor clarifications, referenced network spreadsheet for recording data and calculating sediment load. Updated HAZARDS. Added DOCUMENT REVISION HISTORY.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1133 REVISION 3

TITLE: ACIDITY BY TITRATION -- METHODS EPA 305.1 AND SM2310B

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1/19/07
QUALITY ASSURANCE MANAGER _____ DATE 1/19/07
LABORATORY MANAGER _____ DATE 1-19-07

HISTORY: Was DRAFT, Rev0, 10/22/03; Rev1, 2/25/04 and 3/29/05 (format updated); Rev2, 7/26/05; Rev 3, 1/19/07. re-released without revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references – US EPA Method 305.1 and Standard Methods (SM) 2310B -- are used to determine acidity in environmental water and wastewater samples, and other waters containing ferrous iron or other polyvalent cations in a reduced state.

This method covers the range from approximately 10-1000mg/L as $CaCO_3$, using a 100mL sample volume. The acidity of a water is its quantitative capacity to react with a strong base to a designated pH. The measured value may vary significantly with the end point pH used in the determination. Strong mineral acids, weak acids (i.e., carbonic and acetic acid) and hydrolyzing salts such as iron or aluminum sulfates may contribute to the measured acidity according to the method of determination.

2. SUMMARY

Acidity is determined by adding a small amount of 30% hydrogen peroxide to an acidified sample (pH 4 or less) and the sample is then brought to a boil. After the sample cools, it is titrated to the endpoint (pH 8.2) with 0.02N NaOH. The results are calculated from the volumes and normalities of the acid and base used as well as the sample volume titrated. The results of the analysis are expressed as mg $CaCO_3$/L.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or by the successful analysis of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the data spreadsheet or analytical review sheets indicate that this review for precision, accuracy and completeness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to correct the errors that were found.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Soaps, oily matter, suspended solids, or precipitates may cause a sluggish response with the pH meter. It may be necessary to allow additional time between titrant additions to let the electrode come to equilibrium.

NOTE: The sample may not be altered in any way to remove interferences because they may contribute to its acidity.

5. APPARATUS AND MATERIALS

5.1 beakers, Pyrex™, 150mL. Use an appropriate beaker size that keeps the air space above the solution to a minimum.

5.2 pipettes, plastic transfer

5.3 volumetric flasks, Class A, 500mL and 1L

5.4 top loading balance capable of reading to 0.01g

5.5 Accumet pH/mV Meter 50, or equivalent, capable of reading to 0.05 pH units

5.6 pH electrode, glass, combination style with reference electrode contained within probe body

5.7 hot plate, large

5.8 magnetic stir plate

5.9 magnetic stir bars, Teflon™-coated

5.10 Eppendorf™ pipette or equivalent, adjustable, capable of delivering 1.0mL

5.11 graduated glass pipets for H_2SO_4 addition

6. REAGENTS

6.1 Deionized (DI) water.

6.2 pH Buffers (4.01, 7.00, 10.01): Orion, 910104, 910107, 910110 or equivalents. Store in polypropylene. *Shelf life = 1 year.*.

6.3 Hydrogen peroxide (H_2O_2), 30% solution: Mallinckrodt, 5240 or equivalent. Store in polypropylene. *Shelf life = 1 year.*

6.4 Standardized sulfuric acid (H_2SO_4), 0.02N: EMD, SX1244-5 or equivalent. Purchased from a commercial vendor or made in-house by diluting 1.0mL of 50% H_2SO_4 to 900mL DI water. Standardization of this solution is carried out for each usage by titrating against the standard base (i.e., 0.20N Na_2CO_3). Store in polypropylene. *Shelf life = 1 year or until degradation is evident.*

6.5 Standardized sodium hydroxide (NaOH), 0.02N: JT Baker, 3722-07 or equivalent. Purchased from a commercial vendor or made in-house by diluting 80mL of 0.25N NaOH to 1L of DI water. Standardization of this solution is carried out for each usage by titrating against the standard acid (i.e., 0.02N H_2SO_4). Store in polypropylene. *Shelf life = 1 year or until degradation is evident.*

6.6 Sodium hydroxide solution, 0.25N: Dissolve 10g NaOH in a final volume of 1L using DI water. Shelf Life = 1 year.

6.7 Hydrochloric Acid (HCl), 0.02N: JT Baker, 9530-33 or equivalent. Purchased from a commercial vendor or made in-house by diluting 200mL of 0.1N HCl to 1L with DI water. Standardization of this solution is carried out for each usage by titrating against the standard base (i.e., THAM). Store in polypropylene. *Shelf life = 1 year or until degradation is evident.*

6.8 Hydrochloric Acid (HCl), 0.1N: JT Baker, 9530-33 (concentrated) or equivalent. Purchased from a commercial vendor or made in-house by diluting 8.3mL of concentrated HCl to 1L with DI water. Store in polypropylene. *Shelf life = 1 year or until degradation is evident.*

6.9 Tris(hydroxymethyl)aminomethane (THAM), 0.20N: JT Baker, 4099-06 or equivalent. Dry about 15g primary standard THAM at about 100°C for 1-2 hours and cool in a desiccator. Transfer 12.114g of the dried THAM to a 500mL volumetric flask. Add 200-300mL of DI water to the flask and swirl to dissolve the salt. Fill to the mark with DI water and mix thoroughly. Store in polypropylene. *Shelf life = 1 year.*

6.10 Phenolphthalein indicator solution: VWR, Cat. No. VW3341-2 or equivalent. Store in polypropylene. *Shelf life = 1 year.*

6.11 Bromocresol green indicator solution: EM Science, 2800 or equivalent. Dissolve 0.5g of bromocrescol green sodium salt in 500mL DI water. Store in polypropylene. *Shelf life = 1 year.*

6.12 Sodium carbonate standard solution (Na_2CO_3), 0.20N: JT Baker, 3604-01 or equivalent. Dry about 10g primary standard Na_2CO_3 at 250°C for 4 hours and cool in a desiccator. Transfer 5.300g of the dried Na_2CO_3 to a 500mL volumetric flask. Fill to the mark with DI water and mix thoroughly. Store in polypropylene. *Shelf life = 1 year.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples may be collected in either plastic or glass containers and must be collected according to an approved sampling plan. The sample containers should be filled as full as possible to minimize headspace.

7.2 Water samples should be kept refrigerated (0-6°C) from the time of collection and analyzed as soon as possible. The samples must be analyzed within 14 days after collection.

8. PROCEDURE

8.1 CALIBRATION OF pH METER

Calibrate the pH meter according to manufacturer's instructions by using pH buffers 4.01, 7.00 and 10.01. On the Accumet 50 pH meter, push "standardize" and select choice #2, "clear existing standards". Place the probe in first pH buffer, push "standardize" and select choice #1, "update or add standard". Enter buffer value and push enter. Let the probe sit in the buffer solution for 1-2 minutes, then push enter. Repeat these steps for next two buffers concentrations. Discard the buffer aliquots after each day's use.

8.2 HOT PEROXIDE TREATMENT

8.2.1 Place a 150mL beaker on the top loading balance. Tare the balance. Gravimetrically pipet a 100mL aliquot of sample (or less if a smaller sample size is required) into the beaker. Record the sample volume in the data spreadsheet. If less than a 100mL aliquot of sample is used, bring to a final gravimetric volume of 100mL with DI water.

8.2.2 Measure the pH of the sample. If the pH is above 4.0, add standard sulfuric acid (Section 6.3) in 5.0mL increments to lower the pH to 4.0 or less. If the initial pH of the sample is less than 4.0, the incremental addition of sulfuric acid is not required.

8.2.3 Add 5 drops of hydrogen peroxide.

8.2.4 Heat the sample to boiling and continue boiling for 2 to 5 minutes. In some instances, the concentration of ferrous iron in a sample is such that an additional amount of hydrogen peroxide and a slightly longer boiling time may be required.

8.2.5 Laboratory Duplicate (DUP): Select one sample per batch of 20 or less field samples processed as a unit, and prepare a second aliquot of that sample to serve as the laboratory duplicate. Process as described in Steps 8.2.1 through 8.2.4 above.

8.2.6 Method Blank (MB): Aliquot 100mL of DI water into a 150mL beaker to be processed as the batch method blank. MBs are run to demonstrate that interferences from the analytical system, glassware and reagents are under control. Process as described in Steps 8.2.1 through 8.2.4 above.

8.2.7 Laboratory Control Sample (LCS): Prepare this check sample by transferring 10.0mL of 0.02N HCl standard solution to a 150mL beaker containing a stir bar; dilute to 100mL with DI water. One LCS is to be prepared for each batch of samples processed. The LCS is run at the beginning of each day's analysis following standardization of the titrant, as a measure of the accuracy of the method. Process as described in Steps 8.2.1 through 8.2.4 above.

8.3 STANDARDIZATION OF THE ACID TITRANT

8.3.1 Pipette 1.00mL of 0.20N Na_2CO_3 (Section 6.7) and approximately 2mL of bromocresol green indicator into a 150mL beaker containing 100mL DI water. Add a stir bar and place the beaker + contents on the laboratory balance and tare the balance.

8.3.2 Place the beaker + contents on a stir plate. Adjust the stir plate control so that the beaker's contents mixes slowly.

8.3.3 Place the pH probe in the beaker. Using the pH meter and color indicator as reference points, titrate to a pH of 4.0 by adding 0.02N H_2SO_4 dropwise. When the color of the solution turns from blue to green, the endpoint has been reached. Place the beaker + titrated contents on the balance and record the weight of the titrant used in the data spreadsheet.

8.3.4 Repeat Steps (8.3.1 - 8.3.3) twice more for a total of three standardization replicates. Calculate the average of the standardization results to determine the titrant's concentration.

8.4 STANDARDIZATION OF THE BASE TITRANT

8.4.1 Pipette 10.0mL of standardized 0.02N H_2SO_4 (Section 6.3) and approximately 1 to 2 drops of phenolphthalein solution into a 150mL beaker containing 100mL DI water. Add a stir bar and place the beaker + contents on the laboratory balance and tare the balance.

8.4.2 Place the beaker + contents on a stir plate. Adjust the stir plate control so that the beaker's contents mixes slowly.

8.4.3 Place the pH probe in the beaker. Using the pH meter and color indicator as reference points, titrate to a pH of 8.2 by adding 0.02N NaOH dropwise. When the color of the solution turns pink, the endpoint has been reached. Place the beaker + titrated contents on the balance and record the weight of the titrant used in the data spreadsheet.

8.4.4 Repeat Steps (8.4.1 - 8.4.3) twice more for a total of three standardization replicates. Calculate the average of the standardization results to determine the titrant's concentration.

8.5 TITRATION OF SAMPLES

The samples prepared previously in Section 8.2 must be allowed to cool to room temperature before titrating. Titrate as follows:

8.5.1 Add stir bar and 1-2 drops of phenolphthalein solution to the sample beaker.

8.5.2 Move the sample beaker to the stir plate and submerge the pH probe in the sample solution. Adjust the stir control so that the beaker's contents mix slowly.

8.5.4 Add 0.02N NaOH dropwise until the sample turns pink or the pH meter reads 8.2. Place the beaker with titrated sample on the top loading balance and record the amount of titrant used in the data spreadsheet.

NOTE: Rinse the pH probe with DI water between each sample immersion.

8.6 ANALYTICAL RUN SEQUENCE

Perform the acidity determinations in the following sequence:

1. MB
2. LCS
3. DUP
4. 17 field samples

If a second batch of samples are to be analyzed, the sequence repeats beginning with a MB, LCS, DUP, 17 field samples, etc.

8.7 CALCULATIONS

8.7.1 SULFURIC ACID TITRANT, 0.02N

$$C_{H_2SO_4} = \frac{(C_{Na_2CO_3})(V_{Na_2CO_3})}{V_{H_2SO_4}}$$

where:

$C_{Na_2CO_3}$ = concentration of Na_2CO_3 titrant, N or eq/L (equals 0.20N if preparation is followed without deviation)

$V_{Na_2CO_3}$ = volume (mL) of Na_2CO_3 standard titrated; equals 1.0mL if SOP is followed without deviation)

$V_{H_2SO_4}$ = volume (mL) of H_2SO_4 titrant required to reach endpoint

therefore:

$$C_{H_2SO_4} = \frac{(0.20N)(1.0mL)}{V_{H_2SO_4}}$$

Average the results of the three replicate standardizations to calculate the H_2SO_4 titrant concentration.

8.7.2 NAOH TITRANT, 0.02N

$$C_{NaOH} = \frac{(C_{H_2SO_4})(V_{H_2SO_4})}{V_{NaOH}}$$

where:

$C_{H_2SO_4}$ = concentration of H_2SO_4 titrant, N or eq/L (normality is calculated from the standardization of the acid)

$V_{H_2SO_4}$ = volume (mL) of H_2SO_4 standard titrated; equals 10.0mL if SOP is followed without deviation)

V_{NaOH} = volume (mL) of NaOH titrant required to reach endpoint

therefore:

$$C_{NaOH} = \frac{(\text{calculated normality})(10.0\ mL)}{V_{NaOH}}$$

Average the results of the three replicate standardizations to calculate the NaOH titrant concentration.

8.7.3 CALCULATION OF ACIDITY

$$\text{acidity as mg/L CaCO3} = \frac{[\ (A \times B)\ -\ (C \times D)\ ] \times\ 50{,}000}{\text{mL of sample titrated}}$$

where:

A = Concentration of NaOH

B = Volume of NaOH

C = Concentration of H_2SO_4

D = Volume of H_2SO_4

50,000 = conversion factor (eq/L to mg $CaCO_3$/L)

9. QUALITY CONTROL (QC)

9.1 Various types of QC samples such as method blank (MB), laboratory duplicate (DUP) and laboratory control sample (LCS) are discussed previously in Section 8.2. Acceptance criteria for these quality control measures are shown in the QC Summary Table at the end of this SOP.

9.2 LABORATORY CONTROL SAMPLE RECOVERY

Results obtained for the LCS are compared to results expected. The mathematical evaluation is expressed as Percent Recovery (%R), and is calculated as follows:

$$\%R = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Target}}} \times 100$$

To be acceptable, percent recovery must be between 85% and 115% of the expected concentration.

9.3 LABORATORY DUPLICATE PRECISION

The laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. The duplicate results are compared mathematically (shown below), with the precision expressed as Relative Percent Difference (RPD):

$$\text{RPD (\%)} = \frac{|\ \text{Result}_x - \text{Result}_{\text{Dup}}\ |}{\frac{(\text{Result}_x + \text{Result}_{\text{Dup}})}{2}} \times 100$$

For this procedure, the RPD should not be greater than 15%.

10. DEVIATIONS FROM METHOD

There are no known deviations from the methods.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The aqueous solution left over from the titration shall be disposed of in the Aqueous Laboratory Waste satellite collection vessel.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs; all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.3 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Compliance Officer will address the disposition of these samples.

DOCUMENT REVISION HISTORY

7/26/05: Program specification reference added, Section 3.

1/19/07: Language of program specification reference updated. Added 0.25NaOH and 0.1N HCl recipes to Section 6. Added DOCUMENT REVISION HISTORY.

Analytical Method: EPA 305.1; SM 2310B	**Parameter:** Acidity		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Calibration: analyte content is determined by direct concentration (obtained by calculation from titration)	The titrants are standardized each day of use	Titrant should calculate to be between 0.18-0.22N	If titrant does not meet concentration criteria; prepare fresh and standardize via three replicate analyses.
Method Blank (MB)	One MB per each batch of ≤20 field samples and each time a reagent is changed	No blank's acidity may exceed the reporting limit (RL); usually 10mg $CaCO_3$/L	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All associated samples must also be reanalyzed.
Laboratory Control Sample (LCS)	One per batch of ≤20 field samples	Results obtained must be within 85-115 % of that expected	Check calculations and preparation for documentable errors. If no errors are found, remake and reanalyze. All associated samples must also be reanalyzed.
Laboratory Duplicate (DUP)	One per batch of ≤20 field samples	RPD must be ≤15%	Check all calculations for errors. If no errors are found, discuss with Department/Project/QA Managers.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 127 REVISION 9

TITLE: PROCUREMENT OF SUPPLIES AND MATERIALS, INCLUDING RADIOACTIVE MATERIALS, AND EVALUATION OF PURCHASED ITEMS RECEIVED

FORMS: PURCHASE REQUISITION FORM

APPROVED BY:

TECHNICAL MANAGER _____ DATE 10/2/07
QUALITY ASSURANCE MANAGER _____ DATE 10/2/07
LABORATORY MANAGER _____ DATE 10/4/07

HISTORY: Rev0, 11/16/92; Rev1, 1/14/94; Rev2, PCN #125, 2/1/94, Rev3, PCN #315, 1/3/95; Rev4, 7/15/99; Rev5, 12/31/01; Rev6, 2/14/0; Rev7, combined with SOP 128, 2/9/04, format updated 3/24/05; Rev8, 9/11/06; Rev9, 10/2/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) defines the procedures to be followed for completing and managing procurement requests, as well as those procedures to be used for evaluating the acceptability of the purchased items received.

Also defined herein are the requirements for items that are purchased (e.g., standards, solvents, reagents, laboratory supplies and equipment), including radioactive materials, and for vendors that are approved for use. These requirements are established to ensure that all items used by Paragon are of acceptable quality, and that the purchase of radioactive materials meets Paragon's licensing requirements.

2. SUMMARY

All supplies and materials ordered must meet all applicable technical requirements as established by the appropriate Department Manager, and the Radiation Safety Officer (RSO), as applicable. Only vendors deemed suitable for use, as defined by the appropriate Department Manager and RSO, as applicable, shall be purchased from.

A Purchase Requisition Form is used to request all supplies and materials. Signatures signifying appropriate Departmental and financial approval must be obtained prior to submitting the completed form to Paragon's Purchasing Agent.

Paragon's Purchasing Agent then generates a Purchase Order Form (created electronically within the DataChem accounts system), and completes the acquisition process. All required documentation shall be maintained by the Purchasing Agent.

An initial inspection of all incoming materials upon receipt is performed by the Purchasing Agent or designee. The ongoing evaluation of suppliers used and the acceptability of the materials received from them is the responsibility of the Department Manager, and RSO as applicable.

3. RESPONSIBILITIES

3.1 It is the responsibility of Paragon's Purchasing Agent to provide guidance regarding the procurement protocols to be followed, to process procurement requests in a timely manner, to manage vendor accounts in conjunction with the appropriate Department Manager(s), retain purchasing records as required, and maintain a supply of requisition forms.

3.2 The Department Manger is responsible for establishing and enforcing the quality requirements for all standards, reagents, materials and supplies ordered, as well as evaluating the acceptability of these materials after receipt (evaluative training shall be provided to delegated staff, as applicable). The requirements established for these materials shall be based on method requirements, equipment requirements, quality guidances, and client criteria and user needs, as applicable.

The Department Manager is responsible for directing the purchase of materials and supplies only from suitable vendors. Certification documents may be applicable to some materials and supplies ordered; the Department who purchased the materials is responsible for retaining these records.

The Department Manager, or designee, shall record purchased materials information in the Paragon Standards and Solutions database, as applicable, per LQAP and SOP 300 directives.

3.3 The RSO (or designee) is responsible for the purchase of all radioactive materials. Because of licensing constraints, the RSO must know the quantities of radioactive materials that are present in the laboratory at all times. Therefore, it is appropriate that the RSO be responsible for all radioactive materials purchases.

3.4 The Quality Assurance Department is responsible for providing general support as needed, and for oversight of conformance to the purchase of materials and verification system requirements.

3.5 It is the responsibility of all personnel to perform these procedures according to this SOP and to complete all documentation required for review.

4. PROCEDURE

4.1 All items purchased must meet the applicable technical requirements as defined by the Department Manager. Only vendors deemed suitable for use, as defined by the appropriate Department Manager and RSO, as applicable, shall be purchased from. The following areas may be evaluated when assessing the suitability of a supplier:

- Paragon's experience with the supplier.
- Supplier's product specifications and technical literature.
- Paragon's evaluation of supplier's quality assurance program.

- Supplier's support and service.
- Supplier's referrals and recommendations.
- Results of Paragon's inspection and testing of materials by the appropriate Department.
- Price.

The suppliers that Paragon uses and the materials acquired from them are evaluated on an ongoing basis. If a performance issue occurs, the supplier is contacted for resolution. If the matter cannot be resolved, an acceptable alternate supplier is used.

4.2 The requestor shall completely fill out the Purchase Requisition Form as prompted by the lines indicated, including the desired vendor to be used. The Form shall then be submitted to the appropriate Department Manager or RSO, as applicable.

4.3 All radioactive materials shall be ordered through the RSO. The appropriate Department Manager/designee or RSO shall review the completed Purchase Requisition Form for completeness and accuracy and shall sign and date the Form to signify financial approval for the items to be ordered. Financial approval from an appropriate Senior Manager must also be obtained, as applicable, before submitting the completed Purchase Requisition Form to Paragon's Purchasing Agent.

4.4 Paragon's Purchasing Agent will review the requisition for completeness and correctness, including the approval signatures obtained. The Purchasing Agent is responsible for generation of a purchase order, documenting the date the materials are ordered, managing the acquisition of any items that may be backordered, and maintaining the required documentation associated with the materials' purchase and receipt.

4.5 Sample Receiving personnel notify the Purchasing Agent when incoming materials have arrived. If the materials are radioactive, Sample Receiving staff will first perform a radioactive material contamination survey (SOP 008), and then will contact both the RSO and the Purchasing Agent to notify them that the radioactive material has arrived. The radioactive material contamination survey results must not exceed the limits of contamination as prescribed in Colorado RH 17.15.8 (see Table 5.1 of SOP 008).

4.6 Before accepting any materials, the Purchasing Agent or designee shall perform an initial inspection consisting of the following:

- Verify that materials were not damaged in transit.

- Compare the materials to the Purchase Order and/or Requisition Form and the supplier's packing slip.

As applicable, the RSO shall verify that the removable contamination is within acceptance limits and shall accept the material for distribution.

4.7 The end user is then notified that the materials ordered have arrived and have been accepted.

4.8 The materials are kept in the area received until the Department who ordered them relocates the items. This is done to avoid misplacement or loss and potential contamination, as well as to keep the items segregated should further evaluative testing need to be conducted before the items are released to the laboratory for use.

4.9 Per Departmental direction, further inspection or testing of the acceptability of materials received may be conducted (e.g., review of Certificates of Cleanliness received for VOA vial shipments; lot analysis of Trace Metals grade HNO_3, verification of radioanalytical standards). Associated documentation, including materials certificates received, shall be retained by the applicable Department.

NOTE: Where additional evaluation practices exist, staff are **not** permitted to use the materials until the evaluation has been completed successfully.

4.10 Should any purchased items be deemed damaged (e.g., initial receipt inspection) or unacceptable (e.g., additional review or testing), resolution shall be pursued by the Department Manager in conjunction with the Purchasing Agent. The QA Department shall be notified, as appropriate.

4.11 For solvents and reagents, Departmental end users are responsible for labeling the individual bottles with date of receipt and initials. Other information (e.g., date of expiration) must also be entered into Paragon's Standards and Reagents database, as applicable (see LQAP and SOP 300).

5. SAFETY, HAZARDS AND WASTE DISPOSAL

5.1 SAFETY AND HAZARDS

5.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

5.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), or when handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

5.2 WASTE DISPOSAL
Not Applicable.

STANDARD OPERATING PROCEDURE 132 REVISION 6

TITLE: BUILDING SECURITY

FORMS: 155 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 12/11/06
QUALITY ASSURANCE MANAGER _____ DATE 12/6/06
LABORATORY MANAGER _____ DATE 12-12-06

HISTORY: Rev0, 3/10/92; Rev1, 3/10/93; Rev2, 5/18/01; Rev3, 4/29/02; Rev4, 2/9/04; Rev5, 3/10/05; Rev6, 12/7/06. re-released w/o revision 1/14/07 DAS

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes procedures used to provide a secure environment for staff, equipment, materials, and samples.

2. OVERVIEW

The building is equipped with an alarm system and motion sensors, which are monitored by a contracted security vendor. Each employee is made aware of the current alarm code and is issued an alarm quick reference card. The laboratory's ~~the~~ front office area is separated from the operational area and access is controlled via doorways that require pass code entry. All employees are made aware of the current internal pass code. All visitors, with the exception of previously exempted repair/maintenance personnel (Section 5.3), are required to read the Visitor Orientation Guidelines, sign the Visitor log, and obtain a "VISITOR" badge, which must be worn prominently while in the facility. Visitors must sign out and return the "VISITOR" badge upon exit. All non-exempted visitors must be escorted by a Paragon employee at all times while in the facility.

DAS 12/14/06

3. RESPONSIBILITIES

3.1 All employees are responsible for maintaining the facility in a secure manner. Doorways shall not be propped open and left unattended. Access and pass codes shall remain confidential.

3.2 It is the responsibility of the last staff member leaving the building for the night to properly arm the alarm system.

3.3 The Facilities Manager and designee(s) are responsible for the issuance and maintenance of security codes, for interfacing with the security system vendor, for addressing security issues should they arise, and for enforcing compliance with the procedures outlined in this SOP. The Facilities Manager and designee(s) are available by cell and/or home phone during non-business hours. If a security risk is identified, the security codes shall be changed immediately.

3.4 Paragon's Health & Safety Officer (HSO) is responsible for maintaining the content and availability of the Visitor Orientation Guidelines.

3.5 The Quality Assurance Department provides clerical support to the HSO and Facilities Manager as needed by issuing the Visitor log and maintaining an adequate supply of Visitor badges.

4. APPARATUS AND MATERIALS

4.1 "VISITOR" badges

4.2 Visitor log

4.3 Visitor Orientation Guidelines

4.4 Alarm system

4.5 Employee quick reference cards

4.6 Doorway keycode entry devices

5. PROCEDURE

5.1 All visitors are required to read the Visitor Orientation Guidelines, which is located next to the Visitor log.

5.2 The Visitor log (Form 155) and "VISITOR" badges are maintained in the front lobby area. All visitors who do not have prior permission from an authorized Paragon individual to conduct work on the premises (see 5~~.4~~3 below) are required to sign in. Upon sign in, each visitor must acquire a "VISITOR" badge and wear it prominently at all times while in the facility. Each "VISITOR" badge is numbered, and the number of the badge used must be recorded in the Visitor log. 1/14/07 DAS

5.3 All visitors must be escorted by a Paragon employee or other authorized individual at all times. Exception: Selected vendors are allowed access without continuous escort in order to facilitate maintenance, repairs or deliveries.

5.4 All visitors are required to sign out and to surrender the "VISITOR" badge upon exit.

6. SAFETY AND HAZARDS

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1400 REVISION 6

TITLE: PROCESS SOFTWARE VALIDATION

FORM: 1403 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1/8/07

QUALITY ASSURANCE MANAGER _____ DATE 1/8/07

LABORATORY MANAGER _____ DATE 1-8-07

HISTORY: Rev0, 5/23/97; Rev1, 10/8/99; Rev2, 8/25/00; Rev3, 3/28/02; Rev4, 3/28/03; Rev5, 2/13/04 and 7/26/05 (re-released without revision); Rev6, 1/8/07. re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the validation of a software process that has been created or modified for the purpose of processing laboratory data, manipulating data, or reporting data to our clients in either an electronic format or a report (hardcopy) format. This procedure is applicable for all such software applications or processes that are used throughout the laboratory for the purposes described above.

2. SUMMARY

Paragon uses various types of computer software to collect data, perform calculations on data, and report data to clients. Some of the software used to collect the data is created by the various instrument manufacturers and these software applications are specific to a certain instrument or a particular instrument model number. Upgrades or changes to this kind of software are provided, via software maintenance agreements, by the instrument manufacturers. However, software that is used to manipulate data, perform calculations, and report data, is either purchased by Paragon from other vendors, or it is created by Paragon's Information Systems (IS) Department staff.

Changes may be made to software for one or more of the following reasons:

- An improvement to the way the software performs its particular task is requested;
- Client specification or request requires a slight modification to a particular software process;
- New tests or procedures added to the data handling system; or
- Custom reports or EDD generation are requested.

Each of the items listed above may encompass varying levels of detailed changes to a software process. Whenever these changes, as defined in the Procedures Section of this SOP, are made to a software process, the process must be validated to ensure that the change was made successfully. This validation is documented on a Software Process Validation (SPV) form (Form 1403), that is then retained by the IS Department

indefinitely.

3. RESPONSIBILITIES

3.1 Paragon's Information Systems (IS) Department will maintain the verification/ validation records generated during the performance of this SOP. IS Department staff shall ensure that an SPV form is used and shall verify that the form is appropriately and completely filled out.

3.2 Laboratory Reporting Group staff involved in this process are required to adhere to the requirements of this SOP as they perform the necessary validation/ verification steps. Upon completion of the required documentation, the Reporting Group staff shall return the documentation to the IS Department, along with any supplemental records needed to demonstrate successful completion of this procedure.

4. PROCEDURES

4.1 DEFINITIONS

The following definitions apply exclusively to this SOP. While other SOPs may use some of the same text within their documentation, the meaning of the terms described below must be defined here in order to interpret this procedure properly.

- **Application:** A software program that may serve as a specific tool for data retrieval, processing, manipulation, and reporting.
- **Software Process:** A programming element of an application that performs a specific task within that application.
- **Process Validator:** An individual who has been designated to test a Process Change in order to validate its effectiveness and accuracy.

4.2 PROCESS CHANGES TO SOFTWARE

Process Changes to software are defined as any change that may affect the final result or any supporting flag conventions that were used to report results to clients. The following are examples of Process Changes that would initiate the software process validation procedures discussed in this SOP:

- A change in an equation or equations that are used to obtain a result.
- A change in the logic structure of the program that is used to access equations.
- A change in the logic structure of the program used to flag associated results with any particular set of flagging criteria, including client specific criteria.
- A change in any part of the application process that affects both retrieval and manipulation of data from instruments, or the process of hand data entry.

- A change that may alter or modify the use of a variable (one that is either calculated or logical) in a data process.

4.3 Examples of issues or items that are *not* regarded as Process Changes under the above definitions and descriptions and, therefore, *will not* initiate the software process validation procedure include:

- A change to a field width on a report.
- A change to fonts that are used on a report.
- A change to properties of a field relating to user access and/or privileges.
- Cosmetic changes to the user interface and other supporting screens.
- Adding test codes, client names, or other supporting information to an application.

4.4 When a Process Change, as described above, is made to an application, an SPV form must be issued to a Process Validator who works with the Department(s) for whom the Process Change affects. This Process Validator will verify that the Process Change works as intended and shall complete the SPV form within three (3) working days. The SPV form will then be returned to the IS Department for archival.

4.5 If, however, the Process Change does not perform as expected, the Process Validator shall mark the SPV form with an entry in the appropriate section for an unsuccessful Process Change, and shall initial and date this entry. The SPV form will then be returned to the IS Department who will first correct the problems with the Process Change, then re-issue the same SPV form for re-evaluation. These steps will repeat as necessary until the Process Change can be validated.

5. PROCESS SUMMARY

The following is a summary of the steps required to satisfy the requirements of this SOP:

- A Process Change, as defined in herein, is requested, and is made according to the procedures discussed above.
- A Software Process Validation (SPV) form is issued by the IS Department to a Process Validator for completion.
- The Process Validator tests the Process Change. If the Process Change is successful, all required documentation is returned to the IS Department and the IS Department retains the SPV form indefinitely.
- If the Process Change is unsuccessful, the Process Validator marks an entry indicating such on the SPV form and initials and dates the entry. The SPV form and all support information is given to the IS Department.
- The IS Department makes the appropriate corrections and re-issues the SPV form

to the Process Validator.

- The cycle of circulation of the SPV form between the IS Department and the Process Validator is repeated until the Process Change is successful.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes procedures for backing up network servers and instrument PC hard drives. Archiving of backup tapes and restoration of files is also discussed.

2. SUMMARY

The Information Systems (IS) Manager routinely backs up all instrument computer systems and network files. The files are verified as they are backed up and re-verified subsequently to ensure restorability. Key backup tapes are stored in an off-site bank vault.

3. RESPONSIBILITIES

3.1 The IS Department is responsible for establishing and following procedures regarding backup of network files, and for overseeing PC hard drive backup efforts. The IS Department shall determine what devices and supplies are suitable for accomplishing backups and restorations, and shall maintain these devices and availability of the necessary supplies. Management of archived file information is the responsibility of the IS Department. The IS Department is responsible for file restoration efforts as they become necessary, or when requested.

3.2 Laboratory staff are responsible for coordinating instrument backup with the IS Department in accordance with established schedules.

3.3 It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. PROCEDURES

Several aspects of routine network operations (including backup) are highlighted below:

- The network is scanned constantly for viruses.

- The network is completely backed up every night, with the exception of Saturday and Sunday. Monday through Thursday tapes are kept on-site. Each tape can accommodate three weeks of backup. The IS Manager maintains the tape archive. Friday tapes are stored off-site in a bank vault.
- Database files maintained on the network are backed up three times daily. The files are verified each time they are backed up. LIMS, reporting databases, and accounting databases are all backed up in this manner.
- Patches and upgrades from both Microsoft and Netware are checked for weekly. If found, patches and upgrades are installed during the off-hours so as not to impact laboratory productivity. Laboratory personnel are notified via e-mail of any upcoming network maintenance.
- Most instrument PCs are network interfaced. Stand-alone instrument PC systems and files are backed up periodically, as needed, prompted by the laboratory Department Manager or other applicable staff.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1402 REVISION 6

TITLE: **LABORATORY INFORMATION MANAGEMENT SYSTEM (LIMS) VERSION CONTROL**

FORMS: ~~NONE~~

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11/5/07

QUALITY ASSURANCE MANAGER _____ DATE 11/4/07

LABORATORY MANAGER _____ DATE 11/5/07

HISTORY: Rev0, 3/3/98; Rev1, 8/25/00; Rev2, 3/28/02; Rev3, 3/28/03; Rev4, 2/13/04 (format update) and 7/26/05 (re-released without revision); Rev5, 1/8/07; Rev6, 11/4/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes procedures for tracking and controlling release iterations of LIMS software.

2. SUMMARY

The Laboratory Information Management System (LIMS) is a Microsoft Windows® based product that was developed in-house. The LIMS is maintained and customized by the LIMS Manager as the needs of the laboratory and clients require. Any changes that are made to the LIMS, or portions of the LIMS, are documented and maintained by the LIMS Manager in a version control database. The version control database contains the following information:

- Old version number;
- Name of object that was changed;
- Type of object changed;
- Description of the item changed within the object;
- Date the change was made;
- Detailed description of what function the change addresses or performs ;
- New version number.

3. RESPONSIBILITIES

3.1 The LIMS Manager is responsible for the maintenance and continued development of LIMS. The LIMS Manager is responsible for maintaining a library of changes made to LIMS. The LIMS Manager shall determine what LIMS training is required contingent upon functional position, and shall oversee the employee's receipt of appropriate LIMS training.

(by means of use of discrete data sets; limited application before full release, etc.) 3/9/09 DAS

3.2 All LIMS hardware and communications components changes are proposed and performed by IS/LIMS management staff, with the concurrence of the Laboratory Director. All changes are fully tested before being implemented throughout the laboratory. The acceptance criteria is that the change adequately addresses the need, and provides accurate data/processing.

are

the correct information is referenced or captured, 3/9/09 DAS

All employees shall adhere to IS and LIMS policies as they are directed, and as expressed in Paragon's IS and LIMS policy statements, for which each employee receives annual refresher training.

3.4 It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. PROCEDURES

The LIMS Manager retains a "working copy" of the LIMS -- this copy is used to make any changes to the LIMS. After these changes have been made, the LIMS Manager documents the changes, as described above, and "releases" the newest version of LIMS. A sequence of steps describing the process of making a change in LIMS is shown below:

- The LIMS Manager changes objects (portions) in LIMS as needed.
- The changes are documented in the version control database (as described above).
- The changes are tested by the LIMS Manager prior to release.
- The LIMS Manager releases the newest version of the LIMS to the laboratory.
- LIMS upgrades are automatically installed prompted by a small program that has been incorporated into the network login process.
- The LIMS Manager maintains an archive of version updates.

(i.e., is the outcome independently verifiable), and does the software task run from start to finish without 'freezing' or other glitch (e.g., no error messages) 3/9/09 DAS

5. REFERENCES

None.

DOCUMENT REVISION HISTORY

1/8/07: Updated RESPONSIBILITIES. Added DOCUMENT REVISION HISTORY.

11/4/07: Updated RESPONSIBILITIES to include IS/LIMS management staff with the concurrence of the Laboratory Director, regarding all LIMS hardware and communications components changes. Also noted that the acceptance criteria for these changes is that the change adequately addresses the need, and provides accurate data/processing.

The LIMS Manager is responsible for maintaining documentation of software testing, including the evaluation of test results. 3/9/09 DAS

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 143 REVISION 4

TITLE: **NEW EMPLOYEE QUALITY ASSURANCE ORIENTATION AND TRAINING**

FORMS: **159, 162, 921, 977**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7/18/05
QUALITY ASSURANCE MANAGER _____ DATE 7/18/05
LABORATORY MANAGER _____ DATE 7-19-05

HISTORY: Rev0, 3/28/95; Rev1, 8/23/00; Rev2, 4/17/02; Rev3, 9/22/03; Rev4, 7/20/05.
re-released w/o revision 10/15/07 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) provides an overview of the Quality Assurance (QA) training received by new employees. The scope and content of the Health & Safety and waste disposal training also received by new employees is not addressed in this SOP.

2. OVERVIEW

QA training is given to new employees in five phases: (1) General Introduction and Initial QA Training, (2) Departmental Orientation and SOP Review, (3) On-the-Job Training, (4) Initial Demonstration of Capability (IDOC), and (5) supplemental QA and Department Training sessions, as topical needs arise. Health & Safety and waste disposal training are managed and conducted by the Health & Safety and Facilities Departments.

3. RESPONSIBILITIES

3.1 Only staff that have previously demonstrated competency in the area for which training is to be conducted are permitted to train.

3.2 Management of training content, scheduling, and documentation of training conducted is the responsibility of the appropriate Department Manager.

3.3 The QA Department is responsible for the oversight and maintenance of all QA and skills training records.

3.4 The Health & Safety and Facilities Departments are responsible for the oversight and maintenance of all Health & Safety and waste disposal training records.

4. PROCEDURE

4.1 A representative of the QA Department meets with each new employee, usually on their first day of hire. Specific employee information (name, employee number, title, group assignment, etc.) is entered into the SOP and Training Records database. Preliminary SOP assignments are also made in the database. An employee folder is created on the network to receive images of the employee's training records.

4.2 The QA Department representative then performs the following steps as part of the General Introduction and Initial QA Training:

- an overview of Paragon's quality culture and training to be received is given.
- The employee's initials and signature are obtained (Form 977, Ongoing Signature and Initials File).
- Signed Professional Conduct (Form 162) and IS and LIMS Policies ethics statements are acquired.
- The employee is informed of obligations and protection under "Whistleblower Protection for Contractor Employees", USDOE General Provision DEAR 952.203.70 (Form 921, Waste, Fraud and Abuse Notification).
- Copies of the employee's resume and degree, transcript or diploma are requested if not already available.

4.3 Credits for the above information are entered into the SOP and Training Records database. Preliminary SOP assignments are made and a printout of the employee's assigned SOPs is provided. The following SOPs, *which must be read and signed-off within two weeks of hire*, are discussed with the new employee:

- Control and Format of Laboratory Logbooks (SOP 303)
- Internal Chain-of-Custody (SOP 318)
- Review, Revision and Distribution of Controlled Documents (SOP 926)
- Issuing and Tracking of Non Conformance Reports (SOP 928)

4.4 The Laboratory Quality Assurance Plan (LQAP) is identified and stipulated as required reading *within the first month of hire.*

4.5 Images of information obtained above, as applicable, are posted to the employee's folder on the network.

4.6 The new employee is then routed to the Health & Safety Manager or Facilities Manager or designee to receive their initial Health & Safety and waste disposal Training.

4.7 Following initial Health & Safety and waste disposal training, the appropriate Department Manager oversees the Departmental Orientation and SOP Review Training received by each new employee. Employee SOP review is managed via the SOP module of the SOP and Training Records database. Dates for each SOP that were read by the new hire are entered into the database by the Department Manager, and the new employee signs a report printout attesting to the SOPs read and understood. The signed SOP report is forwarded to the QA Department for retention.

4.8 Departmental skills are learned by the new employee during On-the-Job Training with appropriate supervision. After sufficient competency has been gained in a particular area or with regard to a specific technical SOP, the new hire substantiates his/her skill via an Initial Demonstration of Capability (IDOC). IDOC summary data, reviewed and signed by the Department Manager, is submitted to the QA Department for tracking and retention.

4.4 Supplemental QA and Department Training (continuing education) is provided to employees via topical training sessions, as the need arises. The QA Department maintains these training files (credits the training in the database, posts documentation images).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 202 REVISION 10

TITLE: LOGIN AND DISTRIBUTION OF SAMPLES AND WORKORDERS

FORMS: 008, 201, 214, 319 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 12/11/06

QUALITY ASSURANCE MANAGER _____ DATE 12/11/06

LABORATORY MANAGER _____ DATE 12-12-06

HISTORY: Rev0, 12/23/94; Rev1, 5/22/97; Rev2, 1/6/99; Rev3, 11/24/99; Rev4, 1/17/00; Rev5, 8/14/01; Rev6, 1/24/02; Rev7, 4/17/02; Rev8, 3/19/03; Rev9, 2/9/04 and 7/18/05; Rev10, 12/7/06.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes procedures for the acceptance and login of samples received by Paragon. Samples are received and processed in a manner that minimizes both exposure risk to laboratory personnel and potential for sample contamination.

Radiation survey, login procedures, workorder folder initiation, sample temperature upon receipt (where applicable), sample identity and condition verification, discrepancy resolution, temporary storage, Project Manager review, and distribution of samples within the laboratory are discussed. Sample chain-of-custody procedures are addressed in SOP 318. SOP 207 addresses sample packaging for subcontracted analysis.

2. SUMMARY

All sample shipping containers are surveyed for external radiation (SOP 008). For chilled samples, cooler temperature is determined. The contents of each shipping container are inspected for breakage, then the cooler is unpacked. A workorder number is assigned and a workorder folder initiated. General sample information is entered into the Laboratory Information Management System (LIMS), and Paragon sample labels are generated and applied to each sample bottle. Where appropriate, samples are prescreened (SOP 703) to roughly determine the nature and level of radioactivity. Where applicable, samples are checked for pH and/or residual chlorine. The samples are then grouped (for future segregated sample storage), but held together in temporary storage pending ~~release by the Project Manager. Samples are not released for~~ distribution to the laboratory areas ~~for processing until additional login steps are completed and the Project Manager has reviewed the workorder folder.~~ 1/7/07 DAS

3. RESPONSIBILITIES

3.1 Only personnel who have been trained regarding Department of Transportation (DOT) survey and the procedures outlined in this SOP will be responsible for

sample receipt and workorder preparation.

3.2 Sample Receiving staff are responsible for observing required sample handling protocol, including secondary containment (SOP 023), and for managing the contents and operation of the cooling units in use in the Sample Receiving area.

3.3 Paragon's Radiation Safety Officer (RSO), in conjunction with the Sample Receiving Department Manager, are responsible for properly maintaining the radiation survey equipment, ensuring that calibration requirements are met and retaining associated documentation, and for keeping an appropriate supply of associated materials (e.g., check standards, wipes, etc.).

3.4 The Quality Assurance Department is responsible for providing verified thermometers, including infrared temperature devices, for use by Sample Receiving staff and for issuing temperature verification logbooks as needed.

3.5 The Sample Receiving Department Manager is responsible for ensuring that all personnel are properly trained in LIMS and all tasks described in this SOP, and for ensuring that the proper equipment and consumables (e.g., labels, acids, bases, test kits, disposable pipets, etc.) needed to perform these tasks are readily available.

3.6 The Project Manager is responsible for communicating all necessary information to Sample Receiving staff, for interfacing with the client to resolve discrepancies, for reviewing all login information, and for releasing the samples electronically in LIMS once the workorder review has been completed, so that the work may begin.

3.7 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.8 It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be documented and corrective action taken and documented.

4. INTERFERENCES

4.1 Samples are received and entered into the laboratory system through the Sample Receiving area. This area is not designated for sample preparation, waste disposal, or solvent/reagent storage or any other practice that could pose undue

risk of contamination of samples during login processes. A fume hood is used when sample shipping containers are initially opened. Benchtop areas used for sample container inspection and staging for labeling are frequently wiped down. With the exception of required pH and/or chlorine residual check, sample containers are to remain closed during login.

4.2 Segregated (e.g., standards vs samples, volatiles only, etc.) cooling units (i.e., refrigerators, freezers) are maintained throughout the laboratory and their temperatures are controlled within method-required limits (SOP 326). Samples for volatile analysis (VOAs) are transferred from temporary (RU#20) storage to the appropriate volatiles laboratory (e.g., GC/Fuels or GC/MS-VOAs) storage units, as quickly as possible to avoid potential cross-contamination. A volatiles refrigerator blank program (SOP 512) is observed by Paragon to monitor potential volatile sample contamination. Samples requiring preparation for organic, inorganic and/or radiochemical analysis are likewise transferred to their designated storage areas.

5. APPARATUS AND MATERIALS

5.1 Radiation Exposure Rate Survey Meter, Ludlum Model 19 or Model 192 MicroRoentgen meter or Ludlum Model 3 Survey Meter with Geiger-Mueller Detector or other equivalent, and appropriate check standards

5.2 Filter Paper, Whatman #42 (47 mm), Rad-Wipe Smears, or other equivalent

5.3 Pre-printed “Radioactive Materials” stickers

5.4 Infrared temperature device, Oakton InfraPro2 or equivalent
(Operation and daily check procedures for this device are detailed in SOP 210)

5.5 File folders, 8½ x 11 size, various designated colors

5.6 Barcode label printer, Seiko Instruments Model 220 or equivalent

5.7 Labels, Seiko SLP-2RLH, 28mm x 89mm, self-adhesive or equivalent

5.8 pH paper: narrow range, acidic (for reading pH<2), narrow range, basic (for reading pH>9), wide range (for reading pH 0-14)

5.9 Pasteur pipette, glass, disposable

5.10 Eppendorf (or equivalent) pipettor, 5mL, and disposable tips

5.11 Specimen cups, disposable, polypropylene

6. REAGENTS

6.1 pH Adjustment:

Nitric Acid (HNO_3), concentrated, trace metals grade

Hydrochloric Acid (HCl), concentrated, reagent grade

Sulfuric Acid (H_2SO_4), 50%, reagent grade

Sodium Hydroxide, NaOH, 20%, reagent grade

6.2 Chlorine Residual Testing and Adjustment:
DPD dispenser, IDEXX Laboratories #WDPD5FD, or equivalent
Sodium Thiosulfate ($Na_2S_2O_3$), 0.008%, reagent grade

7. PROCEDURE

7.1 Inspect the cooler's custody seals, if present, and note presence/intactness on Sample Receipt Form 201.

7.2 DOT SURVEY
All sample shipping containers must be surveyed for external radiation upon receipt. Complete the DOT survey per SOP 008. Document the survey results on Sample Receipt Form 201 (Comments Section) or Form 008 (in cases where a more extensive survey is required). As necessary, notify the Sample Receiving Department and Project Managers of any discrepancies or non-compliance with DOT 49 CFR and IATA regulations.

NOTE: Due to radioactive material license limitations, Paragon will not accept radioactive material packages that require a Radioactive II or III DOT Warning label. Neither will Paragon accept Radioactive Material - Low Specific Activity, N.O.S. packages with more than 0.5 mR/hour surface radiation exposure rate.

7.2.1 Coolers yielding survey results less than two times (2x) laboratory background levels will be processed for normal login.

7.2.2 Samples will be provisionally logged in and routed for prescreening (SOP 703) if:

- the client is listed in LIMS as "Requires Prescreen"
- the samples are from a Department of Energy (DOE) client
- the cooler has been shipped as a radioactive material per 49 CFR or IATA regulations
- the cooler survey yields results greater than two times laboratory background levels.

7.2.3 If the samples were shipped as radioactive materials, or the cooler survey yields results >2X background (see Step 7.2.2 above), the following steps are also performed (SOP 008):

- the outside of the cooler is swiped

- the inside of the cooler is swiped
- a composite swipe of the bottles is done

7.3 INSPECTION AND VERIFICATION
TEMPERATURE DETERMINATION (CHILLED SAMPLES)

7.3.1 If applicable, retrieve the associated Incoming Project Notice (IPN; Form 214), LIMS program specification directives, or any prior communication notes.

7.3.2 Under a fume hood, open the sample shipping container (cooler) and remove all paperwork.

7.3.3 Initially inspect the cooler's contents for breakage. After the initial inspection is complete, the cooler may be unpacked outside of the hood, as appropriate. If it is noted that a sample is broken, the broken sample must be secured appropriately before unpacking the cooler.

7.3.4 Following procedures outlined in SOP 210, obtain a representative temperature of chilled samples as promptly as possible (within two hours of receipt); record result on Form 201. Coolers that are chilled should yield temperatures between 0.1-6 °C. Note on Form 201 if iced samples are received near to the time they were obtained, and have not yet had enough time to cool to required temperature. Notify the Project Manager as soon as possible if temperature is not within specified limits.

7.3.5 Unpack the cooler, further inspecting each sample for integrity (e.g., lid not cracked, no headspace where required to be headspace-free, etc.) Note issues observed on Form 201.

7.3.6 ~~Arrange the sample bottles on a bench top in groups according to client sample ID, and in the order they appear on the client chain-of-custody (COC) form.~~ See amendment on page following 12/24/08 DAS

7.3.7 ~~Verify sample bottle label information against the information given on the client COC. Record discrepancies noted on Form 201. Notify the Project Manager of any documentation discrepancies, missing information, or problems with sample integrity. Complete the field COC form by adding the signature of the receiving technician and the date and time of laboratory sample receipt.~~

7.3.~~8~~10 As applicable, remove the shipping label from the sample cooler and place it in the workorder folder (see Step 7.9).

7.3.6 **Line the samples up on the benchtop, based on presented COC order. Double check the line up and multiple bottle position against the COC. This step is to be performed after the initial line up and after all samples and associated bottles have been placed in the proper order. This step provides for a double check and must include all associated bottles in the sample set.**

7.3.7 Verify sample bottle label information against the information given on the client COC. Record discrepancies noted on Form 201. Notify the Project Manager of any documentation discrepancies, missing information, or problems with sample integrity. Complete the field COC form by adding the signature of the receiving technician and the date and time of laboratory sample receipt.

7.3.8 **Assign laboratory IDs in the sequence of the sample listing on the COC; create labels (see 7.4.3 below).**

7.3.9 **While applying the labels (see also 7.4.3.5 below), verify the label ID against the laboratory ID on the COC, and the client ID number. Make sure that all numbers match accordingly, and that all samples and their associated bottles are in the listed order on the COC. It is strongly encouraged to ask for an independent double check randomly, and for difficult sample sets (e.g., long or convoluted client IDs), while labeling.**

7.4 PRELOGIN

Paragon LIMS is a relational database that was developed in-house and is a proprietary product. Information regarding the structure and function of LIMS may only be viewed by Paragon employees and may <u>not</u> be provided to any non-employee (e.g., client, auditor, validator).

7.4.1 Go to the 'PRELOGIN' section of LIMS, and create a workorder number. Indicate the assigned Paragon workorder number on the field COC and on all other workorder paperwork.

<u>NOTE</u>: The work order number format is based on date (YYMMNNN), with NNN indicating ascending workorder, starting at 001 each month.

For example: The first batch of samples received in January 2007 would be assigned the work order number 0701001.

7.4.2 Enter the following sample information into LIMS:

- client name
- date and time samples received
- number of samples received
- matrix (e.g., soil, water, oil, liquid, solid, filter, wipe)
- preservative used
- number of bottles per sample
- sample storage area designation (upon distribution)
- note if there is a limited volume

7.4.3 Individual sample designations and barcode labels will now be generated:

7.4.3.1 Each sample designation within the workorder is assigned a unique "dash" number (-XX), that is an incremental extension of the workorder number.

For example: The first sample designation within the first batch of samples received in January 2007 would be assigned 0701001-01.

7.4.3.2 The laboratory assigned sample designations (Paragon ID) may be marked on the field COC next to the corresponding

client ID.

7.4.3.3 Multiple containers of the same sample designation receive the same "dash" number, followed by an incremental container number (-N).

For example: The 3rd bottle provided for the first sample designation within the first batch of samples received in January 2007 would be assigned 0701001-01-3.

7.4.3.4 Print the Paragon barcode labels, which also contain text as described above, for all samples in the workorder.

7.4.3.5 Take care to carefully affix each Paragon label to the proper client sample and bottle. To the extent possible, affix the Paragon labels such that no information already present on the sample container is obscured. If necessary, wipe the outside of the containers dry prior to labeling.

7.5 APHIS DESIGNATION

All soil samples that require U.S. Department of Agriculture (USDA) Animal and Plant Health Inspection Service (APHIS) Foreign Soil Quarantine, will be labeled with the APHIS Quarantine Label (available from the Health & Safety Manager). These are soil samples from foreign countries and most states south of Colorado. These samples will require heat treatment (SOP 001) prior to disposal.

7.6 PRESCREEN

If samples do not require prescreening, skip to Step 7.7. Perform the following steps for samples that are only to be provisionally logged in (i.e., that are to remain in prelogin status) to allow for radioactivity prescreening before sample acceptance:

7.6.1 Store the samples in the Sample Receiving walk-in cooler (RU#20).

7.6.2 Enter the sample information (Paragon ID, matrix, etc.) onto the "Prescreen Log" (Form 319). This form serves as both a work request and temporary chain-of-custody documentation.

7.6.3 Copy the field COC on bright pink (or some other eye-catching color) paper. If not all samples listed on the COC are to be prescreened, indicate the ones that *are* to be prescreened by circling them.

7.6.4 Give the prescreen paperwork directly to the Prescreen Analyst or clip it to the Prescreen clipboard located near the doorway of the Prescreen Lab.

7.6.5 Prescreen personnel use the Form 319 to sign out the designated samples from RU#20, aliquotting them for analysis (SOP 703), then returning and signing the samples back into RU#20.

When available, the prescreening results are given to the Sample Receiving Department Manager (or designee) for entry into LIMS. The LIMS evaluation will classify the samples, generate special handling instructions as applicable, and generate additional sample labels as appropriate, based on the prescreen results.

NOTE: Samples designated for prescreening are considered to be 'On Hold' and cannot be removed from 'Hold' status until the special handling instructions have been completed and the samples are released in LIMS (see Section 7.12). **Note that some samples may require RSO approval for release based on the level of radioactivity.**

A copy of the prescreen results, and special handling instructions as applicable, is placed in the workorder folder.

7.6.6 Apply any additional labels provided to the appropriate sample containers, as directed by the special handling instructions.

7.7 pH CHECK

Where applicable, the pH of non-volatile, non-biological aqueous samples is verified (the fume hood may be used when performing this task). *Do not verify the pH of urine samples received*:

7.7.1 Stage several portions of the appropriate pH paper (e.g., narrow range acidic for samples preserved with acid; narrow range basic for samples preserved with NaOH; etc.) for testing.

7.7.2 Use a clean glass Pasteur pipette to remove a *small* aliquot of sample from its container. Dispense the aliquot by spreading a few drops over a piece of pH paper. Dispose of the used pipette properly.

7.7.3 Read the pH paper immediately, and record results on Form 201:

7.7.3.1 the strip must read ≤2 for samples that are acid preserved and whose pH should measure ≤2.

7.7.3.2 the strip must read ≥9 for samples that are base-preserved and whose pH should measure ≥ 9. **Note that the required pH for base preserved samples varies from ≥9 to ≥12, depending on method requirements.**

7.7.3.3 the strip should read approximately 7 (use wide range pH paper), for samples that are non-preserved and whose pH should be neutral.

7.7.4 ***DO NOT** adjust the pH of a sample unless directed to do so by the Project Manager! Notify the PM immediately of any sample pH outside the acceptance limit.* The PM will contact the client for direction on how to proceed.

7.7.4.1 If the PM instructs Sample Receiving personnel to add preservative to the sample, record the sample ID, initial pH, type and amount of preservative used, lot or standard number, new pH, and date and time of addition on Form 201.

7.7.4.2 Label the sample bottle adjusted with the amount and type of preservative used, date and initials of the individual who adjusted the pH.

NOTE: Metals, mercury and various radiochemistry method requirements dictate that samples preserved (or pH adjusted) at the laboratory, must be held for a minimum of ~~16~~ 24 hours in the original sample container before aliquotting for analysis. 1/16/08 DAS

7.8 CHLORINE RESIDUAL DETERMINATION

Some samples, to be analyzed by 600-series (wastewater) methods, may require that a chlorine residual check be performed upon sample receipt. **Perform this task only when directed to do so by the Project Manager:**

7.8.1 Using a 5mL Eppendorf-type pipettor, and a clean pipette tip for each sample container, take an aliquot of sample from its container and dispense it into a labeled plastic specimen cup. Recap the sample container.

7.8.2 Shake the EZ DPD dispenser. Remove the cap and dispense one aliquot of the reagent into each specimen cup by depressing the button.

7.8.3 Gently swirl the specimen cup and watch for any color change.

NOTE: In the event of a color change indicating the presence of residual chlorine, notify the Project Manager immediately. ***DO NOT ADD SODIUM THIOSULFATE OR PROCEED WITHOUT THE PROJECT MANAGER'S PERMISSION!***

7.8.4 If the PM, per client instruction, instructs Sample Receiving personnel to proceed with login of samples containing residual chlorine, check the appropriate box and list the affected samples on page 2 of Form 201.

7.9 FOLDER INITIATION

Initiate a workorder folder. Various colors of file folders are used for easy visual indication:

- red folders are for workorders containing samples that require prescreening
- gray folders are used to indicate normal considerations and turnaround times
- orange folders denote a "RUSH" order

Select the appropriately colored folder and mark the workorder number and client name on the folder's tab. Place all workorder paperwork (e.g., shipping label, IPN, Form 201, field COC, etc.) inside the folder.

7.10 STORAGE, LOGIN, DISTRIBUTION

7.10.1 Regroup the samples based on analysis type, place the samples in bins (SOP 023), and put the bins in RU#20 for temporary storage until the workorder (and special handling instructions resulting from prescreen analysis, if applicable), are released by the PM.

At the discretion of the PM, short-hold or RUSH samples not held for prescreen may be delivered to the appropriate laboratory area.

7.10.2 Check that all paperwork is present in the workorder folder, and forward it to the PM (or designee) for login and subsequent review.

7.10.2.1 Login of the samples is completed by adding additional information (e.g., client sample IDs, date sampled, appropriate test codes for analyses requested, turnaround time, etc.) into LIMS.

7.10.2.2 Various printouts (workorder, cross-reference Table, etc.) are added to the workorder folder. Any notes regarding atypical sample retention or disposal requirements (such as neutralization of quarantine samples per SOP 001) are also placed in the workorder folder, if not already present.

7.10.2.3 The LIMS login information and contents of the folder are then reviewed. Any discrepancies noted are corrected, and

the workorder is electronically released and distributed in LIMS.

7.10.3 Once released by the PM, distribute the remaining samples to the appropriate laboratories observing internal chain-of-custody procedures as outlined in SOP 318. If not already delivered, prioritize delivering short-hold and RUSH samples first.

If a single container is provided for multiple lab analyses, distribute according to the following priority list:

- If volatile organics by GC/MS are requested, deliver to the VOAs lab **or**
- If BTEX or GRO are requested, deliver to the FUELS lab **or**
- If any analysis is requested which requires cold storage, deliver to the cooling unit associated with the shortest hold analysis **or**
- Deliver to the location which has the most analyses designated for that sample.

8. SAFETY, HAZARDS AND WASTE DISPOSAL

8.1 SAFETY AND HAZARDS

8.1.1 The building is equipped with safety showers, eyewash stations, fire extinguishers, fire blankets, and first aid kits. All laboratory personnel must be trained in the use and location of these items.

8.1.2 Read the MSDSs before using any solvents or reagents for the first time.

8.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals, or within a laboratory area

8.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents.and acids).

8.1.5 All flammable compounds must be kept away from ignition sources.

8.1.6 Any non-original containers used to hold reagents (e.g., wash bottles, automatic dispenser bottles, etc.) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

8.1.7 Food and drink are prohibited in all lab areas.

8.2 WASTE DISPOSAL

All empty solvent bottles, pipets and contact wastes are disposed of according to the appropriate SOPs. All labels and markings must be defaced from reagent bottles or the bottles labeled as 'Empty' prior to disposal.

DOCUMENT REVISION HISTORY

7/18/05: Re-released without revision.

12/7/06: Combined with SOP 201-- Laboratory Information Management System (LIMS) Entry of Sample Receipt Information and Distribution of Workorders (SOP 201 retired). Augmented Title to address both samples and workorders. Changed references to 'Sample Control' Department, to Sample Receiving Department throughout. Streamlined Summary (Section 2), expanded Responsibilities (Section 3), reworded Interferences (Section 4). Reordered and augmented Apparatus and Materials (Section 5), revamped Reagents (Section 6). Restructured, reworded and added more details to Procedure (Section 7) as needed. Made sure all acronyms were defined, added task identification headers. Use of Sample Login Book was deleted and replaced with PRELOGIN steps. Use of barcodes added. Additional References added to Section 9. DOCUMENT REVISION HISTORY Section was added; Forms were attached.

See various amendments

Paragon Analytics

SAMPLE LOGIN / DOT SURVEY

Client _____ Workorder No. _____ Project/Site _____

Shipping Container ID ____ ____ ____ ____ ____ ____ ____ ____

External Micro R Meter Reading (μ R/hr) ____ ____ ____ ____ ____ ____ ____ ____

Background Micro R Meter Reading (μ R/hr)_____ Date _____ Initials _____

Notify RSO immediately if shipping container's meter reading is more than twice background reading!!

Samples received from clients designated as "always prescreen" must be routed through the prescreening process (see SOP 202).

If twice background is exceeded, RSO or designee will complete the following Table:

CLIENT SAMPLE ID	CONTAINER DESIGNATION	EXPOSURE RATE (μ R/hr)

Further action (e.g., prescreening, wipe testing per SOP 008, etc.) will be directed by the RSO. As applicable, sample disposition will be communicated via LIMS Project Specifications.

Where applicable, attach LB5100 prescreening and/or wipe testing results.

Form 008r6.doc (6/26/04)

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes procedures for preparing bottle orders (i.e., kit requests), shipping the prepared sample kits to the client, and maintaining an adequate inventory of bottles, preservatives, and labels.

2. OVERVIEW

Kit requests are generated by the Project Manager (PM) and are submitted to the Sample Receiving Department using an Incoming Project Notice (IPN), Form 214 or equivalent (e-mail, etc.). Sample Receiving personnel assemble the number and types of containers, associated paperwork, custody seals, labels and packing material, as needed to fill the request.

Preservatives are added to the containers, as applicable, per the bottle and preservative reference chart (Form 216), which references the sample container preservation limitations stipulated in 40 CFR 136.3, Table II.

The sample kit is then packaged (usually in coolers) and shipped to the client. Paragon chain-of-custody (COC) forms (Form 202) may also be provided with the shipment. The completed IPN (equivalent), is retained by the Sample Receiving Department. After the samples have been collected, the client ships the containers to Paragon for analysis.

Sample Receiving personnel maintain an approximate two-week supply of bottles, preservatives and labels.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 Paragon's LIMS program specification system and associated project analyte

nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

4. APPARATUS AND MATERIALS

4.1 vials, bottles and jars (various materials, sizes and closures), purchased as clean from the manufacturer.

NOTE: Bottle lot numbers and manufacturer's lot analysis information are retained on file by the Sample Receiving Department.

4.2 reagent dispensers (e.g., 0.5mL, 5mL, 25mL, as needed)

4.3 pipets, glass, disposable

4.4 pH paper, narrow range, acidic (pH <2), EMD #1.09580 or equivalent

4.5 pH paper, narrow range, basic (pH >10), EMD #1.09585 or equivalent

4.6 packing material (e.g., foam blocks, bubble wrap, styrofoam peanuts)

NOTE: Per Paragon's Health & Safety Manager, use of vermiculite is not permitted.

4.7 packaging tape

4.8 custody seals

5. REAGENTS – only reagent grade or better chemicals shall be used, only trace metals grade nitric acid shall be used!!

5.1 Sulfuric Acid (H_2SO_4), concentrated, approximately 98%

5.2 Hydrochloric Acid (HCl), approximately 36%

5.3 Nitric Acid (HNO_3), 20% (v/v), **trace metals grade only!!**

5.4 Sodium Hydroxide (NaOH), approximately 20%

5.5 Sodium Thiosulfate ($Na_2S_2O_3$), 10%

5.6 Zinc Acetate, $Zn(C_2H_30_2)_2$, 2N

5.7 Trip Blank Water, unpreserved -- prepared by the GC/MS-Volatiles laboratory, as requested -- preserved in Sample Receiving Department with HCl as needed -- not stored for future use.

6. PROCEDURE

6.1 The PM initiates a kit request (IPN, Form 214 or equivalent), and submits it to the Sample Receiving Department with as much advance notice as possible (a minimum of 3 days prior notification is preferred).

6.2 Generally, the number and types of bottles and preservatives needed are indicated on the IPN (client-specific requests/requirements may apply). A bottle and preservative reference chart (Form 216) is available in the Sample Receiving Department for consultation. The proper amount of preservative is added to the containers, as applicable, after Sample Receiving personnel compile the required sample containers. Preserved bottles are labeled with specific reagent stickers or color-coded labels, indicating the presence of a particular preservative.

NOTE: All dispensing of preservatives is to be done in the fume hood, while wearing safety glasses, latex gloves, and a lab coat.

6.3 Trip Blanks may be requested by clients sampling for Volatile Organic Analytes (VOAs). The number of Trip Blank sets needed, and whether or not the Trip Blanks are to be sent unpreserved or preserved with HCl, is stipulated by the client and indicated on the IPN/equivalent. Trip Blanks are prepared as follows:

6.3.1 Each set of Trip Blanks consists of two 40mL, certified-clean, VOA vials completely filled (i.e., no headspace present) with prepared Trip Blank water (see Section 5.7).

6.3.2 For Trip Blanks that are to be preserved with HCl, a container of Trip Blank water is adjusted to pH <2 with 36% HCl. The pH of the acidified water is verified to be <2 using low range pH paper and a clean Pasteur pipette. The acidified Trip Blank water is then used to fill the VOA Trip Blank vials (headspace free).

6.4 The sample kit is assembled and packaged (usually in coolers) by Sample Receiving personnel. Foam blocks, bubble wrap, styrofoam peanuts, etc. are used to cushion the containers. All preserved containers are placed in secondary containment (i.e., plastic bags). An absorbent pad is placed in the bottom of all coolers that contain preserved bottles. Paragon chain-of-custody forms (Form 202) if requested, and other associated paperwork (i.e., seals and labels) are placed in a Ziploc bag and put on top of the supplies placed inside the cooler. If any of the sample containers were preserved, a "Preservative Warning" statement and appropriate MSDSs are also placed in a Ziploc bag and arranged in such a way that when the cooler is opened, the "Preservation Warning" statement is visible.

6.5 The cooler is sealed with chain-of-custody seals and packaging tape and is shipped to the client with DOT-compliant labeling, as appropriate.

NOTE: Different carriers require different labeling for exempt material.

6.6 The completed IPN/equivalent) is retained in Sample Receiving Department files.

6.7 Per Paragon protocol (SOP 127), Sample Receiving personnel order supplies as needed to maintain an approximate two-week supply of bottles, preservatives and labels.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

7.1.1 The building is equipped with safety showers, eyewash stations, fire extinguishers, fire blankets, and first aid kits. All laboratory personnel must be trained in the use and location of these items.

7.1.2 Read the MSDSs before using any solvents or reagents for the first time.

7.1.3 All handling of acids and bases and other chemicals with a Threshold Limit Value (TLV) (see Section 8.2) of less than 50ppm will be conducted in the fume hood. Safety glasses, latex gloves and a lab coat must be worn when handling all acids and bases.

7.1.4 Stock acids and bases are to be appropriately segregated for storage in the cabinets underneath the fume hood.

7.2 WASTE DISPOSAL

Empty acid and base containers are to be triple-rinsed with tap water before disposal. All container labels must be defaced. Sample Receiving personnel are to contact Waste Management staff if any chemicals require disposal.

DOCUMENT REVISION HISTORY

11/20/06: Changed ‘Sample Control Department’ to Sample Receiving Department, and the term ‘chain-of-custody seal’ to custody seal throughout. Added reference to LIMS program specifications in Section 3.2. Removed statements regarding provision of ‘blue ice’, Sections 4 and 6.4. Added DOCUMENT REVISION HISTORY and Forms. No update to the Operator Aide (Form 216) was required, the posting was checked and found to be accurate, legible and protected.

Sample Container Preservation Limitations As Per 40CFR136.3 Table II

Preservative	Concentration	Container Size	Volume of Preservative (ML)
NOTE: The limits shown below are specified in a memorandum of understanding between the United States Department of Transportation and the United States Environmental Protection Agency in 40CFR136.3. These limits apply to water samples being shipped with an acid or base preservative. Ordinarily, these would be classified as a hazardous material for transportation requiring full U.N. Specification packaging, however, the memorandum of understanding allows water samples preserved with acids or bases to not be considered as a hazardous material for transportation, providing that acid or base concentration does not exceed maximum weight percent concentration specified.			
Sulfuric Acid	98%, Conc.	125 ml	0.2
Sulfuric Acid	98%, Conc.	250 ml	0.25
Sulfuric Acid	98%, Conc.	500 ml	0.5
Sulfuric Acid	98%, Conc.	1000 ml	1.0
Nitric Acid	20%	125 ml	0.75
Nitric Acid	20%	250 ml	1.5
Nitric Acid	20%	500 ml	3
Nitric Acid	20%	1000 ml	6
Nitric Acid	20%	1 Gallon	22
Hydrochloric Acid	36%, Conc.	40 ml VOA	0.05 ml
Hydrochloric Acid	36%, Conc.	500 ml	0.5
Hydrochloric Acid	36%, Conc.	1000 ml	1
Sodium Hydroxide	20%	500 ml	1.5
Sodium Hydroxide	20%	1000 ml	3
NOTE: USDOT restrictions are not applicable to the following two preservatives:			
Zinc Acetate (Total Sulfides Analysis) *	2 N	500 ml	2 ml *
Sodium Thiosulfate	10%	125 ml to 40 ml ** (VOAs); 1000 ml ** (SVOCs)	4 drops (0.2 ml) (VOAs); 0.8 ml (SVOCs)

* Sample bottles supplied for Total Sulfides are to be preserved with both 1.5 ml Sodium Hydroxide and 2 ml Zinc Acetate.

** Proper sample collection must be observed by the client in the field in order to obtain the proper preservation. For Volatile Organics Analytes (VOAs), approximately 4 drops of 10% Sodium Thiosulfate reagent is to be added to each 125 ml amber bottle collection bottle supplied to the client. The client is to collect the sample in the 125 ml amber bottle (without overflow), swirl the contents of the bottle, then decant the sample into two 40 ml VOA vials (headspace free). Contingent upon client requirements, each 40 ml VOA vial may require preservation with 36% Hydrochloric Acid. The Project Manager is responsible for ensuring that the client is aware of the appropriate sample collection procedure.

Form 216r1.frm (2/4/2002)

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes procedures for the daily calibration verification and use of infrared (IR) temperature devices (guns).

2. SUMMARY

IR temperature guns provide a means of measuring temperatures rapidly and non-invasively. Two IR guns, clearly marked as gun "1" and gun "2", are used by Sample Receiving staff to measure the temperature of incoming samples that require thermal preservation. Radiochemistry Department personnel uses a third, dedicated, IR gun to measure the temperature of silica gel samples undergoing evaporation. A functional check, prior to use, is performed per the procedures detailed in this SOP, on each IR gun each day the device is used. The Quality Assurance (QA) Department performs an in-house, NIST-traceable verification of each IR gun, annually, and maintains records of these verifications (SOP 923).

3. RESPONSIBILITIES

3.1 It is the responsibility of all technicians to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 All personnel who work with these procedures are responsible for documenting any anomalies or out-of-control events. Appropriate corrective actions must be taken and documented.

3.3 The QA Department is responsible for verifying the calibration and accuracy of each IR gun annually and for maintaining the annual verification records.

4. PROCEDURES FOR THE CALIBRATION VERIFICATION AND USE OF SAMPLE RECEIVING IR GUNS

4.1 CALIBRATION VERIFICATION CHECK

Per NELAC (and method) requirements, coolers containing samples requiring thermal preservation should be received chilled but not frozen (i.e., ~ 0.1°C to 6°C). Temperature blanks kept in Sample Receiving walk-in cooler RU#20, which is maintained at 4±2°C (SOP 326), are used to provide a one-point verification check of each Sample Receiving IR gun, each day before use.

4.1.1 Obtain, and record on Form 209, a reading from the annually-verified thermometer (SOP 923) assigned to/kept in RU#20.

4.1.2 Select a Sample Receiving IR gun. Remove the one-liter amber water check bottle from the refrigerator. Holding the bottle away from your body and down toward the floor, aim the IR gun at the center of the bottle and obtain a temperature reading. Record this reading on Form 209.

NOTE: Each IR gun is operated at the distance of 1-2 inches from the object, and in the manner prescribed by the manufacturer's instructions.

Repeat this Step using the other Sample Receiving IR gun.

4.1.3 Return the amber water check bottle to RU#20 and remove the 40mL VOA water check vial. Holding the vial away from your body and down toward the floor, aim the IR gun along the length of the vial, and obtain a temperature reading. Record this reading on Form 209.

Repeat this Step using the other Sample Receiving IR gun.

4.1.4 Compare the IR gun readings to the reading obtained from the refrigerator's interior thermometer (Step 4.1.1). The IR gun temperature readings must agree within ±2°C. ***Notify the QA Department immediately if this criterion is not met, so that prompt, appropriate corrective actions may be taken.***

4.1.5 Once the Sample Receiving IR guns have been successfully verified, they may be used to determine representative cooler temperatures, as applicable, per the procedure described below.

4.2 USING SAMPLE RECEIVING IR GUNS TO DETERMINE REPRESENTATIVE COOLER TEMPERATURES

This procedure pertains to coolers containing samples that require thermal preservation (i.e., chilling). It is Paragon's policy to determine the representative temperature for these coolers of samples within 2 hours of receipt. Per NELAC (and method) requirements, coolers containing chilled samples should be received at temperatures between just above freezing (i.e., ~ 0.1°C) to 6°C.

4.2.1 After inspecting the cooler's custody seals for intactness (SOP 202), open the cooler's lid and select a sample container representative of the cooler's contents (i.e., representative of container types present, and representative of container position within the cooler, relative to the ice or ice packs). If a designated temperature blank was provided in the cooler, this sample container may be selected so long as it was packed, relative to the ice or ice packs, in a manner that is representative of the other samples present in the cooler.

4.2.2 Remove the selected container from the cooler and hold it away from your body and down toward the floor. Aim an IR temperature gun at the container and obtain a reading using the technique described in Steps 4.1.2 and 4.1.3 above.

Based on professional judgment, a second representative sample container may be selected and measured to ensure that the temperature measurement obtained, is representative of the cooler's contents. Record the representative temperature determined for each cooler on Form 201, and note the identity of the IR gun that was used to obtain the temperature. ***Notify the Project Manager immediately if the representative cooler temperature determined, is outside the just above freezing (i.e., ~ 0.1°C) to 6°C acceptance limits.***

5. PROCEDURES FOR THE CALIBRATION VERIFICATION AND USE OF THE RADIOCHEMISTRY IR GUN

5.1 CALIBRATION VERIFICATION CHECK

A calibration verification check of the Radiochemistry IR gun is to be performed per the procedure described below, prior to use, each day this IR gun is used. Data from this calibration verification check are recorded in the Radiochemistry IR Gun Verification Check logbook (Form 352).

5.1.1 Oven #3 is located in the Low Level Actinides Lab. Determine the oven's current temperature by reading the annually-verified thermometer (SOP 923) that is kept inside this oven. Record this reading as "Thermometer" (i.e., reference) temperature, on Form 352.

5.1.2 Hold the Radiochemistry IR gun about 1-2 inches in front of, and at the center of, the bottle that holds the oven's assigned interior thermometer. Depress the IR gun trigger and record the reading obtained as "IR Gun" (i.e., check or test) temperature on Form 352.

5.1.3 The normal point of use and accuracy requirement for the Radiochemistry IR gun (SOP 791) is 200±20°C. Oven #3 is maintained at 100-110°C. Use of Oven #3 as a test condition, has been determined to be the closest to the Radiochemistry IR gun's point of

use, that can be readily and accurately verified.

For purposes of the Radiochemistry IR gun verification, the temperature obtained via the IR Gun in Step 5.1.2 above, must agree within ±10°C of the temperature obtained via the thermometer in Step 5.1.1 above, to be acceptable. ***Notify the QA Department immediately if the IR gun fails the verification test, so that prompt, appropriate corrective action may be taken.***

5.2 DETERMINATION OF SILICA GEL EVAPORATION TEMPERATURES
Follow the procedures detailed in SOP 791.

6. SAFETY, HAZARDS AND WASTE DISPOSAL

No special hazard precautions.

7. REFERENCES

7.1 NELAC standard, current revision.

7.2 Operating Instructions, Manufacturer of IR Temperature Device.

DOCUMENT REVISION HISTORY

11/20/06: Changed reference from 'Sample Control Department' to Sample Receiving Department throughout. The term 'Chain-of-Custody' seal was changed to Custody seal, Section 4. Added DOCUMENT REVISION HISTORY and Forms.

QUALITY ASSURANCE MANAGER _____ DATE 3/17/08

LABORATORY MANAGER _____ DATE 3-17-08

HISTORY: Rev0, 12/17/91; Rev1, PCN #275, 9/28/94; Rev2, 4/09/96; Rev3, 2/18/98; Rev4, 11/20/98; Rev5, 12/2/99; Rev6, 2/10/00; Rev7, 3/2/00; Rev8, 10/8/01; Rev9, 3/2/2002; Rev10, 4/3/4; Rev11, 3/9/06; Rev12, 7/5/06. Rev13 (combined with SOP 798), 3/14/08.

1. SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to establish guidelines for the management of standards, solvents, acids, bases and reagents used throughout the laboratory. Guidance pertaining to receipt, records retention, labeling, documentation, containerization, storage and expiration of these materials is given.

All materials purchased by Paragon (SOP 127) are carefully selected based on the performance needs of their application. Records for certified materials (i.e., Certificates of Purity, Certificates of Assay or Analysis) are retained by the Department that uses the material.

Paragon's Standards & Solutions database, is the primary mechanism for logging-in the standards, solvents, acids and bases received, in readiness for their use. Reagents made from these materials are also documented in the Standards & Solutions database. While the Standards & Solutions database is used to catalog these intermediate standards/ solutions (e.g., ICV solutions; LCS and MS spiking standards; SUR spike solutions, radiochemical carriers, etc.), typically daily (working) standards documentation is accomplished by various other means, such as: direct entry into a LIMS datasheet, by use of the instrument run log, etc.

Some materials identified as 'quickly consumeables' [e.g., Methylene Chloride, Hexane, and Sodium Sulfate (Na_2SO_4)] are exempt from some labeling requirements, as described herein. No material is to be used beyond the manufacturer's expiration. Materials must be discarded sooner than manufacturer's expiration if contamination or degradation is evident. The expiration of intermediate materials is not to exceed that of the parent material. Re-verification of materials is permitted where possible/feasible. Also addressed by this SOP are procedures for preparing and verifying radioactive solutions, as well as the stable carriers that are used in radiochemical analyses. Note that these carriers must be verified before use.

Use of the PAR Standards & Solutions database helps to ensure good laboratory practices (GLP) by facilitating consistency in ordering and preparing standards, solvents, acids, bases and reagents, and also facilitates the traceability of these chemicals used. Some aspects of data reporting through the Laboratory Information Management System (LIMS), are also facilitated by interface with the Standards & Solutions database.

This SOP is intended to communicate a 'big picture view' of the policies/practices governing the management and use of standards, solvents, acids, bases and reagents used throughout the laboratory. **Should a conflict exist between the information provided in this SOP and that of a specific preparatory or determinative SOP, the guidance of the preparatory or determinative SOP takes precedence.**

2. SUMMARY

Chemical materials received, as well as the intermediate standards and reagents made from them, are catalogued and tracked in a manner that meets good laboratory practice. Paragon's Standards and Solutions database plays a key role in the management of these materials. This SOP provides an overview of the types of chemical materials used in the laboratories, and gives detailed guidance as to the receipt, records retention, labeling, documentation, containerization, storage and expiration requirements pertinent to the management of these materials.

Radioactive standards are prepared gravimetrically whenever possible, using the same diluent (basis) as the primary solution. The standard concentration is verified against an independent second source, if available. Depending on the nature of the standard, various methods are adapted to prepare the standard for analysis.

Stable (non-radioactive) carrier solutions are prepared according to the individual preparation SOPs. In some cases, verification of the final carrier concentration by ICP-AES analysis is required before use. All preparations for verification are done in triplicate. A reagent blank must accompany each batch. Another technician must witness the addition of tracing and spiking solutions.

3. RESPONSIBILITIES

3.1 Each Department Manager (DPM), in conjunction with their analytical staff, is responsible for ensuring that the management of all standards, solvents, acids, bases and reagents used within the Department, meets the criteria set forth in this SOP. The DPM, along with the Quality Assurance Manager (QAM) is responsible for providing adequate training and oversight pertaining to these requirements. The DPM or designee is responsible for performing a timely review (at minimum, monthly) of the information contained in the Standards & Solutions database. The DPM or designee is also responsible for maintaining certified materials records (e.g., Certificates of Purity/Assay/Analysis).

3.2 Because of the health, safety, cost and potential quality assurance impact of incorrectly prepared solutions, only trained staff members, approved by the Department Technical Manager, will be responsible for the preparation of

radioactive standards. It is the responsibility of the Department Manager to approve any deviations from this procedure. This approval may be noted on the documentation described below (Section 3.5).

3.3 It is the responsibility of the technician preparing the solutions to thoroughly review any pertinent Material Safety Data Sheets (MSDSs), and to follow the specific instructions provided in applicable SOPs. Any material with a TLV or PEL below 50ppm must be used in a fume hood.

3.4 It is the responsibility of the technician preparing the solution to check the stock materials for any applicable expiration dates. Do not prepare any solution using materials that have passed their expiration date.

3.5 It is the responsibility of the technician preparing the solutions to complete any applicable supporting documentation, such as the "RadChem Solutions Entry Form" in the Paragon LIMS system, or a controlled laboratory notebook. Any discrepancies, anomalies, or out-of-control events must be noted and corrective action taken and documented (SOP 928). The technician is also responsible for properly labeling the container of the solution made.

3.6 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data. Note that requirements for particular analytes, concentrations, etc. that differ from Paragon standard practices, may be contained in applicable LIMS program specifications.

3.7 IS Department staff are responsible for maintaining and augmenting the Standards & Solutions database as needed, and for assisting with the provision of necessary training to laboratory staff.

4. APPARATUS AND MATERIALS

4.1 See specific preparatory/determinative SOP. Necessary apparatus includes, but is not limited to: syringes; disposable or scrupulously-cleaned glassware; pipets; and balances. Note that pipets and balances must be operated as prescribed in their respective operational SOPs (321, 305). Where use of volumetric glassware is required (e.g., carrier preparation), only Class A volumetric glassware shall be used.

4.2 In general, Paragon purchases commercially-certified standards when available/feasible. Should standards need to be created in-house, only the highest

purity of materials should be used. For example, only 'Purge-and-Trap' grade methanol is used for creating volatile organics standards; 'Pesticide Residue' or 'HPLC' grade solvents may be used for making other organic standards and spiking solutions. Only 'Trace Metals' grade acids are used for inorganic standards, reagents and analyses.

4.3 Typically, semivolatile organic (SVOC) standards and spike solutions are made in methylene chloride. Standards and spikes used in ECD or FPD gas chromatographic analysis are typically made in hexane. Explosives standards and spike solutions are typically made in acetonitrile. Other organic standards and solutions may be made in methanol. Note that the solvent used for surrogates or other spiking solutions should generally be miscible with water (solubility issues may, however, preclude the use of water-miscible solvents in some procedures).

4.4 The laboratory's deionized (DI) water system is capable of producing water of sufficient quality to be used in laboratory preparations and analyses. See SOP 319 for details regarding Paragon's deionized water systems and requirements. Water used to prepare volatile organics (VOAs) standards will be DI water that has been heated and purged with inert gas to remove volatile substances (SOP 511). Where required by the method or good laboratory practices, HPLC grade water will be used for HPLC preparations and analyses.

Paragon purchases or creates only the necessary amount of standards and reagents in order to minimize waste. The concentrations of the standards and reagents used are also determined with this in mind, as well as method requirements. Note that client-specific criteria (LIMS program specification) may call for the use of standards or reagents that differ in composition from that of typical Paragon materials used. Factors such as limiting the number of dilutions required to obtain final working concentrations; inherent measurement error (i.e., no aliquots less than 5µL whenever possible); and the ratio of solvent to analyte (be sure, however, that sufficient volume of solvent (basis) is used to dissolve all standard materials) should also be considered when determining the volume of standard or reagent to prepare.

5. GENERAL PROCEDURES - ACIDS, BASES, SOLVENTS, REAGENTS

5.1 Retain any Certificates of Purity, Assay or Analysis received in Departmental records. Store materials in the designated area and in a manner that is consistent with manufacturer's recommendations. Materials should also be stored in a manner that facilitates 'first received, first used'.

5.2 Document the material's receipt in the Standards and Solutions database:

5.2.1 In the "Standards Database" application, select "Open Shipment Form".

5.2.2 Click on the tab 'Add New Shipment' and enter in the date the material was received by the lab.

5.2.3 Enter in "Received By".

5.2.4 A "Ship ID" will be assigned automatically.

NOTE: It is often useful to use the material's lot number as the material identification (or some portion thereof). This ensures that the 'ID" appears on the container label.

5.2.5 The "Inventory Item" will be the whole name of analyte (e.g., 'Hydrochloric Acid' or 'Plutonium-242'.

5.2.6 Enter the "Vendor Name", "Lot ID", as well as the "Catalog Number" and "Comments", as needed.

5.2.7 Enter the material's manufacturer's expiration. If no manufacturer's expiration is indicated on the material, apply the applicable duration indicated in the Table at the end of this SOP.

5.2.8 Click Save and Close.

5.3 **Date opened must be indicated on the container when first used.** If necessary, transfer the remainder of the material to another container that is suitable for the material, and that is of sufficient size to permit the proper labeling.

NOTE: In general, date received information is entered into the Standards & Solutions database, and is not marked directly on the material's container. In the case of 'quickly consumeables', the date received is marked on the transport carton, and not directly on the material container, in order to preserve the integrity of the carton structure for safe storage. Because 'quickly consumeables' are rapidly depleted, it is not necessary to mark 'date opened' on these containers.

5.4 The Standards & Solutions database contains the basic recipes for the standards and reagents used in Paragon analyses. Follow the recipes contained in the database, which were derived from the recipes contained in the preparatory and determinative SOPs, which in turn, are method based. Note that each preparation must be assigned a unique identification. **In some cases, it may be useful to incorporate the date made into the ID to assist in unique identification.** Be sure to complete all information (e.g., date, analyst, parent materials, lots, amounts, etc.).

5.5 Properly containerize (e.g., polypropylene bottle, amber glass, no headspace, etc.) the standard or reagent made, in a manner that is appropriate to the contents and method requirements.

5.6 Label or mark the container, at minimum, with the standard/reagent name and/or unique ID, basis (i.e., solvent, acid used) and date of expiration.

5.7 **No material is to be used beyond the manufacturer's expiration. The expiration of intermediate materials is not to exceed that of the parent material. Expirations for standards/reagents prepared from multiple sources shall coincide with the earliest expiration of the source materials used. Materials must be discarded sooner than manufacturer's expiration if contamination or degradation is evident. If no manufacturer's expiration is indicated on the material, apply the applicable duration indicated in the Table at the end of this SOP.**

5.8 **Re-verification of materials is permitted where possible/feasible (e.g., some inorganic source materials, metals standards).** Verifications must be demonstrated by acceptable method blank and laboratory control sample analysis results, or by other suitable means. **Document the material's re-verification in the Standards & Solutions database, and re-label the material appropriately.**

5.9 Store the container in a designated area under conditions that are appropriate to its contents and method requirements (e.g., ambient, refrigerator, freezer, desiccator). Use the Table at the end of this SOP as a quick reference. **Standards and reagents shall be stored separately away from samples. Hazardous materials storage rules shall be observed.**

5.10 All standards that are beyond their expiration shall be removed from the area, materials that cannot be re-verified shall be properly disposed (SOPs 003, 015, 024).

5.11 The Standards & Solutions database is maintained by analysts from each Department and undergoes regular (at minimum, monthly) peer or Supervisory entry review. This ensures that the database entries are accurate and complete.

6. STABLE CHEMISTRY STANDARDS, REAGENTS

Follow the general guidance of Section 5 above.

7. RADIOCHEMICAL STANDARDS, REAGENTS

Follow the general guidance of Section 5 above. **Note that for Radiochemistry Department standards, a Shipment Entry and Review Form (Form 718) must also be completed.** Specific considerations for radiochemical materials are given below.

7.1 PREPARATION AND VERIFICATION - NOMENCLATURE

7.1.1 **Reagents** and **carriers** are defined as those non-radioactive chemicals

whose preparations are described in the various preparation and analytical SOPs, as well as Section 5 above.

7.1.2 A **standard** is defined as a radioactive material, in which the concentration of radioactive analyte is used in the quantification of sample results. Standard Reference Material (SRM) is received directly from a manufacturer or supplier, such as the National Institute of Standards and Technology (NIST). The term Primary Standard applies to a standard that has not been diluted since receipt of the source Standard Reference Material. Generally, all other standards are prepared from the appropriate Primary Standard. The term Intermediate Dilution, applies to a dilution of a standard, in which the concentration of radioactive material is too high for routine laboratory use, and from which working standards are prepared. The term Working Standard applies to a dilute standard routinely used to spike client or quality control (QC) samples. Standards preparations are recorded in the Standards Preparation Logbook, which is kept in the Radiochemistry Instrument Lab, as well as the LIMS Standards Database. Standards are assigned unique and traceable ID's as described directly below:

7.1.2.1 Nuclear Inventory Log (NIL) numbers are assigned sequentially by the Radiation Safety Officer (RSO) upon receipt of radioactive materials in the laboratory.

7.1.2.2 The Standards ID number is generated in three parts. The first set of digits represents the NIL. The following four digits are the unique log number assigned by the QA Department to the particular Standards Preparation Logbook. The last two digits are the page number upon which the dilution/preparation of the standard is documented (e.g., 450.1284.25 is NIL 450, on page 25 of logbook #1284).

7.2 PREPARATION OF STANDARDS

7.2.1 All standards and calibration standards will be prepared only by, or under the close supervision of, a trained staff member.

7.2.2 All preparation steps will be recorded in the Standard Preparation Logbook. An entry must be made into this logbook, even if only transferring an aliquot into a new container. Meticulously record tares, aliquot start mass, finish mass or volume, aliquot units, dilution factor, starting and finishing activity, reference date, diluent, bottle description, etc. If converting between mass and volume, a density calculation should be performed and recorded in the Standard Preparation Logbook. The lot number of the diluent (normally a

diluted concentration of HCl or HNO_3), is recorded in the Standard Preparation Logbook.

7.2.2.1 The standard ID of the radioactive SRM(s) must be recorded. A description of the source material and the reference date for the activity must also be documented.

7.2.2.2 The source of all non-radioactive materials used in the preparation must be documented.

7.2.2.3 During the preparation, verify that all balances, pipettes and ovens, etc., are in control as defined by the appropriate QA SOPs. Record the pipette and balance numbers used in the preparation.

7.2.3 Upon completion of the preparation, calculate the final anticipated activity of the standard. Record these calculations in the logbook. Be sure to distinguish isotopic activity from total activity where applicable (e.g., $^{238}U/^{234}U$ activities vs. total activity of U).

7.2.4 Standards are normally diluted in the same diluent in which they were prepared by the manufacturer. In cases where the diluent is not documented, or where end use dictates that the solution matrix be changed, consult with the Radiochemistry Manager prior to dilution of the standard.

7.2.5 Use only tight-sealing bottles for storing radioactive standards. The useful life of a standard may be years, unless the solution integrity is compromised by evaporation. Nalgene® bottles, borosilicate vials (e.g., VOA vials), and tight-sealing bottles with rubber-lined caps are advisable choices for extended storage of standards. Liquid scintillation vials and specimen cups, etc., are NOT satisfactory containers for the storage of stock, primary, and intermediate standards.

7.2.6 The mass of stock, primary, and intermediate standards may be tracked to minimize the risk of uncontrolled, unnoticed evaporation. Discrepancies in solution mass between uses should be reported to the Radiochemistry Manager. Tracking standards mass often provides the opportunity to run a redundant check of solution aliquot versus mass removed. Discrepancies should be resolved prior to use of a dilution.

7.3 CREATING A STANDARD IN THE LIMS SOLUTIONS DATABASE

7.3.1 CHECKING FOR A PRIMARY SOLUTION

7.3.1.1 Click on ‘Open Rad Form’. The RadChem Solutions Entry Form will appear. If a shipment form was already created,

the parent standard may also already be entered. To check for this, do the following:

7.3.1.2 The number in the field "Solution ID" will be highlighted. Press <CTRL + F> to search the records. Enter the primary solution in the search field. If the primary solution has already been created, the primary solution will appear in the main form behind the search utility. Close the search box and proceed to Section 7.3.3.

7.3.1.3 If the primary solution has not been created, the message "search item not found" will appear. Close the search box and proceed to Section 7.3.2.

7.3.2 ADDING THE PRIMARY SOLUTION

7.3.2.1 Click the "Add" button. Type in the primary solution ID in the "Solution ID" field.

7.3.2.2 In the 'Sol Name' field, type the descriptive name of the standard (i.e., Am-241 Primary Standard).

7.3.2.3 Choose 'Type' as is appropriate (for a primary standard use PS, for primary reagent use PR).

7.3.2.4 Choose the appropriate Inventory Name. Be careful to watch the Lot # of the solution you are selecting. There may be several choices for your selection.

7.3.2.5 Lot and Vendor should automatically appear.

7.3.2.6 Fill in matrix (usually liquid), and the final volume/units found on the certificate. Fill in Opened and Received By. Fill in the Department and appropriate location.

7.3.2.7 Choose a component name, using abbreviated analyte names such as Am-241 versus Americium-241, H-3 versus Tritium.

7.3.2.8 Enter the calibrated activity that is found on the certificate, conventionally in pCi/g. Uncertainty should be in 2σ percentages, from the certificate. The calibration date is the reference date found on the certificate.

7.3.2.9 After all fields are completed, this form must be reviewed by someone else (who logs into LIMS to do an official review) before it can be used in order to create other

standards.

7.3.3 CREATING A STANDARD/REAGENT FROM A PRIMARY SOLUTION

7.3.3.1 Open RadChem Solutions Entry Form of the primary solution and push the button "Copy to New". This will open a new Solutions Form, which is now linked to the primary solution.

7.3.3.2 First change the solution ID by clicking on the underlined "Solution ID". A box will appear with the given, current ID. Fill in the "Change ID to" box with the new, Paragon-formatted ID.

7.3.3.3 Change the Solution Name from Primary Standard/Reagent to either Intermediate Standard/Reagent or Working Standard/Reagent, and select the appropriate "Type" (generally IS or IR; an Intermediate Standard/Reagent implies that other standards will be made from it).

7.3.3.4 Fill in the Preparation By, and if applicable, Verified and Validated By, and Expiration Date boxes. The reference date is set to today, but is a changeable date.

7.3.3.5 Choose the correct matrix.

7.3.3.6 IMPORTANT: Units must stay consistent throughout each form; if each level of the standard was prepared gravimetrically, the units must remain in grams until the final working dilution, which may then be density corrected. Therefore, if this standard is to be an intermediate standard (i.e., other standard dilutions will be made from this standard), do not fill in density. The 'final volume' field should be entered in from the standards logbook, depending on whether a standard was prepared gravimetrically (as is generally done) or volumetrically. If this standard is the final dilution (i.e., it was a dilution made directly from the original ampoule), enter in the determined density and the Final Volume with the appropriate units.

7.3.3.7 Choose a parent ID from the pick list. The Component Name should appear. Fill in the volume/units of how much of the parent was used. If two parents were used equally to create this standard, divide the final volume of parent used, in half. (i.e., if 10.0g of 615 and 616 were used to create

this standard, both 615 and 616 would be chosen as components, 5.0g each.)

7.3.3.8 This standard must be independently reviewed before it can be used in the preparation of future standards or on benchsheets.

7.3.3.9 Once this standard is created, it may be used to create other standards (i.e., be an intermediate standard). Follow Section 7.3.3. Again, final dilutions may be density corrected to volumetric units, since they are generally aliquotted at the bench volumetrically.

7.4 VERIFICATION OF STANDARDS AND CARRIERS

7.4.1 In the preparation and analysis of standard verifications, an in-house work order number is assigned, either manually or through LIMS, so that the verification data can be linked to the standard.

7.4.2 Standards and carriers will be prepared in triplicate for verification. In addition, standard verifications that employ a radioactive tracer will include an un-traced analysis to demonstrate that the standard is free of potentially interfering radionuclides.

7.4.3 Acceptance criteria will be handled on a case-by-case basis. The count result should, in general, match the expected value to within the limits of the total estimated error. As a default, agreement within 5% is an acceptable minimum tolerance for verification of standards. The 1-sigma counting uncertainty should be ½ of the acceptance criteria. For example, in instances where the acceptance criteria is 5%, the 1-sigma counting uncertainty, should be equal to or less than 2.5%. Stable carriers should be verified to within 10% of the expected value.

7.4.4 In addition, the verification data for radioactive standards should meet the criteria described below. Any standard that fails to meet any of these criteria may be rejected for use in certain work, but may be approved for other uses at the discretion of the Radiochemistry Manager.

7.4.4.1 For the triplicate analyses in a standard verification, a mean value (xav) and standard deviation (σ) must be calculated.

7.4.4.2 The value of 2σ must be less than or equal to 10% of xav.

7.4.5 If the verification results meet the acceptance criteria described above, the standard or carrier is considered to be acceptable for general use. If the verification results fail to meet any of the requirements in this Section, any usage limitations are noted on the verification summary.

Alternately, the standard or carrier may be prepared for reanalysis. In either case, the Radiochemistry Manager must then review and sign the bottom of the form. Completed forms are available through the Radiochemistry Department.

7.4.6 If reanalysis is required, the preparation analysts and Radiochemistry Manager must confer and decide how to proceed. Additional preparations, alternate preparations, or counting strategies may be considered. In this case, the involved personnel may not approve the verification form until the situation is resolved. Complete documentation is available through the Radiochemistry Department.

7.4.7 See Section 7.5 for the assignment of expiration dates.

7.4.8 A designee in the Instrument Lab will prepare a packet containing a copy of the completed and signed logbook page, all applicable traceability documents provided by the RSO, any applicable documentation of dilutions, a copy of the sheet showing calculation verification, the standards verification summary, instrument raw data, and instrument run log. This packet is forwarded to the Instrument Laboratory Supervisor for validation. Copies of this information are available through the Radiochemistry Department.

7.4.9 After verification of a standard is completed, working standards are given final approval in LIMS by the Radiochemistry Manager. Refer to Section 0. The Radiochemistry Manager will note completion of the verification in the Standards Preparation Logbook. This entry must be dated and initialed and a completed label must be attached to both the logbook and the standard bottle. Verification of carriers may be approved in LIMS by the Radiochemistry Manager, or their designee. The standard or carrier is now available for general use.

7.5 ASSIGNING EXPIRATION DATES

7.5.1 For radioactive standards, calculate an expiration date that is five half-lives, or one year after the verification analysis date, whichever is less.

Standards containing nuclides with relatively short half-lives (i.e., whose expiration dates would thus be shorter than 6 months), may be exempted from this restriction as long as useable standards may still be prepared from the activity remaining in the stock material. Approval of the Radiochemistry Manager must be obtained in these cases, as noted by his/her signature on the standard preparation documentation.

7.5.2 The expiration date for carriers will be 1 year from the verification analysis date.

7.5.3 The chemical stability of a material must be taken into account when assigning an expiration date for a standard. For example, iodine solution may not be chemically stable. Follow the manufacturer's guidance or consult with the Radiochemistry Manager to determine an expiration date in such cases.

7.5.4 Do not use a solution that shows visual or other signs of degradation. Floating particulate, color or clarity changes or unexplained vapors in the sample container are examples of possible indicators of degradation of a solution.

7.5.5 Standards and carriers that have passed their expiration date must be removed from service. Expired standards and carriers may be reused if they are re-verified as described above; a new expiration date may then be assigned. Stock, primary, and intermediate standards need not be re-verified during storage, or prior to subsequent dilutions, if the working standards being prepared are to be verified. The verification of a serial dilution or preparation of a parent standard is, in kind, considered to be verification of that material itself.

7.6 LABELING

7.6.1 Duplicate labels are prepared for the standard. The data entry for the label is reviewed by a designee prior to final release. One label is released to the applicable Prep Lab Supervisor to be placed on the verified standard container. The duplicate label is put into the Standards Preparation Logbook, with the entry corresponding to the standard ID.

7.6.2 Radioactive standard labels must include the following information:

- Standard ID number
- Name of standard or reagent
- Expiration date
- Activity concentration (include units)
- Standard Uncertainty (2-sigma), as given on the original radiostandard certificate, where applicable (include units)
- Activity reference date, where applicable
- Date of preparation
- Preparation analyst initials
- Chemical form, constituents
- Half-life

7.7 CONSIDERATIONS FOR SPECIFIC STANDARDS AND CARRIERS

Due to the wide variety of materials that could potentially fall under this SOP, the exact means of verifying standards and carriers must be handled on a case-by-case basis. Standards are verified against independent, NIST-traceable second source standards and/or instrument calibrations, which themselves have been generated using independent, NIST-traceable second sources. Difficult to obtain materials and very short-lived nuclides may occasionally require verification against a surrogate material that possesses similar decay properties as the material in question. Again, such situations must be addressed with the Radiochemistry Manager on a case-by-case basis.

7.7.1 AMERICIUM-241

7.7.1.1 Label four 220mL plastic specimen cups with the internal workorder ID numbers.

7.7.1.2 Using a calibrated pipette (SOP 321), transfer a volume of 243Am, equivalent to 20-80dpm, to three of the four cups. Add the same activity of the new 241Am standard to all four cups.

7.7.1.3 Place the cups on the steam bath and evaporate to dryness.

7.7.1.4 Continue with Am micro-precipitation as outlined in SOP 751.

7.7.2 AMERICIUM-243

The method for ^{243}Am is the same as ^{241}Am, however, three cups are traced with ^{241}Am and all four cups are spiked with the ^{243}Am solution to be verified.

7.7.3 BARIUM-133

7.7.3.1 For verification by gamma spectroscopy, the preferred technique is a direct comparison, in triplicate, of the standard to an independent second source. For this technique, the preparation of the standard into an established counting geometry is not necessary as long as the counting geometry for the two sources is identical. The volume and activity of the standard to be verified should be considered when choosing the container or geometry. Whenever possible, an effort should be made to avoid unnecessary dilutions of the standard.

7.7.3.2 If no second source is available, the standard must be prepared, in triplicate, in an established counting geometry for comparison to the current mixed-gamma efficiency

calibration for that geometry.

7.7.3.3 If there is insufficient standard volume to prepare triplicate samples for analysis, a single sample may be prepared, however, that sample must be analyzed on three separate gamma detectors.

7.7.3.4 If a second source is available:

- Label six containers with the internal work-order ID numbers.
- Add the appropriate amount of ^{133}Ba standard (target 1,000–5,000dpm) to three containers. Add a similar amount of activity of ^{133}Ba from a second source, to three different containers.
- Submit the samples and proper documentation to the Instrument Lab for gamma spectroscopy counting.

7.7.3.5 If a second source is NOT available:

- Label three containers with the internal work-order ID numbers.
- Add the appropriate amount of 133Ba standard (target 1,000–5,000dpm) to the three containers.
- Submit the samples and proper documentation to the Instrument Lab for gamma spectroscopy counting.

7.7.4 CARBON-14

7.7.4.1 Label nine 20mL liquid scintillation vials with the internal work-order ID numbers.

7.7.4.2 Add 5mL of DI water to each scintillation vial.

7.7.4.3 Determine the volume of 14C standard needed to deliver approximately 1,000dpm activity. Remove that volume of water from the scintillation vials that will be spiked with 14C.

7.7.4.4 Add the volume of the 14C standard to be verified, determined in the previous Step, to three of the vials. Add the same activity of a second, independent 14C standard to three different vials. If the diluent or the spiking volume is

different for the two standards, see the Technical Manager for further instructions.

7.7.4.5 Add 15mL of Ultima Gold LLTTM cocktail to each vial. Cap the vials tightly, mix thoroughly, and wipe clean with methanol and a lint-free laboratory wipe..

7.7.4.6 Submit the samples and proper documentation to the Instrument Lab for liquid scintillation counting.

7.7.5 CURIUM-244
The method for ^{244}Cm is the same as ^{241}Am, however, three cups are traced with ^{243}Am and all four cups are spiked with the ^{244}Cm solution to be verified.

7.7.6 IODINE-129
Refer to Section 7.7.4, using ^{129}I instead of ^{14}C.

7.7.7 IRON-55
Refer to Section 7.7.12, using ^{55}Fe instead of ^{241}Pu.

7.7.8 LEAD-210
Refer to Section 7.7.12, using ^{210}Pb instead of ^{241}Pu.

7.7.9 NICKEL-63
Refer to Section 7.7.12, using ^{63}Ni instead of ^{241}Pu.

7.7.10 NEPTUNIUM-237
The method for ^{237}Np is the same as ^{239}Pu, however, three cups are traced with ^{239}Pu and all four cups are spiked with the ^{237}Np solution to be verified.

7.7.11 PLUTONIUM-239

7.7.11.1 Label four 220mL plastic specimen cups with the internal workorder ID numbers.

7.7.11.2 Using a calibrated pipette, transfer a volume of 242Pu, equivalent to 20-80dpm, to three of the four cups. Add the same activity of the new 239Pu standard to all four cups.

7.7.11.3 Place the cups on the steam bath and take the solutions to dryness.

7.7.11.4 Continue with Pu micro-precipitation as outlined in SOP 777.

7.7.12 PLUTONIUM-241

7.7.12.1 Label nine 20mL glass liquid scintillation vials with the internal work-order ID numbers.

7.7.12.2 Add the appropriate amount of 241Pu standard (target 1200dpm) to three of the vials. Add the appropriate amount of 241Pu standard (target 1200dpm), of a second source, to three different vials. Note the matrix of the diluent, e.g. 5M HNO3. This will be used to prepare the three blank vials. If the diluent or the spiking volume is different for the two standards, see the Technical Manager for further instructions.

7.7.12.3 Add the same volume of unspiked diluent to the three blank vials.

7.7.12.4 Take all nine vials to dryness on a hotplate set to low temperature. Vials should be uncapped and taken just to dryness, not baked hard.

7.7.12.5 Remove vials from heat. Add 5mL 0.1M HNO3 to each vial.

7.7.12.6 Add 15mL Ultima Gold LLTTM cocktail.

7.7.12.7 Cap the vials tightly, mix thoroughly, and wipe clean with methanol and a lint-free laboratory wipe.

7.7.12.8 Submit the samples and proper documentation to the Instrument Lab for liquid scintillation counting.

7.7.13 PLUTONIUM-242

The method for ^{242}Pu is the same as ^{239}Pu, however, three cups are traced with ^{239}Pu and all four cups are spiked with the ^{242}Pu solution to be verified.

7.7.14 POLONIUM-209

7.7.14.1 Label four 220mL disposable cups with the internal work-order ID numbers.

7.7.14.2 Using a calibrated pipette (SOP 321), transfer a volume of 209Po, equivalent to 80-160dpm, to all four cups. Add the same activity of 210Po standard to three of the cups.

7.7.14.3 Place the sample cups on the steambath and take to complete dryness.

7.7.14.4 Re-dissolve the residue in 100mL of 1N HCl.

7.7.14.5 Add approximately 0.1g of ascorbic acid.

7.7.14.6 Electro-deposition is carried out per SOP 711.

7.7.15 POLONIUM-210
The method for ^{210}Po is the same as ^{209}Po, however, three cups are traced with ^{209}Po and all four cups are spiked with the ^{210}Po solution to be verified.

7.7.16 PROMETHIUM-147
Refer to Section 7.7.12, using ^{147}Pm instead of ^{241}Pu.

7.7.17 RADIUM-226
Refer to Section 7.7.3, using ^{226}Ra instead of ^{133}Ba. Also note that gamma analysis must be done by the 186 keV photopeak, NOT the emissions of the various progeny.

7.7.18 RADIUM-228
Refer to Section 7.7.3, using ^{228}Ra instead of ^{133}Ba.

7.7.19 STRONTIUM-89
Refer to Section 7.7.12, using ^{89}Sr instead of ^{241}Pu.

7.7.20 STRONTIUM-90
Refer to Section 7.7.12, using ^{90}Sr instead of ^{241}Pu.

7.7.21 TECHNICIUM-99

7.7.21.1 Label nine 20mL liquid scintillation vials with the internal work-order ID numbers.

7.7.21.2 Add 5mL of DI water to each scintillation vial.

7.7.21.3 Determine the volume of 99Tc standard needed to deliver approximately 1,000dpm activity. Remove that volume of water from the sample vials that will be spiked with 99Tc.

7.7.21.4 Add the volume of the 99Tc standard to be verified, determined in the previous Step, to three of the vials. Add the same activity of a second, independent 99Tc standard to three different vials. If the diluent or the spiking volume is different for the two standards, see the Technical Manager for further instructions.

7.7.21.5 Add 15mL of Ultima Gold ABTM cocktail to each vial. Cap the vials tightly, mix thoroughly, and wipe clean with

methanol and a lint-free laboratory wipe.

7.7.21.6 Submit the samples and proper documentation to the Instrument Lab for liquid scintillation counting.

7.7.22 THORIUM-229

7.7.22.1 Label four 220mL plastic specimen cups with the internal workorder ID numbers.

7.7.22.2 Transfer a volume of 230Th equivalent to 40-80dpm to three of the four cups. Spike a volume of the 229Th standard, at approximately half the 230Th activity into all four cups.

7.7.22.3 Take the cups to dryness on a steam bath and re-dissolve with 50mL 8N HNO3.

7.7.22.4 Load the solution onto a nitrate column and proceed with the Th separation and micro-precipitation as outlined in SOP 777.

7.7.23 THORIUM-230

The method for ^{230}Th is the same as ^{229}Th, however, three cups are traced with ^{229}Th and all four are spiked with ^{230}Th solution to be verified. Note that the ^{230}Th activity should, again, be approximately twice the ^{229}Th activity. This is to minimize the "tailing effect" of ^{229}Th that introduces a high bias to the ^{230}Th results.

7.7.24 TRITIUM (HYDROGEN-3)

Refer to Section 7.7.4, using ^{3}H instead of ^{14}C.

7.7.25 URANIUM-232

7.7.25.1 Label four 220mL plastic specimen cups with the internal workorder ID numbers.

7.7.25.2 Transfer a volume of 238U equivalent to 40-80dpm to three of the four cups. Add the same activity of 232U to all four cups.

7.7.25.3 Take the cups to dryness on a steam bath and re-dissolve with 50mL 9N HCl.

7.7.25.4 Load the solution onto a chloride column and proceed with the U separation and micro-precipitation as outlined in SOP 778. A chemical separation is necessary to remove the

ingrown 228Th progeny, which interferes with the 232U analytical region of interest (ROI).

7.7.26 URANIUM-238
The method for ^{238}U is the same as ^{232}U, however, three cups are traced with ^{232}U and all four cups are spiked with the ^{238}U solution to be verified.

7.7.27 STABLE CARRIERS (E.G., BA, FE, NI+CO, PB, SM, SR, Y)
Stable carriers are verified by ICP-AES in the metals Department. Prior to preparation, consult the metals Analyst to determine the appropriate dilution factor for the carrier solutions to be analyzed. Typically a 10,000-fold dilution will be acceptable, and is described below:

7.7.27.1 Label two sets of three 15mL ICP tubes with the internal workorder ID numbers or the carrier solution ID obtained from the reagent recipe logbook. One set will contain the intermediate dilution and the other will contain the final dilution.

7.7.27.2 Transfer 9.9mL DI water into each of the three intermediate tubes. Add 0.1mL of the carrier solution to be verified. Invert repeatedly and mix well.

7.7.27.3 Transfer 9.9mL ICP dilution solution into each of the three final tubes.

7.7.27.4 Remove 0.1mL of the intermediate dilution and add it to one of the final tubes containing 9.9mL of ICP diluent. Invert repeatedly and mix well.

7.7.27.5 Submit the final dilutions and proper documentation to the Metals Lab for analysis.

7.7.27.6 In addition to the normal LIMS entry, record all raw data and final results in the reagent recipe logbook.

8. QUALITY CONTROL

The successful routine analysis of batch Method Blanks and spiked Laboratory Control Samples serve as verification of the integrity of the standards and reagents used.

9. SAFETY, HAZARDS AND WASTE DISPOSAL

9.1 SAFETY AND HAZARDS

9.1.1 Read the component MSDSs prior to preparing standards or using any solvents or reagents.

9.1.2 Standards will be prepared using all reasonable precautions against the spread of contamination. The work area and all equipment will be surveyed at the end of the preparation.

9.1.3 Read the appropriate MSDSs before preparing standards or using any reagents.

9.1.4 Safety glasses and lab coats must be worn in the radiochemistry prep labs at all times.

9.1.5 Gloves, safety glasses, and a lab coat must be worn when working with any chemicals (e.g., standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

9.1.6 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

9.1.7 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

9.2 WASTE DISPOSAL

9.2.1 Remove expired standards from the storage area; submit to waste management personnel for disposal.

9.2.2 Non-halogenated solvent rinses are disposed of in the Non-Halogenated Organic Waste satellite collection vessel. Dichloromethane (Methylene Chloride) is disposed of in a separate Halogenated solvent waste stream.

9.2.3 All empty solvent bottles are disposed of appropriately. Please note that all labels and markings must be removed or defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/5/06: **SOP 300**: Completely restructured; storage considerations enhanced; discussion of Paragon's Standards & Solutions database augmented. Added 'RESPONSIBILITIES' and 'DOCUMENT REVISION HISTORY' Sections.

2/22/07: **SOP 798**: Rev5 expanded to include radioactive standards in the entire Radiochemistry Department, rather than just the Actinides Group. Verifications of carrier solutions, where required by the individual preparation SOPs, have also been included. The updated title of this SOP reflects these changes. Carrier solution verification was previously addressed in SOP 734 (now retired). Requirements for the preparation of carriers and other reagents is sufficiently addressed in SOP 300.

3/14/08: **Combined**: Incorporated IA061101 corrective action text into existing SOP 300r12 content; restructured. Added SOP 798r5 content (no changes except updating internal Section references). Updated existing SOP 300r12 Table content. Added Form 718.

Summary of Chemical Materials Requirements

Type	***Storage***	***Source***	***Expiration****
Concentrated Acids, Concentrated Bases	Ambient	Vendor	Shorter of vendor-supplied or 10 years from receipt
Solvents	Ambient	Vendor	Shorter of vendor-supplied or 5 years from receipt
Primary Reagents & Neat Chemicals	As required by method	Vendor	Shorter of vendor-supplied or 10 years from receipt

Type	***Storage***	***Source***	***Expiration****
Volatiles (includes all purgeable hydrocarbons, such as VOAs, Aromatics, GRO)	Freezer	Stock, Unopened	**Non-gases**: Vendor-supplied, if absent 1 year from receipt; **Gases**: **Vendor-supplied, if absent 1 year from receipt**
	As required by method	Stock, Opened	**Non-gases**: 3 months from date opened **Gases**: 1 week from date opened
	As required by method	Intermediate **	**Non-gases**: 1 month from preparation **Gases**: 1 week from preparation

* Replace sooner if contamination or degradation is evident.

** Date of expiration shall not exceed soonest of component materials.

Summary of Chemical Materials Requirements

Type	***Storage***	***Source***	***Expiration****
TOC	Refrigerate	Stock, Unopened or Opened Intermediate **	Shorter of vendor-supplied or 1 year 6 months from preparation

Type	***Storage***	***Source***	***Expiration****

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 303 REVISION 10

TITLE: CONTROL, FORMAT AND REVIEW OF LABORATORY LOGBOOKS

FORMS: 353

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9.10.06
QUALITY ASSURANCE MANAGER _____ DATE 9/7/06
LABORATORY MANAGER _____ DATE 9-10-06

HISTORY: Rev0, 2/3/92; Rev1, 7/30/92; Rev2, PCN #60, 12/20/93; Rev3, PCN #247, 8/01/94; Rev4, PCN #405, 2/28/95; Rev5, 7/15/99; Rev6, 10/08/01; Rev7, 4/07/03; Rev8, 9/15/03; Rev9, 6/5/04; Rev10, 9/11/06.

1. SCOPE AND APPLICATION

All analytical services performed by Paragon must be documented thoroughly in a legible, organized manner so that all information may be easily understood from laboratory records. The documentation must be available and defensible during casual inspection, internal and external audit, and legal testimony. Laboratory records must be retrievable, and kept in a manner that prevents loss, damage or deterioration (see also SOP 069).

This standard operating procedure (SOP) discusses the issuance, use and review of laboratory logbooks. Paragon uses both hardcover and custom (i.e., made in-house) laboratory logbooks (as well as electronic benchsheets which are utilized, protected, and archived in LIMS). Sample receipt and login functions are primarily addressed electronically, this SOP applies also to sample preparation and analysis, monitoring of support equipment (e.g., recording cooling unit and oven temperatures, balance calibration verifications, etc.), and instrument maintenance, where documented in laboratory logbooks. Chain-of-custody is documented electronically (see ~~SP~~ SOP 318). Preparation of standards and reagents is documented via use of Paragon's Standards and Reagents database (see SOP 300). Requirements pertaining to waste logs, Health & Safety, and training records are beyond the scope of this SOP.

2. SUMMARY

Use of laboratory logbooks helps to ensure that records are kept in a consistent, detailed, traceable and legally defensible manner. The user of the laboratory logbook must request the logbook from the QA Department. Key information pertaining to the laboratory logbook (e.g., title, unique laboratory identification number, etc.) is maintained by the QA Department in an electronic index. New logbooks are placed into service as needed; used logbooks are replaced and archived (electronically imaged) as needed.

All information pertinent to the task being conducted must be recorded, in a real time

manner, by the person performing the task, in the appropriate laboratory logbook (or electronic benchsheet). Any equipment used to perform analytical services (e.g., instruments, balances, pipettes, etc.) must be identified by their unique identifier.

Where the information maintained in an Operations' laboratory logbook has a direct effect on sample results (instrument run log, maintenance log, balance calibration verification logbook, etc.), that logbook's data must be reviewed ~~monthly~~ formally (see Section 4.7 for further details). Logbooks that do not contain original and official records (e.g., duplicate Radiochemistry sample transmittal logbooks -- official transmittal of prepared samples to Counting Room documented by LIMS benchsheets; out-going mail log, etc.) are exempted from ~~monthly~~ formal review. *Consult the Quality Assurance (QA) Manager for exemptions. Exempted Operations' logbooks must bear an annotation on the cover, dated and initialed by the QA Department, indicating that that particular laboratory logbook is exempt from monthly review.*

3. RESPONSIBILITIES

3.1 The QA Department is responsible for maintaining a current index of laboratory logbooks and for issuing controlled laboratory logbook numbers. The QA Department also maintains an on-going record of the printed names, signatures and initials of all personnel, to assist with ciphering logbook entries. The QA Department shall provide oversight as needed to ensure that archiving ~~monthly~~ and established logbook review processes are performed appropriately and in a timely manner.

3.2 It is the responsibility of the Department Manager to ensure that the laboratory logbook formats implemented sufficiently prompt all required information that needs to be recorded. The Department Manager is responsible for training laboratory staff in this procedure, and for monitoring satisfactory on-going performance.

Each Department shall perform and document a ~~monthly~~ formal review of the group's logbooks as applicable that addresses the accuracy, completeness and correctness of logbook entries and/or corrections. The review shall be documented by the entry of a second set of dated initials, that are independent from the dates and initials corresponding to the logbook entries themselves.

3.3 The Data Reporting Group is responsible for maintaining an organized system of scanned logbook images, and for processing logbooks submitted for scanning (archival) in a timely manner.

3.4 It is the responsibility of all personnel to maintain logbooks in accordance with this SOP, to guard against their damage or loss, and to submit them for archival, in a timely manner, when they are no longer in use.

4. PROCEDURES

4.1 ISSUING LOGBOOKS

4.1.1 Laboratory logbooks are controlled documents. The QA Department

issues laboratory logbooks via a sequential numbering system that is maintained via an electronic index. The following information is recorded in the electronic index for each logbook issued:

- laboratory logbook number
- title of laboratory logbook
- form reference or hardcover
- employee or group issued to
- date issued
- initials of issuer.

4.1.2 Identification as a Paragon Analytics logbook must be indicated on the front or inside cover of all laboratory logbooks. This identification must include Paragon's street address.

4.1.3 The following information must be marked on the outside front cover of the issued laboratory logbook:

- title
- group issued to
- assigned laboratory logbook number
- date issued
- ~~prompt for date started~~
- ~~prompt for date retired~~.

~~The user of the logbook must fill-in date started when the logbook is placed in service, and must fill-in date retired when the logbook is no longer to be used~~.

Where logbooks are dedicated to a specific piece of equipment, the unique identifier or serial number of the piece of equipment must also be indicated in the laboratory logbook.

4.1.4 End users and Departmental and QA staff may work with Paragon IS personnel to develop electronic benchsheets (for use in lieu of laboratory logbooks) where practicable.

4.2 PAGINATION

Numbering of logbooks pages is used to assure that the logbook is intact (i.e., that no pages have been removed or are missing).

4.2.1 All custom-made spiral bound logbooks are paginated in-house prior to issuance. The format of the pagination consists of a unique six-digit number, the first four of which indicates the assigned laboratory

logbook number, and the last two indicates page number (01 through 99, or less).

4.2.2 Hardcover logbooks are generally purchased with pre-numbered pages. Regardless, the binding of hardcover logbooks is such that intactness is inherently assured (i.e., page removal would be evident).

4.2.3 Some instrument run logs are printed out, annotated as needed, a copy is placed in the sample workorder folder, and the original is maintained in a designated three-ring binder. Pagination of the run log print out pages contained in the three-ring binder is not required as they are uniquely identified by their contents (e.g., contain unique sequence designations in the print out's header; depict unique batches as log entries).

A slip-sheet that depicts the information described in items 4.1.2 and 4.1.3 above, is placed as a cover to the three-ring binder. When the binder becomes full, the analyst clips the contents together, along with the slip-sheet cover, submits the contents to the Data Reporting Group for archival, and requests a new slip-sheet from the QA Department.

~~The contents of the three-ring binder are reviewed monthly in accordance with the procedures outlined in this SOP~~.

4.3 RECORDING ENTRIES IN LOGBOOKS

4.3.1 All logbook entries must be legible and must be recorded in indelible black or blue ink. Other colored ink may not be used as it may not photocopy well. Pencil may not be used as the original data must be recorded in an indelible manner (i.e., in a manner that cannot be easily altered).

4.3.2 All data and observations must be recorded directly, in a real time manner, by the person generating the data or making the observation. Use of "post-it" notes to record data for subsequent transcription into a laboratory logbook is prohibited.

4.3.3 Each person making entries in a laboratory logbook must review his/her work to ensure that all entries are clear, legible, and formatted well enough that a reviewer -- several years after the work is complete, working from a photocopy, and without the help of laboratory personnel -- can easily read and understand the entry.

4.3.4 Each entry (i.e., set of information recorded in the same time frame) must be dated and initialed by the person making the entry. If an entry requires more than one page, the preceding page number should be

referenced at the top of each following page.

Arrowing down is permissible as long as it is clear where the arrow stops. Arrowing down is not permissible if recording measured values (i.e., record gravimetric values as actual weights).

Use leading zeroes when recording values less than one (e.g., 0.0255g).

4.3.5 If multiple entries are made on the same page on various dates, then each entry must be dated and initialed separately.

4.3.6 Unused portions of a page or unused pages must be voided to prevent additional information being added at a later date. A large "Z" or "slash" can be used to void out a space or page (or group of errors). The mark used to void the space or page must be dated and initialed proximate to the mark.

4.3.7 Any information added to the logbook (e.g., run sequence logs, spectra) must be stapled or taped to a logbook page, and then signed and dated such that the signature/date is half on the attached sheet and half on the logbook page itself.

4.3.8 Benchsheets and other electronic records in LIMS are subject to restricted access controls to assure that entries (or corrections) are made only by appropriate authorized personnel.

4.4 MAINTENANCE LOG ENTRIES

Definition of Paragon's maintenance program, including requirements for documentation, are given in Section 8.0 of the LQAP.

Some data systems associated with instruments (e.g., ICP, **CVAA, LC/MS-MS**) can accommodate maintenance entries that appear as run log headers in lieu of using maintenance logbooks. Use of this type of electronic record is permissible.

Hardcover logbooks are assigned to each piece of major Paragon instrumentation. Where practicable, laboratory benchsheet logbooks may be modified to include maintenance attestations. The hardcover maintenance logbooks should be physically located in the laboratory in a convenient location proximate to the instrument. Routine maintenance, scheduled preventive maintenance and repairs are to be recorded.

At a minimum, each logbook entry must contain the following:

- **the date of the maintenance or repair;**
- **the reason for the maintenance or repair, including any modifications made to the instrument (e.g., preventive, replaced broken part, HPLC component switched-out);**
- **a full description of the maintenance or repair conducted;**
- **the name of the analyst or vendor who performed the maintenance or repair; and**
- **the initials of the analyst making the entry and date of entry.**

See SOP 317 for directives pertaining to tagging equipment out of service and placing repaired equipment back into service. Remember that the equipment must be demonstrated to be functioning within acceptable parameters before being placed back into service. **A reference that the equipment was verified and where this information can be found, should be noted in the maintenance log. Also, where applicable, the identity of the reference material used as an instrument check must also be recorded. Where applicable, a statement as to the calibration's expiration must also be made.**

4.5 ANCILLARY INFORMATION

Anomalies must be explained by annotation. For example, if the normal sequence of dates recorded in a laboratory logbook indicate a longer gap than usual, that gap must be explained by a comment indicating why the gap occurred (e.g., holiday, inadvertently missed reading, etc.) The annotation must be dated and initialed by the person making the entry.

Similarly, if a temperature excursion occurs, an explanation indicating why (e.g., refrigerator left open) and what corrective measures were taken, as applicable (e.g., ambient temperature higher, so adjusted temperature control colder) must be noted.

4.6 CORRECTING ERRORS

4.6.1 Information may not be obliterated in any manner. No correction devices or fluids (e.g., erasers, whiteout, labels) may be used. Information may not be cut out, pages must remain intact.

Errors must be corrected with a single line drawn completely through the erroneous entry, making it clear that the error is being crossed out but leaving it legible. The corrected entry must be initialed and dated by the person making the correction. If not evident, the reason for making the correction must be clearly stated.

4.6.2 It is acceptable to block or bracket a group of changes and initial and date those changes as a unit. However, it must be clear as to what group is being changed, the date the changes are made, and who made the changes.

A large "Z" or “slash” can also be used to void out a group of errors. The mark used to void the group of errors must be dated and initialed proximate to the mark, thus indicating the date the change was made and the person making the change. A comment may also be written to explain the reason that the entry was voided.

4.7 REVIEWING LOGBOOKS

All laboratory logbooks not cited as exempt from ~~monthly~~ **formal** review must be reviewed by a peer or Supervisor ~~on a monthly basis~~. ~~Custom~~ logbooks requiring ~~monthly~~ review contain a review prompt signature line on each page, hardcover logbooks contain a pre-printed signature line at the bottom of each page.

with direction to obtain a review signature at the time each page is completed.

4.7.1 The Department Manager is responsible for determining who may perform logbook reviews. It is Paragon’s policy that review/sign-off is performed by a knowledgeable, independent party. A technician or

Because the pages that comprise instrument run logs are copied as completed and included with the workorder/run documentation (reviewed subsequently), formal review of these logbook originals is not required.

analyst may not review his/her own work; however, in instances where multiple parties make entries onto a logbook page, it is permissible for one of the participants to function as the final review signature. Review by QA staff is also permissible.

4.7.2 The reviewer shall verify the following conditions:

- complete information for every entry; all information is legible
- all entries made in indelible black or blue ink
- all entries are initialed and dated
- no information obliterated; no correction devices or fluids used; corrections made properly (single line cross-out, date, initials)
- all pages intact
- supplemental information stapled or taped to logbook page and initialed and dated
- corrective actions recorded for non-compliant situations.

The QA Department issues monthly logbook review request attestations to each Department to assure that appropriate logbook review procedures are being followed.

The reviewer shall place his/her initials and date at the end of each page of entries reviewed to demonstrate that a review has been performed.

4.7.3 In instances where logbook entries are infrequently made (i.e., where a long duration of time is needed to complete a logbook page), the logbook shall ~~still~~ be reviewed monthly. The reviewer shall draw a line under the last entry made and place his/her initials and date at the end of the line to indicate an independent review.

4.8 ARCHIVING

Electronic records are subject to frequent backup and redundancies as explained in Paragon's IS and LIMS Policies and Procedures (posted to network for ready reference). A system for archiving (see SOP 069 for additional details) hardcopy laboratory logbooks by imaging (scanning) is in place. Transference of these records to electronic images preserves and protects them (via frequent backup and redundancies). The scanned images are accessible for reference lab-wide, hence completed logbooks should be turned in promptly to prevent loss or damage.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 305 REVISION 10

TITLE: BALANCE CALIBRATION, VERIFICATION, AND UTILIZATION

FORMS: 301 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1/15/07
QUALITY ASSURANCE MANAGER _____ DATE 1/12/07
LABORATORY MANAGER _____ DATE 1-12-07

HISTORY: Rev0, 1/24/92; Rev1, 12/20/93; Rev2, PCN #65, 1/6/94; Rev3, PCN #99, 1/20/94; Rev4, PCN #542, 10/18/95; Rev5, 5/9/97; Rev6, 1/10/00; Rev7, 4/17/02; Rev8, 9/22/03; Rev9, 7/20/05; Rev10, 1/12/07. re-released without revision 3/12/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) outlines the procedures to be followed for the daily use of laboratory balances (i.e., calibration verification and operation). The annual cleaning, calibration and certification of balances performed by a qualified vendor is also discussed.

2. SUMMARY

The calibration of all certified laboratory balances is to be verified daily before use, using annually verified laboratory weights, and per the calibration scheme prescribed in the balance's dedicated logbook (Form 301).

3. RESPONSIBILITIES

3.1 The Department Manager shall designate appropriately trained staff to conduct and record daily balance calibration verifications. The Department Manager or designee shall notify the QA Department of any new application the balance is used for, if the masses weighed for that application are not already bracketed by the balance's current verification scheme.

3.2 The Department Manager or designee shall notify the QA Department of any new balance acquisition so that certification can be arranged and a dedicated logbook issued before the balance is placed into service.

3.3 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review. Any anomalies or out-of-control events must be noted and corrective action taken and documented. It is the responsibility of the Technician to notify the QA Department of any balance that is malfunctioning or is not operational.

3.4 The QA Department is responsible for coordinating the annual balance servicing

and calibration certification performed by a qualified vendor. The QA Department shall also coordinate vendor servicing as needed when a balance malfunctions or is transported (by vehicle), thereby invalidating its certification.

3.5 The 3-point calibration verification scheme (Form 301) developed for each balance by the QA Department, brackets the balance's normal range of use and is based on the balance's intended use, capabilities, client quality control criteria, and other "good science" considerations. The QA Department shall evaluate the calibration schemes periodically to assure their appropriateness and adequacy.

3.6 The QA Department is responsible for coordinating the annual certification of Master weights, and performing the annual in-house verification of laboratory weights (SOP 901). The QA Department is responsible for the annual acquisition and change-out of static masters. Records of all balance certificates, servicing records, and an inventory of balances and their locations shall be maintained by the QA Department..

4. INTERFERENCES

4.1 The balance must be level and stable for proper operation.

4.2 Drafts can cause the balance to drift, yielding unstable readouts. Draft shields either integral to or external to the balance, must be used where needed.

4.3 The balance pan, and chamber, where applicable, and the weights used for verification must be clean or error may result. Use a Kimwipe™ or brush to clean the pan as needed. In the event of a spill, consult the operating manual (obtainable from the QA Department) if more thorough cleaning is required.

Use gloves, a Kimwipe™, or some other barrier (e.g., tweezers) when handling the weights. Do not handle the weights with bare hands. If the weights must be cleaned, use acetone or another suitable solvent and a Kimwipe™. Make sure the weights have air-dried completely before using them.

4.4 Use of static masters, to dissipate static charge and aid in drift control, is recommended for chambered analytical balances.

4.5 A balance's total capacity is usually incorporated in the model designation. For example, an AE104 balance has a total operational capacity of 104 grams. ***Know the limits of the balance being used. Never attempt to weigh anything whose mass exceeds the balance's capacity.***

5. APPARATUS AND MATERIALS

5.1 Balance with current certification (refer to balance's calibration sticker, good through one year from date of certification).

5.2 Verified laboratory weights (refer to verification sticker, good through one year from date of verification).

5.3 Dedicated balance calibration verification logbook.

6. PROCEDURE

6.1 GENERAL PROCEDURES

6.1.1 Note the considerations discussed in Section 4 Interferences; resolve any issues.

6.1.2 It is not necessary to turn the balance off after each use; the balance may be left on indefinitely. If the balance is not already on, power it on and allow it to warm up for a few moments before using it. Make sure all draft shields are tightly closed or in place, and zero the balance. Check the balance's readout to verify that the reading is stable.

6.1.3 Before using the balance to weigh any mass recorded for analytical use, check the dedicated balance logbook to determine if a daily balance calibration verification has been performed. If the balance's calibration has not yet been verified, perform the procedures outlined in Section 6.2 below. If the balance has been verified, tare the balance.

6.1.4 All objects to be weighed should be placed in the center of the balance pan. Allow the balance's readout to stabilize before recording the observed weight on the appropriate laboratory benchsheet. Where balances are interfaced with LIMS, the software monitors and requires the balance to stabilize before transmitting the mass information to LIMS. Allow the balance to completely return to zero between each weighing. Know the balance's limit! ***Never weigh anything whose mass exceeds the balance's total capacity!***

6.1.5 Remove the object. The balance may be left on when finished.

6.2 CALIBRATION VERIFICATION

The following procedures are to be carried out by qualified staff, near the beginning of the workshift, each day the balance is in use:

6.2.1 Verified laboratory weights are located strategically throughout the laboratory (e.g., Organics Extractions Lab, Organic Standards Lab, Actinides Water Lab). Obtain the appropriate weights/weight sets.

6.2.2 Use gloves, a Kimwipe™, or some other barrier (such as tweezers) when handling the weights.

6.2.3 Weigh each mass of the weight scheme (Form 301), and record the observed weight. Evaluate the recorded weight against the acceptance range depicted on Form 301.

If the observed weight does not fall within the acceptance range, check that the balance is level, stable, shielded from drafts, and that the balance pan and weights are clean. Reweigh.

If the observed weight still does not fall within the acceptance range, turn the balance off, wait a moment, then power the balance on again. Zero. Reweigh each weight per the 3-point verification scheme. If acceptance limits still are not met, notify the QA Department immediately so that appropriate corrective action may be taken.

6.2.4 Replace the weight(s) in the protective case and return them to their proper storage location.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

7.2 Safety glasses, a lab coat, and gloves must be worn at all times when working in the laboratory.

7.3 Food and drink are prohibited in all lab areas.

8. REFERENCES

None.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 306 REVISION 4

TITLE: **THE USE OF SIGNIFICANT FIGURES AND RULES FOR ROUNDING NUMBERS**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7/20/06
QUALITY ASSURANCE MANAGER _____ DATE 7/20/06
LABORATORY MANAGER _____ DATE 7-21-06

HISTORY: Rev0, 4/4/94 and 12/15/95; Rev1, 2/10/01; Rev2, 8/19/02; Rev3, 2/9/04; Rev4, 3/24/05 & 7/24/06.
re-released without revision 3/12/09 DAS

1. SCOPE AND APPLICATION

In order to report numerical results accurately and consistently, the laboratory must round numbers correctly and report the appropriate number of significant figures. This Standard Operating Procedure (SOP) describes the methods by which numerical values are rounded and the correct number of significant figures is reported.

2. SUMMARY

The rules presented below provide a consistent, systematic approach for rounding numbers and reporting the correct number of significant figures. These rules ensure that the "numbers reported are significant and that no significant numbers are lost in the calculations." (Reference 8.2)

3. RESPONSIBILITIES

3.1 It is the analyst's responsibility to understand and follow the procedures set forth in this SOP, to round numbers correctly, and to report the correct number of significant figures.

3.2 It is the Department Manager's responsibility to ensure that numbers have been rounded correctly and that the correct number of significant figures has been reported.

4. DEFINITIONS

4.1 Significant Figures: the number of leading non-zero digits in the reported value. Terminal zeros may or may not be significant (see Section 6.2 for details).

4.2 Experimental Observation: the measured quantity that is determined experimentally. It is the "raw" information that is recorded. The following are examples of such quantities - the height or area count from a chromatographic analysis; the measured volume of a pipette; the readout value from a balance or

spectrometer. Calculated values produced by a computer are not experimental observations.

5. ANALYTICAL MEASUREMENTS

5.1 Always record an experimental observation to the greatest number of significant figures possible. In general, it is not necessary to record more than 5 significant figures. Record all significant figures after the decimal place on the balance or other readout device. Rounding shall be performed ***after*** the final calculation.

5.2 Use the rules presented in Table 1 below to report the correct number of significant figures in the final result:

Table 1

SIGNIFICANT FIGURES TO BE REPORTED – DEFAULT REPORTING STANDARDS

Organics Sample Data:	Report 2 significant figures
Metals Sample Data:	Report 2 significant figures
General Chemistry Sample Data:	Report 2 significant figures
Radiochemistry Sample Data (use ANSI standard):	Report 2 significant figures for uncertainty, activity and MDC
Quality Control (QC) Data:	Report 3 significant figures for spikes; Report 2 significant figures for blanks; Report to the whole number units place for precision (%R) and accuracy (%RPD)

5.3 The only exception to the in-house rules presented in this SOP may be provided by a client's SOW or QAPjP.

6. RULES FOR ROUNDING NUMBERS AND REPORTING SIGNIFICANT FIGURES

6.1 ROUNDING

To round a numerical result to a certain place value, locate the digit in that place and the digit to its immediate right.

6.1.1 If the digit immediately following those to be retained is less than 5, drop the terminal digit(s) and do not change the digit in the rounding place.

Examples: 11.44 rounds to 11.4
0.480 rounds to 0.48
1233 rounds to 1230

6.1.2 If the digit following those to be retained is greater than 5, drop the terminal digit(s) and increase the digit in the rounding place by 1.

Examples: 11.46 rounds to 11.5
0.489 rounds to 0.49
1678 rounds to 1680

6.1.3 There are two different approaches to rounding if the digit following those to be retained is equal to 5:

- The simplest approach states that if the figure following those to be retained is equal to 5, increase the digit in the rounding place by 1. Most commercial applications (e.g., Excel, Access) follow this rule when rounding. Paragon's Laboratory Information Management System (LIMS) follows this convention.

- The second approach, for example, that required by the US EPA CLP SOW, states that: If the figure following those to be retained is equal to 5, and there are no figures other than zeroes beyond the 5, and the rounding place is even, drop the terminal digit(s) and do not change the digit in the rounding place.

Examples: 12.250000 rounds to 12.2
0.2445 rounds to 0.244
145 rounds to 140

If the figure following those to be retained is equal to 5, and there are no figures other than zeroes beyond the 5, and the rounding place is odd, drop the terminal digit(s) and increase the digit in the rounding place by 1.

Examples: 0.487500 rounds to 0.488
11.35 rounds to 11.4
135 rounds to 140

If the figure following those to be retained is equal to 5, and there are non-zero figures beyond the five, drop the terminal digit(s) and increase the digit in the rounding place by 1.

Examples: 0.48751 rounds to 0.488
11.352 rounds to 11.4

6.2 SIGNIFICANT FIGURES

The number zero may or may not be a significant figure. The "significance" of the number zero is case specific.

6.2.1 Final zeros after a decimal point are always significant figures, if the value of the number is greater than 1.

Example: To the nearest milligram, the number 9.8 is reported as 9.800 grams (four significant figures total).

6.2.2 Zeros before a decimal point with nonzero digits preceding them are significant. With no preceding nonzero digits, a zero before the decimal point is not significant.

Example: The zeros are significant in the number 100.8 (four significant figures total); the zero is not significant in the number 0.8 (one significant figure total).

6.2.3 If there are no nonzero digits preceding the decimal point, the zeros after the decimal point but preceding other nonzero digits are not significant. These zeros are intended as placeholders only and are written to indicate the position of the decimal point.

Example: The zeros are not significant in the number 0.00042 (two significant figures total).

6.2.4 One way to determine the significance of one or more zeros interspersed in a number is to write the number in exponential form. If the zeroes may be deleted when the number is expressed in exponential form, then the zeroes are not significant.

Example: 0.00042 may be written as $4.2 \bullet 10^{-4}$. The zeroes are not significant and may be deleted. This number has two significant figures.

Example: 100.01 may be written as $1.0001 \bullet 10^{2}$. The zeroes are significant and may not be deleted. This number has five significant figures.

6.2.5 Final zeros in a whole number may or may not be significant, depending upon the situation.

7. REPORTING DATA

7.1 Table 1 lists the number of significant figures to be reported for each kind of analysis. Use the rules for rounding and significant figures along with Table 1 to

report the correct number of significant figures. Reporting limits with less than (<) signs follow the rules listed in Table 1.

7.2 Values pertaining to QC raw data -- i.e., amount spiked, spike result, etc. -- shall be reported to three significant figures. The percent recovery shall be reported in whole numbers (to the units place) and the relative percent difference shall be reported in whole numbers (to the units place).

7.3 Paragon's LIMS does not display terminal zeroes.

re-released without revision 3/12/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) details procedures for removing improperly or non-functioning equipment from use and gives guidelines for placing new or repaired equipment in service. This SOP applies to, but is not limited to, the following types of equipment: ovens, balances, cooling units, weights, thermometers, hoods, pipettors, and radiation survey equipment.

Corrective actions and documentation requirements for data generated using non-conforming equipment are prescribed in SOP 928 - Issuing and Tracking of Non-Conformance Reports.

2. SUMMARY

In order to ensure the generation of accurate and reproducible data, all analytical, reference and support equipment are maintained and operated in a controlled manner. When equipment is either not working at all, or is not working within specifications, the equipment is considered to be nonconforming and must be removed from service.

Equipment removed from service must be prominently tagged-out (see Example placard at end of SOP) and may be placed into service only after appropriate adjustments/repairs have been made and reliable performance within specifications has been demonstrated.

The parameters of performance for each equipment type are detailed in the associated operational SOP and/or the instrument's operator's manual.

3. RESPONSIBILITIES

3.1 Each equipment/instrument operator is responsible for the proper operation of the equipment and for inspecting the equipment for proper functioning prior to use. If the equipment/instrument is determined not to be in acceptable working order, the operator must tag-out the equipment per the requirements of this SOP and notify the Department Manager, and the Quality Assurance (QA) Manager, as applicable, in a timely manner. Excepting identified support equipment (records

for support equipment maintenance are retained by the QA Department, the equipment/instrument operator is also responsible for documenting the need for repair, and for maintaining repair records.

3.2 The Department Manager and QA Manager are responsible for coordinating and ensuring that appropriate corrective actions are taken, including the equipment's repair or replacement, and notification to clients of suspect data, as applicable. The Department Manager is responsible for ensuring that the repaired or replacement equipment is properly functioning before being placed into service.

4. PROCEDURE

4.1 Equipment is tested/inspected for proper functioning before use. Only properly functioning equipment that meets the calibration/performance criteria set forth in the unit's associated operational SOP can be used. If the equipment is not operational or does not function within the prescribed control parameters, it must be tagged-out as "Not In Service," and the Department Manager, and QA Manager, as applicable must be notified.

A "Not In Service" placard (see Example at end of SOP) must be prominently displayed on the nonconforming equipment. This equipment cannot be used until satisfactory repair has been completed and the unit demonstrates reliable performance. Appropriate corrective actions for potentially affected data shall be initiated by the Department Manager, or designee, per SOP 928.

4.2 As applicable, the Department and QA Mangers will coordinate the failed equipment's repair or replacement. Equipment found to be repeatedly out-of-service shall be removed from service entirely or shall be replaced.

4.3 Repaired or replaced equipment must demonstrate accurate and reliable performance before being placed into service. The "Not In Service" placard must remain in place while the unit is being repaired and during determination of reliable performance.

4.4 Notations documenting the equipment's failure, and detailing the equipment's repair order and status, shall be made in the associated equipment's logbook. Additional maintenance and repair records shall be maintained by the laboratory Department, as applicable.

5. REFERENCES

This SOP describes in-house procedures developed by Paragon. The requirements established herein are compliant with various quality assurance guidance documents, such as the most current versions of the National Environmental Laboratory Accreditation Conference (NELAC) Standard, the Department of Energy (DOE) Quality Systems for Analytical Services (QSAS) document, and the Department of Defense (DoD) Quality Systems Manual (QSM) for Environmental Laboratories.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 318 REVISION 6

TITLE: **CHAIN OF CUSTODY**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7/7/06
QUALITY ASSURANCE MANAGER _____ DATE 7/7/06
LABORATORY MANAGER _____ DATE 7/7/06

HISTORY: Rev1, 3/15/93; Rev2, 8/25/93; Rev3, PCN # 86, 1/18/94 and 10/18/95 (re-released w/o revision); Rev4, 4/23/02; Rev5, 2/13/04; Rev6, 7/5/06.

1. SCOPE AND APPLICATION

Chain-of-custody (COC) is a documented procedure used to demonstrate the flow of and responsibility for samples from field acquisition, receipt and analysis by the laboratory, to disposal or return to the client. COC is used to establish an intact and continuous record of the physical possession, storage and use of the sample, its fractioned aliquots, leachates, extracts, digestates, and remnants.

The USEPA defines custody of a sample as:

- in one's actual possession, *or*
- in one's view, after having been in one's physical possession, *or*
- in one's possession and then locked or sealed to prevent tampering, *or*
- kept in a secure area, restricted to authorized personnel only.

This standard operating procedure (SOP) describes Paragon's practices for barcoding and maintaining electronic COC through our Laboratory Information Management System (LIMS).

2. SUMMARY

A field COC is received with the samples. Paragon's Sample Custodian or designee uses the information on the field COC, as well as other laboratory information, to log the samples into LIMS (SOP 201~~1~~2. The sample receipt process is completed (SOP 202) and unique barcode labels are generated and applied to each sample container. Scanning of the barcoded samples is the means by which custody is transferred and tracked throughout the laboratory. Unique barcode labels are also generated and applied to all fractions, leachates, extracts and digestates derived from the samples.

Two types of paired events are performed and documented in LIMS to move samples, fractions, leachates, extracts and digestates throughout the laboratory. These paired events are: 'check out/check in' and 'relinquish/receive'. The sample (and like-wise fraction, leachate, extract and digestate) transactions are accomplished by scanning, using

the many hand-held scanners located throughout the laboratory, and on-screen data entry. The transaction events are traceable to the individual performing them because entry of the individual's unique LIMS username and password is required. Once initiated, the paired event must be completed before another custody event can be initiated.

Please note that Paragon's LIMS is proprietary and only limited detail is provided in this SOP. Access to LIMS and associated guidance materials is restricted to authorized personnel only.

3. RESPONSIBILITIES

3.1 All Sample Receiving, preparatory, analytical, and Waste Disposal staff are responsible for carrying out the procedures as described in this SOP, and for reporting problems encountered to the IS Department in a timely manner.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 IS Department staff are responsible for maintaining and augmenting LIMS as needed and for providing the necessary internal chain-of-custody (ICOC) training to laboratory staff.

4. PROCEDURE

4.1 Samples are received from the courier or directly from the client and logged in by Sample Receiving staff who enter information such as number of containers, sample matrix, etc. into LIMS for each workorder processed. Unique barcode labels are generated and applied to each sample container. The Sample Receiving staff maintains custody of the samples until they are 'relinquished' to the respective laboratory Groups who 'receive' them.

4.2 A list of storage and sample processing areas is maintained in LIMS. During the 'receive' event, the recipient has the opportunity to refine the sample's location to a shelf and bin designation if so desired. A 'search' utility exists in LIMS to assist with locating samples (or fractions, leachates, extracts and digestates thereof).

4.3 Laboratory personnel 'check out' samples as needed for preparation and/or analysis. The distinction between a 'check out/check in' event and a 'relinquish/receive' event is that sample containers that are expected to be returned to the sample location they were acquired from are 'checked out' then 'checked back in' when returned; whereas samples (or fractions, leachates,

extracts and digestates) that are not to be returned to the location acquired from are 'relinquished/received'. **

A "batch" barcode may be used to transfer the custody of entire sets of planchets, liquid scintillation vials, gamma containers, etc. from a laboratory preparatory Group to an analysis Group.

4.4 When samples are depleted upon preparation and/or analysis, their "depleted" status is designated as such in LIMS.

4.5 Sample remnants, including leachates, extracts and digestates, as well as unconsumed fractions such as counted planchets and gamma containers, are retained by Paragon for a period of 90 days (unless otherwise specified by the client). These sample remnants, unconsumed fractions, leachates, extracts and digestates may be transferred to designated sample archive areas for storage.

4.6 When a workorder is designated in LIMS for disposal, Paragon either returns the sample to the client according to contractual requirements, or proceeds with disposal in accordance with applicable local, State and Federal regulations. The Waste Compliance Officer coordinates and maintains records of final disposal.

5. REFERENCES

None.

DOCUMENT REVISION HISTORY

7/5/06: Complete re-write transitioning from hardcopy COC logs to barcoding and electronic chain-of custody. Added standard LIMS program specification reference to 'RESPONSIBILITIES' Section; added DOCUMENT REVISION HISTORY Section.

**** NOTE: For RUSH direct count work, the entire client sample(s) is `checked out' into the custody of Radiochemistry Prep. Lab personnel. However, a paper benchsheet (to accomplish the timeliness needed), is used to document the transfer of the sample(s) to the Instrument Lab for counting. The same benchsheet is then used to document the return of the sample(s) to the Prep. Lab for subsequent preparations. Note that for this RUSH counting, the sample(s) is not altered, it is merely counted `as is' (i.e., as received). After subsequent sample preparation(s) are completed, the remaining client sample, if not depleted, is `checked back in' via LIMS. The paper benchsheet used to accommodate the RUSH count work is included as part of the final data package report.**

Paper benchsheets are also used to transact non-RUSH filters from the Radiochemistry Prep. Lab to the Instrument Lab for direct gamma counting. The benchsheet is then used to document the return of the filters to the Prep. Lab for preparation for additional analytical testing. The benchsheet is included in the final data package report.

Must Discard 30 Days from _____ (date printed)

LABORATORY MANAGER _____ DATE 3-1-07

HISTORY: Rev0, 3/19/93; Rev1, PCN #128, 2/4/94; Rev2, PCN # 507, 7/12/95; Rev3, 10/21/98; Rev4, 1/08/99; Rev5, 3/02/02; Rev6, 9/8/03; Rev7, 9/11/06; Rev8, 3/1/07.

re-released w/o revision 3/12/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the processes that Paragon uses during the monitoring and use of reagent water in the laboratory. The procedures described herein apply only to water that is purified and generated on-site, as part of Paragon's deionized (DI) water system, and does not apply to specialty grades of water (e.g., HPLC water) that are purchased from vendors.

Because water is such a 'universal solvent', it is susceptible to a host of extraneous materials (contaminants), such as: suspended particles (turbidity), ions (e.g., dissolved inorganics that constitute 'hard water'), dissolved organics (carbon-based materials that can particularly impact low-level HPLC analyses), bacteria (both live and cell debris), etc. The characteristics (purity) of the water (as reagent, diluent, laboratory control sample media, etc.) required, is contingent on the analytical method used and based on what properties could critically affect the measured outcome. This includes physical effects, such as turbidity, which may clog analytical columns, as well as interfere with photometric readings.

This SOP does not address the generation of reagent water used in volatile organic analyses (see SOP 511), nor does it address additional treatments that may be required by specific analytical methods (see appropriate method SOPs). Because the characteristics of water can change even as it sits in a sealed container (for extended periods), storage is a consideration, but is not addressed by this SOP (see applicable method SOP).

Laboratory staff must be aware that the meaning of the term 'reagent water' varies per application, and that not all 'reagent water' is the same thing.

2. SUMMARY

Water is highly susceptible to contamination. Considerations of 'purity' vary per application. Use of high purity water only is relevant to analytical processes, but not necessary or economically practical for initial stages of dishwashing (SOPs 334, 720).

Paragon operates several DI water systems to support the laboratory's needs. The quality of the DI water generated for general laboratory use is evaluated by measuring resistivity, which must be monitored and documented each business day. Veracity of the DI system monitoring sensors is verified monthly. Vendors are used to replenish and maintain the DI water systems.

3. RESPONSIBILITIES

3.1 Laboratory staff members are designated to perform the monitoring functions described in this SOP. It is their responsibility to conform to the requirements of this SOP, and to promptly notify the Paragon point-of-contact for vendor interface (currently Lance Steere), and the QA Manager, in the event of a failure of the purification system(s).

3.2 Department Managers are responsible for ensuring that staff are properly trained regarding concepts and procedures addressed by this SOP. The Department Managers must also assure that only reagent water as specified by each method is used for analytical procedures.

When Department Managers are informed of purification system problems or failures, their first responsibility is to determine the impact of the situation on the laboratory's analyses, and to take action to minimize the detrimental effects the situation may have on generated data. Temporary procedures that will alleviate any adverse effects must be implemented, and the general laboratory staff must be informed accordingly.

3.3 In the event that either routine maintenance or system failure require Paragon to contact the vendor, the Paragon point-of-contact is Lance Steere. All requests for equipment maintenance/service should be routed through him. Lance is responsible for maintaining the non-benchtop water purification system service records.

This individual is also responsible for conducting and documenting the monthly resistivity meter verification, and for properly maintaining the equipment necessary to conduct this testing.

3.4 The Quality Assurance Department is responsible for providing oversight of adherence to water purification system policies, and for providing monitoring logbooks as needed.

4. INTERFERENCES

For some of the water purification systems, prolonged disuse of the system can cause small amounts of organic and inorganic materials to be leached from the plumbing, thus compromising the quality of the water delivered. This disuse can cause resistivity readings to be lower than normal, or outside of acceptance limits. In cases where the DI system has not been used for some time (e.g., 4 days or more), it is good practice to open a DI faucet for approximately 30 seconds to briefly flush the DI lines of any accumulated dissolved material.

5. APPARATUS AND MATERIALS

Within the laboratory, there are two main DI water distribution systems available for glassware cleaning, bulk reagent preparation and general use. One system is located in the janitor's area and serves the radiochemistry side of the facility (ASTM Type II water generated). The other system is located adjacent to the metals laboratory area and serves the stable chemistry side of the facility (ASTM Type I water generated). These DI water systems are capable of continuously delivering water that meets the requirements specified for the ASTM water type, and are monitored and documented each business day to ensure that the water produced meets these criteria. Paragon also maintains a third treated water system that is used to support washing of laboratory glassware. Additionally, a benchtop Millipore Synergy 185^{TM} unit is available for laboratory use should further finishing be desired.

5.1 STABLE CHEMISTRY WATER PURIFICATION SYSTEM

5.1.1 Deionized Water Purification System (ASTM Type I)

Municipal (tap) water is passed serially through five tanks that contain ion exchange resins and organic adsorbents. These resins and adsorbents remove anions, cations and organic matter from the water. An in-line probe that monitors the water purity continually as it exits these tanks, is in place in the outflow of the fifth tank. This probe is connected to a meter whose display indicates the resistivity of the water passing over the electrode.

5.1.2 Millipore Purification System (ASTM Type I)

The DI water purified by the primary purification system is circulated through the Millipore system for further purification via high-quality ion exchange resins and carbon filters. This system generates ultra high-purity water to be used for critical applications. The Millipore system is equipped with an internal detector that indicates the resistivity of the water being produced.

5.2 RADIOCHEMISTRY WATER PURIFICATION SYSTEM (ASTM Type II)

Incoming municipal water is passed through a series of four ion exchange cylinders for initial purification. The water then enters a large fiberglass holding

tank. Water in this tank is pumped through two finishing resin cylinders, operating in parallel, and into a recirculating loop that continuously circulates water between the holding tank and the finishing cylinders. As deionized water is used in the laboratory areas, the initial incoming resin-washed tap water acts as the makeup volume for the holding tank.

System function and water quality is monitored at two points. The first monitoring point is a light (on vs off) located at the outflow of the fourth ion exchange cylinder, and the second monitoring point is the resistivity meter whose sensor is located at the outflow of the two parallel finishing scrubbers. Control systems also include a low level monitor in the holding tank, and sensors to control the flow of makeup water into the holding tank.

5.3 GLASSWARE WATER PURIFICATION SYSTEM

Tap water is passed through two tanks containing ion exchange resins and organic adsorbents, which remove anions, cations and organic matter from the water. The second tank is equipped with a resistivity detector that monitors the water purity continually as it exits this tank. This meter has a light that indicates, when lit, effective and correct operation of the purification system.

Water from this system is used only for the final rinsing of stable chemistry laboratory glassware, and not in the preparation of any reagents or standards used in the laboratory. Therefore, this water purification system is not routinely monitored. The system is, however, maintained by the vendor per the established maintenance schedule.

In concert with vendor requirements, an upgrade to this third system is under consideration. The upgrade will likely include installation of a carbon filter, followed by a particulate filter, before the resin tanks. This upgrade will prolong the service life of the resin tanks. With this configuration, ASTM Type II water will be able to be produced. Daily (each business day) monitoring of this system will likely be implemented once these system improvements are made. Staff notification and training will occur accordingly.

5.4 Conductivity probe, dedicated to resistivity meter verification.

NOTE: This dedicated probe must **never** be used for any other purpose than monitoring purification system water quality. Use of this probe for any other purpose, my ruin the probe's viability for the monitoring application.

6. REAGENTS

Not Applicable

7. PROCEDURE

7.1 DEFINITIONS

7.1.1 **DI water** is defined as municipal tap water that has been treated by passing it through a particulate filter, activated carbon unit, cation exchange resin, anion exchange resin, mixed bed resin, and a final "polishing" cartridge. This water contains no detectable heavy metals or inorganic compounds of interest, and is free of organic compounds of analytical interest above Paragon's routine analyte reporting limits (RLs). Additionally, a benchtop Millipore Synergy 185™ unit is available for laboratory use should further finishing be desired.

7.1.2 **ASTM D1193-91 Standard Specification for Reagent Water.** This specification covers requirements for water suitable for use in methods of chemical analysis and physical testing. Four grades are specified:

Property	Type I	Type II	Type III	Type IV
Conductivity (uS/cm at 25° C)	0.056	1.0	0.25	5.0, max
Resistivity (megohm-cm at 25° C)	18.0	1.0	4.0	0.2, min
pH at 25° C	NA	NA	NA	5.0 to 8.0
Total Organic Carbon (µg/L)	50	50	200	no limit
Sodium (µg/L)	1	5	10	50, max
Chlorides (µg/L)	1	5	10	50, max
Total silica (µg/L)	3	3	500	no limit

Type I water is typically used for analytical procedures. Type II water is routinely used to wash and rinse glassware.

7.2 MONITORING THE STABLE CHEMISTRY AND MILLIPORE SYSTEMS

7.2.1 These systems are monitored each business day. Designated laboratory staff record the resistivity readings shown in the display window of the system's meter in the DI water quality logbook (Form 712).

7.2.2 The acceptance criterion for both systems is resistivity ≥18 Meg ohm-cm (18 M Ω-cm).

7.2.3 Note that for the Millipore system, it may take a few minutes for the meter reading to stabilize if the unit has not been used for several hours.

7.2.4 If the resistivity meter of the primary purification system displays a value lower than the acceptance criterion, the laboratory staff should first attempt to flush the system to rid it of materials leached from the

piping. This can be done by opening a DI faucet in the laboratory for approximately 30 seconds. This will cause any accumulated residue to be flushed out of the system, and allow freshly purified water to come in contact with the resistivity probe. If this flushing procedure is effective in raising the resistivity of the system to required levels, no further action is necessary, except to record that day's reading in the water quality monitoring logbook.

7.2.5 In the event that the DI system cannot meet acceptance requirements, the laboratory staff must follow the procedures specified in Section 7.6.

7.2.6 Conductivity is inverse to resistivity. A monthly conductivity check is performed at a delivery tap of each DI system. A dedicated conductivity probe with a meter is used to take a reading at this tap under flow conditions. This reading must be $\leq$0.06 µmho (i.e., reciprocal to ≥18 M Ω-cm), for ASTM Type I specifications. This monthly check is conducted to ensure that the probe from which daily readings are taken is accurate. Documentation that this check was performed is recorded in the system's water quality monitoring logbook.

7.3 MONITORING THE RADIOCHEMISTRY WATER SYSTEM

7.3.1 The DI water purification system is monitored daily by designated staff who record the operational light's status and resistivity reading shown on the display window of the meter, in the DI water quality logbook (Form 712).

7.3.2 The acceptance criterion for this system is resistivity ≥1.0 Mega ohm-cm (1.0 M Ω-cm). Typically, this system produces a resistivity reading of about 17.5 M Ω-cm. If the reading falls below 5 M Ω-cm, notify Lance Steere so that the vendor can be contacted for maintenance to be performed before a system failure occurs.

7.3.3 The monitoring light on the outflow of the first four purification tanks is examined daily to ensure that it is on, thus ensuring that these initial purification tanks are performing properly. If this light is not on, this is an indication that the purification capacity of these tanks has been exhausted, and that they need to be replaced. Replacement is done to prevent rapid saturation of the "finishing" tanks that perform the final purification of the water. **It is not necessary to shut off the DI system if the monitoring light is not on.** However, a visit from the service vendor for this system should be scheduled as soon as possible (coordinate through Lance Steere).

7.3.4 In the event that the DI system cannot meet acceptance requirements,

the laboratory staff must follow the procedures specified in Section 7.6.

7.3.5 A monthly conductivity check is conducted at the outflow of the system under flow conditions. The acceptance criteria for this system check is that the inverse of the conductivity reading must agree to within ±0.01 µmho of the current resistivity value recorded in the daily log. For example, given a typical log reading of 17.5 M Ω-cm (i.e., 0.057µmho), the conductivity should read between 0.04–0.07µmho. **Note that per ASTM conductivity requirements, the conductivity reading for this system must always be <1.00 µmho.**

7.4 MONITORING THE GLASSWARE WATER SYSTEM

Because water from this system is only used for rinsing glassware, and not used to prepare reagents or standards for use in the laboratory, this organic water purification system is not routinely monitored. This system is serviced once or twice a year by the vendor, at Paragon's request. See also Section 5 of this SOP regarding potential upgrades under consideration for this system.

7.5 All water purification systems, except for the Millipore system which is maintained by Paragon staff, are maintained, under contract, currently by United States Filter Corporation. A vendor service representatives performs any required maintenance, repairs, or replacements to the systems. Documentation (service records) are managed by Lance Steere.

7.6 CORRECTIVE MEASURES

7.6.1 Immediately upon discovering that the water purification system cannot meet the acceptance criterion, the person discovering this situation must notify their Department Manager, Lance Steere, and the QA Manager, so that appropriate corrective actions can be effected.

7.6.2 If the situation cannot be corrected immediately, the purification system must be turned off to prevent it from delivering inadequately purified water to the laboratory areas. All systems discussed in this SOP have inlet water valves that prevent the inflow of municipal tap water into the purification tanks. These valves should be turned off. For the radiochemistry system, the delivery pump at the foot of the holding tank should also be turned off.

A tag must be placed over the closed valve (or pump switch) that indicates that the unit should remain off until maintenance is performed (refer to SOP 317).

7.6.3 All laboratory groups that use the affected purification system should be immediately notified of the failure, and be cautioned against using

the system for any purpose. Taps should be tagged out (SOP 317) until successful system repairs have been achieved.

7.6.4 The vendor point-of-contact (Lance Steere) will contact the service agency so that maintenance and repair can be performed.

7.6.5 The service agency will be responsible for correcting the problem, and ensuring that the systems are properly flushed after their activities are completed. Only the vendor point-of-contact (Lance Steere) can inform the laboratory staff that the purification system is fully operational, and that laboratory staff can remove the tag-out placards and resume use of the delivered reagent water.

7.6.6 Department Managers must determine the impact of the situation on the laboratory's analyses, and take action to minimize the detrimental effects the situation may have on data that has been generated. As necessary, these Managers will implement temporary procedures that will alleviate any adverse effects.

8. QUALITY CONTROL

Quality control measures are addressed with PROCEDURES above.

9. DEVIATIONS FROM METHOD

Not Applicable.

10. SAFETY, HAZARDS AND WASTE DISPOSAL

Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents), or within a laboratory area.

re-released w/o revision 3/12/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes procedures for the operation and monitoring of laboratory ovens within specified limits. Procedures to follow in the event of oven malfunction, or other impairment such as catastrophic loss of power, and requirements for placing new or repaired ovens in service are also provided.

2. SUMMARY

Paragon uses laboratory ovens for a variety of applications -- in the course of sample preparation (e.g., ashing), analytical testing (e.g., TDS, percent moisture determinations) or to dry or condition glassware or reagents. Proper use and operation of each laboratory oven is the responsibility of the laboratory Department utilizing that oven. The Quality Assurance (QA) Department assists with facilitating repair when needed, record keeping, and in establishing and overseeing the temperature acceptance limits assigned to each oven.

Oven thermometers are managed by the QA Department. With the exception of the muffle furnaces, each oven is assigned a liquid-in-glass or digital thermometer (verified annually against a NIST-traceable master; SOP 923). Unless otherwise excepted, oven temperatures are read each business day from the dedicated thermometer and the temperature is recorded in a laboratory logbook (Form 312).

3. RESPONSIBILITIES

3.1 Each laboratory is responsible for maintaining operation of the ovens located in that laboratory area within acceptable limits. The Department Manager shall designate and train staff to read and record the oven temperatures each business day (unless oven is otherwise excepted). The Department Manager or designee is also responsible for coordinating oven repair or replacement as needed with the QA Department, and for reviewing temperature record logbooks per SOP 303.

3.2 It is the responsibility of the staff assigned to perform these duties to complete these tasks as described in this SOP, including all documentation required for review.

Laboratory staff are also responsible for ensuring that the thermometer(s) are functioning properly and that the correct thermometer is indicated in the laboratory logbook. Laboratory staff shall make minor adjustments to oven settings as needed (must be recorded in logbook) and are responsible for reporting malfunctions of thermometers or ovens to the Department Supervisor and the Quality Assurance Department.

3.3 The QA Department is responsible for managing thermometers, providing temperature record logbooks, and, in conjunction with Department Managers, assigning oven temperature acceptance limits (contingent upon oven's application). Oven repair or replacement is coordinated between the Department and QA Managers. The QA Department is also responsible for maintaining records of all laboratory oven identifications, the identities of the dedicated thermometer assigned to each oven, and oven repair records.

3.4 It is the responsibility of all personnel who are involved with this process to note any anomalies or out-of-control events. Corrective action must be taken and documented for any discrepancies noted.

4. PROCEDURES

4.1 Ovens and thermometers are uniquely identified (managed by the QA Department). Each business day and near to the beginning of the workshift, temperature readings are obtained from dedicated thermometers that have been verified in-house annually against a certified Master.

Exceptions: Wet Chemistry Department OV#12 is only used intermittently; muffle furnaces are used only intermittently and are not monitored with laboratory thermometers.

The oven thermometers are immersed in containers filled with sand or vermiculite to prevent fluctuations due to drafts when the oven's door is opened. The readings are recorded in laboratory logbooks (Form 312).

4.2 The QA Department issues dedicated logbooks that indicate the oven's acceptance limits. The acceptable temperature range varies with the oven's use (e.g., analytical testing, drying glassware, etc.). The established limits are set to address the requirements of analytical methods, where applicable.

As needed, laboratory staff shall perform minor temperature setting adjustments and shall document these adjustments in the oven's temperature record logbook.

4.3 The Department Supervisor and QA Department must be notified immediately if a significant excursion occurs, so that appropriate corrective actions may be taken. An excursion is deemed significant if the current temperature reading is significantly outside the unit's acceptable range, or if two or more sequential readings exceed the acceptance limits. **An oven cannot be used for analytical testing if it cannot maintain its temperature within specified limits.**

4.4 If an oven is taken out of service, it must be properly tagged-out (SOP 317). All corrective actions taken must be documented or referenced in the oven's temperature record logbook. Where the oven is used for analytical testing, potential impact to client data must be assessed. Repair or replacement of the oven will be coordinated between the Department and QA Managers. Additionally, refer to the Paragon Emergency & Contingency Plan (ECP) for further information regarding actions to be taken in cases of extended power outages or other catastrophic failures.

4.5 Before a new or repaired oven can be placed into service, evidence that the oven can maintain a stable and appropriate temperature must be documented. This is accomplished by recording acceptable oven temperatures for several readings over a span of time before the oven is used (allow the thermometer to come to a stable temperature before beginning the readings). Be aware that the oven may require additional temperature setting adjustment after samples or glassware have been loaded.

5. SAFETY, HAZARDS AND WASTE DISPOSAL

5.1 SAFETY AND HAZARDS

5.1.1 Use tongs, asbestos gloves, or other barrier when removing items from ovens.

5.1.2 Safety glasses, a lab coat, and gloves must be worn at all times when working in the laboratory.

5.1.3 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

5.2 WASTE DISPOSAL

Place damaged or broken **spirit-filled** thermometers in containers that can be sealed to safely contain the pieces and contents. Give container to Waste Disposal personnel for proper discard. **NOTE:** Broken **mercury-filled** thermometers can *only* be handled for cleanup and disposal by the laboratory Health & Safety Manager. *Under no circumstances are other laboratory personnel to handle or dispose of these mercury-containing materials.*

re-released w/o revision 3/12/09 DAS

1.0 SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the practices performed by laboratory personnel to verify the calibration of mechanical pipettes and pipettors. This SOP does not apply to volumetric glassware (i.e., transfer) pipettes.

2.0 SUMMARY

Mechanical pipettes (i.e., Eppendorf, Oxford, etc.) are hand-held devices that assist in drawing up and delivering specific volumes of liquid (µL to several mL amounts) in a manner that can be repeated rapidly and with accuracy. Mechanical pipettes may be fixed volume or adjustable, with tips (i.e., dispensing ends) integral to the device or disposable. Pipettors are devices with delivery spouts and a 'feeding tube' that resides in the liquid, that are used to dispense larger amounts of liquid (e.g., reagents) repeatedly and rapidly, when fitted onto a container of liquid, and set to deliver a specified volume. Mechanical pipettes are typically used to measure critical volumes of sample or reagent (e.g., used to prepare standards, perform laboratory quality control sample spikes, etc.) and, therefore, must be uniquely identified (for traceability purposes) and verified before each use (of a particular volume setting), whereas the accuracy requirements for pipettor dispensers (e.g., solvent delivery in the Organics Extractions Lab, preservative addition when preparing bottle kits, etc.) are typically not critical, these devices need not be uniquely identified, and may be checked periodically (monthly).

Mechanical pipette verification is performed gravimetrically, by weighing a dispensed aliquot of deionized water and evaluating the resultant mass against specified tolerance limits. Pipettor dispensers are verified volumetrically, by dispensing a volume of liquid into a graduated cylinder and comparing the amount delivered to the nominal volume setting of the pipettor. Only devices that perform within limits can be used in the laboratory. Those devices that do not meet criteria must be segregated and clearly marked 'DO NOT USE' (refer also to SOP 317) until they can be repaired and verified successfully. Verification checks are recorded in laboratory logbooks (Form 311).

Each laboratory area is responsible for maintaining its own pipettes and pipettors.

3.0 RESPONSIBILITIES

3.1 Each chemist shall perform the tasks described herein, strictly as prescribed by this SOP. Each chemist must notify their Supervisor of malfunctioning devices promptly.

3.2 Department Managers are responsible for ensuring that staff are properly trained regarding concepts and procedures addressed by this SOP. The Department Managers must determine the type of pipette or pipettor suitable for each task, and assure that only the correct type of device is used for each application.

Department Managers are responsible for overseeing the maintenance of all pipettes and pipettors, for ordering new/replacement devices that are suitable to their Department's applications, and for ensuring that each mechanical pipette is uniquely identified.

3.3 The Quality Assurance Department is responsible for providing oversight of adherence to pipette/pipettor policies, and for providing logbooks as needed.

4.0 INTERFERENCES

4.1 The analytical balance must be level and stable for proper operation.

4.2 Drafts can cause the balance to drift, yielding unstable readouts. Draft shields either integral to or external to the balance, must be used where needed.

4.3 The balance pan and chamber (where applicable), must be clean or error may result. Use a Kimwipe™ or brush to clean the pan as needed.

5.0 MATERIALS AND APPARATUS

5.1 pipettes and pipettors, disposable tips, as applicable

5.2 analytical balance, 0.0001g resolution

5.3 graduated cylinder of appropriate volume

6.0 REAGENTS

Deionized (DI) water, obtainable from the laboratory's deionized water system.

7.0 PROCEDURE

7.1 The tolerance guide for pipette verification is given on page 2 of Form 311 (attached). A tolerance of ±1.0% has been established for all mechanical pipettes.

7.2 Mechanical pipettes must be verified before each use of a specified volume setting, pipettor dispensers should be verified periodically (monthly).

7.3 To verify **mechanical pipettes**:

7.3.1 Make sure the analytical balance is turned on, and that the balance's calibration has been verified per SOP 305. Tare out a container of suitable size to receive the volume to be dispensed by the pipette.

7.3.2 Perform any needed maintenance on the pipette, attach a suitable tip (if applicable), and adjust the setting (if applicable).

7.3.3 Draw up and dispense the volume measured by the pipette into the container tared on the analytical balance.

NOTE: Pipettes set to deliver <2uL may require multiple aliquots to be dispensed so that a sizeable enough mass can be successfully weighed by the analytical balance.

7.3.4 Compare the mass delivered to the tolerance guide. If acceptable, record the results in the logbook (Form 311). If not acceptable, repeat maintenance and test again. If still not acceptable, segregate the device, clearly marking it 'DO NOT USE', and inform your Supervisor.

7.4 To verify **pipettors**:

7.4.1 Obtain a graduated cylinder of suitable size.

7.4.2 Perform any needed maintenance on the pipettor, set adjustment to deliver the desired volume.

7.4.3 Draw up and dispense one volume into the graduated cylinder, read the volume delivered. If the result is acceptable, record the results in the logbook (Form 311). If not acceptable, repeat maintenance, readjust setting, and test again. If still not acceptable, clearly mark the device 'DO NOT USE', and inform your Supervisor.

7.5 New pipettes must have an ID number marked before being placed into service.

8.0 QUALITY CONTROL

Quality control measures are addressed with PROCEDURES above.

9.0 DEVIATIONS FROM METHOD

Not Applicable.

10.0 SAFETY, HAZARDS AND WASTE DISPOSAL

Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents), or within a laboratory area.

11.0 REFERENCES

HISTORY: Rev0, PCN #206, 1/12/94; Rev1, PCN #386, 2/20/95; Rev2, PCN #527, 9/6/95; Rev3, 11/4/99; Rev4, 4/17/02; Rev5, 10/3/03; Rev6, 7/20/05; Rev7, 7/24/06 and 2/27/07. re-released w/o revision 3/12/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes procedures for the operation and monitoring of laboratory cooling units (i.e., refrigerators and freezers) within specified limits. Procedures to follow in the event of unit malfunctions, or other impairment such as catastrophic loss of power, and requirements for placing new or repaired cooling units into service are also provided.

2. SUMMARY

Paragon uses refrigerators and freezers to store samples, extracts and standards (segregated in dedicated units) per analytical method requirements. The proper operation of each cooling unit is to be verified each day the unit is in use. Temperature is monitored using dedicated electronic min/max thermometers that are verified in-house annually (SOP 923). These thermometers provide for continuous cooling unit monitoring (7 days/week, 24 hrs/daily). The observed temperatures are recorded in laboratory logbooks (Form 347). The min/max memory of the thermometers is reset each time a reading is taken.

Laboratory refrigerated storage areas are maintained at just above freezing to 6°C (centered at 4±2°C). Laboratory freezer units are maintained at 0°C and lower (centered at -15±5°C). These limits address the sample and standard storage requirements specified in analytical methods. However, certain sample or container types may require different storage temperature ranges to be assigned to specifically designated cooling units.

3. RESPONSIBILITIES

3.1 Each laboratory is responsible for maintaining operation of the cooling units located in that laboratory area within acceptable limits. The Department Manager is responsible for designating and training personnel to monitor the operation and

record the temperatures of all cooling units in that particular laboratory area. The Department Manager or designee is also responsible for coordinating repair or replacement as needed with the QA Department, and for reviewing temperature record logbooks per SOP 303.

3.2 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review. Any anomalies or out-of-control events must be noted and corrective action taken and documented.

Laboratory staff are also responsible for ensuring that the thermometer(s) are functioning properly (as needed, replacement batteries can be obtained from the QA Department) and that the correct thermometer is indicated in the laboratory logbook. Laboratory staff shall make minor adjustments to unit settings as needed (must be recorded in logbook) and are responsible for reporting malfunctions of thermometers or units to the Department and Quality Assurance Managers.

3.3 The QA Department is responsible for managing thermometers, providing temperature record logbooks, and, in conjunction with Department Managers, assigning cooling unit temperature acceptance limits (contingent upon units's application and other client criteria, as applicable). Unit repair or replacement is coordinated between the Department and QA Managers. The QA Department is also responsible for maintaining records of all laboratory cooling unit identifications, the identities of the dedicated thermometer assigned to each unit, and repair records.

4. PROCEDURE

4.1 Cooling units and thermometers are uniquely identified (managed by the QA Department). Each business day and near to the beginning of the workshift, temperature readings are obtained from electronic thermometers that have been verified in-house annually against a certified Master. The electronic thermometer probes are immersed in containers of liquid to prevent fluctuations due to drafts when the unit's door is opened. The current, minimum and maximum readings are recorded in laboratory logbooks (Form 347). The min/max memory of the electronic thermometers are reset each time a temperature reading is taken.

4.2 The QA Department issues dedicated logbooks that indicate the unit's acceptance limits (typically just above freezing to 6°C -- centered at 4±2°C for refrigerators; and 0°C and lower -- centered at -15±5°C for freezers). The established limits are set to address the requirements of analytical methods, where applicable, and other client quality assurance guidance documents.

4.3 As needed, laboratory staff shall apply minor temperature setting adjustments to the cooling units and shall document these adjustments in the cooling unit's

temperature record logbook. As needed, laboratory staff shall replace the batteries of the electronic thermometer. Electronic thermometers that are rendered unusable are to be immediately removed from service. Notify the QA Department so that the unusable thermometer can be disposed and a suitable replacement thermometer provided.

4.4 The Department and QA Managers must be notified immediately if a significant excursion occurs so that appropriate corrective actions may be taken. An excursion is deemed significant if the current temperature reading is significantly outside the unit's acceptable range, or if two or more sequential readings exceed the acceptance limits. Appropriate corrective actions may include NCR initiation (SOP 928) and/or temporary transfer of the cooling unit's contents to another suitable location. Where applicable, potential impact to client data must be assessed.

4.5 If a cooling unit is taken out of service, it must be properly tagged-out (SOP 317). All corrective actions taken must be documented or referenced in the unit's temperature record logbook. Repair or replacement of the unit will be coordinated between the QA Department and the laboratory staff. Additionally, refer to the Paragon Emergency & Contingency Plan (ECP) for further information regarding actions to be taken in cases of extended power outages or other catastrophic failure.

4.6 Before a new or repaired cooling unit can be placed into service, evidence that the unit can maintain a stable and appropriate temperature must be documented. This is accomplished by recording acceptable temperatures for several readings over a span of time before the unit is placed into service (be sure to allow the thermometer's probe to come to a stable temperature before beginning the readings). Be aware that the unit may require additional temperature setting adjustment after samples, extracts or standards have been added.

5. SAFETY, HAZARDS AND WASTE DISPOSAL

5.1 SAFETY AND HAZARDS

5.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

5.1.2 Safety glasses, a lab coat, and gloves must be worn at all times when working in the laboratory

5.2 WASTE DISPOSAL

5.2.1 Unusable electronic thermometers may be disposed in the sanitary trash.

5.2.2 Inoperable cooling units must be disposed in accordance with local and

other regulatory requirements.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 329 REVISION 6

TITLE: **METHOD DEMONSTRATION PROCEDURES: INSTRUMENT DETECTION LIMIT (IDL) AND METHOD DETECTION LIMIT (MDL) STUDIES; DEMONSTRATION OF CAPABILITY (DOC)**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/31/07

QUALITY ASSURANCE MANAGER _____ DATE 8/31/07

LABORATORY MANAGER _____ DATE 8/31/07

HISTORY: NEW, PCN #520, 8/10/95; Rev1, 7/15/99; Rev2, 11/12/99; Rev3, 8/25/02; Rev4, 4/3/04; Rev5, 9/11/06; Rev6, 8/28/07.

1. SCOPE, APPLICATION AND SUMMARY

This standard operating procedure (SOP) specifies the requirements for performance and documentation of IDL and MDL studies, and demonstrations of capability (both method and analyst).

IDLs and MDLs are stable chemistry concepts. IDLs pertain to metals analysis methods, and establish instrument performance capabilities. MDLs apply to both inorganic and organic procedures (see 5.2.1 for exceptions), and establish the capabilities of the method (i.e., preparatory and analysis techniques).

Note that the sample-specific radiochemistry concept of minimum detectable concentration (MDC) is not addressed by this SOP (refer to SOP 708).

Also not addressed by this SOP are analyte Reporting Limits (RLs), which are values equal to or above the MDL, that the laboratory establishes for each analyte of a stable chemistry method, that *represent the lowest concentration of an analyte that can reliably (i.e., within specified limits of precision and accuracy) be achieved and reported, under routine operating conditions*. (RLs are also corrected for sample aliquot size, and moisture content, as applicable).

Refer to LQAP Chapter 14-Glossary, for definitions of terms used in this SOP. Refer to 40 CFR 136 Appendix B, for further information on conducting MDL studies.

2. RESPONSIBILITIES

2.1 Each Department Manager is responsible for ensuring that all studies and demonstrations are conducted and documented as needed. The Department Manager shall ensure that all staff are properly trained regarding concepts and procedures addressed by this SOP. All work performed under this SOP must be reviewed by the Department Manager, or his or her qualified designee. The

Department Manager is responsible for submitting all documentation to designated parties for management and retention.

2.2 Where creation of a workorder is necessary to accomplish the work (i.e., MDL studies, DOCs) and to report through LIMS, the workorder shall be created by Data Reporting Group staff, the Department Manager, or other designated individual.

2.3 Data Reporting Group staff are responsible for managing the IDL and MDL data in LIMS.

2.4 The Quality Assurance Manager (QAM) is responsible for retaining and managing DOC (and other training records) as described in the LQAP. The QAM shall provide oversight of the effectiveness and conformance to IDL, MDL and DOC processes.

2.5 Laboratory staff are responsible for performing the tasks described in this SOP as prescribed, and for completing all documentation required for review.

3. INTERFERENCES

Varies with type of analyses performed. Refer to applicable preparation and determinative SOPs.

4. APPARATUS, MATERIALS, REAGENTS

Varies with type of analyses performed. Refer to applicable preparation and determinative SOPs.

5. PROCEDURE

5.1 IDL STUDIES

5.1.1 IDL studies are to be performed for each analyte per instrument.

5.1.2 IDL studies must be completed quarterly as defined by the method, including whenever there is a significant change in instrument components or reagents.

5.1.3 The manner in which IDL studies are to be performed is described in US EPA CLP SOW ILMO4.0 (see References section of this SOP).

5.1.4 IDL studies must include the following information:

- Analyst who performed IDL study
- Instrument identifier
- Spike Level
- Measured concentration of seven replicates
- Standard Deviation
- Mean

- Determined IDL
- Concentration Units
- Date(s) the study was analyzed
- Analysis Method Number
- Raw data
- Supervisor or senior analyst review signature

5.1.5 Per CLP requirements, all IDLs must meet the Contract Required Detection Limit (CRDL), as specified in the US EPA CLP SOW (ILMO4.0).

Generally, the analyte IDL must be < the analyte MDL.

Other client-specified guidance may apply. Refer to applicable LIMS program specification.

5.2 MDL STUDIES

5.2.1 MDL studies are to be performed for each analyte per matrix, per preparatory and determinative method combination, and instrument (analytical column).

An MDL study must be performed for each PCB analyzed (i.e., Aroclors 1016, 1221, 1232, 1242, 1248, 1254, 1260).

MDL studies are <u>not</u> performed for any parameter for which spiking solutions are not available or relevant (e.g., pH, ignitability).

5.2.2 MDL studies must be completed annually, or as otherwise defined by the method (i.e., ion chromatography and flow injection analyzer methods stipulate every six months). An MDL study must also be performed as a component of method validation, or whenever the basic chemistry of a procedure changes.

5.2.3 MDL studies shall be performed according to 40 CFR Part 136 Appendix B.

In summary, a minimum of seven, but typically eight, replicates are spiked with the same concentration of the analytes of interest, such that the spike concentration is between 1 and 10 times the calculated MDL. These replicates are processed using the same procedures used for field samples. The MDL is defined to be equal to the standard deviation (σ) of the values times the appropriate student t value (t, 99% confidence interval).

5.2.4 An MDL check sample shall be run with each MDL study (immediately following). The concentration of this check sample is

about half the concentration spiked for the MDL study, and approximately twice the calculated MDL. Performance criteria is that the MDL check is acceptable if it yields a confident positive detection (i.e., all analytes in the check sample can be identified by method-specified criteria).

If MDL check sample results do not support the determined MDL, appropriate corrective actions must be taken (e.g., repeat MDL check sample analysis, repeat MDL study, raise MDL).

5.2.5 All MDL studies must include the following information:

- Analyst(s) who performed extraction and analysis
- Instrument and column identifier
- Spike Level
- Recovery of replicates
- Standard Deviation
- Mean
- Student t factor (99% confidence interval)
- Calculated MDL value
- Reporting limit currently in use, (typically lowest)
- Units
- Dates(s) of analysis
- Date(s) of digestion or extraction (if applicable)
- Raw Data (including copy of digestion or extraction log)
- Method Number (for digestion, extraction, and analysis)
- MDL check standard verification (~2-5x calculated MDL value)
- Reviewer's signature and date

5.2.6 All MDL studies must be submitted to the Data Reporting Group for LIMS processing. After the data are incorporated into the LIMS MDL application and the application is run, summary reports are provided to the Department Manager for review.

5.2.7 The Department Manager shall review the study information:

- compare spike value to calculated MDL
- if calculated MDL is > spike concentration, repeat study at a higher spike concentration.
- If spike concentration is > 10x times calculated MDL, repeat study at a lower spike concentration

After review and sign-off, the Department Manager forwards the MDL information to the QA Department for review and approval.

5.2.8 Paragon's MDL application allows for the Dixon Outlier test to be applied. If any datapoints are excluded as outliers, all datapoints for that analytical run must be excluded (specific analytes within an analytical run cannot be selected for exclusion ***except*** in the case where one or two datapoints represent a separate injection that was made).

5.2.9 The MDL should be 2 to10 times lower than the RL. In the case of methods that include many target compounds (e.g., SW8260 and SW8270), Paragon will accept sporadic marginal failures for this relationship.

It should be noted that MDL studies are performed on interference-free matrix. Hence, the calculated MDL may not be achievable in environmental matrices, and adjustment of the MDL (and/or RL), based on practical performance experience, may be required. Additionally, client-specified criteria may apply (consult applicable LIMS program specifications). The QAM in conjunction with the Department Manager, will establish MDL and RL values based on these considerations.

5.2.10 Once the MDL study receives final approval from the QAM, the information is submitted to the Data Reporting Group for scanning and retention.

5.3 DEMONSTRATIONS OF CAPABILITY

5.3.1 Method DOCs are to be performed for each analyte per matrix, per preparatory and determinative method combination, and instrument (analytical column). Method DOCs must be performed each time a method is modified. Unless otherwise defined by the method, the successful analysis of a PT sample can serve as a method DOC.

5.3.2 Chemist DOCs are to be performed for each analyte per matrix and preparatory and determinative method combination. A chemist must demonstrate a successful initial demonstration of capability (IDOC) ***before*** that chemist is permitted to prepare or analyze client samples.

The IDOC is generally accomplished by the chemist preparing and/or analyzing four replicates of laboratory media (i.e., DI water or Ottawa sand), spiked with the same concentrations of analytes of interest. An average and standard deviation is calculated for the results for each analyte. If the results meet established control criteria, then the DOC is accepted, and the chemist is permitted to process client samples.

Each chemist must also perform a successful continuing DOC (CDOC) annually. This requirement can be fulfilled by compiling results from

four acceptable LCS analyses, or by the successful participation in IDL, MDL or PT studies.

DOC summary and raw data are submitted to the QA Department for review/approval, and retention as a training record.

5.3.3 All DOC studies must include the following information:

- Analyst who performed the DOC
- Instrument identifier
- Spike level
- Concentration of four replicates (as applicable)
- Acceptable recovery (per established acceptance criteria)
- Average and standard deviation of recoveries
- Units
- Date(s) of analysis
- Date(s) of extraction (if applicable)
- Extraction Technician's Name (as applicable)
- Analysis and Extraction Method Number

6. QUALITY CONTROL

See 40 CFR 136 Appendix B for further details pertaining to how MDL studies are conducted and evaluated. See also applicable determinative methods.

7. DEVIATIONS FROM METHOD

None.

8. SAFETY, HAZARDS AND WASTE DISPOSAL

Refer to applicable preparatory and determinative SOPs.

DOCUMENT REVISION HISTORY

9/11/06: Rearranged sequence and reformatted. Updated RESPONSIBILITIES. Introduced preparatory and determinative method combination concept. Included directives for outliers. Included statements regarding method DOCs, augmented discussions of IDOCs and CDOCs. Augmented QC limit discussion. Incorporated Data Reporting

Group involvement and imaging for record retention. Added MDL check sample analysis and performance criteria. Added DOCUMENT REVISION HISTORY.

8/28/07: Removed QC limit discussion (just doesn't belong here, addressed in LQAP); edited RESPONSIBILITIES accordingly. Moved some technical information from RESPONSIBILITIES to PROCEDURE. Added 'whenever there is a significant change in instrument components or reagents' to the requirements of when an IDL study needs to be performed (5.1.2). Expanded IDL criteria (5.1.5). Some general re-structuring/re-formatting. Refined role of Data Reporting Group (rather than IS Department) throughout. Augmented discussion of when an MDL study is to be performed (5.2.2). Expanded/revamped MDL check standard discussion (5.2.4). Added discussion re: adjustments to MDLs or RLs (5.2.9). Restructured DOC section.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps to be followed for cleaning glassware used in the various laboratory Departments. General measures used to identify levels of radioactivity for the segregation of glassware used by the Radiochemistry Department, are also outlined.

2. SUMMARY

Interferents/contaminants cause difficulty in the interpretation of analytical results. To prevent cross-contamination, suitable disposable glassware and plasticware is used for laboratory processes wherever technically practical and economically feasible. If glassware, particularly specialty glassware, must be reused, then stringent cleaning protocols are followed in order to minimize the potential for cross-contamination. Additionally, for radiochemical applications, glassware is segregated according to levels of radioactivity processed.

Particular care must be taken with glassware such as Soxhlet extractors, Kuderna-Danish evaporative concentrators, or any other glassware that comes in contact with an extract or digestate that will be evaporated to a smaller volume. The process of concentrating the extract or digestate may cause contaminants to be concentrated as well, thus potentially distorting analytical results.

Radiochemical glassware is dedicated to the analysis of either low-level, routine or elevated levels of radioactivity. Glassware is disposed of, or re-assigned for use with higher level radioactive samples, when necessary.

3. RESPONSIBILITIES

It is the responsibility of the technician to perform these procedures according to this

SOP. Consult your Supervisor should any questions or problems arise.

4. INTERFERENCES

4.1 Glassware used for the analysis of elevated levels of radioactivity is not to be re-used for routine level determinations. Such glassware is either to be disposed of, or permanently marked to allow immediate identification as high-level glassware.

4.2 Glassware labeled as "LL" is dedicated exclusively for use in the determination of ultra-low levels of radioactivity (i.e., levels of less than one-half routinely detectable levels), or for ambient or environmental level monitoring where the absence of analyte at routine levels is expected. This glassware may be re-assigned for routine or elevated levels as long as the "LL" label is permanently removed and the glassware is re-labeled for use at the appropriate level.

4.3 Only clean, rinsed glassware shall be hung on the pegboards. Inversion of clean glassware prevents re-contamination of glassware prior to use.

5. APPARATUS AND MATERIALS

5.1 Assorted brushes

5.2 Dishwasher

5.3 Drying Racks or fresh bench paper

5.4 Drying oven

5.5 Kiln

5.6 Aluminum foil, heavy-duty, clean

6. REAGENTS

Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

6.1 Tap water

6.2 Detergent: Alconox™ or Alcojet™ commercial detergent or equivalent; a suitable domestic (i.e., grocery store) detergent may also be used. Particularly for stable chemistry applications, use of phosphate-free detergents is desirable.

6.3 Deionized (DI) water, obtainable from the laboratory's deionized water system.

6.4 2N HCl / 2N HNO_3 Solution (used to rinse Metals Department glassware): Make by adding 3.3L concentrated HCl and 2.5L HNO_3 (***use Trace Metals grade HNO_3 only***) to 14L DI water. Store in a stoppered container. *Shelf Life = Until degradation is evident* TLV HCL = 5ppm; TLV HNO_3 = 2ppm (TWA); irritant, corrosive.

6.5 Aqua Regia (used in the Radiochemistry Department): Make fresh for each use. Only make as much as needed, or, preferably, mix directly in the vessel to be

cleaned or to be used for cleaning. **CAUTION: Never keep aqua regia in a tightly closed container.** Carefully mix 12N HCl and 16N HNO_3 in an approximate ratio of 3:1. *The mixture is highly reactive and will evolve gas,* ***mix and use in a fume hood****.* TLV HCL = 5ppm; TLV HNO_3 = 2ppm (TWA); irritant, corrosive.

6.6 RadiacWash™ or equivalent

6.7 **Solvents** (stable chemistry applications) - **Only pesticide residue grade or chromatography grade solvents shall be used**:

6.6.1 Acetone

6.6.2 Methylene Chloride

6.6.3 Methanol, purge & trap grade (volatiles) or pesticide residue grade (organic extractions)

6.6.4 Isopropanol, chromatography grade

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

Not applicable.

8. STABLE CHEMISTRY PROCEDURES

8.1 The following Sections detail procedures to be used in cleaning the types of glassware specified. In general, however, the basic stable chemistry (Organics and Inorganics Departments) cleaning steps include:

- Remove surface residue immediately after use.
- Soak in hot water to loosen and float most particulate material. Soap may be used to facilitate the removal of oily residues.
- Rinse with tap water to remove soap residue.
- Soak or rinse with acid (metals only).
- Thoroughly rinse with DI water.
- Rinse with alcohol, i.e., isopropanol or methanol, (organic analyses only), to flush any traces of organic materials and to remove the water. **This step is used only if the glassware will *not* be dried in a kiln.**

  NOTE: Although rinsing with alcohol is a means of removing trace levels of organic materials, SW-846 3rd Edition, Chapter, 4 Section 4.1.4 does allow the use of a high temperature bake-out (>300°C) as an alternative.

- Air dry or dry in an oven or kiln.

Even after glassware has been rigorously cleaned and stored, it is good laboratory practice to rinse the glassware with small aliquots of the extraction/digestion solvent that will be used in the analysis, just before the glassware is used.

8.2 VOLATILE ORGANICS ANALYSIS (VOAS) GLASSWARE

8.2.1 Rinse with tap water.

8.2.2 Scrub all surfaces with a brush in warm soapy water.

8.2.3 Rinse with hot tap water.

8.2.4 Place glassware in a drying oven (110-150 ºC), and dry overnight. Store glassware in drying oven until use.

8.2.5 SYRINGES: After use, flush by drawing and expelling several volumes of clean methanol.

8.3 SEMIVOLATILE ORGANICS (SVOCs) VOLUMETRIC GLASSWARE

NOTE: Never place volumetric glassware in the kiln!

8.3.1 Use solvent (medium polarity) to remove any external labels or writing on the outside of the glass.

8.3.2 Rinse glassware with tap water.

8.3.3 Scrub all glassware surfaces with a brush in warm soapy water.

8.3.4 Rinse with hot tap water.

8.3.5 Rinse 4 times with DI water.

8.3.6 Rinse with alcohol.

8.3.7 Wrap opening of glassware with clean aluminum foil.

8.3.8 Dry in 110-150 °C oven for 1/2 hour (minimum).

8.3.9 After cooling, store glassware promptly to avoid contamination.

8.4 SEMIVOLATILE ORGANICS NON-VOLUMETRIC GLASSWARE

8.4.1 Follow Steps 8.3.1.through 8.3.5 above.

Concentrating Tubes: **Never place more than one layer in the sink at one time.** Always use a brush when washing; check the brush to ensure that no metal is exposed that can scratch the glassware, thereby allowing sites where contamination can collect. Check the ends of the concentration tubes for residue.

8.4.2 DO NOT rinse glassware with solvent before placing in kiln.

8.4.3 Wrap glassware with clean aluminum foil:

- Rip squares of foil in advance.
- Cover all open ends of glassware.
- Cover all ground glassware joints (rough to the touch).
- Cover funnels, stirring rods, Snyder columns, GPC tubes, and thimbles completely.
- Glass Stoppers. wrap as many as possible (same size) in one piece of foil.
- Set Soxhlets aside. These are the first items to be placed in the kiln (upright).

8.4.4 Dry glassware in a kiln set at approximately 450 °C for a minimum of three hours.

8.4.5 After cooling, store glassware promptly to avoid contamination.

8.5 METALS GLASSWARE

8.5.1 Follow Steps 8.4.1.through 8.4.4 above.

8.5.2 Rinse glassware with 2N HCl / 2N HNO_3 acid solution, allowing the acid to drain into the sink. Alternatively, immerse and store glassware in a covered acid bath.

8.5.3 Rinse with DI water.

8.5.4 Invert glassware and air dry.

8.5.5 Return glassware to storage cabinet; glassware is ready to use.

8.6 WETCHEM GLASSWARE

8.6.1 Use a solvent to remove any external labels or writing on the outside of the glass.

NOTE: If oily residue is present inside the glassware, rinse with methylene chloride, then wipe with a KimWipe®; repeat until glassware is free from oily residue.

8.6.2 Rinse 4 times with DI water.

8.6.3 Invert glassware and air dry.

8.6.4 Return glassware to storage cabinet; glassware is ready to use.

9. RADIOCHEMISTRY PROCEDURES

9.1 SEGREGATION OF REUSABLE GLASSWARE

Reusable glassware is segregated according to working levels (broadly defined below). Method blank experience may be used to indicate the need for more or less restrictive levels than these listed here:

- ROUTINE GLASSWARE
  Glassware designated for routine use need not be specifically marked. Routine levels are defined as expected levels approximately one-half to five hundred times routinely detected levels for target analytes. This glassware is generally available for use in the laboratory and need not be physically segregated.

- ELEVATED ACTIVITY GLASSWARE
  Glassware designated for use with elevated samples is permanently marked "H". This glassware is physically segregated from other glassware for purposes of storage, processing and cleaning. Elevated levels are defined as expected levels greater than approximately five hundred times routinely detected levels for target analytes. Glassware used for elevated activities may be preferentially disposed of if levels exceed 10,000 times routinely analyzed levels.

- ULTRA-LOW LEVEL GLASSWARE
  Glassware designated for use with ultra-low level samples is marked "LL". This glassware is physically segregated from other glassware for purposes of storage, processing and cleaning. Ultra-low levels are defined as requested detectable and/or expected levels less than approximately one-half routine minimum detectable levels for target analytes, or samples for environmental, drinking water or ambient monitoring work where no or extremely low analyte or minimum detectable levels are expected. Glassware used for Ultra-low level activities may be re-designated for routine or elevated levels if potential for contamination at those levels is suspected.

9.2 RADIOCHEMISTRY CLEANING PROCEDURE FOR SMALL GLASSWARE

9.2.1 For very small glassware, see Step 9.2.4, otherwise, rinse the glassware with copious amounts of hot tap water at the sink. Transfer the dishes into the sinks, fill the sink with hot water. Add ~25mL of RadiacWash™ per manufacturer's instructions. Soak glassware for at least 2 hours.

9.2.2 Rinse the glassware with hot tap water.

9.2.3 Load the glassware into the dishwasher so that the items will not break during washing. Wash the glassware with detergent (6.2).

NOTE: To save energy, use the short cycle on the automatic dishwasher. Do not use the drying cycle, as glassware must be DI rinsed before drying.

9.2.4 **Acid washing** is done only when the prep. method to be used requires it; otherwise, skip to Step 9.2.5.

9.2.4.1 Place the very small glassware in a 4L glass beaker (or in a larger container that needs to be acid washed). In a fume hood, add aqua regia to produce significant fumes. Cover with a watch glass. Allow the very small glassware to sit for a minimum of 4 hours or preferably overnight.

9.2.4.2 In the fume hood, carefully decant the aqua regia into a waste beaker containing a small amount of water. Rinse the small glassware collectively with DI water, decant the rinse water into the waste beaker. Discard the waste beaker's contents down the laboratory drain (which discharges into Paragon's wastewater system), with large amounts of cold water.

9.2.5 Continue by rinsing each piece of cleaned glassware with liberal quantities of DI water at the sink.

9.2.6 Allow the glassware to dry on clean bench paper or on a clean drying rack.

9.3 RADIOCHEMISTRY DISHWASHING PREPARATION FOR LARGE GLASSWARE

9.3.1 Rinse the glassware with copious amount of hot water at the sink.

9.3.2 Fill glassware with hot water and ~5-10mL RadiacWash™. Soak for a minimum of 2 hours.

9.3.3 Rinse the glassware with hot tap water.

9.3.4 Load the glassware in the dishwasher so that the items will not break during washing. Wash with detergent (6.2).

NOTE: To save energy, use the short cycle on the automatic dishwasher. Do not use the drying cycle, as glassware must be DI rinsed before drying.

9.3.5 **Acid washing** is done only when the prep. method to be used requires it; otherwise, skip to Step 9.3.6. If acid washing cannot be done immediately, rinse the washed glassware with DI water and hang on the drying rack until acid washing can be done.

9.3.5.1 Place the glassware inside a fume hood. Add 10-30mL aqua

regia to each vessel. Cover and leave for 4 hours or preferably overnight so that the aqua regia fumes will clean the sides of the vessel.

9.3.5.2 In the fume hood, carefully decant the aqua regia into a waste beaker containing a small amount of water. Rinse the glassware with DI water and decant the rinse into the waste beaker.

9.3.5.3 Discard the waste beaker's contents down the laboratory drain (which discharges into Paragon's wastewater system), with large amounts of cold water.

9.3.6 Remove glassware from the hood and rinse with liberal quantities of DI water at the sink.

9.3.7 Allow the glassware to dry on clean bench paper or a clean drying rack.

10. QUALITY CONTROL

Not applicable

11. DEVIATIONS FROM METHOD

This method was developed in-house; there are no deviations from a promulgated method.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the appropriate MSDSs before using any reagents.

12.1.2 Gloves, safety glasses and lab coats must be worn when working with any chemicals (e.g., standards, solvents, reagents, or samples) or when handling materials potentially contaminated with chemicals.

12.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids).

12.1.4 All non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with: the compound name, NFPA Health, Flammability and Reactivity ratings, and date.

12.1.5 Use extreme care when working with aqua regia. Work only in a fume hood that has adequate ventilation and personnel safety features. Never inhale or allow skin or clothing to be exposed to aqua regia fumes.

12.1.6 Care should be taken when diluting acids. Always add acids to water, NOT water to acid.

12.1.7 Wearing Kevlar® gloves is recommended when handling glassware prone to breakage. This material minimizes the risks of lacerations in the event of glassware breakage.

12.1.8 Wearing insulated gloves is required when removing glassware from the kiln.

12.2 WASTE DISPOSAL

12.2.1 Wastes that are "corrosive only" (i.e., have no hazardous components or characteristics other than corrosivity), such as hydrochloric and nitric acid waste, are disposed of by discharging into the Paragon wastewater treatment facility.

12.2.2 All empty solvent bottles are to be disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

2/27/07: (SOP 334) Tie-in with SOP 720 Radiochemistry glassware cleaning, added to SCOPE AND APPLICATION. Under PROCEDURES (5.6), WetChem glassware is not acid-rinsed; corrected in text and in Operator's Aide. Excerpted Operator's Aide Section created, postings replaced. Added DOCUMENT REVISION HISTORY Section.

3/4/08: Combined current iterations of SOP 334r6 and 720r6. Revamped acid washing for Radiochemistry sections.

GLASSWARE CLEANING – STABLE CHEMISTRY

Basic cleaning steps:
(Surface residue should be removed immediately after use)

- Use solvent to remove labels and markings
- Rinse with tap water
- Soak in hot water
- Use soap to remove oily residues (scrub only glassware that is not excepted)
- Rinse thoroughly with tap water
- Soak or rinse with acid (metals glassware only)
- Thoroughly rinse with DI water
- Rinse with alcohol, isopropanol or methanol, (only non-kilned organics glassware)
- Dry by appropriate means (air, oven, kiln -- note restrictions)

VOAs glassware:

Perform first five steps above, use a hot tap water rinse. Oven-dry.

SVOCs glassware (volumetric, **un-kilned**):

Perform first five steps above, use a hot tap water rinse.
Rinse 4 times with DI water, then alcohol.
Wrap opening of glassware with clean aluminum foil, oven-dry.

SVOCs glassware (**kilned**):

Observe special handling for concentrating tubes.
Perform first five steps above, use a hot tap water rinse.
Rinse 4 times with DI water
Wrap appropriately with aluminum foil, kiln.

Metals glassware:

Perform first five steps above, use a hot tap water rinse.
Rinse or bathe using 2N HCl / 2N HNO_3 acid solution.
Rinse thoroughly with DI water.
Invert glassware and air-dry.

WetChem glassware:

Use solvent to remove labels and markings.
(methylene chloride may be used to remove oily residues)
Rinse 4 times with DI water.
Invert glassware and air-dry.

GLASSWARE CLEANING – RADIOCHEMISTRY

Keep glassware segregated! Dispose of or re-label for use as necessary.

Follow acid washing procedure for small glassware.

Basic cleaning steps:

- Use solvent to remove labels and markings
- Rinse with hot tap water
- Soak in hot tap water, to which RadiacWash^{TM} is added
- Rinse with hot tap water
- Wash in dishwasher (short cycle, do not use drying cycle)
- Rinse thoroughly with tap water
- Acid wash as necessary
- Thoroughly rinse with DI water
- Air dry

Must Discard 30 Days from _____ (date printed)

Amended 12/30/07 - Section 5.2 'Allow sample to warm to room temperature before subsampling.' removed. DAS

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 336 REVISION 0

TITLE: **REPRESENTATIVE LABORATORY SUBSAMPLING**

FORMS: **302, 631** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 12-28-07

QUALITY ASSURANCE MANAGER _____ DATE 12/28/07

LABORATORY MANAGER _____ DATE 12-28-07

HISTORY: **Formerly SOP 721:** Rev1, 4/26/93; Rev2, PCN #35, 11/17/93; Rev3, PCN #80, 1/12/94; Rev4, PCN #276, 9/29/94; Rev5, PCN #471, 5/3/95; Rev6, 10/7/99; Rev7, 11/1/00; Rev8, 6/15/01; Rev9, 8/20/01; Rev10, 3/19/03; Rev11, 4/22/04; Rev12, 11/29/04; Rev13, 9/8/06; Rev14, 8/24/07. **As SOP 336**: Rev0, 12/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the physical procedures used to prepare environmental samples prior to chemical preparation and analysis. These physical preparations are crucial to ensuring that subsamples (aliquots), and their subsequent test results, are representative of the client sample as a whole.

2. SUMMARY

Subsamples must be representative to avoid bias in the analytical result. Incorrect analytical results could lead to making wrong environmental decisions that could impact environmental preservation or human health. Correct subsampling allows for the results to be duplicated (i.e., minimizes variability and the associated uncertainty of the resultant test value). Incorrect subsampling can be a significant source of error in the whole measurement process.

The specific subsampling techniques to employ vary with matrix and constituents of interest. This document is not intended to be stand-alone guidance; the procedures described herein must be used in close conjunction with established preparation SOPs.

Section 4 of this SOP addresses general representative laboratory subsampling concepts, and is applicable labwide. Stable chemistry, organic and inorganic, representative subsampling considerations are highlighted in Section 5. SOP Section 6 addresses additional representative subsampling concepts that are particularly applicable to radiochemical procedures.

3. RESPONSIBILITIES

3.1 Departmental Supervisory staff or designees are responsible for providing adequate training and oversight of proper subsampling technique.

3.2 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review, including completion of Sample Condition Form 631, as dictated by Departmental policy. Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification (text directives) and associated project analyte nicknames (electronic controls) are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. Criteria defined in the applicable program specification supercede Paragon's standard criteria. All personnel are responsible for consulting the applicable LIMS program specification prior to initiating handling of project samples or data.

3.4 Internal chain-of-custody procedures (SOP 318) must be observed.

3.5 It is the responsibility of all personnel who process/analyze samples or data, to note and document all anomalous conditions (generally recorded on a Quality Assurance Summary Sheet, QASS, Form 302), and any occurrences that may impact data quality (a Non-Conformance Report, NCR, must be initiated in LIMS). Supervisory, QA and Project Management staff must be notified in a timely manner, as applicable, so that proper corrective actions may be directed and taken.

4. GENERAL CONCEPTS

4.1 Good subsampling technique is especially critical where only small portions of sample are aliquotted for testing.

4.2 Always work using clean surfaces.

4.3 Work as quickly as possible to minimize potential degradation or loss of constituents.

4.4 Unlike evenly dispersed liquids, soil and sediment samples are not homogeneous. Therefore, special steps must be taken to obtain aliquots that are 'representative' of the source material. For example, sticks, leaves, rocks, etc. that are not characteristic of the overall sample must be excluded from the subsample. **Do not take one "grab" sample**, instead, select several small, 'random' increments. Then, thoroughly mix these increments to achieve homogeneity. A disposable tongue depressor can generally be used to acquire/mix solid matrix subsamples.

4.5 Discard excess quantity taken from the original sample container, do not return unused homogenized subsample to original sample container.

4.6 After acquiring sufficient mass (use laboratory balance with calibration verified per SOP 305), record aliquot weight on appropriate datasheet.

4.7 Do not adjust for moisture unless directed by SOP or project requirements.

5. STABLE CHEMISTRY PROCEDURES

5.1 Apply general concepts discussed above.

~~5.2 Allow samples to come to room temperature before subsampling.~~ 12/30/07 DAS

5.3 **Organics**: Unless otherwise directed by LIMS program specification, decant and discard any water layer on top of a sediment sample when preparing for Soxhlet extraction.

For volatile (VOAs, BTEX, etc.) analyses, and for inorganics, gently mix/blend contents of sample container, obtain portions for subsample while in the process of mixing/blending. **Note that the subsample obtained for % Moisture analysis (SOP 642) must be acquired in the same manner as the subsample for constituent analysis.**

For volatile (VOAs, BTEX, etc.) samples that are tightly packed, carefully scrape off a thin top layer of sample before proceeding with subsampling (due to the nature of volatile compounds, this top layer may not be representative of sample constituents due to potential analyte loss).

5.4 **Inorganics**: Use only non-metal scooping devices.

Subsample particles that are larger than the others can be gently mashed.

6. RADIOCHEMICAL SUBSAMPLING PROCEDURES

6.1 GENERAL CONSIDERATIONS

6.1.1 This SOP serves as the starting point for nearly all radiochemical analyses, and is referenced by the SOPs relating to the analysis of individual nuclides or other radiochemical tests. After this pretreatment has been performed, the remainder of the analysis is performed according to the individual preparation SOPs

6.1.2 For radiochemical preparations, any abnormal conditions encountered during storage/receipt and preparation of the samples must be documented on a Quality Assurance Summary Sheet (QASS). A copy of the QASS must accompany the benchsheet. A copy of the sample preparation logbook is also attached to the benchsheet for all analyses that use the dried, and milled sample fraction.

6.1.3 Water samples having visible sediment will generally be filtered through a qualitative paper filter prior to chemical separation.

6.1.4 If a particular analysis requires no preparations, then a subsample is taken before any other preparations are started. The general sequence of soil preparations starts with removing an appropriate representative aliquot followed in turn by drying, sieving and milling. The preparation steps used on a soil depend on the analyses requested for that sample. The requirements for each analysis are described in the individual SOPs. When more than one analysis is requested for a sample, it is possible that a sub sample will be aliquoted at various points in the preparations.

6.1.5 Soil samples are routinely milled in a half-pint ball mill. By specific request, the samples may, instead, be milled with a Spex #8500 shatter box miller. Solid samples that have been milled in the half-pint ball mill are stored in the same clean, labeled containers. The containers are not reusable. A logbook is maintained to document the sample information such as sample ID, date, balance number, oven number, milled sample weight, batch ID (page#) for preparation.

6.1.6 It is important that soil samples for tritium analysis be handled at a minimum so as to preserve their original moisture content. If a separate container is not provided for tritium analysis, coordinate with the tritium analyst and arrange to complete tritium analysis before preparing the sample for other analyses.

6.1.7 Paragon typically reports solid sample results on a dry weight basis. The basis on which water sample results are reported depends on whether the samples require filtration. For moisture content determinations, refer to SOP 642. If the sample volume is very limited, the sample aliquot used for moisture content analysis may subsequently be used for milling.

6.1.8 Before beginning any actual preparations, the LIMS program specs must be reviewed to determine whether project instructions indicate non-routine analytical requirements or special handling due to Health and Safety concerns or sample activity levels (e.g., retaining the "+" fraction of a solid matrix, removing organic and metallic debris). This may influence the quantity of sample needing to be processed through each stage of the preparation sequences. The sample preparation logbook is filled out with the work order numbers.

For each soil sample, determine the total weight of material required to be prepared at each of the stages, (i.e., no-prep, #4 sieve, mill, etc.). Refer to Table 1 for a summary of the amount of material and type of preparation required for various analyses. If unsure of the type or

quantity of required soil preparation, consult the Department Manager or the Project Manager.

6.2 APPARATUS AND MATERIALS

6.2.1 drying oven, set at 105+5°C

6.2.2 sieves, #4 (4.75mm) and others, as specified by the client, and associated collection pan

6.2.3 mortar and pestle (M/P), 150mL, 1L, 4L sizes

6.2.4 Red Devil 5400 shaker or Spex #8500 shatter box miller, or equivalents

6.2.5 Scotch BriteTM scrubbing sponge, or equivalent

6.2.6 SOS™, Brillo™ or equivalent steel wool cleaning pads

6.2.7 gamma spec containers (16oz LERMER JARS) and Ra containers (#2 steel cans)

6.2.8 half-pint steel paint cans

6.2.9 tongue depressors, spatulas or scupulas

6.2.10 Snap-cap vials, 60mL, plastic

6.2.11 balance, top loading, readable to 0.1g

6.2.12 weighing dishes and pans, aluminum

6.2.13 steel ball bearings, 1/2”

6.2.14 rubber mallet

6.2.15 qualitative fluted filter paper, VWR #313 or equivalent

6.2.16 Quartz sand, reagent grade

6.3 DOCUMENT CLIENT SAMPLE ID, LABEL CONTAINERS

6.3.1 Sign-out the samples (scan barcodes to record transaction in LIMS) from Sample Storage. Return samples promptly to Sample Storage once aliquots have been obtained (sign samples back in by scanning barcodes to record transaction in LIMS).

6.3.2 Label the necessary drying pans and dishes with the Paragon work order number.

6.3.3 Assemble and label the required number of secondary containers for each sample (refer to Table 1). More than one container may be needed for each type of preparation if the amount required for the total number of analyses will exceed the capacity of the listed container. Label the containers with the Paragon sample number, type of preparation, date and your initials. If more than one container is

needed for a given type of preparation, also serialize the containers (e.g., 1 of 3, 2 of 3, etc.).

6.3.4 The secondary container may be a LERMER JAR if the only analysis requested on a soil sample is gamma spectrometry.

6.4 NO-PREP SOIL SAMPLEs

6.4.1 Soil sample analyses such as tritium, C-14, and I-129 are performed on an "As Received" basis due to the potential volatility of the analyte. These samples should not be dried or milled prior to analysis, and can be taken directly from the original container with minimum handling. Percent moisture results are used to subsequently convert from 'wet weight' to final reporting dry weight results.

6.4.2 Using a minimal amount of handling, stir and blend the sample with a new tongue depressor before taking an aliquot. Document non-homogeneous, non-stirrable or problematic samples on a Quality Assurance Summary Sheet (QASS, Form 302).

6.5 DRYING

6.5.1 Use labeled aluminum pans and weighing dishes to dry the samples. Add up the total weights required for all preps needing sieving or milling. Weigh out roughly double this amount of sample into the drying trays.

6.5.2 The amount needed for drying will depend on the moisture content of the sample. Extra sample must be dried to account for the weight loss expected. Drier soils may require less and wet soils may require more than double the needed dry weight mass. If the percent moisture has already been determined in prescreening, use this value to estimate the amount required for drying. Consult the Department Manager for directions especially for wet soils and sludges, or if unsure of how to estimate the required amount.

6.5.3 If the sample amount required for gamma fraction (#4 sieving) will use up most or the entire sample, notify the Department Manager. The γ analysis may have to be completed before releasing the sample for the remainder of the soil preparations.

6.5.4 If the weight needed for drying exceeds the total received amount of sample, dry the entire sample immediately. Inform the Project Manager of the insufficient sample size.

6.5.5 Dry the samples in a drying oven set at 105$\pm$5°C. Samples should be dried for a minimum of 16 hours or to a constant weight (+/-2%). Wet

samples may require drying overnight until a constant weight (+/-2%) is obtained.

6.5.6 Examine each container as it is removed from the oven. Return to the oven any that still contain moisture until sample is thoroughly dry. This can be determined by weighing the sample every hour until constant weight (+/-2%) is achieved (overnight is generally more convenient).

6.6 NUMBER 4 SIEVING

NOTE: If the client requires the inclusion of rocks and large material with the final sample aliquot, consult the Department Manager for further instruction.

6.6.1 If the sample will pass a #4 sieve without further processing, proceed to Step 6.6.3.

6.6.2 If the sample requires size reduction before it can pass the #4 sieves, use a mortar and pestle to break up the sample.

6.6.3 Sieve the material, using a #4 sieve, into a clean sieve collection pan. Return the unsievable material to an appropriately labeled soil waste container, if the sample remaining is in excess of what is needed for all analyses. (If the unsievable material must be retained, place it in a new appropriately sized container labeled with the sample identification and the words “dry, unsievable material”.)

6.6.4 Remove the amount of #4 sieved material required to the labeled, tared, secondary container(s) from Section 6.3. If only γ analysis was requested, or if the γ analysis must be completed first due to limited sample size, the sieved material may be weighed into a 16oz LERMER JAR. Document the net weight on the secondary container as well as the sample preparation logbook.

6.6.5 The remaining sample continues through additional preparation in the following Steps. If no further preparation is required, the unused portion may be disposed of in an appropriately labeled soil waste container.

6.6.6 Thoroughly wash and dry the sieve after each use to avoid potential cross-contamination of the samples. First remove any gross sample remaining on the sieve, then wash in Radiacwash™ solution. A nylon brush may be used if necessary. Rinse the sieve with DI water and air dry completely before use.

6.7 MILLING

Milling is accomplished through the use of the Red Devil 5400 paint can shaker (or equivalent). The Spex #8500 shatter box is only used when requested by the client or in special cases where needed to address particular matrices

6.7.1 HALF-PINT SHAKER

6.7.1.1 Transfer the entire dried sample, up to 30g, from the small weighing dish into the labeled half-pint steel can.

6.7.1.2 The maximum mass in the paint can should not exceed 30g. If larger quantity of the same sample needs to be milled, multiple cans should be used. Add 5 clean and dry, half-inch, steel ball bearings into the can. Cover the can with the lid and tighten it using the rubber mallet. The ball bearings stay in the cans and they are not reusable.

6.7.1.3 The paint shaker is equipped with two clamping jaws that can hold up to four cans each. The cans are secured between the jaws by turning the clamp handle clockwise. Care should be taken when tightening the clamp handle because excess pressure may damage the can or the clamping assembly.

6.7.1.4 Turn the timer knob to 15 minutes and the paint shaker will begin shaking. The clamping assembly will move quickly in a vertical and horizontal motion so caution should be taken when working near the shaker. The operator and anyone else in the room should wear hearing protection.

6.7.1.5 Once the shaker stops, loosen the clamps and remove the cans from the clamping jaws. Check the approximate weight of the milled sample by taring a common “empty can with 5 steel ball bearings” as a weight for all the empty cans used to mill samples. Document the milled weight in the sample preparation logbook. Here the exact weight of the milled sample is not required; therefore, a standard can with 5 ball bearings is used as a common empty weight.

6.7.2 SPEX #8500 SHATTER BOX

6.7.2.1 Used only by specific client request or the Department Manager’s instructions.

NOTE: The shatter box may only be operated in an operating fume hood. The pre-screening data, if available, should be reviewed prior to starting.

When feasible, the samples should be ground in order of increasing activity to minimize the potential for sample cross-contamination.

6.7.2.2 Load the dry sample aliquot into the outer ring of the puck portion of the shatter box, ensuring the sample does not protrude above the neoprene 0-ring. The capacity of the mill is up to 100mL of material with a particle size smaller than 1/4" on a side.

6.7.2.3 Place the cover over the puck making sure a tight seal is made with the neoprene O-ring and the lid, and place the puck on shatter box. Bring the damping lever down and tighten the hand knob firmly. To prevent loosening of the knob insert the locking pin in the hole ahead of the knob.

6.7.2.4 Set the timer for one (1) minute by turning the timer switch past five minutes first and then turn it back to the one (1) minute position. Allow the unit to come to a complete stop after one (1) minute.

6.7.2.5 Remove the clamping lever. Remove the puck from the shatter box. Remove the cover and inner puck and ring.

6.7.2.6 Transfer the milled soil to the tared, labeled secondary container from Section 6.3. Use a spatula or small scoop. Document the weight on the container. Place any unused milled material into an appropriately labeled soil waste container.

6.7.2.7 Replace the inner puck and ring, and then cover.

6.7.2.8 Transfer to a sink filled with water and RadiacwashTM detergent and completely submerse the puck. Disassemble under the water.

6.7.2.9 Using a Scotch Brite™ sponge or equivalent, scrub the components of the puck assembly to remove any gross material. Drain the sink and re-fill with fresh RadiacwashTM solution. Thoroughly scrub each component with a new steel wool pad. DO NOT USE ABRASIVE PADS ON THE RUBBER O-RING.

6.7.2.10 Rinse the puck assembly with deionized water and dry immediately with hot air dryer as the puck rusts easily when exposed to water for any length of time. Proceed to the next

sample.

6.7.2.11 It has been demonstrated that a five-minute timed grind using the shatter box achieves a nominal 200-mesh particle size (See Reference 12.1). A five minute timed grind may be used to meet this requirement, if the client requests a mesh size reduction as low as 200 mesh.

6.8 HOMOGENIZATION OF PREPARED SAMPLE ALIQUOTS

When multiple grinds are needed to meet a client's prep requirements, the individual fractions may be combined into a one quart steel can, with five 1/2" steel ball bearings, and shaken as described in Section 6.7 for five minutes. This will adequately homogenize up to 500 grams of ground sample material.

6.9 STORAGE OF PREPARED SAMPLE ALIQUOTS

6.9.1 Verify that all containers are labeled properly. Wipe off the exteriors of all containers before taking them to the Sample Storage unit.

6.9.2 Following procedures given in SOP 318 and the LIMS User Manual, create the proper designations for the prepared sample aliquots in LIMS (appropriate fraction identities must be created for the milled samples and gamma containers). Scan the barcodes to sign the prepared samples into the Sample Storage area, the Sample Custodian will take the responsibility distributing them to the appropriate location.

6.9.3 The preparation analyst is responsible for logging out the prepared samples and gamma containers on behalf of the Actinides Preparation Lab and Gamma Counting Lab.

6.10 EQUIPMENT CLEANING

6.10.1 Sieves, mortar/pestle, blender parts, mixing pans, hand trowels, spatulas and scoops are thoroughly washed with regular water first to remove all gross dirt. Then they are soaked in the sink filled with hot water w/approximately 20oz/gal Radiacwash™.

6.10.2 Mortar/Pestle may be scrubbed with a clean Scotch Brite pad (or equivalent). Do not use cleansing powders (e.g., Ajax, Comet, etc.) on m/p unless authorized to do so by the Department Manager.

6.11 PROCEDURE FOR WATER SAMPLES

Water samples with visible sediment will be filtered through a VWR #313 qualitative fluted filter paper or equivalent before proceeding with other preparation procedures. This practice does not apply to tritium analyses, in which the presence of sediment is not believed to be a significant interferent. In cases

where EPA drinking water methodologies are required, the sample is to be analyzed in total to estimate the actual dose to the consumer.

6.12 CALCULATIONS

6.12.1 Estimated tare weights needed in this SOP may be obtained by weighing another dry, empty container of identical kind

6.12.2 Intermediate prep weights may be obtained by zeroing the balance to include the clean, dry, empty container.

7. QUALITY CONTROL

7.1 Quality control procedures for the drying ovens and top loading balances are covered in SOPs 320 and 305, respectively.

7.2 Reagent grade quartz sand is milled for every batch of samples when the shatter-box mill is used. These serve as equipment blanks to verify that no cross contamination between samples has occurred in the grinding process. The milled sand blank is labeled with an in-house number and documented in the sample preparation logbook. The milled sand blanks are stored with the client samples. When a ground fraction of the client samples are analyzed, the equipment blank will also be analyzed. Detectable quantities of man-made radionuclides will be reported to the client as a Non-Conformance Report (NCR) and the original sample will be re-ground and re-analyzed. Analysis of naturally occurring uranium and thorium isotopes will be evaluated against previously measured quantities occurring in the sand material.

8. SAFETY, HAZARDS AND WASTE DISPOSAL

8.1 SAFETY AND HAZARDS

8.1.1 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or potentially contaminated materials or equipment.

8.1.2 Any chemicals with a Threshold Limit Value (TLV) of less than 50PPM shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

8.1.3 Loose hair and clothing must be restrained while working with or near machinery.

8.1.4 Perform any operation that produces noticeable dust in a working fume hood (especially sieving and milling).

8.1.5 Wipe down all working areas with damp paper towels whenever dust accumulation is evident, even between each sample handling if necessary. Cross-contamination of samples with dust can thus be

avoided. Wipe down all working areas at the end of the day (or shift), even if dust accumulation seems minimal or unnoticeable.

8.1.6 Hearing protection must be worn during milling.

8.2 WASTE DISPOSAL

8.2.1 Materials contaminated with dust residues such as paper towels must be surveyed prior to disposal in trash. Materials with no readings above background may be disposed of in the sanitary trash. This should include most environmental level soils.

8.2.2 Special disposal instructions may be imposed for certain samples with higher activity levels, as identified by the Radiation Safety Officer (RSO) through the prescreening process.

STANDARD OPERATING PROCEDURE ~~721~~ 336

APPENDIX A: SUBSAMPLING PROTOCOL FOR ENVIRONMENTAL SOILS AND INDUSTRIAL FILL SAMPLES FOR MWH (FMC POCATELLO, IDAHO)

HISTORY: Rev0, 5/30/07.

1. OVERVIEW

This protocol describes the proposed procedures for sub-sampling environmental soils samples and industrial fill samples from the FMC site, for MWH.

Sub-sampling of environmental soils will be performed on the entire dried sample, up to 1 kg, using a standard riffle splitter to partition the aliquot for gamma analyses and approximately 30 – 50 g. for metals, fluorides and other radionuclides prior to grinding. The equipment will then be cleaned prior to use for the next sample by wet wiping the splitting mechanism with a lint-free lab wipe, followed by a dry wipe.
Due to the nature of the slag matrix, good homogeneity in a single grab sample is reasonably expected. Also, the extreme hardness of the sample matrix is expected to cause the potential metallic contamination in the grinding of large aliquots for analysis as well as significant time. Consequently, entire fill samples, up to 1 kg. will be dried and sieved, using a standard #10 sieve (1.5 mm mesh size) and the sieved material will be mixed by hand and aliquotted directly for analyses. In the event that sieving does not produce enough fine material for analysis, a 100-200 g. portion of the sample will be ground in a Roalox ceramic jar mill until sufficient material is obtained for analysis. After sub-sampling, digestion and analysis will proceed per the individual preparation SOPs for the requested analyses.

2. INTERFERENCES

Fill samples that require grinding in a jar mill may acquire trace amounts of alumina (Al_2O_3) from the Roalox mill jars during the grinding process. While the possibility of this potential contaminant should be noted to the client, aluminum is not an analyte of interest for this project and should be of no consequence to the data quality.

3. APPARATUS AND MATERIALS

3.1 forced air drying oven, set at 25±5°C
3.2 balance, top loading, readable to 0.1g
3.3 sieves, #10 (1.50 mm) and associated collection pans
3.4 mortar and pestle, ceramic
3.5 Riffle Splitter, Gilson SP-3 or equivalent, with collection pans
3.6 Roalox mill jar, with o-ring and lid
3.7 ½" Burundum grinding cylinders
3.8 weighing dishes and pans, aluminum

4. PROCEDURE

NOTE: Any abnormal conditions encountered during storage/receipt and preparation of the samples must be documented on a Quality Assurance Summary Sheet (QASS) and a copy of the sheet must accompany the benchsheet. A copy of the sample preparation logbook is also attached to the benchsheet for all analyses that use the dried, and milled sample fraction.

4.1 ENVIRONMENTAL SOILS

4.1.1 Sign-out the samples (scan barcodes to record transaction in LIMS) from Sample Storage. Return samples promptly to Sample Storage once aliquots have been obtained (sign samples back in by scanning barcodes to record transaction in LIMS).

4.1.2 Label the necessary drying pans and dishes with the Paragon work order number.

4.1.3 Assemble and label the required number of secondary containers for each sample. More than one container may be needed for each type of preparation if the amount required for the total number of analyses will exceed the capacity of the container. Label the containers with the Paragon sample number, type of preparation, date and your initials. If more than one container is needed for a given type of preparation, also serialize the containers (e.g., 1 of 3, 2 of 3, etc.).

4.1.4 Use labeled aluminum pans and weighing dishes to dry the entire sample. If the entire sample mass exceeds approximately 1 kg, a maximum of 1 kg. may be dried.

4.1.5 Either air-dry the samples in ambient conditions, or use a forced-air drying oven, set at 25±5°C. Samples should be dried for a minimum of 16 hours or to a constant weight (+/-2%). Wet samples may require drying overnight until a constant weight (+/-2%) is obtained.

4.1.6 Examine each container as it is removed from the oven. Return to the oven any that still contain moisture until sample is thoroughly dry. This can be determined by weighing the sample every hour until constant weight (+/-2%) is achieved (overnight is generally more convenient).

4.1.7 After drying, thoroughly mix the sample and load the entire dried sample into a riffle splitter, making sure that the catch pans are in place and the door is in the closed position. The sample may be manually crushed with a ceramic mortal and pestle (to break up dirt clods, etc.), if necessary, to allow passage through the riffle splitter.

4.1.8 Open the splitter door to divide the sample into the two pans. One pan will be randomly assigned for "accumulated residuals" and the other will contain the "analytical fraction".

4.1.9 Place two additional empty pans under the splitter and, repeating step 4.1.7, load the contents of the remaining "analytical fraction" pan for further splitting. With each successive split of the sample, the residual fraction may be added to the pan designated for accumulating residuals. When sufficient residuals have been accumulated, the contents of this pan may be used, as necessary, for gamma analyses.

4.1.10 Continue this process until a representative aliquot of 30 – 50 grams is deposited into each of the two catch pans. Take the contents of one pan as the analytical fraction.

4.1.11 Aliquots for metals, fluoride, and mercury analysis may be taken, by fractional shoveling, directly from the analytical fraction. The 336 remainder may be ground, per SOP ~~721,~~ as required for radiochemistry analyses. Note that analytical fractions for gamma spectroscopy are not ground prior to analysis, but are taken from the "accumulated residuals".

4.1.12 After placing the remaining material in an appropriately labeled container, to be retained for future use, the drying pans may be wet cleaned in Radiacwash and water, then rinsed and dried for later use.

4.1.13 The riffle splitter mechanism, including the body, hopper, riffle fingers, and door will be hand wiped with a lint-free laboratory wipe (large Kimwipe), moistened with DI water, then wiped again with a dry wipe to prepare the mechanism for the next sample.

4.2 FILL SAMPLES

4.2.1 Dry the sample material, as described in sections 4.1.1 through 4.1.6, above.

4.2.2 If necessary, split the dried sample by alternate shoveling, dedicating one fraction for gamma analysis and one fraction for further sample preparation..

4.2.3 Sieve the appropriate dried material, using a #10 sieve, into a clean, tared sieve collection pan. Return the remaining (>#10-sized) material to an appropriately labeled container, to be retained for future use.

4.2.4 Weigh the mass of sieved material, to determine whether additional material is needed. If no additional sieved material is needed, clean the sieve, per SOP ~~721~~, in preparation for the next sample, and proceed to

section 4.2.9.

4.2.5 If additional sieved material is needed, aliquot by fractional shoveling 100 – 200 grams of material and load into an appropriately sized Roalox mill jar. Add approximately ten individual ½" Burundum grinding cylinders, then close and seal the lid.

4.2.6 Rotate on a jar roller at approximately 40-50 rpm, overnight.

4.2.7 Transfer the contents of the jar to a #10 sieve and proceed from step 4.2.1, adding the retrieved sieved material to the previously collected, sieved material. Repeat this process, as necessary to acquire sufficient material for the requested analyses

4.2.8 After use, the Burnundum grinding media will be disposed in the appropriate waste stream. All other equipment, including the jar, lid, o-ring, etc. will be cleaned with Radiacwash (20oz/gal solution), rinsed in DI water, and thoroughly dried prior to re-use.

4.2.9 After sieving, the sample may be split by fractional shoveling for various analyses. Sample fractions for metals, fluoride and mercury analysis will be aliquotted directly from the sieved material. Sample fractions for radiochemistry analyses (non-gamma) will be ground and homogenized, per SOP ~~721~~. 336

5. SAFETY, HAZARDS AND WASTE DISPOSAL

5.1 SAFETY AND HAZARDS

5.1.1 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or potentially contaminated sample materials or equipment.

5.1.2 Loose hair and clothing must be restrained while working with or near machinery.

5.1.3 Perform any operation that produces noticeable dust in a working fume hood (especially sieving and milling).

5.1.4 Wipe down all working areas with damp paper towels whenever dust accumulation is evident, even between each sample handling if necessary. Cross-contamination of samples with dust can thus be avoided. Wipe down all working areas at the end of the day (or shift), even if dust accumulation seems minimal or unnoticeable.

5.2 WASTE DISPOSAL

5.2.1 Materials contaminated with dust residues such as paper towels must be surveyed prior to disposal in trash. Materials with no readings

above background may be disposed of in the sanitary trash. This should include most environmental level soils.

5.2.2 Special disposal instructions may be imposed for certain samples with higher activity levels, as identified by the Radiation Safety Officer (RSO) through the prescreening process.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE ~~721~~ 336

APPENDIX B: CONING AND QUARTERING (NFS SAMPLES)

HISTORY: Rev0, 8/14/07.

PROCEDURE

1. Place two sheets of 8 x 16 copy paper (Sheets A and B) onto a tray, where A is slightly overlapping B.
2. *Slowly* pour the entire sample from the bottle onto the middle of paper A, so that a cone shape forms. The slow pouring allows natural particle distribution to occur.
3. Lightly flatten the sample with a clean spatula until it is circular in shape, with an approximate depth of ~1/2 inch.
4. Using a clean putty knife, quarter the sample evenly (by approximation), then slightly separate each quarter.
5. Move two **opposite** quarters onto Paper B.
6. Carefully move Paper B to another tray and set aside. This is considered the residual sample.
7. Lift both sides of Paper A to form a U-shape. Pour the remaining sample back into the original sample container.
8. Place Paper A back onto the tray. Place another paper (Paper C) onto the tray. Paper A should slightly overlap Paper C.
9. Repeat Steps 2-4.
10. Move two **opposite** quarters onto Paper C.
11. For the contents remaining on Paper A, repeat Steps 2-5 (placing residuals on a clean piece of paper) until a sample of ~30-50g is achieved. This sample can then be placed in the puck grinder to be ground for alpha-spec and Pu-241 analysis.
12. Use Paper C contents as the gamma fraction. If the amount of sample is still too much for a geometry 11 gamma, the sample may be coned and quartered again by following Steps 1-5, until an ideal volume is reached. If the volume of sample is too small for a geometry 11, the residuals from this Step and from paper B may be coned and quartered until an appropriate amount is achieved.
13. Place all remaining sample back into the original sample container for reserve.

Must Discard 30 Days from _____ (date printed)

Amended 12/30/07 - Section 5.2 'Allow sample to warm to room temperature before subsampling.' removed. DAS

TECHNICAL MANAGER _____ DATE 12-28-07

QUALITY ASSURANCE MANAGER _____ DATE 12/28/07

LABORATORY MANAGER _____ DATE 12-28-07

HISTORY: **Formerly SOP 721:** Rev1, 4/26/93; Rev2, PCN #35, 11/17/93; Rev3, PCN #80, 1/12/94; Rev4, PCN #276, 9/29/94; Rev5, PCN #471, 5/3/95; Rev6, 10/7/99; Rev7, 11/1/00; Rev8, 6/15/01; Rev9, 8/20/01; Rev10, 3/19/03; Rev11, 4/22/04; Rev12, 11/29/04; Rev13, 9/8/06; Rev14, 8/24/07. **As SOP 336**: Rev0, 12/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the physical procedures used to prepare environmental samples prior to chemical preparation and analysis. These physical preparations are crucial to ensuring that subsamples (aliquots), and their subsequent test results, are representative of the client sample as a whole.

2. SUMMARY

Subsamples must be representative to avoid bias in the analytical result. Incorrect analytical results could lead to making wrong environmental decisions that could impact environmental preservation or human health. Correct subsampling allows for the results to be duplicated (i.e., minimizes variability and the associated uncertainty of the resultant test value). Incorrect subsampling can be a significant source of error in the whole measurement process.

The specific subsampling techniques to employ vary with matrix and constituents of interest. This document is not intended to be stand-alone guidance; the procedures described herein must be used in close conjunction with established preparation SOPs.

Section 4 of this SOP addresses general representative laboratory subsampling concepts, and is applicable labwide. Stable chemistry, organic and inorganic, representative subsampling considerations are highlighted in Section 5. SOP Section 6 addresses additional representative subsampling concepts that are particularly applicable to radiochemical procedures.

3. RESPONSIBILITIES

3.1 Departmental Supervisory staff or designees are responsible for providing adequate training and oversight of proper subsampling technique.

3.2 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review, including completion of Sample Condition Form 631, as dictated by Departmental policy. Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification (text directives) and associated project analyte nicknames (electronic controls) are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. Criteria defined in the applicable program specification supercede Paragon's standard criteria. All personnel are responsible for consulting the applicable LIMS program specification prior to initiating handling of project samples or data.

3.4 Internal chain-of-custody procedures (SOP 318) must be observed.

3.5 It is the responsibility of all personnel who process/analyze samples or data, to note and document all anomalous conditions (generally recorded on a Quality Assurance Summary Sheet, QASS, Form 302), and any occurrences that may impact data quality (a Non-Conformance Report, NCR, must be initiated in LIMS). Supervisory, QA and Project Management staff must be notified in a timely manner, as applicable, so that proper corrective actions may be directed and taken.

4. GENERAL CONCEPTS

4.1 Good subsampling technique is especially critical where only small portions of sample are aliquotted for testing.

4.2 Always work using clean surfaces.

4.3 Work as quickly as possible to minimize potential degradation or loss of constituents.

4.4 Unlike evenly dispersed liquids, soil and sediment samples are not homogeneous. Therefore, special steps must be taken to obtain aliquots that are 'representative' of the source material. For example, sticks, leaves, rocks, etc. that are not characteristic of the overall sample must be excluded from the subsample. **Do not take one "grab" sample**, instead, select several small, 'random' increments. Then, thoroughly mix these increments to achieve homogeneity. A disposable tongue depressor can generally be used to acquire/mix solid matrix subsamples.

4.5 Discard excess quantity taken from the original sample container, do not return unused homogenized subsample to original sample container.

4.6 After acquiring sufficient mass (use laboratory balance with calibration verified per SOP 305), record aliquot weight on appropriate datasheet.

4.7 Do not adjust for moisture unless directed by SOP or project requirements.

5. STABLE CHEMISTRY PROCEDURES

5.1 Apply general concepts discussed above.

~~5.2 Allow samples to come to room temperature before subsampling.~~ 12/30/07 DAS

5.3 **Organics**: Unless otherwise directed by LIMS program specification, decant and discard any water layer on top of a sediment sample when preparing for Soxhlet extraction.

For volatile (VOAs, BTEX, etc.) analyses, and for inorganics, gently mix/blend contents of sample container, obtain portions for subsample while in the process of mixing/blending. **Note that the subsample obtained for % Moisture analysis (SOP 642) must be acquired in the same manner as the subsample for constituent analysis.**

For volatile (VOAs, BTEX, etc.) samples that are tightly packed, carefully scrape off a thin top layer of sample before proceeding with subsampling (due to the nature of volatile compounds, this top layer may not be representative of sample constituents due to potential analyte loss).

5.4 **Inorganics**: Use only non-metal scooping devices.

Subsample particles that are larger than the others can be gently mashed.

6. RADIOCHEMICAL SUBSAMPLING PROCEDURES

6.1 GENERAL CONSIDERATIONS

6.1.1 This SOP serves as the starting point for nearly all radiochemical analyses, and is referenced by the SOPs relating to the analysis of individual nuclides or other radiochemical tests. After this pretreatment has been performed, the remainder of the analysis is performed according to the individual preparation SOPs

6.1.2 For radiochemical preparations, any abnormal conditions encountered during storage/receipt and preparation of the samples must be documented on a Quality Assurance Summary Sheet (QASS). A copy of the QASS must accompany the benchsheet. A copy of the sample preparation logbook is also attached to the benchsheet for all analyses that use the dried, and milled sample fraction.

6.1.3 Water samples having visible sediment will generally be filtered through a qualitative paper filter prior to chemical separation.

6.1.4 If a particular analysis requires no preparations, then a subsample is taken before any other preparations are started. The general sequence of soil preparations starts with removing an appropriate representative aliquot followed in turn by drying, sieving and milling. The preparation steps used on a soil depend on the analyses requested for that sample. The requirements for each analysis are described in the individual SOPs. When more than one analysis is requested for a sample, it is possible that a sub sample will be aliquoted at various points in the preparations.

6.1.5 Soil samples are routinely milled in a half-pint ball mill. By specific request, the samples may, instead, be milled with a Spex #8500 shatter box miller. Solid samples that have been milled in the half-pint ball mill are stored in the same clean, labeled containers. The containers are not reusable. A logbook is maintained to document the sample information such as sample ID, date, balance number, oven number, milled sample weight, batch ID (page#) for preparation.

6.1.6 It is important that soil samples for tritium analysis be handled at a minimum so as to preserve their original moisture content. If a separate container is not provided for tritium analysis, coordinate with the tritium analyst and arrange to complete tritium analysis before preparing the sample for other analyses.

6.1.7 Paragon typically reports solid sample results on a dry weight basis. The basis on which water sample results are reported depends on whether the samples require filtration. For moisture content determinations, refer to SOP 642. If the sample volume is very limited, the sample aliquot used for moisture content analysis may subsequently be used for milling.

6.1.8 Before beginning any actual preparations, the LIMS program specs must be reviewed to determine whether project instructions indicate non-routine analytical requirements or special handling due to Health and Safety concerns or sample activity levels (e.g., retaining the "+" fraction of a solid matrix, removing organic and metallic debris). This may influence the quantity of sample needing to be processed through each stage of the preparation sequences. The sample preparation logbook is filled out with the work order numbers.

For each soil sample, determine the total weight of material required to be prepared at each of the stages, (i.e., no-prep, #4 sieve, mill, etc.). Refer to Table 1 for a summary of the amount of material and type of preparation required for various analyses. If unsure of the type or

quantity of required soil preparation, consult the Department Manager or the Project Manager.

6.2 APPARATUS AND MATERIALS

6.2.1 drying oven, set at 105+5°C

6.2.2 sieves, #4 (4.75mm) and others, as specified by the client, and associated collection pan

6.2.3 mortar and pestle (M/P), 150mL, 1L, 4L sizes

6.2.4 Red Devil 5400 shaker or Spex #8500 shatter box miller, or equivalents

6.2.5 Scotch BriteTM scrubbing sponge, or equivalent

6.2.6 SOS™, Brillo™ or equivalent steel wool cleaning pads

6.2.7 gamma spec containers (16oz LERMER JARS) and Ra containers (#2 steel cans)

6.2.8 half-pint steel paint cans

6.2.9 tongue depressors, spatulas or scupulas

6.2.10 Snap-cap vials, 60mL, plastic

6.2.11 balance, top loading, readable to 0.1g

6.2.12 weighing dishes and pans, aluminum

6.2.13 steel ball bearings, 1/2”

6.2.14 rubber mallet

6.2.15 qualitative fluted filter paper, VWR #313 or equivalent

6.2.16 Quartz sand, reagent grade

6.3 DOCUMENT CLIENT SAMPLE ID, LABEL CONTAINERS

6.3.1 Sign-out the samples (scan barcodes to record transaction in LIMS) from Sample Storage. Return samples promptly to Sample Storage once aliquots have been obtained (sign samples back in by scanning barcodes to record transaction in LIMS).

6.3.2 Label the necessary drying pans and dishes with the Paragon work order number.

6.3.3 Assemble and label the required number of secondary containers for each sample (refer to Table 1). More than one container may be needed for each type of preparation if the amount required for the total number of analyses will exceed the capacity of the listed container. Label the containers with the Paragon sample number, type of preparation, date and your initials. If more than one container is

needed for a given type of preparation, also serialize the containers (e.g., 1 of 3, 2 of 3, etc.).

6.3.4 The secondary container may be a LERMER JAR if the only analysis requested on a soil sample is gamma spectrometry.

6.4 NO-PREP SOIL SAMPLEs

6.4.1 Soil sample analyses such as tritium, C-14, and I-129 are performed on an "As Received" basis due to the potential volatility of the analyte. These samples should not be dried or milled prior to analysis, and can be taken directly from the original container with minimum handling. Percent moisture results are used to subsequently convert from 'wet weight' to final reporting dry weight results.

6.4.2 Using a minimal amount of handling, stir and blend the sample with a new tongue depressor before taking an aliquot. Document non-homogeneous, non-stirrable or problematic samples on a Quality Assurance Summary Sheet (QASS, Form 302).

6.5 DRYING

6.5.1 Use labeled aluminum pans and weighing dishes to dry the samples. Add up the total weights required for all preps needing sieving or milling. Weigh out roughly double this amount of sample into the drying trays.

6.5.2 The amount needed for drying will depend on the moisture content of the sample. Extra sample must be dried to account for the weight loss expected. Drier soils may require less and wet soils may require more than double the needed dry weight mass. If the percent moisture has already been determined in prescreening, use this value to estimate the amount required for drying. Consult the Department Manager for directions especially for wet soils and sludges, or if unsure of how to estimate the required amount.

6.5.3 If the sample amount required for gamma fraction (#4 sieving) will use up most or the entire sample, notify the Department Manager. The γ analysis may have to be completed before releasing the sample for the remainder of the soil preparations.

6.5.4 If the weight needed for drying exceeds the total received amount of sample, dry the entire sample immediately. Inform the Project Manager of the insufficient sample size.

6.5.5 Dry the samples in a drying oven set at 105$\pm$5°C. Samples should be dried for a minimum of 16 hours or to a constant weight (+/-2%). Wet

samples may require drying overnight until a constant weight (+/-2%) is obtained.

6.5.6 Examine each container as it is removed from the oven. Return to the oven any that still contain moisture until sample is thoroughly dry. This can be determined by weighing the sample every hour until constant weight (+/-2%) is achieved (overnight is generally more convenient).

6.6 NUMBER 4 SIEVING

NOTE: If the client requires the inclusion of rocks and large material with the final sample aliquot, consult the Department Manager for further instruction.

6.6.1 If the sample will pass a #4 sieve without further processing, proceed to Step 6.6.3.

6.6.2 If the sample requires size reduction before it can pass the #4 sieves, use a mortar and pestle to break up the sample.

6.6.3 Sieve the material, using a #4 sieve, into a clean sieve collection pan. Return the unsievable material to an appropriately labeled soil waste container, if the sample remaining is in excess of what is needed for all analyses. (If the unsievable material must be retained, place it in a new appropriately sized container labeled with the sample identification and the words “dry, unsievable material”.)

6.6.4 Remove the amount of #4 sieved material required to the labeled, tared, secondary container(s) from Section 6.3. If only γ analysis was requested, or if the γ analysis must be completed first due to limited sample size, the sieved material may be weighed into a 16oz LERMER JAR. Document the net weight on the secondary container as well as the sample preparation logbook.

6.6.5 The remaining sample continues through additional preparation in the following Steps. If no further preparation is required, the unused portion may be disposed of in an appropriately labeled soil waste container.

6.6.6 Thoroughly wash and dry the sieve after each use to avoid potential cross-contamination of the samples. First remove any gross sample remaining on the sieve, then wash in Radiacwash™ solution. A nylon brush may be used if necessary. Rinse the sieve with DI water and air dry completely before use.

6.7 MILLING

Milling is accomplished through the use of the Red Devil 5400 paint can shaker (or equivalent). The Spex #8500 shatter box is only used when requested by the client or in special cases where needed to address particular matrices

6.7.1 HALF-PINT SHAKER

6.7.1.1 Transfer the entire dried sample, up to 30g, from the small weighing dish into the labeled half-pint steel can.

6.7.1.2 The maximum mass in the paint can should not exceed 30g. If larger quantity of the same sample needs to be milled, multiple cans should be used. Add 5 clean and dry, half-inch, steel ball bearings into the can. Cover the can with the lid and tighten it using the rubber mallet. The ball bearings stay in the cans and they are not reusable.

6.7.1.3 The paint shaker is equipped with two clamping jaws that can hold up to four cans each. The cans are secured between the jaws by turning the clamp handle clockwise. Care should be taken when tightening the clamp handle because excess pressure may damage the can or the clamping assembly.

6.7.1.4 Turn the timer knob to 15 minutes and the paint shaker will begin shaking. The clamping assembly will move quickly in a vertical and horizontal motion so caution should be taken when working near the shaker. The operator and anyone else in the room should wear hearing protection.

6.7.1.5 Once the shaker stops, loosen the clamps and remove the cans from the clamping jaws. Check the approximate weight of the milled sample by taring a common “empty can with 5 steel ball bearings” as a weight for all the empty cans used to mill samples. Document the milled weight in the sample preparation logbook. Here the exact weight of the milled sample is not required; therefore, a standard can with 5 ball bearings is used as a common empty weight.

6.7.2 SPEX #8500 SHATTER BOX

6.7.2.1 Used only by specific client request or the Department Manager’s instructions.

NOTE: The shatter box may only be operated in an operating fume hood. The pre-screening data, if available, should be reviewed prior to starting.

When feasible, the samples should be ground in order of increasing activity to minimize the potential for sample cross-contamination.

6.7.2.2 Load the dry sample aliquot into the outer ring of the puck portion of the shatter box, ensuring the sample does not protrude above the neoprene 0-ring. The capacity of the mill is up to 100mL of material with a particle size smaller than 1/4" on a side.

6.7.2.3 Place the cover over the puck making sure a tight seal is made with the neoprene O-ring and the lid, and place the puck on shatter box. Bring the damping lever down and tighten the hand knob firmly. To prevent loosening of the knob insert the locking pin in the hole ahead of the knob.

6.7.2.4 Set the timer for one (1) minute by turning the timer switch past five minutes first and then turn it back to the one (1) minute position. Allow the unit to come to a complete stop after one (1) minute.

6.7.2.5 Remove the clamping lever. Remove the puck from the shatter box. Remove the cover and inner puck and ring.

6.7.2.6 Transfer the milled soil to the tared, labeled secondary container from Section 6.3. Use a spatula or small scoop. Document the weight on the container. Place any unused milled material into an appropriately labeled soil waste container.

6.7.2.7 Replace the inner puck and ring, and then cover.

6.7.2.8 Transfer to a sink filled with water and RadiacwashTM detergent and completely submerse the puck. Disassemble under the water.

6.7.2.9 Using a Scotch Brite™ sponge or equivalent, scrub the components of the puck assembly to remove any gross material. Drain the sink and re-fill with fresh RadiacwashTM solution. Thoroughly scrub each component with a new steel wool pad. DO NOT USE ABRASIVE PADS ON THE RUBBER O-RING.

6.7.2.10 Rinse the puck assembly with deionized water and dry immediately with hot air dryer as the puck rusts easily when exposed to water for any length of time. Proceed to the next

sample.

6.7.2.11 It has been demonstrated that a five-minute timed grind using the shatter box achieves a nominal 200-mesh particle size (See Reference 12.1). A five minute timed grind may be used to meet this requirement, if the client requests a mesh size reduction as low as 200 mesh.

6.8 HOMOGENIZATION OF PREPARED SAMPLE ALIQUOTS

When multiple grinds are needed to meet a client's prep requirements, the individual fractions may be combined into a one quart steel can, with five 1/2" steel ball bearings, and shaken as described in Section 6.7 for five minutes. This will adequately homogenize up to 500 grams of ground sample material.

6.9 STORAGE OF PREPARED SAMPLE ALIQUOTS

6.9.1 Verify that all containers are labeled properly. Wipe off the exteriors of all containers before taking them to the Sample Storage unit.

6.9.2 Following procedures given in SOP 318 and the LIMS User Manual, create the proper designations for the prepared sample aliquots in LIMS (appropriate fraction identities must be created for the milled samples and gamma containers). Scan the barcodes to sign the prepared samples into the Sample Storage area, the Sample Custodian will take the responsibility distributing them to the appropriate location.

6.9.3 The preparation analyst is responsible for logging out the prepared samples and gamma containers on behalf of the Actinides Preparation Lab and Gamma Counting Lab.

6.10 EQUIPMENT CLEANING

6.10.1 Sieves, mortar/pestle, blender parts, mixing pans, hand trowels, spatulas and scoops are thoroughly washed with regular water first to remove all gross dirt. Then they are soaked in the sink filled with hot water w/approximately 20oz/gal Radiacwash™.

6.10.2 Mortar/Pestle may be scrubbed with a clean Scotch Brite pad (or equivalent). Do not use cleansing powders (e.g., Ajax, Comet, etc.) on m/p unless authorized to do so by the Department Manager.

6.11 PROCEDURE FOR WATER SAMPLES

Water samples with visible sediment will be filtered through a VWR #313 qualitative fluted filter paper or equivalent before proceeding with other preparation procedures. This practice does not apply to tritium analyses, in which the presence of sediment is not believed to be a significant interferent. In cases

where EPA drinking water methodologies are required, the sample is to be analyzed in total to estimate the actual dose to the consumer.

6.12 CALCULATIONS

6.12.1 Estimated tare weights needed in this SOP may be obtained by weighing another dry, empty container of identical kind

6.12.2 Intermediate prep weights may be obtained by zeroing the balance to include the clean, dry, empty container.

7. QUALITY CONTROL

7.1 Quality control procedures for the drying ovens and top loading balances are covered in SOPs 320 and 305, respectively.

7.2 Reagent grade quartz sand is milled for every batch of samples when the shatter-box mill is used. These serve as equipment blanks to verify that no cross contamination between samples has occurred in the grinding process. The milled sand blank is labeled with an in-house number and documented in the sample preparation logbook. The milled sand blanks are stored with the client samples. When a ground fraction of the client samples are analyzed, the equipment blank will also be analyzed. Detectable quantities of man-made radionuclides will be reported to the client as a Non-Conformance Report (NCR) and the original sample will be re-ground and re-analyzed. Analysis of naturally occurring uranium and thorium isotopes will be evaluated against previously measured quantities occurring in the sand material.

8. SAFETY, HAZARDS AND WASTE DISPOSAL

8.1 SAFETY AND HAZARDS

8.1.1 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or potentially contaminated materials or equipment.

8.1.2 Any chemicals with a Threshold Limit Value (TLV) of less than 50PPM shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

8.1.3 Loose hair and clothing must be restrained while working with or near machinery.

8.1.4 Perform any operation that produces noticeable dust in a working fume hood (especially sieving and milling).

8.1.5 Wipe down all working areas with damp paper towels whenever dust accumulation is evident, even between each sample handling if necessary. Cross-contamination of samples with dust can thus be

avoided. Wipe down all working areas at the end of the day (or shift), even if dust accumulation seems minimal or unnoticeable.

8.1.6 Hearing protection must be worn during milling.

8.2 WASTE DISPOSAL

8.2.1 Materials contaminated with dust residues such as paper towels must be surveyed prior to disposal in trash. Materials with no readings above background may be disposed of in the sanitary trash. This should include most environmental level soils.

8.2.2 Special disposal instructions may be imposed for certain samples with higher activity levels, as identified by the Radiation Safety Officer (RSO) through the prescreening process.

TITLE: DETERMINATION OF ORGANOCHLORINE PESTICIDES BY GAS CHROMATOGRAPHY - METHODS SW8081A OR B, AND EPA 608

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 4.7.09

QUALITY ASSURANCE MANAGER _____ DATE 4/7/09

LABORATORY MANAGER _____ DATE 4-7-09

HISTORY: New, Rev0, 8/4/92; re-released without revision (updated format), 4/13/94; Rev1, PCN #482, 5/25/95; Rev3, 3/26/96; Rev4, 6/10/96; Rev5, 1/29/99; Rev6, 11/10/01; Rev7, 8/29/02; Rev8, 2/12/03; Rev9, 3/14/03; Rev10, 4/16/04; Rev11, 11/22/04; Rev12, 7/5/06; Rev13, 3/19/09.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references – SW8081A or B, and EPA 608, are used to determine the concentration of certain organochlorine pesticides in liquid (SW8081 and EPA 608) and solid matrices (SW8081). The following compounds typically comprise ALS Laboratory Group - Fort Collins (ALSLG-FC)'s target analyte list:

aldrin	4,4'-DDD	endrin
alpha(α)-BHC	4,4'-DDE	endrin aldehyde
beta(β)-BHC	4,4'-DDT	endrin ketone
gamma(γ)-BHC (lindane)	dieldrin	heptachlor
delta(δ)-BHC	endosulfan I	heptachlor epoxide
alpha(α)-chlordane	endosulfan II	methoxychlor
gamma (γ) chlordane	endosulfan sulfate	toxaphene
technical chlordane		

Other compounds may be analyzed if successful demonstration of capability (DOC) and method detection limit (MDL) studies are performed.

2. SUMMARY

Samples are extracted and the extracts concentrated and solvent exchanged using appropriate ALSLG-FC SOPs (i.e., 625 [Soxhlet]; 626 [Separatory Funnel]; 607 [Kuderna-Danish Reduction]; and 637 [Concentration and Solvent Exchange]). The extracts are injected into a gas chromatograph (GC) containing a sample splitter and two columns of varying selectivity (i.e., dissimilar elution and retention time properties). The target analytes are separated in the columns and detected by two electron capture detectors (ECDs). This chromatography system allows tentative identification by one column and confirmation by the other column to be performed simultaneously. Quantitation is performed using the best column response yielded for each analyte. The Analyst considers performance data such as separation of interferences, calibration performance and matrix

spike results in selecting the primary quantitation column for each analyte detected and reported. The particular value that is selected for reporting is often marked (designated) in the raw data (e.g., quantitation report, run log). If results from both columns are comparable, the highest result is reported.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 ALSLG-FC 's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede ALSLG-FC's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Interference from phthalate esters can be minimized by using plastic-free solvent containers and scrupulously cleaned glassware (SOP 334) that has been kiln-baked or solvent-rinsed prior to use. Use of low phthalate gloves, such as nitrile, may also important. These practices are important both in the field and in the laboratory.

4.2 Method SW3620B Florisil cleanup may be used to remove polar interferences from sample extracts (SOP 648).

4.3 Elemental sulfur (particularly in sediment samples) may interfere with early-eluting pesticides. Method SW3660B sulfur cleanup may be performed (SOP 634).

NOTE: The recovery of endrin aldehyde can be drastically reduced when using the TBA procedure in Method SW3660B. For this reason, only the copper powder technique will be used.

4.4 Dilution is performed if high molecular weight organic interferences are present. Alternatively these may be removed using Method SW3640A GPC cleanup (SOP 641).

4.5 The presence of Aroclors in the sample may interfere with the recognition and quantitation of single components, such as 4,4'-DDT, or multi-component pesticides such as technical chlordane and toxaphene. Interpretive examples are provided in Appendix I of this SOP. If multi-component interference is observed, the interference is discussed in the data package narrative. Consult the LIMS program specification and ensure that the Project Manager is informed if interferences are present.

4.6 Particular caution is used in identifying the presence of interferences. It should be noted that methoxychlor may also be susceptible to interference.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH (GC), AUTOSAMPLER AND DETECTORS - Hewlett Packard (HP) 5890 Series II GC equipped with HP 7673A autosampler and electron capture detectors (ECDs) or equivalents

5.2 CHROMATOGRAPHIC DATA ACQUISITION AND PROCESSING SYSTEM - Hewlett Packard ChemStation (Enviroquant™) or equivalent

5.3 COLUMNS -

RTx-CLPesticides or equivalent (30m, 0.25 or 0.32mm ID, 0.5µm film), RTx-CLPesticides II or equivalent (30m, 0.25 or 0.32mm ID, 0.25µm film), guard column

Restek Pesticide Column:	RTX-CLPesticides	#11123	(0.25mm)
Restek Pesticide Column:	RTX-CLPesticides2	#11323	(0.25mm)
Restek Pesticide Column:	RTX-CLPesticides	#11139	(0.32mm)
Restek Pesticide Column:	RTX-CLPesticides2	#11324	(0.32mm)

5.4 GASES - ultra high purity (99.999%)
Helium - carrier gas
Nitrogen - make-up gas

5.5 MEASURING DEVICES
Syringes - 10µL-1000µL
Volumetric flasks, Class A with stoppers, 10mL-100mL

5.6 GC CONSUMABLES:

- Vials - National Scientific C4011-1, or equivalent

- Caps - National Scientific C4000-51B, or equivalent
- Inlet Seals, dual vespel ring - Restek 0.8mm #21243, or equivalent
- Septa, 11mm - Restek #20365 or equivalent
- O-ring, graphite, 6.5mm - Restek #20299, or equivalent
- O-ring, Viton - Restek #20377, or equivalent
- Liner, splitless, 4mm ID - Restek #20799-214.5, or equivalent
- Glass Wool, deactivated - Restek #20789, or equivalent
- Gold Seal - Restek #21306, or equivalent
- Universal Presstight Y - Restek #20469, or equivalent
- Vespel/Graphite Ferrule (detector) - Restek #20221, or equivalent
- Compact Vespel/Graphite Ferrule - Restek #20249, or equivalent
- Graphite Ferrules - various sizes
- Split Vent Trap (SW8081) - Agilent RDT-1023, or equivalent

6. REAGENTS

6.1 SOLVENTS - **Only pesticide residue grade or equivalent may be used.**
Hexane - Burdick and Jackson 216-4, or equivalent
Methanol - Burdick and Jackson 230-4, or equivalent

6.2 STANDARDS
All standards are stored following ALSLG-FC SOP 300 guidance, which is superseded by any guidance in this SOP. Generally after opening vials, the standards for this procedure are stored in the freezer (-10°C and -20°C), in PTFE-capped, or equivalent vials. Unopened stock standards in flame-sealed ampules are valid until the manufacturer's expiration date and may be stored at room temperature, if recommended by the manufacturer. Opened stock standards and intermediate standards expire six months from opening (preparation) or the manufacturer's expiration date, whichever is sooner. Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

All stock and intermediate standards are documented in ALSLG-FC's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

6.2.1 Stock standards are generally purchased as mixes from vendors with certified concentrations. At a minimum, two independent sources of stock standards are needed for target analytes. An appropriate volume of stock standard is diluted (in hexane) to a specified volume to create intermediate standards. The intermediate standards are further diluted to volume using an appropriate solvent to create the working standards.

Working standards are prepared the day of use and documented in the analytical run log. A detailed description of the concentrations of the working standards and how they are used can be found in Section 8 of this SOP.

6.2.2 ICV Solution - Second source confirmation is required, this is accomplished by preparing an initial calibration verification (ICV) solution at a concentration near the midpoint of the calibration curve.

6.2.3 Endrin and 4,4'-DDT Standard (Breakdown Standard) - This standard is used to check inertness of injector system and columns prior to running standards or samples. Only one source is needed and primary, intermediate and working standards are created as described above and detailed in Section 8.

6.2.4 Surrogate Spike Solution - A primary standard containing tetrachloro-meta-xylene (TCMX) and decachlorobiphenyl (DCB) is purchased from a vendor. A solution containing 500ng/mL is prepared in methanol or other suitable solvent. This solution is used by the Organics Extraction Group to spike all samples for this test prior to extraction. Other concentrations or solvents may be used as needed (i.e., as defined in the applicable LIMS Program Specification).

6.2.5 Spike Solution - A primary standard (or standards) is used to prepare a solution to be used by the Organics Extractions Group in preparing laboratory control samples (LCS/LCSD) or matrix spiked samples (MS/MSD). This standard typically contains all the single component analytes listed in Section 1 at 400ng/mL in methanol. Other concentrations and solvents may be used as appropriate. Technical chlordane and toxaphene are not included in this matrix spike solution because either would interfere with the quantification of the single component pesticides. Technical chlordane and toxaphene-spiked samples are prepared separately when required (i.e., as indicated in the LIMS program specification).

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are generally not chemically preserved and must be collected in amber glass containers (generally 1000mL) with Teflon-lined lids. Samples must be maintained at 4±2°C and extracted within 7 days of collection. Sodium thiosulfate ($Na_2S_2O_3$) may be used to dechlorinate liquid samples that contain residual chlorine. This should be accomplished by the client in the field. The Project Manager may designate need for residual chlorine check of the sample upon receipt. Additionally, samples for Method EPA 608 may need to have pH adjusted upon receipt.

7.3 Solid samples are collected in 250mL wide mouth glass containers with Teflon-lined lids. Solid samples are not chemically preserved but must be maintained at 4±2°C. Solid samples must be extracted within 14 days of collection.

7.4 Extracts from solids or liquids must also be maintained at 4±2°C and analyzed within 40 days of preparation.

8. PROCEDURE

8.1 TYPICAL GAS CHROMATOGRAPHIC CONDITIONS

Carrier gas (He):	1.5mL/min (constant flow mode 9.3psi)
Make-up gas (N_2):	20-40mL/min
Injector temperature:	205°C
1µl injection:	splitless mode (purge off)
Purge:	on, 0.75min
Detector temperature:	325°C

Oven Temperature Program:

Initial temperature:	110°C, hold 0.5min
Oven ramp 1:	20°C/min to 140°C
Oven ramp 2:	11°C/min to 240°C, hold 4.09min
Oven ramp 3:	20°C/min to 300°C ,hold 8.00min

8.2 ROUTINE MAINTENANCE/ENDRIN AND 4,4'-DDT BREAKDOWN CHECK
Routine injector maintenance is performed, to limit and control both endrin and DDT breakdown, approximately once per 24 hours of system use. This includes septum replacement, liner (clean or replace), new deactivated glass wool, cut column (approximately 4cm), clean injection port and rinse of the gold seal.

Endrin and 4,4'-DDT breakdown must be checked and found acceptable before calibration or sample analyses may proceed. This check of system inertness must be performed at the start of any sequence. A working standard containing endrin and 4,4'-DDT at 100ng/mL and 200ng/mL, respectively, in hexane is injected. The peak areas of endrin, endrin aldehyde, endrin ketone, 4,4'-DDT, 4,4'-DDE and 4,4'DDD are integrated. Endrin and 4,4'-DDT breakdown as a percentage are calculated using the equations below:

$$endrin\ breakdown\,(\%) = (100)\left[\frac{peak\ area\ (endrin\,aldehyde + endrin\,ketone)}{peak\ area\,(endrin + endrin\,aldehyde + endrin\,ketone)}\right]$$

$$4,4'\text{–}DDT\ breakdown\,(\%) = (100)\left[\frac{peak\ area\ (4,4'\text{–}DDD + 4,4'\text{–}DDE)}{peak\ area\,(4,4'\text{–}DDT + 4,4'\text{–}DDD + 4,4'\text{–}DDE)}\right]$$

If the calculated breakdown of either endrin or 4,4'-DDT exceeds 15% on either column, corrective maintenance must be done before the analysis of any calibration standards or extracts may proceed. Endrin breakdown is typically indicative of injection port contamination. Other preventive maintenance such as clipping the guard column or analytical columns may be needed to bring the breakdown within criteria. Further injection port maintenance, such as cleaning the entire port and gas feeder lines, may also be needed.

ECD detector leak checks are performed semi-annually per the SOP 016.

8.3 INITIAL CALIBRATION

8.3.1 Prepare calibration standards as suitable for the requirements of the samples to be analyzed. A typical calibration sequence and preparation steps are shown below in Table 1. A one-point calibration at or below the report level for toxaphene and technical chlordane is performed unless these multi-component compounds are expected to be present in extracts. The concentrations of the single-point calibration for toxaphene and technical chlordane are typically 250 and 50ng/mL, respectively. When toxaphene or technical chlordane is known or expected to be present, a five-point calibration is performed to more accurately quantify these compounds. A typical calibration range for the single component pesticides is 5ng/mL to 75ng/mL, with the exception of methoxychlor at 15 to 375ng/mL. Calibration standards are prepared with surrogates at similar levels to target analytes. When toxaphene or technical chlordane curves are needed to quantify these compounds, a similar approach to that shown below for single component initial calibration is used.

TABLE 1
CALIBRATION STANDARDS

Working Standard	Hexane (µL)	Intermediate Std (or std specified) (µL)	Standard Concentration (ng/mL)
Breakdown Check	1000	250	DDT 0.2 Endrin 0.1
Toxaphene	975	25	250
Technical Chlordane	975	25	50
40% Standard	750	500	100
Single Component ICAL Level 7	250	750 of 40% std	75
Single Component ICAL Level 6	750	250	62.5
Single Component ICAL Level 5	1000	250	50
Single Component ICAL Level 4	500	500 of ICAL 7	37.5
Single Component ICAL Level 3	1000	250 of 40% Std	20
Single Component ICAL Level 2	500	500 of ICAL 3	10
Single Component ICAL Level 1	750	250 of ICAL 3	5
Single Component 2nd source ICV	varied over time	varied over time	typically 37.5

8.3.2 Note that because of the low concentration of pesticide standards injected on a GC/ECD, column adsorption may be a problem when the GC has not been used for a day or more. Therefore, the GC column may need to be primed by injecting a pesticide standard mixture at high concentration prior to calibration. The total chlorinated organic concentration of the solution should be approximately 5-10 ug/mL. Solvent blanks are typically injected following the priming in order to avoid contamination of later injections due to the high concentration levels of the priming standard.

8.3.3 Inject 1µL of calibration standard under the GC conditions listed previously. Each data file quantitation is accomplished via the external standard method of quantitation. Analyte Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{integrated peak area of analyte}}{\text{analyte concentration}}$$

Since each CF represents the slope of the line between the response for that standard and the origin, then if the observed deviation between the CF's is constant (i.e., ≤20% RSD), then the response is assumed to be invariant and the average (mean) CF may be used to quantitate sample content.

Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean response factor}} \right)(100)$$

When %RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be ≥0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 calibration points, following the guidelines in SW-846 Method 8000C. A quadratic regression should not be used to compensate for detector saturation.

The mathematics used in least squares regression have a tendency to favor numbers of larger value over numbers of smaller value. The regression curves that are generated will therefore tend to fit points that are at the upper calibration levels better than those points at the lower calibration levels. To compensate for this, a "weighting" factor which reduces this tendency can be used. The analyst may weight the curve to either the

inverse of the concentration or to the inverse of the square of the concentration.

The type of curve fit applied should be chosen to best represent the data.

NOTE: If an initial calibration point is not used for any reason, the analyst must clearly notate why the data point was not used for instrument calibration. "Picking and choosing" among calibration points in order to meet criteria is NOT acceptable. Generally, calibration points are only discarded due to easily demonstratable causes.

If regression criteria cannot be met, a new initial calibration must be performed.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is run after calibration. The concentration of the ICV should be different from that of the continuing calibration verification (CCV) and varied over time. The acceptance criteria for the ICV are identical to those of CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The concentration of the CCV is at or near the midpoint of the initial calibration. A CCV check is performed at the beginning (when initial calibration is not performed) and end, of each 12-hour analytical sequence (or batch of 20 samples). While QC samples are counted as part of the number of samples, solvent blanks are not.

NOTE: The CCV frequency given above should be considered a bare minimum, and some clients' LIMS program specifications may require more frequent CCV analysis. Even if this is not the case, a higher CCV frequency is strongly recommended. ALSLG-FC typically analyzes a CCV every 10 samples in order to reduce the amount of repeat injections necessary in the event of CCV failure.

Calibration is verified when all compounds are ≤20%D, when calculated as shown below:

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

If a compound shows *elevated* response (> 20%D) and is not detected in any samples associated with the CCV, re-analysis of those samples are not necessary. If a compound shows *low* response (> 20%D) and was not detected in the samples associated with the CCV, reinjection is necessary to ensure that a false negative

result is not reported.

If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.6 RETENTION TIME WINDOWS

Retention Time Windows (RTWs) are established by analyzing replicates (typically three injections) of a mid-level standard containing all single and multi-component analytes, non-consecutively, over a 72-hour period each time a new column is installed. The standard deviation of these analyses is calculated based on the absolute retention time yielded for each component. Each component's RTW is defined as the mean retention time $\pm 3\sigma$ such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

RTWs should be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the beginning CCV when samples are not directly preceded by an initial calibration. Sample matrices may cause drift that requires further Analyst interpretation. In the chromatography data system, RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system. See Appendix I for chromatographic interpretation examples.

8.7 SAMPLE ANALYSIS, CALCULATIONS AND REPORTING

A constant volume, generally 1µL of each standard, blank, QC or field sample extract is directly injected into the GC via the automated injector. Sample extracts are diluted to maintain response within the linear range when necessary. All prepared extracts contain the surrogate (see Section 9). Extract concentration and sample concentration are determined as discussed below.

8.7.1 Note that ALSLG-FC employs a sample splitter that facilitates simultaneous dual column injections; therefore, both columns are calibrated in the same manner and either column may serve as the column for quantitation.

8.7.2 The tentative identification of an analyte occurs when a peak from a concentrated sample extract falls within the RTW of one column. If the retention time of the analyte falls within its RTW on the second column, the analyte's presence has been confirmed. Quantitation is calculated from both column responses and the best result is reported. The analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the primary quantitation column for each analyte detected and reported. If results from both columns are comparable, the higher concentration is reported.

8.7.3 Multi-response compounds (e.g., toxaphene, chlordane) are identified through pattern recognition. Because samples may contain more than one multi-component analyte of interest and/or contain significantly weathered compounds, analyst expertise is crucial to the identification and quantitation of multi-response target compounds.

For multi-component analytes, four to eight peaks are used for identification and quantitation depending upon how many peaks are clearly defined. The same selected peaks ***must*** be consistently used for quantitation between the standard and sample set.

8.7.4 Extract concentration is calculated using the following equation:

$$\text{extract conc. (ng/mL)} = \frac{(\text{area} - \text{intercept})}{\text{slope}}$$

8.7.5 Sample concentration is calculated using the following equations:

$$\text{liquid sample conc. (ng/mL)} = \frac{(\text{extract conc.})(\text{extract volume})(\text{D})}{\text{sample volume}}$$

where:

extract conc. = ng/mL
extract vol. = mL
sample volume = mL
D = dilution factor (if applicable)

$$\text{solid sample conc. (ng/g)} = \frac{(\text{extract conc.})(\text{extract volume})(\text{D})}{\text{dry weight of sample}}$$

where:

extract conc. = ng/mL
extract vol. = mL
D = dilution factor (if applicable)
dry weight of sample = g and is the product of the weight extracted multiplied by the fraction solids in the sample.

8.7.6 If the dual column results for any analyte exceed 40% Relative Percent Difference (RPD; see calculation below), then it is necessary to investigate possible high bias of the greatest result by checking the chromatogram for apparent interferences and to check both results for appropriate integration. If no interference is evident, the highest result that is properly integrated and quantitated is reported. The elevated RPD is also discussed in the data package narrative or flagged in accord with the LIMS program specification.

$$RPD = \left[\frac{(concentration\ sample - concentration\ duplicate)}{1/2(concentration\ sample + concentration\ duplicate)} \right](100)$$

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

For this method, an analysis batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specification for additional or alternative requirements.

9.2 BLANKS

Method blanks are aliquots of matrix (i.e., organic-free water for liquids analyses; Ottawa sand for solids analyses) that have been prepared and analyzed in the same manner as the associated field samples. To be acceptable, concentrations of analytes of interest detected (if any) in the MB must be below the analyte reporting limit, or as otherwise specified in the LIMS program specification. If this criterion is not met, analyses should be halted and the source of the contamination found and corrected.

A reagent or instrument blank is an injection of solvent analyzed to demonstrate that the analytical system is free from contamination. These blanks are typically analyzed following extremely contaminated samples.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percen**t** recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this analysis, either a field sample containing target compound contamination may be analyzed in duplicate (DUP), or the laboratory control sample (LCSD) or matrix spike analysis (MSD) can be performed in duplicate. The results of the duplicate analyses are evaluated in terms of RPD (calculation shown previously). See QC Table for evaluation criteria.

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. See QC Table for evaluation criteria. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \frac{A_{found} - A_{sample}}{A_{target}} \times 100$$

where:

A_{found} = Calculated analyte concentration in the MS or MSD sample

A_{sample} = Calculated analyte concentration in the unspiked field sample

A_{target} = The target (anticipated) concentration of the added analyte spike

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation will be made in the data package narrative.

9.6 SURROGATE RECOVERY AND ACCEPTANCE CRITERIA

The two surrogates (SUR) used for this procedure are suggested in SW8081. Both surrogates are added to all field and quality control samples prior to extraction; recovery is calculated per the recovery formula shown previously for the LCS. The two surrogates used were selected because they respond in a similar manner as the target compounds respond at the detector. Additionally these surrogates are not similar enough chemically to the target compounds to co-elute with the single component targets, nor do they suffer interferences from the multiple component targets. Tetrachloro-m-xylene (TCMX) elutes before any of the target compounds, and decachloro-biphenyl (DCB) elutes after all of the target compounds. However, because the surrogates are not deuterated analogs of targets as in GC/MS methods, they are not extracted with exactly the same efficiencies as the target compounds. Therefore, surrogate recovery problems may not be representative of target analyte recoveries.

Heavy co-extractive non-target compounds generally do not interfere with TCMX; light co-extractive non-target compounds generally do not interfere with DCB. However, some samples may produce matrix effects that cause surrogate recovery to be high or low; because of high concentrations of target and/or non-target compounds, quantification of the surrogates may even be precluded in some

samples. Muddy aqueous samples, for example, generally adsorb DCB after spiking and limit recovery to a few percent. High concentrations of heavy hydrocarbons in soils oftentimes have a similar matrix effect on DCB recovery.

The extraction process itself can have an effect on surrogate recovery. An example of this process-caused effect is use of Method SW3520 for extraction of aqueous samples and associated "low" recoveries of DCB. DCB is a heavy molecule and very hydrophobic. When spiked into water, this compound tends to rapidly adsorb to particulates at the liquid-liquid interface and thus exhibits a low recovery.

For the reasons listed above, ALSLG-FC does not view the evaluation of surrogate recovery in this procedure to be a straightforward process. Therefore, the following guidance for evaluating surrogate recovery is observed:

- Evaluate and report the recovery of both surrogates. When one or both surrogates are within laboratory control limits, the process is considered to be in control and no further action is taken (unless additional measures are stipulated in the LIMS program specification.

- When, due to elevated target concentrations, an extract requires a dilution of greater than 5X, the surrogate recoveries are not controlled; no further action is taken.

- When both surrogates are outside of laboratory control limits (or other limits specified in the LIMS program specification), the extract is re-injected to assure that instrument error was not the cause. If after re-injection the recoveries of both surrogates remain out of control, then re-extraction and re-analysis may be performed as directed by the client. A non-conformance report (NCR; SOP 928) to document the problems is required.

This process of evaluating surrogate recovery is based on several methods and guidance documents and has evolved in particular from Method SW8080 guidance as well as from the National Functional Guidelines for Data Review.

9.7 A METHOD DETECTION LIMIT (MDL) STUDY shall consist of the analysis of a minimum of seven replicate analyses for a target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at a minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM THE METHODS

10.1 This SOP meets the requirements of Method SW8081A and B. Note that ALSLG-FC analyzes a breakdown check every 24hrs, not every 12hrs.

10.2 Deviations from Method EPA 608

Because samples from several sites are usually batched together, only one spiking

level is used for each compound. It is impractical to match each compound's spike amount with the amount of the compound in the samples chosen for spiking and also matching the spike amount to the appropriate regulatory level for each compound. This difference must be stated in the data package narrative that accompanies each batch of samples.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), and when handling materials or equipment potentially contaminated with chemicals, or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 All flammable compounds must be kept away from ignition sources.

11.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.6 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport. The cylinder must be stored capped and secured at all times.

11.2 WASTE DISPOSAL

11.2.1 Any hexane or other nonhalogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste.

11.2.2 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.3 The extract vials, associated extracts, and any PCB contaminated debris that may contain PCBs in excess of 50ppm shall be disposed of intact in the PCB Debris Waste.

11.2.4 All empty solvent bottles are disposed of appropriately. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/5/06: Strengthened LIMS program specification references, analytical columns and consumables used, breakdown check and ICV concentrations, and dual column interpretation. Added DOCUMENT REVISION HISTORY.

3/19/09: Added methoxychlor comment to INTERFERENCES Section (4.6). Added reference to SOP 016 detector leak checks performance semi-annually to Section 8.2. Updated calibration discussion in Section 8.3.3, and CCV discussion in Section 8.5. Section 8.6 RTW discussion was also updated. Method references were updated to include SW8081B and 8000C (QC criteria were updated accordingly). Included in DEVIATIONS 10.1 that ALSLG-FC analyzes a breakdown check every 24hrs, not every 12hrs.

Analytical Method: SW8081, EPA 608	**Parameter:** Organochlorine Pesticides		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point; all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, use mean RFs and CFs to quantitate. If RSD >20% , calculate linear regression (not forced through origin); use for quantitation if coefficient of determination (r^2) is ≥ 0.990 or calculate quadratic regression (minimum of six points required); use for quantitation if COD (r^2) ≥0.990	Evaluate/correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Endrin and DDT Breakdown Check; approx. midpoint of calibration	Daily prior to calibration verification	If ≤15% analyses may proceed.	Perform GC maintenance (e.g., change liner, clip column, inject primer, etc.); recalibrate.
Initial Calibration Verification (ICV); second source	After each initial calibration	≤20%D of each compound or as otherwise specified in applicable LIMS program specification	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); first source	Brackets each set of 20 field sample analyses (standard practice is every 10 samples injections)	≤20%D of each compound or as otherwise specified in applicable LIMS program specification	Evaluate/correct instrument malfunction as needed (e.g., remove 1 meter from the guard column of the GC, prepare a new standard); reanalyze. - If CCV still non-compliant, recalibrate using a new curve. Samples analyzed after a failed CCV will be reanalyzed. - if target(s) in CCV fails high (>20%) and target is not present in samples, re-analyses of samples are not necessary. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW)	Whenever a new column is installed; based on at least 3	Column and compound specific. Window is ±3x the standard deviation of the 3-injection average	If SD=zero, then either do additional injections or use a default SD of 0.01 minutes. Experience of analyst weighs heavily in

	given matrix		narrative.
Matrix Spike Duplicate (MSD) or Duplicate	1 per batch of samples, not to exceed 20 samples of a given matrix.	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits.	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). If no errors are found and, if analyzed, LCSD RPD is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Surrogate Spike	All extractions including field and laboratory QC samples.	See laboratory limits; recoveries should be within current limits for one or both surrogates; alternative criteria as defined in the LIMS program specifications may apply.	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with both surrogate recoveries outside the recovery limits, with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if both surrogate recoveries in the associated MB are not within limits, and the samples are within the holding time, then re-extract and reanalyze all associated samples. - if samples are outside the holding time, then contact the PM via an NCR. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration.
Method Detection Limit (MDL) Study	As needed and at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If `criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

Appendix I
Chlorinated Pesticide Data Interpretation Examples

- The presence of multi-component target analytes, such as toxaphene and/or chlordane, or non-target analytes such as Aroclors, in a sample may interfere with proper identification of target analytes by retention time and may cause false positives on both columns. Typically, the presence of either Aroclor 1254 or Aroclor 1260 result in peaks on both columns that are RT matches (potential false positives) for 4,4'-DDT. Aroclor 1254 also results in peaks on both columns that are RT matches for dieldrin. When either of these Aroclors is observed or suspected, the analyst may need to inject the appropriate Aroclor standard in order to better interpret the data with respect to presence or absence of single component pesticides.

- The retention times of surrogates in each extract injected provide useful information about the effects of sample matrices on retention times during each analysis. The surrogates used for this procedure have very early and very late retention times compared to the target analytes. If the observed TCMX and DCB retention times in sample analysis are the same as in bracketing CCVs, then it can be assumed that there is little or no matrix effect on the RT of target analytes. If, for example, DCB is 0.01 minutes later in a sample analysis than in surrounding calibration verifications, then the analyst may assume that late-eluting targets may also be eluting slightly later, and use this observation to assist with peak identification.

- Retention time difference between columns can also be used as an aid to identification. If both surrogates in a sample have the equivalent RTs to nearby standards and, for example, heptachlor is 0.03 minutes early on column 1 and 0.02 minutes late on column 2, then the analyst may decide that heptachlor is not confirmed as present and to not report heptachlor based on the relative retention time differences.

- The retention times and peak shapes of analytes in matrix spikes may be used as an aid to the analyst in identification in similar matrix samples. If endrin, for example, is identified on both columns and is 0.03 minutes later in the MS/MSD than in nearby calibration verifications, and this is consistent with other late-eluting peak RTs in the MS/MSD, then the analyst should use this information in evaluating and identifying targets in samples of similar matrix. If a sample has a peak that is within the RT window for example at 12.01 (column 1) and 13.07 (column 2), but the matrix spikes have peaks at 11.99 and 13.04, and both show evidence of a shoulder on the main peak, and the shoulder is on the later eluting side of the main peak, the analyst may document that the RT match appears to be a false positive match and not report the target as confirmed.

- The presence of alpha- and gamma-chlordane in a sample is a primary indicator of the presence of chlordane even if little or no pattern can be observed due to low concentrations of the technical mixture. ALSLG-FC does not analyze for individual components of toxaphene, so pattern recognition of toxaphene is the only mechanism of identifying this multi-component analyte. Weathered chlordane or toxaphene can produce patterns that are not good matches to fresh standards. Also, several producers manufactured multi-component pesticides, so patterns may not be identical between sources. The presence of moderate to high concentrations of single component pesticides such as 4,4'-DDT and its degradation products can also make pattern recognition of toxaphene or chlordane more difficult in real samples than in standards. Analyst experience is essential in properly identifying and quantifying such complex mixtures. For multi-component analytes, four to eight peaks are used for identification/quantitation, depending upon how many peaks are clearly defined. The same selected peaks must be consistently used for quantitation between the standard and sample set.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 404 REVISION 15

TITLE: **ANALYSIS OF NITROAROMATICS AND NITROAMINES (EXPLOSIVES RESIDUES) BY HPLC -- METHOD SW8330**

FORMS: **410 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8-13-07

QUALITY ASSURANCE MANAGER _____ DATE 8/12/07

LABORATORY MANAGER _____ DATE 8-13-07

HISTORY: Rev1, 1/28/92; Rev2, PCN #42, 12/17/93; Rev3, PCN #78, 1/10/94; Rev4, PCN #336, 1/23/95; Rev5, PCN #465, 4/24/95; Rev6, PCN #470, 8/10/95; Rev7, 1/23/96; Rev8, 9/21/99; Rev9, 3/6/02; Rev10, 3/26/03; Rev11, 4/16/04; Rev12, 3/13/06; Rev13, 7/24/06; Rev14, 2/8/07; Rev15, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references – SW-846 Method 8330, are used to determine the concentration of certain nitroaromatics and nitroamines (i.e., explosives residues) in aqueous and solid matrices. The following compounds typically comprise Paragon's target analyte list:

HMX	4-Amino-2,6-Dinitrotoluene
RDX	2-Amino-4,6-Dinitrotoluene
1,3,5-Trinitrobenzene	2,6-Dinitrotoluene
1,4-Dinitrobenzene	2,4-Dinitrotoluene
1,3-Dinitrobenzene	2-Nitrotoluene
Tetryl	4-Nitrotoluene
Nitrobenzene	3-Nitrotoluene
2,4,6-Trinitrotoluene	

Other compounds may be analyzed if successful method detection limit (MDL) and demonstration of capability (DOC) studies are performed.

2. SUMMARY

Aqueous and solid matrix samples are extracted and concentrated using appropriate methods (SOP 665). Aqueous samples can also be analyzed by direct injection if concentrations are expected to be high. An aliquot of sample or extract is injected into a high performance liquid chromatograph (HPLC) that contains a C_{18} reverse phase (primary) chromatography column and/or an ether-linked phenyl phase (ELP) confirmation column. Target analytes are separated under isocratic (i.e., constant composition) solvent flow conditions on the primary column, and under gradient conditions on the confirmation column. The target analytes are then detected by an

ultraviolet (UV) detector using absorbance at 254nm. Detected analyte responses are recorded and calculated by a data acquisition system using the external standard method of quantitation. Solid matrix sample results are normally reported on an air-dried basis.

NOTE: Aqueous samples for direct injection must first be diluted 1:1 with methanol (preferred if HMX is an important target analyte) or acetonitrile, and filtered before this technique is applied.

All procedures must be conducted with care as the analytes of interest present an explosive hazard.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Analyst to perform the analysis according to the SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret results acceptably to utilize this method. Demonstration of performance may include Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Paragon Project Manager is responsible for directing a chlorine residual check to be performed upon sample receipt as applicable.

3.5 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of the measures taken to correct those errors.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Contaminants in reagents, from glassware or within the analytical system may

cause the appearance of discrete artifacts or elevated baselines. Use of high purity reagents, scrupulously cleaned glassware (SOP 334) and frequent maintenance of the analytical system minimizes these interferences.

4.2 Interferences coextracted from the sample matrix will vary considerably from source to source. If observed, the presence of significant interferences is discussed in the laboratory data package narrative.

4.3 Tetryl may decompose in water and with exposure to heat. Aqueous samples expected to contain tetryl should not be exposed to temperatures above room temperature.

4.4 Degradation products of tetryl may interfere with the quantification of 2,4,6-trinitrotoluene or 4-amino-2,6-dinitrotoluene. The degradation products of tetryl may impact quantitation of these compounds if tetryl is present at high concentrations relative to 2,4,6-trinitrotoluene and 4-amino-2,6-dinitrotoluene.

5. APPARATUS AND MATERIALS

5.1 HPLC, AUTOSAMPLER, DETECTORS

A Hewlett-Packard (HP) 1050 or 1090 or equivalent HPLC equipped with:

- gradient pumping system
- system controller
- column oven
- ultraviolet detectors
- autosampler

5.2 DATA SYSTEM

Any data acquisition system capable of acquiring, storing and processing HPLC data (e.g., LC ChemStation™ or equivalent)

5.3 COLUMNS - Equivalent columns may also be used

C_{18} column:	Phenomenex Ultracarb™	#00G-0206-E0	(5µ ODS (20); 250x4.6mm)
ELPcolumn:	Synergi POLAR-RP 80Å	#00G-4336-E0	(4µ Polar RP; 250x4.6mm)
Guard Cartridge Holder:	#KJO-4282		
Cartridge:	Phenomenex (C_{18})	#AJO-4287	(5µ ODS; 4.0 x 3.0mm)
	Synergi (Polar RP)	#AJO-6076	(4.0 x 3.0mm)

5.4 MEASURING DEVICES

Microsyringes, Hamilton Precision™ or equivalent, various µL sizes

Volumetric flasks, Class A with ground glass or Teflon™ stoppers, 10-100mL sizes

5.5 CONSUMABLES

- solvent inlet filter frit-1/4", 4.6mm, 2µm, Restek #25071 or equivalent

- HPLC pump maintenance kit, Restek #25270 or equivalent
- autosampler maintenance kit, Restek #25259, or equivalent
- PTFE syringe filters, 0.45µm
- autosampler vials
- glass pipets, disposable

6. REAGENTS

6.1 SOLVENTS - **Only HPLC grade solvents with acceptable UV cutoffs may be used!**

6.1.1 methanol (CH_3OH; MeOH), Burdick & Jackson #230-4 or equivalent

6.1.2 acetonitrile (ACN; CH_3CN), Burdick & Jackson #015-4 or equivalent

6.2 REAGENTS

6.2.1 HPLC grade water, Burdick & Jackson #365-4 or equivalent

6.2.2 sulfuric acid (H_2SO_4), concentrated, EMD #SX1244-5 or equivalent

6.2.3 HPLC grade water-acidified (use to prepare working standards): Create by adding 1 drop of conc. H_2SO_4 to 500mL HPLC grade water

6.3 STANDARDS

6.3.1 All standards are maintained per PAR SOP 300. Target analyte stock standards, typically 1,000µg/mL, are generally purchased as certified solutions, but may be prepared from pure standard materials dissolved in MeOH or ACN. For neat standards or standard materials of a purity <95%, adjust concentration for purity when calculating standard concentration. Two independent sources (first, second) of target analyte stock standards are needed. A (non-target analyte) surrogate stock standard is also purchased. The surrogate used for this method is 1,4-dinitrobenzene.

Intermediate standards are made by diluting an appropriate aliquot of stock standard to a specific volume using acetonitrile, and are stored in Teflon™-sealed vials. Typically, a 50-fold dilution is made, thus creating intermediate standards at a concentration of 20µg/mL. First source target analyte materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards (used by the Organics Extraction Group). Second source target analyte materials are used to create the initial calibration verification (ICV) solution. Typically, 1.0mL of intermediate surrogate standard is added into each calibration check, field and quality control (QC) sample. Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

Unopened stock standards are valid until the manufacturer's expiration

date. Transfer remainders of opened stock standards to Teflon™-sealed vials for storage. All stock and intermediate standards are stored in the freezer (i.e., dark, ˉ10 to ˉ20°C). Opened stock or prepared intermediate standards expire 30 days from opening (preparation), or per the manufacturer's expiration date (whichever is sooner). Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

6.3.2 The intermediate target analyte standards are further diluted to create working standards. These working standards (ICAL, ICV, CCV) are prepared on the day of use, directly in analysis vials (µL injections), using portions of acidified water and acetonitrile as the diluents to create sufficient standard volume for analysis. The working standards must contain all target analytes and the surrogate. Calibration standards are documented in the analytical run log (Form 410). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.3.3 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are not generally chemically preserved and must be collected in amber glass containers (typically 1L) with Teflon™-lined lids. Samples must be maintained at 4±2°C and extracted within 7 days of collection. Dechlorination using sodium thiosulfate ($Na_2S_2O_3$) may be necessary at the time of sampling if water is known to contain residual chlorine as part of a treatment process. The Project Manager may designate the need for residual chlorine check of the sample upon receipt.

7.3 Solid samples are collected in glass containers with Teflon™-lined lids. Solid samples are not chemically preserved and must be maintained at 4±2°C. Exception: Solid sample aliquots in the process of being prepared for analysis are air-dried, prior to subsequent extraction. Solid samples must be extracted within 14 days of collection.

7.4 Extracts, from liquid or solid samples, must be maintained in the dark at 4±2°C and analyzed within 40 days of preparation.

8. PROCEDURE

8.1 TYPICAL HPLC RUN CONDITIONS

Column 1: C_{18} isocratic analysis conditions with wash gradient, below:

Flow Rate: 0.8mL/min flow
MP A: 45% H_2O (±1.5%)
MP B: 55% CH_3OH (±1.5%)
Column Temperature: 28°C
Injection Volume: 50-100µL injections (no change during acquisition)

Linear Gradient Elapsed Time (min)	MP A: Water (%)	MP B: Acetonitrile (ACN) (%)
0	55	45
27	55	45
27.5	80	20
31.5	80	20
32	55	45
35 (equilibration)	55	45

Column 2: ELP analysis conditions (or as suitable):

Flow Rate: 1.6mL/min flow
Column Temperature: 32.0°C
Injection Volume: 50-100µL injections

Linear Gradient Elapsed Time (min)	MP A: Water (%)	MP B: Acetonitrile (ACN) (%)
0	70	30
27	45	55
30	70	30
35 (equilibration)	70	30

8.2 ROUTINE MAINTENANCE and PRE-RUN CHECK

Prior to analyzing samples or establishing calibration curves, the following suggested maintenance can be performed to aid in achieving more consistent results:

- Change the column frits as needed (i.e., if pressure increase is observed).
- Change the cartridge on the guard column as necessary (i.e., pressure increase or poor chromatography).
- Install fresh HPLC water for every run.
- Restart the computer and instrument before starting equilibration and analysis.

- Minimize air currents blowing on the instrument and vials loaded on the autosampler tray.
- Replace lamps at 2yr or upon observation of degraded signal.
- Major repairs on contract (by Full Spectrum or equivalent).
- Ensure that instrument is equilibrated and retention times have stabilized; instrument may be primed with one or more injections of the CCV solution prior to initiation of the CCV for the acquisition sequence.

8.3 INITIAL CALIBRATION

8.3.1 Set pump at flow rate used for the column in use. Turn on the detector lamp. Allow the HPLC system to equilibrate for a minimum of 15min.

8.3.2 Prepare a minimum of 5 concentrations of calibration standards (typically 6 are used) as shown below in Table 1 or as required for each sample set to be analyzed. The purpose of the initial calibration (ICAL) is to define the linear range of the detector. The ICAL can be used for analysis of both soil or water extracts. Each ICAL standard must include all target analytes and the surrogate. The lowest standard's concentration standard shall be at or below the reporting limit (RL) of each analyte. Create calibration standards by diluting aliquots of the first source intermediate calibration standard using an acetonitrile/acidified water mix. The mid-range calibration standard is used for continuing calibration verification (CCV).

TABLE 1
CALIBRATION STANDARDS

ACN (µL)	Acidified HPLC H_2O (µL)	5µg/mL Intermediate (µL)	Final Conc. (µg/mL)
0	500	500	2.5
300	500	200	1.0
400	500	100	0.5
480	500	20	0.1
495	500	5	0.025
498	500	2	0.01
400 CCV	500	100	0.5
480 ICV	500	20	0.1

8.3.3 Inject an appropriate volume (50µL) of each ICAL standard into the HPLC and analyze. Alternatively, a 100µL injection may be used for

all blank, standard, quality control and field sample injections. The data system accomplishes quantitation via the external standard method (i.e., area responses are tabulated against the concentration injected). Analyte Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{Peak Area}}{\text{Concentration of Analyte}}$$

If the CFs over the working range of the detector are constant (i.e., $\leq$20% RSD), then response can be assumed to be invariant (linear through zero) and the average (mean) CF may be used to quantitate sample content.

Relative Standard Deviation (RSD) is calculated as:

$$\text{RSD (\%)} = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean response factor}} \right)(100)$$

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first (minimum of 5 ICAL points used, r) or second (minimum of 6 ICAL points used, r^2) order regression curve fit that does not pass through zero (e.g., least squares method) may be constructed. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000B. A quadratic regression should not be used to compensate for detector saturation. Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

If a first order regression fit is applied, the correlation coefficient (r) value yielded must be $\geq$0.995. If a second order regression fit is applied, the coefficient of determination (COD, r^2 value) yielded must be $\geq$0.99. Note that the curve fit value expresses "goodness of fit", with perfect fit being a value of 1.0.

If the curve fit value does not meet criteria, check that the calibration standards were prepared properly, reanalyze and generate a new initial calibration curve.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The acceptance criteria for the ICV is the same as for the CCV (described below). If the control criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new

initial calibration must be generated. See QC Summary Table for further details.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when responses for all analytes are within $\leq$15%. If a CCV does not meet acceptance criteria, reanalyze the CCV. See QC Summary Table for further details and corrective action to be taken should the CCV still fail.

So long as CCV analyses yield compliant results, and other QC samples are analyzed as required, the series of ten sample analyses bracketed before and after by successful CCV analyses may continue as long as the reserve of solvents lasts.

8.6 RETENTION TIME WINDOWS

For chromatographic methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used to compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (σ) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time $\pm 3\sigma$, such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time shifts). Sample matrices may cause RT differences that require further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system

8.7 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)

The calibration of the analytical system is verified. A constant volume, generally

50 or 100uL of each standard, blank, QC or field sample extract is injected into the HPLC via the automated injector. All prepared extracts contain the surrogate (see Section 9). Sample extracts are diluted to maintain response within the linear range when necessary. Note that where sample concentrations are expected to be significant enough, filtered aqueous sample aliquots may be directly injected into the HPLC. Allow the HPLC system to equilibrate after each injection/analysis.

8.7.1 Tentative identification occurs when a peak's response falls within the RTW of the C_{18} column. Confirmation occurs when the peak's response also falls within the RTW on the ELP confirmation column. Note that per LIMS program specification, diode array detection spectral confirmation may also be used.

8.7.1 Sample concentration may be calculated using the average calibration factor or using the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

Average CF:

$$\text{Concentration}_{(ug/L,\ ug/kg)} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(V_s \text{ or } W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor

V_s or W_s = volume or weight of sample extracted (mL or g)

Linear Curve Equation:

$$x = \frac{(y - b)\,(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte in ng/mL, ng/g (equal to ug/L, ug/Kg)

y = analyte instrument response (area units)

b = calculated intercept (area units)

m = calculated slope of the line (area units/conc. units-ng/mL)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples of like matrix that is associated with one unique set of QC samples and processed together as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS) and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Check LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method blanks (MBs) are aliquots of matrix (i.e., HPLC water for liquid analyses; Ottawa sand for solid analyses) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is processed, or there is a change in reagents, an MB must be prepared. Concentrations of target analytes, if any, must be less than the analyte reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this requirement is not met, analyses must be halted and the source of the contamination found and corrected. See also QC Table.

As the analyst deems necessary, aliquots of solvent may be injected to clean the analytical system and demonstrate that it is free from contamination.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

See QC Table for evaluation criteria.

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical

results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below:

$$\text{RPD} = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

See QC Table for evaluation criteria.

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%\text{R} = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

See QC Table for evaluation criteria.

9.6 SURROGATE RECOVERY AND ACCEPTANCE CRITERIA

Paragon uses the compound 1,4-dinitrobenzene as the surrogate for this method. Surrogates are selected for chemical structure and detection characteristics that are similar to the target analytes, but not so much so that it co-elutes with any of the single component targets. It should be noted, however, that because the surrogate is not a deuterated analog of a target analyte, as in GC/MS methods, it is not extracted with exactly the same efficiency as the target compounds. Therefore, surrogate recovery problems are not entirely representative of target analyte recoveries.

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. If the recovery is outside QC limits, the

sample is reanalyzed to verify that analytical error was not the problem. If after re-injection the recovery is still out-of-control, initiate an NCR (SOP 928) to consult with the Project Manager (and client as needed), and apply the decided upon action.

9.7 A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses for each target analyte at a concentration level near to the capabilities of the method. The MDL study should be performed as needed, at a minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW8330. There are no known deviations from the method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 ***Samples containing explosive material may under no circumstances be heated in any fashion (e.g., boiling a solution; drying in an oven).***

11.1.2 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.3 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.4 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.5 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.6 All flammable compounds must be kept away from ignition sources.

11.1.7 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Any rinse waters used for rinsing syringes or other devices prior to

sample contact may be disposed of in the Aqueous Lab Waste.

11.2.2 The ACN-Water HPLC waste may be discarded into the ACN Waste Stream container.

11.2.3 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.4 The extract vials, associated extracts, and any PCB-contaminated debris that may contain PCBs in excess of 50ppm, shall be disposed of intact in the PCB Debris Waste.

11.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be removed or defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/23/06: LIMS program specification references strengthened; analytical columns used clarified; consumables list added; standards discussion revamped storage temperatures confirmed to reflect actual practice. DOCUMENT REVISION HISTORY Section added.

2/8/07: Format updated. References to RFs changed to CFs. STANDARDS section updated, ICV added to standards table. Calculations updated.

8/12/07: Calibration discussion further clarified, Section 8.3.3 and QC Table.

Analytical Method: SW8330	**Parameter:** Nitroaromatics and Nitroamines by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
Initial Calibration (ICAL); minimum 5-points, all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitate If RSDs over calibrated range exceed 20%, first order linear regression (using a minimum of 5 ICAL points) may be applied; $r \geq 0.995$ Higher order regression fits may be applied if more than 6 ICAL points are used; $r^2 \geq 0.99$	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Initial Calibration Verification (ICV); conc. not equal to midpoint of calibration curve; second source	After each ICAL	If ≤15%, analyses may proceed	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8330 allows bracketing of 20 field sample analyses)	If ≤15%, analyses may proceed	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of variation	Whenever a new column is installed	Column and compound specific. Window is ±3x the standard deviation of the 3-injection average for the respective column Note that the ICV and CCV analyses are also used to	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms (refer also to RT Shift).

Analytical Method: SW8330	**Parameter:** Nitroaromatics and Nitroamines by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
		monitor RT drift	
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per each preparation batch of ≤20 samples of like matrix	See laboratory oir other applicable limits; recoveries for spiked compounds must be within these limits	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the

Analytical Method: SW8330	**Parameter:** Nitroaromatics and Nitroamines by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
			samples are within the extraction holding time, then initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per batch, not to exceed 20 samples of like matrix	See laboratory or other applicable limits; recoveries for spiked compounds should be within these advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per batch , not to exceed 20 samples of like matrix	See Matrix Spike information above for MSD recoveries. RPDs should not exceed value specified in LIMS program specification (typically 20%)	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Surrogate Spike	All extractions including field and laboratory QC samples	See laboratory or other applicable limits; recoveries should be within these limits	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with surrogate recovery outside the QC limits with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if surrogate recovery in the associated MB and LCS is not within limits and the samples are

TITLE: **EXTRACTABLE PETROLEUM HYDROCARBONS ANALYSIS BY GAS CHROMATOGRAPHY (TEPH, DRO)**

FORMS: **531** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2.12.09

QUALITY ASSURANCE MANAGER _____ DATE 2/12/09

LABORATORY MANAGER _____ for KOC DATE 2/12/09

HISTORY: Rev0, 2/11/92; Rev1, PCN #243, 7/15/94; Rev2, 12/12/95; Rev3, 7/19/96; Rev4, 2/01/99; Rev5, 6/15/99; Rev6, 2/17/00; Rev7, 1/15/02; Rev8, 3/2/02; Rev9, 3/14/03; Rev10, 2/25/04; Rev11, 11/22/04; Rev12, 9/1/06; Rev13, 7/18/08; Rev14, 2/12/09.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the determination of extractable petroleum hydrocarbons in aqueous and solid matrices, using analysis by gas chromatograph (GC) with flame ionization detection (FID). This basic GC-FID technique is comparable to analysis protocols such as SW-846 Method SW8015B or D, Cal LUFT, and various State-specific protocols such as FL-PRO.

Note that the various analytical protocols may define the quantitated hydrocarbon range differently. For example, Method SW8015B defines the alkane range corresponding to diesel range organics (DRO) as approximately C_{10} to C_{28}. The FL-PRO method defines the extractable petroleum hydrocarbon range of interest as C_8 to C_{40}. The following substances can be analyzed using this method:

diesel #1	mineral spirits
aviation jet fuel (JP-4)	miscellaneous extractable petroleum products
diesel #2	Stoddard solvent
jet fuel (JP-5)	motor oil

Analyst expertise is crucial to this method as multiple petroleum hydrocarbon patterns may be present in a sample. Also, pattern responses in environmental samples may differ from textbook characterizations because of weathering. The alkane range of hydrocarbons present in a sample is reported to the client if concentrations are greater than or equal to the reporting limit (RL).

2. SUMMARY

Concentrated sample extracts prepared via SOP 603 (e.g., SW8015, FL-PRO) and SOP 626 (e.g., SW3510, Cal LUFT), are injected into a GC-FID chromatographic system that is temperature programmed. Detector responses are recorded by a data acquisition system to facilitate processing of data. The total peak area from the designated petroleum hydrocarbon retention time window (RTW) is measured using baseline-to-baseline

integration. Quantitation is accomplished using the external standard method of quantitation. Performance of a surrogate (s) is also monitored. RLs are set at or above the concentration of the low standard incorporated into the calibration curve. Typically, both the amount and type of petroleum hydrocarbon observed are reported.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 ALSLG-FC's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede ALSLG-FC's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the handling or analysis of the samples. Any discrepancies found must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Interference from phthalate esters can be minimized by using plastic-free solvent containers and scrupulously cleaned glassware (SOP 334) that has been kiln-baked or solvent-rinsed prior to use. Use of low phthalate gloves, such as nitrile, may also be important. These practices are important both in the field and in the laboratory.

4.2 Column compensation may be used because the chromatographic conditions employed for extractable petroleum hydrocarbon analysis can result in significant column bleed and a resultant rise in the baseline, it is appropriate to perform a

subtraction of the column bleed from the area of the petroleum hydrocarbon chromatogram. A column comparison is performed on a dry run (no solvent injected, temperature program executed) to determine the area caused by column bleed. This area is subsequently stored by the GC system and used to correct the baseline for all associated standards and samples. This procedure is acceptable provided that the column bleed is consistent throughout the run. A consistent dry run or blank baseline confirms proper column compensation.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH (GC), AUTOSAMPLER, DETECTORS
Hewlett Packard (HP) 7673 Automated Injection System; HP 5890 Series II GC equipped with a flame ionization detector (FID), or equivalents

NOTE: An FID must be used because FID response is essentially proportional to the number of carbons and can, therefore, provide a useful total area for evaluation of total hydrocarbon concentration; other detectors will not produce adequate quantitative results.

5.2 COLUMN - Equivalent columns may also be used

J&W Capillary Column:	DB-5.625 # 200-0056*	30m x 0.250mm ID, 0.5µm film thickness

*J&W columns are available through Agilent, part numbers are Agilent numbers

5.3 DATA SYSTEM
Agilent EzChrome Elite, or equivalent

5.4 GASES - **Use only high purity gases!**
Helium - carrier gas
Hydrogen - to supply FID
Compressed Air - to supply FID

5.5 MEASURING DEVICES

5.5.1 Microsyringes, Hamilton Precision™ or equivalent, 1µL-1.0mL sizes

5.5.2 Top loading balance, capable of weighing to ±0.01g

5.5.3 Volumetric flasks, Class A with ground glass stoppers, 10-500mL sizes

5.6 GC CONSUMABLES

- Vials and caps, National Scientific #C4011-1 and # C4000-51B or equivalents
- Inlet seal, dual Vespel ring, 0.8mm, Restek #21243 or equivalent
- Septa, 11mm, Restek #20365 or equivalent
- O-ring, graphite, 6.5mm, Restek #20299 or equivalent
- Liner, splitless, 4mm ID, Restek #20799-214.5 or equivalent
- Glass wool, deactivated, Restek #20789 or equivalent
- Gold seal, Restek #21306 or equivalent

- Vespel/graphite ferrule (detector), Restek #20221 or equivalent
- Compact Vespel/graphite ferrule, Restek #20249 or #20264 or equivalent
- Graphite ferrules, various sizes

6. REAGENTS

6.1 SOLVENTS - **Only chromatography grade or higher quality solvents may be used**

n-hexane, Burdick & Jackson #216-4 or equivalent

methanol, Burdick & Jackson #230-4 or equivalent

methylene chloride, Burdick & Jackson #299-4 or equivalent

6.2 STANDARDS

NOTE: All standards are maintained per PAR SOP 300

6.2.1 Target analyte stock standards are generally acquired through locally available commercial sources. Two independent sources (first, second) of target analyte stock standards are needed. To set correct integration windows, ALSLG-FC currently makes use of a TRPH Standard (Ultra-Scientific TRPH Florida Standard or equivalent) that contains even numbered alkanes C_8-C_{40}. Alternate standards may be used if required by the LIMS program specification.

A non-target analyte surrogate stock standard is also purchased. The surrogate used in this procedure is o-terphenyl.

Unopened stock standards are valid until the manufacturer's expiration date, and may be stored at room temperature in flame-sealed ampules, if recommended by the manufacturer. After ampules are opened, stock standards are transferred to Teflon™-lined septum seal vials for storage. Opened stock standards and prepared intermediate standards are stored in the freezer (dark, ˉ10 to ˉ20°C). Open stock standards expire 3 months from opening (preparation), or per the manufacturer's expiration date (whichever is sooner). Intermediate standards must be made monthly. Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

6.2.2 Intermediate standards are made by diluting an appropriate aliquot of stock standard to a specific volume using hexane, and are stored in Teflon™-sealed vials. First source target analyte materials are used to create calibration, continuing calibration verification (CCV) and quality control (QC) sample spike standards (used by the Organics Extraction Group). Second source target analyte materials are used to create the initial calibration verification (ICV) solution.

6.2.3 The intermediate target analyte standards are further diluted using an appropriate solvent (hexane) to create working standards. These working calibration/check standards (ICAL, ICV, CCV) are prepared

on the day of use and documented in the analytical run log (Form 531). They must contain all target analytes and the surrogate. A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.2.4 Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

6.2.5 All stock and intermediate standards are documented in ALSLG-FC's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials, and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples are collected in 1L amber-glass bottles with screw-top caps equipped with Teflon™ liners. Aqueous samples are usually preserved in the field immediately after sampling with the addition of enough hydrochloric acid (HCl) to adjust to pH<2. The samples must be maintained chilled (4±2°C).

7.3 Soil samples are collected in wide-mouth glass containers with Teflon™-lined lids. Samples are not chemically preserved and must be maintained chilled (4±2°C).

7.4 The holding time to extraction for aqueous extractable petroleum hydrocarbon samples is 7 days (unpreserved) or 14 days (preserved with HCl) from collection. The hold time to extraction for solid matrix extractable petroleum hydrocarbon samples is 14 days from collection. Consult the LIMS program specification as other hold times may be specified.

7.5 Extracts, from liquid or solid samples, must be maintained chilled (4±2°C) and analyzed within 40 days of preparation.

8. PROCEDURES

8.1 TYPICAL GC CONDITIONS

Note that conditions may be altered to improve resolution, or simplified if a single product, such as motor oil, is to be analyzed.

Carrier Gas Flow Rate:	3-5mL/min
FID H_2 Flow Rate:	30mL/min
FID Air Flow Rate:	350mL/min
Injector Temperature:	320°C

Initial Oven Temperature:	60°C for 3min
Oven Ramp:	17°C/min to 320°C
Hold:	320°C for 15min
FID Temperature:	320°C

8.2 CHROMATOGRAPHIC MAINTENANCE

8.2.1 Reagent blanks are an injection of solvent analyzed to show that the analytical system is free from contamination. They may be injected following samples of unusually high concentration to check the status of the analytical system and to facilitate re-equilibration of the system. Reagent blank results should be below the RL.

8.2.2 Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming.

8.2.3 Peak tailing for all components will be exacerbated by a dirty injector.

8.2.4 If the instrument has sat idle for a period of time, it may be primed with one or more injections of hexane prior to initiation of the acquisition sequence.

8.3 INITIAL CALIBRATION

8.3.1 Create multi-concentration level (i.e., spanning the calibration range) DRO, or other window-defining standard such as motor oil, using hexane or methylene chloride per methods SW8000C and SW8015D. Hexane is less volatile than methylene chloride, hence standards prepared in hexane are less prone to concentration. Each standard must contain the surrogate. A minimum of five concentration levels are required, typically seven standards are prepared, as shown below:

Level	Petroleum Hydrocarbon Concentration (µg/mL)	Surrogate Concentration (µg/mL)
7	5000	500
6	2500	250
5	1000	100
4	500	50
3	100	10
2	50	5
1	20	2

ICV	100	10
CCV	500	50

8.3.2 Typically 1µL of standard or field or QC sample extract is injected by automated injector for analysis. TEPH is identified by pattern recognition.

8.3.3 For each data file, quantitation is accomplished via the external standard method of quantitation using baseline-to-baseline integration across the hydrocarbon range of interest. The surrogate area is subtracted from the total area integrated in order to obtain the area associated with the injected extract.

8.3.4 A calibration factor (CF) for each standard is calculated as follows:

$$CF = \frac{\text{TEPH Area Total}}{\text{Concentration of TEPH Injected (mg/mL)}}$$

If the CFs over the working range of the detector are constant (i.e., ≤20% RSD), then response can be assumed to be invariant and the average (mean) CF may be used to quantitate sample content. Relative Standard Deviation (RSD) is calculated as:

$$\text{RSD (\%)} = \frac{\text{Standard Deviation (SD)}}{\text{Average (mean) CF}} \times 100$$

When RSD over the calibration range is >20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW8000C. However, a quadratic regression should not be used to compensate for detector saturation.

Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV

are identical to those of CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or near the midpoint of the initial calibration. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

NOTE: Method SW8015D specifies that the CCV must be analyzed at the beginning of each 12-hour shift (allows approximately 20 samples to be analyzed between CCVs). ALSLG-FC commonly analyzes 10 samples between CCVs to reduce the amount of repeat injections, should they be required.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when all compounds are within 20%D. If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed. So long as CCV analyses yield compliant results, and other QC samples are analyzed as required, the series of ten sample analyses bracketed before and after by successful CCV analyses may continue indefinitely.

NOTE: When analyzing samples by the Cal LUFT method, for California compliance reporting, the CCV criteria of $\pm$10%D **must** be observed (electronically controlled via the specific test code used in association with ALSLG-FC's LIMS program specification system).

8.6 RETENTION TIME WINDOWS

8.6.1 Evaluate bracketing standards and set the retention time window (RTW) to include the designated petroleum hydrocarbon pattern. The standard contains the even numbered aliphatic hydrocarbons from C_8 – C_{40}. The default window is typically set from C_{10} through C_{32}, and needs to be adjusted to meet project requirements.

8.6.2 RTWs are used to define the integration envelope for quantifying various products in samples. Peak area integration will begin

immediately prior to elution of the first chromatographic peak of interest and will stop after the last peak of interest.

8.6.3 The experience of the analyst weighs heavily in interpretation of the chromatogram. Environmental samples may contain more than one type of product, and loss of light end components may indicate weathering or poor extraction techniques.

8.7 SAMPLE ANALYSIS, IDENTIFICATION, CALCULATIONS, REPORTING

8.7.1 Prior to initiating acquisition, ensure that that there is an adequate supply of gases and rinse solvents to complete the run.

8.7.2 When necessary, sample extracts are diluted to maintain response within the linear range.

8.7.3 If the average CF is used for quantitation, the sample concentration is calculated using the following equation:

$$\text{Concentration}_{(\text{ug/L, ug/kg})} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(V_s \text{ or } W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor (area/concentration in mg/mL)

V_s or W_s = volume or weight of sample extracted (L or kg)

8.7.4 Sample concentration, in ppm (mg/L or mg/kg), is calculated using the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte (TEPH, ppm)

y = intercept for analyte instrument response (area)

b = calculated intercept (area)

m = calculated slope of the line (area/concentration in mg/mL)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (L or kg)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with

one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All QC samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specification for additional or alternative requirements.

9.2 BLANKS

MBs are aliquots of matrix (i.e., organic-free water for liquids, Ottawa sand for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the RL, or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and corrected.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

MSs consist of field samples into which known concentrations of target analytes are spiked and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. See QC Table for evaluation criteria. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS/MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate the MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 SURROGATE RECOVERY

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. See QC Table for evaluation criteria.

9.7 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicate analyses of an extractable petroleum hydrocarbon standard at a concentration level near the sensitivity limit of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of SW8015D; there are no known deviations from the method. Cal LUFT method criteria are also met with the following exception: Cal LUFT specifies a %D criteria of ±10% for daily calibration verification. ALSLG-FC defaults to the criteria listed in SW8015D of ±20% D, unless client or regulatory contractual needs dictate otherwise. ALSLG-FC notes that the SW-846 suggested carbon range for diesel (C_{10} to C_{28}) may be modified to meet our client's requirements.

11. SAFETY HAZARDS AND WASTE

11.1 SAFETY HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents

and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Any methanol, hexane or other nonhalogenated organic solvents that has not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste.

11.2.2 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

11.2.4 Any rinse waters used for rinsing syringes or other devices prior to contact with samples must be disposed of in the Aqueous Lab Waste.

11.2.5 Halogenated wastes (if any) are disposed of in the halogenated waste stream.

DOCUMENT REVISION HISTORY

9/1/06: LIMS program specification language strengthened. Calculations reformatted. DOCUMENT REVISION HISTORY section added.

7/18/08: Corrections to Section 2 SUMMARY made. Methanol is not used and was removed from the reagents list, Section 6. No technical revisions were made.

12/18/08: Section 8.6 amended to establish typical DRO quantitation range as C_{10}-C_{38}.

2/12/09: Changed Title, Sections 1 and 2, as needed throughout, and QC Table Method Reference header to indicate petroleum hydrocarbons more generically. Added SW8015D and FL-PRO to REFERENCES. Added Appendix A (FL-PRO).

Analytical Method: Extractable Petroleum Hydrocarbons by GC-FID	**Parameter:** Total Extractable Petroleum Hydrocarbons Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5-point, all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitate Calculate linear regression (not forced through origin); use for quantitation if coefficient of determination (r^2) ≥0.99 or Calculate quadratic regression (minimum of six points required); use for quantitation if COD ≥0.99	Evaluate/correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Initial Calibration Verification (ICV); conc. not equal conc. to midpoint of calibration curve; second source	After each ICAL	≤20%D of each compound	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8015B allows bracketing of 20 field sample analyses)	≤20%D of each compound **NOTE:** Cal LUFT method requirements state that analyses may continue only when CCV is ±10%D. Check the LIMS Project Specification to ensure that appropriate criteria are applied.	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. - Samples analyzed before and after a failed CCV (bracketing with acceptable calibration fails) must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV (bracketed by acceptable CCVs) will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition..
Retention Time Window (RTW); set to include the designated extractable petroleum	Whenever a new column is installed or if a new extractable petroleum hydrocarbon	Brackets appropriate hydrocarbon elution range Note that the ICV and CCV analyses are also used to	Perform system maintenance to correct drift. Experience of analyst weighs heavily in interpretation of chromatograms.

Analytical Method: Extractable Petroleum Hydrocarbons by GC-FID	**Parameter:** Total Extractable Petroleum Hydrocarbons Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
hydrocarbon reference standard	range is required	monitor RT drift	
Retention Time Shift; RT of pattern in CCV is evaluated against the midpoint of the ICAL or the preceding CCV	Each CCV; RT of analytes evaluated against the ICAL or preceding CCV to ensure that the designated extractable petroleum hydrocarbon range has not significantly shifted	Instrument performance supports accurate quantitation of TEPH	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition.
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be

Analytical Method: Extractable Petroleum Hydrocarbons by GC-FID	**Parameter:** Total Extractable Petroleum Hydrocarbons Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries RPDs should be within advisory limits	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Surrogate Spike	All field and laboratory QC samples	See laboratory limits; recoveries should be within current limits alternative criteria as defined in the LIMS program specifications may apply	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if surrogate recovery in the associated MB is not within limits and the samples are within the holding time, then re-extract and reanalyze all associated samples - if samples are beyond the holding time, then contact the PM via an

Analytical Method: Extractable Petroleum Hydrocarbons by GC-FID	**Parameter:** Total Extractable Petroleum Hydrocarbons Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			NCR. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration.
Method Detection Limit (MDL) Study	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

APPENDIX A

EXTRACTABLE PETROLEUM HYDROCARBON ANALYSIS VIA THE FL-PRO METHOD

1. SCOPE AND APPLICATION

SUMMARY

The procedural particulars given in this Appendix supercede the guidance given in the main body of SOP 406. The procedures depicted in this Appendix are applicable to the GC-FID analysis of aqueous and solid matrix sample extracts using the Florida Residual Petroleum Organic Method (FL-PRO).

The FL-PRO Method is designed to measure concentrations of extractable petroleum hydrocarbons in water and soil in the alkane range of C_8-C_{40}. Other organic compounds, including chlorinated hydrocarbons, phenols, and phthalate esters, are measurable by this procedure, thus the resultant EPH results include these compounds.

The MDL is approximately 0.1 mg/L for water, and 4 mg/kg for soil (each laboratory must establish a laboratory-specific MDL for all matrices prior to analyzing any sample).

2. RESPONSIBILITIES
INTERFERENCES
APPARATUS AND MATERIALS

Refer to SOP 406 main text.

3. REAGENTS, SOLVENTS, STANDARDS

Note that both the surrogate and spike standard is specific to this test. The surrogate standard contains o-terphenyl at 100ug/mL, and nonatriacontane at 600ug/mL (in acetone). [These concentrations are 2X those specified in the Method (Section 7.4.1), which directs the addition of 2mL surrogate solution. ALSLG-FC will add 1mL, therefore the doubling in concentration.]

The QC spike solution contains even-numbered straight-chain alkanes from C_8 to C_{40}. The water spiking solution should be 5000ug/mL Total PHS (Petroleum Hydrocarbon Standard), and the soil spike should be 3000ug/mL Total PHS. 1mL of spike will give the required concentrations in the sample.(Method Sections 7.4.3, 7.4.4). Acceptance criteria for surrogate, LCS, and MS recoveries are method criteria and can be found in the Method (Table 2, p.28), or the LIMS test code (see SOP 3.4 for a discussion of ALSLG-FC LIMS program specifications).

4. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

Certain sampling considerations apply, refer to Method for more details.
Water samples must be acidified to pH<2 with HCl or H_2SO_4.
All samples must be stored at 4±2°C until extraction.
Extraction must be performed within 7 days of collection for aqueous samples, and within 14 days of collection for solid samples.
All analyses must be performed within 40 days of extraction.

5. CALIBRATION

5.1. INSTRUMENT CONDITIONS

Recommended instrument conditions are given in Method Section 9.2.1. Other conditions may by used as long as satisfactory performance is achieved (C_8 must be resolved from the solvent front, and the surrogate must be separated from the petroleum hydrocarbon components). Refer to Method Sections 9.2.1 through 9.2.2.3 for further details.

5.2. RETENTION TIME WINDOWS (RTWs)

Method Sections 9.3.2.2 through 9.4.3 direct that RTWs must be established on each GC column by making 3 injections of the method standard throughout the course of a 72-hour period. The standard deviation of the absolute RTs for the two surrogates, and for the C_8 and C_{40} peaks are then calculated, and the RTW for individual peaks is established as the mean RT +/- 3 times the standard deviation. Instead, ALSLG-FC utilizes the results of the first daily CCV run prior to sample analysis, and establishes the hydrocarbon region of interest window as just prior to the RT of the first designated peak and just beyond the RT of the last designated peak of interest.

5.3. INITIAL CALIBRATION

5.3.1. For both qualifying (setting retention times) and quantifying, this Method (Section 3.2), uses a 17-component mix of (even numbered) straight-chain alkanes from C_8 thru C_{40} (ALSLG-FC already uses this standard for setting retention time window).

5.3.2. Although the Method (Section 7.4.3) states that surrogates are to be kept at constant concentration in the different ICAL points (50ug/mL for oTP and 300ug/mL for C_{39}), ALSLG-FC will vary their concentrations (like targets) in order to be able to quantitate surrogate recoveries in extracts that have to be diluted.

5.3.3. Note that a blank must be analyzed with the ICAL (Method Section 9.3.1). The blank may be analyzed before the ICAL to demonstrate that the system is free of interferences.

5.3.4. Per Method Section 9.3.1, integration should be continuous and encompass all peaks (excluding surrogates) beginning from a point just prior to elution of the C_8 peak and ending just subsequent to elution of the C_{40} peak.

5.3.5. Initial calibration may be by average calibration factor (%RSD must be **≤20%),** or linear regression (correlation coefficient, r, must be **≥0.995**). Note that although this Method (Sections 9.3.1.1 through 9.3.1.2) does not contain provision for a quadratic regression, ALSLG-FC may use a quadratic fit if it best represents the data (quadratic fit will NOT be used to compensate for detector saturation).

5.3.6. The Initial Calibration Verification (ICV) standard (2nd source), should be prepared at the midpoint of the curve, and must quantitate within **20%** of the expected value. (Method Section 9.3.1.3).

5.4. CONTINUING CALIBRATION

The Continuing Calibration Verification (CCV) standard should be prepared at the midpoint of the curve, and must quantitate within **25%** of the expected value. Although the Method (Sections 9.3.2; 9.3.2.1; 9.5.3) states that a CCV's failure to meet this criteria automatically necessitates analysis of a new ICAL, ALSLG-FC may analyze a 2nd CCV as a precaution against a bad injection in the case of the first (if the 2nd CCV passes critieria, analyses may continue).

RTs for the surrogates and C_8 and C_{40} should be within the established RTWs for these 4 compounds. The windows will be 'reset' on these four compounds, and the 'reset' windows will apply to all field, QC, and standard analyses in that analytical sequence. (see Method Section 9.3.2.2).

CCVs should be analyzed at the beginning and end of each analytical sequence. Additionally, a CCV should be analyzed every 10 field or QC samples (solvent blanks excluded). The concentration of the CCVs should vary, based on *expected* concentrations of target in the samples. At least one of the CCVs should be at a level 1 to 2 times the RL as a verification of sensitivity. (see Method Section 9.5.2).

6. ANALYSIS

Dilutions may be performed as necessary to put the chromatographic envelope within the linear range of the method (dependent in part upon column type, detector sensitivity and injection volume; typically 170-17,000ng on column of Total PHS). Each laboratory must establish and document the linear range for the instrument(s) in use. A Dilution Technique is specified, to be used for product or waste samples which are soluble in Methylene Chloride (refer to Method for further details).

Per Method Section 9.5.4, a dichloromethane blank must be run in every sequence to determine the area generated from normal baseline bleed. This blank is integrated in the same manner as standards and samples, and the calculated quantitation should be less than the MDL of the method.

Contamination by carryover can occur whenever high-level and low-level samples are analyzed sequentially. Whenever an unusually concentrated sample is encountered, it should be followed by an analysis of a solvent blank to check for instrument contamination.

7. QUALITY CONTROL

See Method (Table 2, p.28), or the LIMS test code.

8. DEVIATIONS FROM THE METHOD

No technical deviations.

9. HEALTH, SAFETY, AND WASTE DISPOSAL

See SOP 406 main text.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- SW8141A and EPA 614, are used to determine the concentrations of organophosphorous pesticides in extracts from liquid or solid matrices. Method SW8141A addresses liquid and solid matrices and Method EPA 614 addresses liquid matrices (municipal and industrial wastewater). Currently, Paragon analyzes the following compounds using this SOP:

Azinphos methyl	Merphos (including its degradation product)
Chlorpyrifos	Methyl parathion
Coumaphos	Mevinphos
Demeton (total o- and s-)	Naled
Diazinon	Phorate
Dichlorovos	Ronnel
Disulfoton	Tetrachlovinphos
Ethoprop	Tokuthion
Fensulfothion	Trichloronate
Fenthion	Sulprofos
Malathion	

Other compounds may be analyzed if successful method detection limit (MDL) and demonstration of capability (DOC) studies are performed.

2. SUMMARY

Samples are extracted and the extracts concentrated and solvent exchanged using appropriate Paragon Analytics SOPs (i.e., PAR 617, 625, 622, 607, 637). The extracts are injected into a gas chromatograph (GC) containing a sample splitter and two columns of varying selectivity (i.e., dissimilar RT elution properties). The target analytes are

separated in the columns and detected by two flame photometric detectors (FPDs). This chromatography system allows tentative identification by one column and confirmation by the other column to be performed simultaneously. Quantitation is performed using the best column for each analyte. The analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the primary quantitation column for each analyte detected and reported. If results from both columns are comparable, the highest result is reported.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon’s standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Use of flame photometric detectors in phosphorous mode will minimize interferences from materials that do not contain phosphorous. Method SW8141A states that elemental sulfur may interfere with the determination of certain organophosphorous compounds by flame photometric gas chromatography.

4.2 If a sulfur cleanup is employed, only the tetrabutylammonium (TBA)-sulfite option should be chosen, because copper may destroy organophosphorous pesticides. The stability of each analyte must be tested to ensure that the recovery from the TBA-sulfite cleanup step is not less than 85%.

4.3 Analytical difficulties encountered for target analytes include:

4.3.1 The water solubility of dichlorvos is 10g/L at 20°C and recovery may be poor from aqueous solutions.

4.3.2 Naled is converted to dichlorvos in water or by injection on column by debromination. This reaction may also occur during sample extraction and preparation. The extent of debromination will depend upon the nature of the matrix being analyzed. The analyst must consider the potential for debromination when naled is to be determined or when dichlorovos is detected.

4.3.3 Trichlorfon can rearrange by hydrodechlorination in acidic, neutral, or basic media to form dichlorvos and hydrochloric acid. If this method is to be used for the determination of organophosphates and the presence of trichlorfon is known, the analyst should be aware of the possibility of rearrangement to dichlorvos if dichlorovos is detected.

4.3.4 Demeton (Systox) is a mixture of two compounds - O, O-diethyl O- [2-(ethylthio) ethyl] phosphorothioate (demeton-O) and O, O-diethyl S-[2-(ethylthio) ethyl] phosphorothioate (demeton-S). Two peaks are observed in demeton standards. The two peaks correspond to the two isomers.

4.3.5 Merphos (tributyl phosphorotrithioite) is readily oxidized to its phosphorotrithioate (merphos oxone). Chromatographic analysis of merphos almost always results in two peaks (unoxidized Merphos elutes first). As the relative amounts of oxidation of the sample and the standard are probably different, quantitation based on the sum of both peaks is most appropriate.

4.3.6 Many analytes will degrade on reactive sites in the chromatographic system. Analysts must ensure that injectors and splitters are free from contamination. Columns should be installed and maintained properly.

4.4 Interferences may be caused by contaminants in solvents, reagents, glassware and other sample processing hardware that leads to discrete artifacts or elevated baselines in gas chromatograms. All these materials must be routinely demonstrated to be free from interferences under the condition of the analysis by analyzing reagent blanks with every batch of 20 or fewer field samples. Because

the FPD with P filter is an element-specific detector, the probability of non-target contamination is minimal.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH (GC), AUTOSAMPLER AND DETECTORS
Hewlett Packard (HP) 5890 Series II GC equipped with HP 7673A autosampler and dual FPD detectors (complete with accessories for on-column or split/splitless injection), or equivalents

5.2 CHROMATOGRAPHIC DATA ACQUISITION AND PROCESSING SYSTEM
Hewlett Packard ChemStation (Enviroquant™), or equivalent

5.3 COLUMNS - Equivalent columns may also be used

Restek Column: RTX-1 #10139 (30m x 0.32mm ID, 0.5µm film thickness)
Restek Column: RTX-OP Pesticides #11239 (30m x 0.32mm ID, 0.5µm film thickness)

5.4 GASES - ultra high purity (99.999%)
Helium - carrier gas
Nitrogen - make-up
Air -detector
Hydrogen -detector

5.5 MEASURING DEVICES
Syringes - 10µL-1000µL
Volumetric flasks, Class A with stoppers, 10mL-100mL

5.6 GC CONSUMABLES

- Vials - National Scientific C4011-1, or equivalent
- Caps - National Scientific C4000-51B, or equivalent
- Inlet Seals, dual Vespel ring - Restek 0.8mm #21243, or equivalent
- Septa, 11mm - Restek #20365 or equivalent
- O-ring, graphite, 6.5mm - Restek #20299, or equivalent
- O-ring, Viton - Restek #20377, or equivalent
- Liner, splitless, 4mm ID - Restek #20799-214.5, or equivalent
- Glass Wool, deactivated - Restek #20789, or equivalent
- Gold Seal - Restek #21306, or equivalent
- Universal Presstight Y - Restek #20469, or equivalent
- Vespel/Graphite Ferrule (detector) - Restek #20221, or equivalent
- Compact Vespel/Graphite Ferrule - Restek #20249, or equivalent
- Graphite Ferrules - various sizes

- Split Vent Trap (SW8081) - Agilent RDT-1023, or equivalent

6. REAGENTS

6.1 SOLVENTS - Only pesticide residue grade or equivalent may be used!

Hexane (C_6H_{14}), Burdick and Jackson #216-4, or equivalent

Methanol (CH_3OH, MeOH), Burdick and Jackson #230-4, or equivalent

6.2 STANDARDS

6.2.1 All standards are maintained per PAR SOP 300, which supercedes any guidance in this SOP. Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules, if recommended by the manufacturer. Generally after opening ampules, the standards for this procedure are stored in the freezer (-10--20°C), in PTFE-capped, or equivalent, vials. Opened stock standards and intermediate standards expire six months from opening (preparation) or per the manufacturer's expiration date (whichever is sooner). Standards may be replaced sooner if laboratory quality control (QC) analyses or other factors indicate deterioration.

6.2.2 Two independent sources of commercial stock standards are required for target analytes. These certified stock standards are purchased from suitable vendors. First source materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards. Second source materials are used to create the initial calibration verification (ICV) solution. A (non-target analyte) surrogate stock standard is also purchased. The surrogate used for this method is triphenylphosphate. Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

An appropriate volume of stock standard is diluted (in hexane) to a specific volume to create intermediate standards (the QC sample and surrogate spike standards, used by the Organics Extraction Group, are intermediate standards). The intermediate calibration standards are further diluted to volume using an appropriate solvent to create working standards. Working standards are prepared on the day of use and documented in the analytical run log (Form 530). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.2.3 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures

traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples must be collected in amber glass containers (generally 1000mL) with Teflon™-lined lids. Samples must be maintained at 4±2°C and extracted within 7 days of collection. Additionally, samples for EPA Method 614 may need to have pH adjusted to be between 5 and 8, using sodium hydroxide or sulfuric acid solution, upon receipt.

7.3 Solid samples are collected in wide-mouth glass containers with Teflon™-lined lids. Solid samples are not chemically preserved and must be maintained at 4±2°C. Solid samples must be extracted within 14 days of collection.

7.4 Extracts, from liquid or solid samples, must be maintained between 4±2°C and analyzed within 40 days of preparation.

8. PROCEDURE

8.1 TYPICAL GC OPERATING CONDITIONS

Carrier gas:	Helium
Hydrogen (detector fuel gas)	75mL/min
Air (detector oxidizing gas)	100mL/min
Injection port temperature	210°C
Injection volume	3µL
Detector temperatures	275°C
Initial oven temperature	105°C, hold 1min
Purge	On, 1min
Initial oven ramp	20°C/min to 185°C, hold 5min
2nd oven ramp	2°C/min to 205°C, hold 2min
3rd ramp	20°C/min to 300°C, hold 8.25min

8.2 CHROMATOGRAPHIC MAINTENANCE

8.2.1 Dual columns are connected using a press-fit Y-shaped glass splitter or a Y-shaped fused-silica connector. Reattach the columns after cleanly cutting off at least two loops from the injection port side of the column using a capillary cutting tool or scribe. The accumulation of high boiling residues may change split ratios between dual columns and thereby change calibration factors. Clip a loop from the guard column or replace as necessary.

8.2.2 Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Polar columns (including DB-210, DB-1701 and DB-608) are more prone to oxidation. Oxidized columns will exhibit baselines that rise rapidly during temperature programming.

8.2.3 Peak tailing for all components will be exacerbated by dirty injectors, dirty guard columns, and dirty glass Y's. Components such as fensulfothion, naled, methyl azinphos, dimethoate, and triphenyl phosphate are good indicators of system performance.

8.2.4 FPDs may be susceptible to stray light in the photomultiplier tube compartment. This stray light will decrease the sensitivity and the linearity of the detector. Analysts may check for leaks by initiating an analysis is a dark room and turning on the lights. A shift in the baseline indicates that light may be leaking into the photomultiplier tube compartment. Additional shielding should be applied to eliminate light leaks and minimize stray light interference.

8.2.5 FPDs use a flame to generate a response. Flow rates of air and hydrogen should be optimized to give a sensitive, but linear detector response for target analytes.

8.2.6 If the instrument has sat idle for a period of time, it may be primed with one or more injections of the CCV prior to analysis of the CCV for the acquisition sequence.

8.3 INITIAL CALIBRATION

8.3.1 Prepare a minimum of 5 concentrations of calibration standards (generally 8 or 9 are used), defining the linear range of the detector (SW8141A). Fewer calibration levels are required by EPA 614, but the use of 8 or 9 calibration levels is recommended. Create calibration standards by diluting aliquots of the intermediate calibration standard using hexane. Each ICAL standard must include all target analytes and the surrogate (at a level similar to the target analytes). The typical range of the calibration is 50ng/mL to 10000ng/mL. The lowest concentration standard shall be at a level at or below the reporting limit (RL) of each analyte. Not all compounds can be detected at the lowest levels of the calibration. Reporting limits are higher for compounds that do not respond well and cannot be detected in the lowest calibration standards. The mid-range calibration standard is used for continuing calibration verification (CCV). A typical calibration sequence and preparation steps are shown below in Table 1.

TABLE 1
CALIBRATION STANDARDS

Working Standard	Hexane (µL)	10,000 PPB Primary Standard (µL)	Standard Concentration (µg/L)
ICAL Level 1 (100%)	0	500	10,000
ICAL Level 2 (80%)	100	400	8,000
ICAL Level 3 (60%)	200	300	6,000
ICAL Level 4 (50%)	250	250	5,000
ICAL Level 5 (40%)	300	200	4,000
ICAL Level 6 (20%)	400	100	2,000
ICAL Level 7 (10%)	450	50	1,000
ICAL Level 8 (5%)	475	25	500
ICAL Level 9 (0.5%) (diazinon only)	995	5	50
2nd source ICV (40%)	300	200	4,000
CCV (50%)	250	250	5,000

8.3.2 Inject and analyze 1µL of each calibration standard. Each data file quantitation is accomplished via the external standard method of quantitation. Analyte Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{Selected Peak Areas}}{\text{Mass of Analyte Injected On-Column (ng)}}$$

If the CFs over the working range of the detector are constant (i.e., ≤20% RSD), then response can be assumed to be invariant and the average (mean) CF may be used to quantitate sample content. Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \frac{\text{Standard Deviation (SD)}}{\text{Average (mean) CF}} \times 100$$

When RSD over the calibration range is >20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The type of curve fit applied should be chosen to best represent the data. The regression calculation will yield a coefficient of determination (r2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit" with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of

6 points, following the guidelines in SW-846 Method 8000. A quadratic regression should not be used to compensate for detector saturation.

Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is near the midpoint of the initial calibration. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

NOTE: Method SW8141A allows 20 samples to be analyzed between CCVs. Paragon commonly analyzes 10 samples between CCVs to reduce the amount of repeat injections.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when all compounds are within 15%D or when the average of the %Ds for all compounds is $\leq$15% (individual compounds that exceeded 15% are noted in the data package narrative). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.6 RETENTION TIME WINDOWS

For GC methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used to compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a

mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (σ) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time $\pm 3\sigma$, such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time drift). Sample matrices may cause drift that requires further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system.

8.7 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)
A constant volume, generally 1µL of each standard, blank, QC or field sample extract is directly injected into the GC via the automated injector. Sample extracts are diluted to maintain response within the linear range when necessary. All prepared extracts contain the surrogate (see Section 9). Extract concentration and sample concentration are determined as discussed below.

8.7.1 Note that Paragon employs a sample splitter that facilitates simultaneous dual column injections; therefore, both columns are calibrated in the same manner and either column may serve as the column for quantitation.

8.7.2 Tentative identification occurs when a peak from a sample extract falls within the RTW of one column. If the peak also falls within the RTW of the second column, then the analyte's presence has been confirmed. Quantitation is calculated from both column responses and the best result is reported. The analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the quantitation column for each analyte detected and reported. If there are interferences present on one column, these need to be documented by printouts of that region of the chromatogram; the lower (i.e., other column's) results may be reported in this case. If results from both columns are of comparable quality, the higher concentration is reported (per SW8000).

8.7.3 Sample concentration is calculated using the equation of the linear curve generated during initial calibration (i.e., $y = mx + b$), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte

y = analyte instrument response (area units)

b = calculated intercept

m = calculated slope of the line

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

If the average CF is used for quantitation, the sample concentration is calculated using the following equation:

$$\text{Concentration}_{(ug/L,\ ug/kg)} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(V_s \text{ or } W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 METHOD BLANKS

MBs are aliquots of matrix (i.e., organic-free water for liquids, boiling chips for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and

corrected. As the analyst deems necessary, aliquots of solvent may be injected to clean the analytical system and demonstrate that it is free from contamination.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. See QC Table for evaluation criteria. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 SURROGATE RECOVERY

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. If the recovery is outside QC limits, the sample is reanalyzed to verify that analytical error was not the problem. If after re-injection the recovery is still out-of-control, initiate an NCR (SOP 928) to consult with the Project Manger (and client, as needed) and apply the decided upon action.

9.7 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM THE METHOD

10.1 This SOP meets the requirements of Method SW8141A. There are no known deviations from the method.

10.2 As of this writing, Paragon does not analyze wastewater samples for compliance monitoring purposes. Paragon extracts aqueous samples according to SW-846 protocol. Following are deviations from EPA Method 614:

10.2.1 EPA Method 614 prescribes preparation via a separatory funnel shakeout. Paragon extracts samples using continuous liquid-liquid extractors (CLLEs).

10.2.2 EPA Method 614 prescribes an extraction mixture of 15% methylene chloride and 85% hexane. Paragon extracts samples with methylene chloride only, per SW3520C protocol.

10.2.3 EPA Method 614 requires a relative standard deviation (RSD) of less than 10% in order to quantify samples by the average response factor. Paragon requires an RSD of less than 20% to quantify samples by the average response factor, per SW8141A protocol.

10.2.4 EPA Method 614 requires a percent difference of ±10% for continuing calibration standards. Paragon requires a percent difference of ±15%, per SW8141A protocol.

10.2.5 Paragon does not analyze the full list of compounds from EPA Method 614.

10.2.6 For Health & Safety and waste stream management reasons, Paragon does not support use of mercuric chloride as a preservative.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.5 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.2 WASTE DISPOSAL

11.2.1 Any hexane, acetone, or other nonhalogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste stream.

11.2.2 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.3 The extract vials, associated extracts, and any PCB contaminated debris that may contain PCBs in excess of 50ppm shall be disposed of intact in the PCB Debris Waste stream.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be removed or defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/18/06: LIMS program specification language strengthened. Dual column identification and interpretation of results clarified. List of consumables added. DOCUMENT REVISION HISTORY section added.

Analytical Method: SW8141A, EPA614	**Parameter:** Organophosphorous Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5-points, all analytes (SW 8141A); Methods EPA 614 does not require 5-points	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean CF to quantitate Calculate linear regression (not forced through origin); use for quantitation if correlation coefficient (r^2) ≥0.99 or Calculate quadratic regression (minimum of six points required); use for quantitation if COD ≥0.99	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Initial Calibration Verification (ICV); conc. not equal to midpoint of calibration curve; second source	After each ICAL	≤15%D of each compound or mean %D ≤15%	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8141A allows bracketing of 20 field sample analyses)	≤15%D of each compound or mean %D ≤15%	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of	Whenever a new column is installed	Column and compound specific Window is ±3x the standard deviation of the 3-injection average for the respective column	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms

Analytical Method: SW8141A, EPA614	**Parameter:** Organophosphorous Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
variation		Note that the ICV and CCV analyses are also used to monitor RT drift	(refer also to RT Shift).
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction

Analytical Method: SW8141A, EPA614	**Parameter:** Organophosphorous Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per batch, not to exceed 20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per batch not to exceed 20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits.	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Surrogate Spike	All extractions including field and laboratory QC samples	See laboratory limits; recoveries should be within current limits, alternative criteria as defined in the LIMS program specifications may apply	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if surrogate recovery in the

STANDARD OPERATING PROCEDURE 408 REVISION 11

TITLE: **ANALYSIS OF NITROGLYCERIN AND/OR PETN BY HPLC -- METHOD SW8332**

FORMS: **410 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8-13-07

QUALITY ASSURANCE MANAGER _____ DATE 8/12/07

LABORATORY MANAGER _____ DATE 8-13-07

HISTORY: Rev0, 2/21/92; Rev1, 2/18/93; Rev2, PCN #109, 4/4/94; Rev3, 9/21/99; Rev4, 3/2/02; Rev5, 3/28/03; Rev6, 4/16/04; Rev7, 7/26/05; Rev8, 3/13/06; Rev9, 8/24/06; Rev10, 2/8/07; Rev11, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references – SW-846 Method 8332 -- is used to determine the concentration of nitroglycerin (NG) and/or pentaerythrite tetranitrate (PETN) in liquid and solid matrices.

2. SUMMARY

Aqueous and solid matrix samples are extracted and concentrated using appropriate methods (SOP 665). Aqueous samples can also be analyzed by direct injection if concentrations are expected to be high. An aliquot of sample or extract is injected into a high performance liquid chromatograph (HPLC) containing a C_{18} (primary) column and an ether-linked phenyl phase (ELP) confirmation column. Target analytes are separated under isocratic (i.e., constant composition) solvent flow conditions on the primary column, and under gradient conditions on the confirmation column. The target analytes are then detected by an ultraviolet (UV) detector using absorbance at 215nm. Detected analyte responses are recorded and calculated by a data acquisition system using an external standard method of quantitation. Solid matrix sample results are normally reported on an air-dried basis.

NOTE: Aqueous samples for direct injection must first be diluted 1:1 with methanol or acetonitrile, and filtered before this technique is applied.

CAUTION: Use extreme care at all times. Target analytes present an explosive hazard. Nitroglycerin at concentrations over 1% is particularly unstable and explosion may be initiated by concussion or heat.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform this determination according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review or the performance of precision and accuracy tests.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Paragon Project Manager is responsible for directing a chlorine residual check to be performed upon sample receipt as applicable.

3.5 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.6 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Contaminants in reagents, from glassware or within the analytical system may cause the appearance of discrete artifacts or elevated baselines. Use of high purity reagents, scrupulously cleaned glassware (SOP 334) and frequent maintenance of the analytical system minimizes these interferences.

4.2 Interferences co-extracted from the sample matrix will vary considerably from source to source. If observed, the presence of significant interferences is discussed in the laboratory data package narrative.

5. APPARATUS AND MATERIALS

5.1 HPLC, AUTOSAMPLER, DETECTORS

A Hewlett-Packard (HP) 1050 or 1090 (or equivalent) HPLC equipped with:

- gradient pumping system
- system controller
- column oven

- ultraviolet detectors
- autosampler

5.2 DATA SYSTEM

Data acquisition system capable of acquiring, storing and processing HPLC data (e.g., LC ChemStation™ or equivalent).

5.3 COLUMNS - Equivalent suppliers, columns may also be used

C_{18} column:	Phenomenex Ultracarb™	#00G-0206-E0	(5µ ODS (20); 250x4.6mm)
ELPcolumn:	Synergi POLAR-RP 80Å	#00G-4336-E0	(4µ Polar RP; 250x4.6mm)
Guard Cartridge Holder:	#KJO-4282		
Cartridge:	Phenomenex (C_{18})	#AJO-4287	(5µ ODS; 4.0 x 3.0mm)
	Synergi (Polar RP)	#AJO-6076	(4.0 x 3.0mm)

5.4 MEASURING DEVICES

Microsyringes, Hamilton Precision™ or equivalent, various µL sizes
Volumetric flasks, Class A with ground glass or Teflon™ stoppers, 10-100mL sizes

5.5 CONSUMEABLES

- solvent inlet filter frit, 1/4", 4.6mm, 2µm, Restek #25071 or equivalent
- HPLC pump maintenance kit, Restek #25270 or equivalent
- autosampler maintenance kit, Restek #25259 or equivalent
- PTFE syringe filters, 0.45µm
- autosampler vials
- glass pipets, disposable

6. REAGENTS - Only HPLC grade solvents with acceptable UV cutoffs may be used!

6.1 SOLVENTS

6.1.1 methanol (CH_3OH; MeOH), Burdick & Jackson #230-4 or equivalent

6.1.2 acetonitrile (ACN; CH_3CN), Burdick & Jackson #015-4 or equivalent

6.2 REAGENTS

6.2.1 HPLC grade water, Burdick & Jackson #365-4 or equivalent

6.2.2 sulfuric acid (H_2SO_4), concentrated, EMD #SX1244-5 or equivalent

6.2.3 HPLC grade water-acidified (use to prepare working standards): Create by adding 1 drop of conc. H_2SO_4 to 500mL HPLC grade water

6.3 STANDARDS

6.3.1 All standards are maintained per PAR SOP 300. Target analyte stock standards, typically 1,000µg/mL, are generally purchased as certified solutions, but may be prepared from pure standard materials dissolved in MeOH or ACN. For neat standards or standard materials of a purity

<95%, adjust concentration for purity when calculating standard concentration. Two independent sources (first, second) of target analyte stock standards are needed. A (non-target analyte) surrogate stock standard is also purchased. The surrogate used for this method is 1,4-dinitrobenzene.

Intermediate standards are made by diluting an appropriate aliquot of stock standard to a specific volume using acetonitrile, and are stored in Teflon™-sealed vials. Typically, a 50-fold dilution is made, thus creating intermediate standards at a concentration of 20µg/mL. First source target analyte materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards (used by the Organics Extraction Group). Second source target analyte materials are used to create the initial calibration verification (ICV) solution. Typically, 1.0mL of intermediate surrogate standard is added into each calibration check, field and quality control (QC) sample. Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

Unopened stock standards are valid until the manufacturer's expiration date. Transfer remainders of opened stock standards to Teflon™-sealed vials for storage. All stock and intermediate standards are stored in the freezer (i.e., dark, ˉ10 to ˉ20°C). Opened stock or prepared intermediate standards expire 30 days from opening (preparation), or per the manufacturer's expiration date (whichever is sooner). Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

6.3.2 The intermediate target analyte standards are further diluted to create working standards. These working standards (ICAL, ICV, CCV) are prepared on the day of use, directly in analysis vials (µL injections), using portions of acidified water and acetonitrile as the diluents to create sufficient standard volume for analysis. The working standards must contain all target analytes and the surrogate. Calibration standards are documented in the analytical run log (Form 410). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.3.3 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are not generally chemically preserved and must be collected in amber glass containers (typically 1L) with Teflon™-lined lids. Samples must be maintained at 4±2°C and extracted within 7 days of collection. Dechlorination using sodium thiosulfate ($Na_2S_2O_3$) may be necessary at the time of sampling if water is known to contain residual chlorine. The Project Manager may designate the need for residual chlorine check of the sample upon receipt.

7.3 Solid samples are collected in glass containers with Teflon™-lined lids. Solid samples are not chemically preserved and must be maintained at 4±2°C. Exception: Solid sample aliquots in the process of being prepared for analysis are air-dried, prior to subsequent extraction. Solid samples must be extracted within 14 days of collection.

7.4 Extracts, from liquid or solid samples, must be maintained in the dark at 4±2°C and analyzed within 40 days of preparation.

8. PROCEDURE

8.1 TYPICAL HPLC CONDITIONS

Column 1: C_{18} isocratic analysis conditions with wash gradient, below:

Flow Rate:	0.8mL/min flow
MP A:	40% H_2O (±1.5%)
MP B:	60% CH_3OH (±1.5%)
Column Temperature:	28°C
Injection Volume:	50µL injections

Linear Gradient Elapsed Time (min)	MP A: Water (%)	MP B: MeOH (%)
0	40	60
21.5	30	70
23.5	30	70
25	40	60
28 (equilibration)	40	60

Column 2: ELP analysis conditions (or as suitable):

Flow Rate:	1.6mL/min
MP A	65% H_2O (±1.5%)
MP B	35% ACN (±1.5%)
Column Temperature:	30.0°C
Injection Volume:	50µL injections

Linear Gradient Elapsed Time (min)	MP A: Water (%)	MP B: Acetonitrile (ACN) (%)
0	65	35
21	60	40
22	35	65
23 (equilibration)	35	65

8.2 CHROMATOGRAPHIC MAINTENANCE

Prior to analyzing samples or establishing calibration curves, the following suggested maintenance might be performed to aid in achieving more consistent results:

- Change the column frits as needed (i.e., control pressure).
- Change the cartridge on the guard column as necessary (i.e., correct pressure increase or poor chromatography).
- Install fresh HPLC water for every run.
- Restart the computer and instrument before starting analysis.
- Minimize air currents blowing on the instrument and vials loaded on the autosampler tray.
- Replace lamps at 2yr or upon observation of degraded signal.
- Major repairs on contract (by Full Spectrum or equivalent).
- When installing a new column, any column deficiencies with the old column should be documented, at a minimum, on the column box.
- Ensure that instrument is equilibrated and retention times have stabilized; instrument may be primed with one or more injections of the CCV solution prior to initiation of the CCV for the acquisition sequence.

8.3 INITIAL CALIBRATION

8.3.1 Set pump at flow rate used for the column in use. Turn on detector lamp. Allow the HPLC system to equilibrate for a minimum of 15min.

8.3.2 Prepare a minimum of 5 concentrations of calibration standards (typically 6 are used) as shown below in Table 1 below or as required for each sample set to be analyzed. The purpose of the initial calibration (ICAL) is to define the linear range of the detector. The ICAL can be used for analysis of both soil or water extracts. Each ICAL standard must include all target analytes and the surrogate. The lowest standard's concentration standard shall be at or below the reporting limit (RL) of each analyte. Create calibration standards by diluting aliquots of the first source intermediate calibration standard using an acetonitrile/acidified water mix. The mid-range calibration standard is used for continuing calibration verification (CCV).

Table 1
CALIBRATION STANDARDS

ACN (µL)	Acidified HPLC H_2O (µL)	Intermediate (µL)	Final Conc. (µg/mL)
0	500	500	2.5
300	500	200	1.0
400	500	100	0.5
480	500	20	0.1
495	500	5	0.025
498	500	2	0.01
400 CCV	500	100	0.5
300 CCV	500	200	1.0
400 ICV	500	100	0.5

8.3.3 Inject an appropriate volume (50µL) of each ICAL standard into the HPLC and analyze. The data system accomplishes quantitation via the external standard method (i.e., area responses are tabulated against the concentration injected). Analyte Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{Peak Area}}{\text{Concentration of Analyte}}$$

If the CFs over the working range of the detector are constant (i.e., ≤20% RSD), then response can be assumed to be invariant (linear through zero) and the average (mean) CF may be used to quantitate sample content.

Relative Standard Deviation (RSD) is calculated as:

$$\text{RSD (\%)} = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean response factor}} \right)(100)$$

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first (minimum of 5 ICAL points used, r) or second (minimum of 6 ICAL points used, r^2) order regression curve fit that does not pass through zero (e.g., least squares method) may be constructed. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000B. A quadratic regression should not be used to compensate for detector saturation. Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

If a first order regression fit is applied, the correlation coefficient (r)

value yielded must be ≥0.995. If a second order regression fit is applied, the coefficient of determination (COD, r^2 value) yielded must be ≥0.99. Note that the curve fit value expresses "goodness of fit", with perfect fit being a value of 1.0.

If the curve fit value does not meet criteria, check that the calibration standards were prepared properly, reanalyze and generate a new initial calibration curve..

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The acceptance criteria for the ICV is the same as for the CCV (described below). If control criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated. See QC Summary Table for further details.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when responses for all analytes are within ≤15%. If a CCV does not meet acceptance criteria, reanalyze the CCV. See QC Summary Table for further details and corrective action to be taken should the CCV still fail.

So long as CCV analyses yield compliant results, and other QC samples are analyzed as required, the series of ten sample analyses bracketed before and after by successful CCV analyses may continue as long as the reserve of solvents lasts.

8.6 RETENTION TIME WINDOWS

For chromatographic methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used to compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections) of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (σ) of the absolute retention time yielded for

each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time ±3σ, such that the Upper Limit = +3σ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time shifts). Sample matrices may cause RT differences that require further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system

8.7 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATION, REPORTING)

8.7.1 If ICAL, verification and method blank analyses have been successfully performed, analyses may proceed. If ICAL is not necessary, inject a CCV and determine compliance with acceptance criteria. Up to 10 samples (including QC samples) may be injected after calibration check criteria are met. End the analytical sequence with a CCV analysis.

8.7.2 A constant volume, generally 50µL, of each standard, standard verification, blank, field or QC sample extract (each containing the surrogate) is injected via the autosampler into the HPLC for analysis.

Sample extracts are diluted to maintain response within the linear range when necessary. Note that where sample concentrations are expected to be significant enough, filtered aqueous sample aliquots may be directly injected into the HPLC.

Allow the HPLC system to equilibrate after each injection/analysis.

8.7.3 Tentative identification occurs when a peak's response falls within the RTW of the C_{18} column. Confirmation occurs when the peak's response also falls within the RTW on the ELP confirmation column. Note that per LIMS program specification, diode array detection spectral confirmation may also be used.

8.7.4 Sample concentration may be calculated using the average calibration factor, or using the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

Average CF:

$$\text{Concentration}_{(ug/L,\ ug/kg)} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(V_s \text{ or } W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor

V_s or W_s = volume or weight of sample extracted (mL or g)

Linear Curve Equation:

$$x = \frac{(y - b)(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte
in ng/mL, ng/g (equal to ug/L, ug/Kg)

y = analyte instrument response (area units)

b = calculated intercept (area units)

m = calculated slope of the line (area units/conc. units-ng/mL)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples of like matrix that is associated with one unique set of QC samples and processed together as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS) and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Check LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method blanks (MBs) are aliquots of matrix (i.e., HPLC water for liquid analyses; Ottawa sand for solid analyses) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is processed, or there is a change in reagents, an MB must be prepared. Concentrations of target analytes, if any, must be less than the analyte reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this requirement is not met, analyses must be halted and the source of the contamination found and corrected. See also QC

Table. As the analyst deems necessary, aliquots of solvent may be injected to clean the analytical system and demonstrate that it is free from contamination.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

See QC Table for evaluation criteria.

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as follows:

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

See QC Table for evaluation criteria.

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an

analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

See QC Table for evaluation criteria.

9.6 SURROGATE RECOVERY AND ACCEPTANCE CRITERIA
Paragon uses the compound 1,4-dinitrobenzene as the surrogate for this method. Surrogates are selected for chemical structure and detection characteristics that are similar to the target analytes, but not so much so that it co-elutes with any of the single component targets. It should be noted, however, that because the surrogate is not a deuterated analog of a target analyte, as in GC/MS methods, it is not extracted with exactly the same efficiency as the target compounds. Therefore, surrogate recovery problems are not entirely representative of target analyte recoveries.

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. If the recovery is outside QC limits, the sample is reanalyzed to verify that analytical error was not the problem. If after re-injection the recovery is still out-of-control, initiate an NCR (SOP 928) to consult with the Project Manager (and client as needed), and apply the decided upon action.

9.7 A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses for each target analyte at a concentration level near to the capabilities of the method. The MDL study should be performed as needed, at a minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM THE METHOD

This SOP meets the requirements of Method SW8332, with the following exceptions:

10.1 The C_{18} column is used as the primary column and the ELP column is used for confirmation. The C_{18} column provides resolution and identification performance that meet method criteria and it outperforms the ELP column and is therefore used as the primary quantitation column.

10.2 A detector wavelength setting of 215nm is used for analysis (Method SW8332 states a 214nm detector setting).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.2 ***These samples are to be handled as explosive material and extreme caution should be applied as well as knowledge of explosives. The procedure is not intended for operations involving pure product explosives or non-environmental levels of explosives.***

11.1.3 ***Samples containing explosive material may under no circumstances be heated in any fashion (e.g., boiling a solution; drying in an oven).***

11.1.4 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.5 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.6 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.7 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.8 All flammable compounds must be kept away from ignition sources.

11.1.9 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.10 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Any rinse waters used for rinsing syringes or other devices prior to sample contact may be disposed of in the Aqueous Lab Waste.

11.2.2 Any hexane or other nonhalogenated organic solvent that has not been potentially contaminated with PCBs (e.g., the ACN:Water HPLC waste), may be discarded into the Acetonitrile/Nonhalogenated Waste stream.

11.2.3 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.4 The extract vials, associated extracts, and any PCB-contaminated debris that may contain PCBs in excess of 50ppm, shall be disposed of intact in the PCB Debris Waste.

11.2.5 All empty solvent bottles are disposed of according to the appropriate

SOPs. ***Please note that all labels and markings must be defaced prior to disposal.***

DOCUMENT REVISION HISTORY

8/24/06: LIMS program specification references strengthened; analytical columns used clarified; consumables list added; standards discussion revamped. DOCUMENT REVISION HISTORY Section added.

2/8/07: Minor format updates. Precedence of SOP 300 deleted. ICV added to standards table. Calculations expanded and units better defined.

8/12/07: Calibration discussion further clarified, Section 8.3.3 and QC Table.

Analytical Method: SW8332	**Parameter:** NG / PETN by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
Initial Calibration; minimum 5-point; all analytes	As needed (i.e., at on-set of analyses, or when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitate If RSDs over calibrated range exceed 20%, first order linear regression (using a minimum of 5 ICAL points) may be applied; r≥0.995 Higher order regression fits may be applied if more than 6 ICAL points are used; r^2≥0.99	Evaluate/correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve
Initial Calibration Verification (ICV); conc. not equal to midpoint of calibration curve; second source	After each ICAL	If ≤15%, analyses may proceed	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8330 allows bracketing of 20 field sample analyses)	If ≤15%, analyses may proceed	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed before and after a failed CCV must be reanalyzed. If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of	Whenever a new column is installed	Column and compound specific. Window is ±3x the standard deviation of the 3-injection average for the respective column Note that the ICV and CCV analyses are also used to	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms (refer also to RT Shift).

Analytical Method: SW8332	**Parameter:** NG / PETN by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
variation		analyses are also used to monitor RT drift	(refer also to RT Shift).
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per each preparation batch of ≤20 samples of like matrix	See laboratory or other applicable limits; recoveries for spiked compounds must be within these limits	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause.

Analytical Method: SW8332	**Parameter:** NG / PETN by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
			- if still non-compliant and the samples are within the extraction holding time, then initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per batch, not to exceed 20 samples of like matrix	See laboratory or other applicable limits; recoveries for spiked compounds should be within these advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per batch ~~of samples~~, not to exceed 20 samples of like matrix	See Matrix Spike information above for MSD recoveries. RPDs should not exceed value specified in LIMS program specification (typically 20%)	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Surrogate Spike	All extractions including field and laboratory QC samples	See laboratory or other applicable limits; recoveries should be within these limits	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. STANDARD OPERATING PROCEDURE 409 REVISION 6

TITLE: ANALYSIS OF POLYCHLORINATED BIPHENYLS (PCBs) BY GAS CHROMATOGRAPHY -- METHODS SW8082 and EPA 608

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 4.7.09

QUALITY ASSURANCE MANAGER _____ DATE 4/7/09

LABORATORY MANAGER _____ DATE 4-7-09

HISTORY: Rev0, 2/15/99, Rev1, 10/7/01; Rev2, 3/14/03; Rev3, 4/16/04; Rev4, 3/13/06; Rev5, 7/5/06; Rev6, 3/19/09.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references - SW846 Method 8082 and EPA 608, are used to determine the concentration of Aroclors 1016 through 1268 in various matrices. The following Aroclors may be analyzed:

Aroclor 1016	Aroclor 1242	Aroclor 1260
Aroclor 1221	Aroclor 1248	Aroclor 1262*
Aroclor 1232	Aroclor 1254	Aroclor 1268*

* Aroclors 1262 and 1268 are not routinely analyzed by the laboratory, but may be determined upon request. Decachlorobiphenyl (DCB) is normally added as a surrogate standard. However it can be reported as an analyte.

Aroclors are multi-component mixtures. Qualitative and quantitative determination may be more difficult if a sample contains more than one Aroclor, has been subjected to environmental degradation (weathering), or has been degraded by treatment technologies. Weathered and degraded samples exhibit patterns that differ from Aroclor standards.

The body of this SOP specifies the procedures to be used for Method SW8082 analysis. Any additional or contradictory requirements for Method EPA 608 are addressed in Section 10.

2. SUMMARY

Samples are extracted and the extracts concentrated and solvent exchanged using appropriate ALSLG-FC SOPs (i.e., 617 [CLLE]; 626 [Separatory Funnel]; 625 [Soxhlet]; 622 [Waste Extraction]; 607 [Kuderna-Danish Reduction]; and 637 [Concentration and Solvent Exchange]).

NOTE: With prior arrangement with the laboratory, solid samples may also be extracted using pulse sonication techniques.

The extracts are injected into a gas chromatograph (GC) containing a sample splitter and

two columns of varying selectivity (i.e., dissimilar elution and retention time properties). The target analytes are separated in the columns and detected by two electron capture detectors (ECDs). This chromatography system allows tentative identification by one column and confirmation by the other column to be performed simultaneously.

Quantitation is performed using the best column response yielded for each analyte. The Analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the primary quantitation column for each analyte detected and reported. The particular value that is selected for reporting is often marked (designated) in the raw data (e.g., quantitation report, run log). If results from both columns are comparable, the highest result is reported. Second column confirmation is not required if the primary column does not detect an Aroclor pattern, and may not be necessary if the sample matrix is well characterized by previous analyses.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 ALSLG-FC's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede ALSLG-FC's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Interference from phthalate esters can be minimized by using plastic-free solvent

containers and scrupulously cleaned glassware (SOP 334) that has been kiln-baked or solvent-rinsed prior to use. Use of low phthalate gloves, such as nitrile, may also important. These practices are important both in the field and in the laboratory.

4.2 Sulfuric acid clean up techniques may be used to remove interferences caused by the presence of organochlorine and/or organophosphorous pesticides. See SOP 651 for instructions regarding Method SW3665A sulfuric acid clean up.

4.3 Elemental sulfur (particularly in sediment samples) may interfere with PCB pattern identification and can be removed by using appropriate clean up techniques prior to sample analysis. See SOP 634 for instructions regarding Method SW3660B sulfur cleanup.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH (GC), AUTOSAMPLER AND DETECTORS - Hewlett Packard (HP) 5890 Series II GC equipped with HP 7673A autosampler, dual on-column injection, and electron capture detectors (ECDs) or equivalents

5.2 CHROMATOGRAPHIC DATA ACQUISITION AND PROCESSING SYSTEM - Hewlett Packard ChemStation (Enviroquant™) or equivalent

5.3 COLUMNS –
The following specified columns or equivalent columns are used with this analytical method.

RTx-CLPesticides or equivalent (30m, 0.25 or 0.32mm ID, 0.5µm film), RTx-CLPesticides II or equivalent (30m, 0.25 or 0.32mm ID, 0.25µm film), guard column

Restek Pesticide Column:	RTX-CLPesticides	#11123	(0.25mm)
Restek Pesticide Column:	RTX-CLPesticides2	#11323	(0.25mm)
Restek Pesticide Column:	RTX-CLPesticides	#11139	(0.32mm)
Restek Pesticide Column:	RTX-CLPesticides2	#11324	(0.32mm)

5.4 GASES - ultra high purity (99.999%)
Helium - carrier gas
Nitrogen - make-up gas

5.5 MEASURING DEVICES
Syringes - 1.0µL-1000µL precision Hamilton™, or equivalent
Volumetric flasks, Class A with ground glass stoppers, 10mL and 25mL

5.6 GC CONSUMABLES

- Vials - National Scientific C4011-1, or equivalent
- Caps - National Scientific C4000-51B, or equivalent
- Inlet Seals, dual vespel ring - Restek 0.8mm #21243, or equivalent

- Septa, 11mm - Restek #20365 or equivalent
- O-ring, graphite, 6.5mm - Restek #20299, or equivalent
- O-ring, Viton - Restek #20377, or equivalent
- Liner, splitless, 4mm ID - Restek #20799-214.5, or equivalent
- Glass Wool, deactivated - Restek #20789, or equivalent
- Gold Seal - Restek #21306, or equivalent
- Universal Presstight Y - Restek #20469, or equivalent
- Vespel/Graphite Ferrule (detector) - Restek #20221, or equivalent
- Compact Vespel/Graphite Ferrule - Restek #20249, or equivalent
- Graphite Ferrules - various sizes
- Split Vent Trap (SW8081) - Agilent RDT-1023, or equivalent

6. REAGENTS

6.1 SOLVENTS - **Only pesticide residue grade or equivalent may be used.**
Hexane - Burdick and Jackson 216-4, or equivalent
Methanol - Burdick and Jackson 230-4, or equivalent

6.2 STANDARDS
All standards are stored following ALSLG-FC SOP 300 guidance, which is superseded by any guidance in this SOP. Generally after opening vials, the standards for this procedure are stored in the freezer (-10°C and -20°C), in PTFE-capped, or equivalent vials. Unopened stock standards in flame-sealed ampules are valid until the manufacturer's expiration date and may be stored at room temperature, if recommended by the manufacturer. Opened stock standards and intermediate standards expire six months from opening (preparation) or the manufacturer's expiration date, whichever is sooner. Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

All stock and intermediate standards are documented in ALSLG-FC's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

6.2.1 Stock Standards: An approximately 1000mg/L (per component) stock solution is purchased from a suitable vendor or prepared in-house gravimetrically by accurately weighing 0.0100g of pure material into a 10mL Class A volumetric flask and diluting to volume with n-hexane. If purity of the compound is 96% or greater, no weight correction is necessary; if compound purity is less than 96%, the concentration must be corrected mathematically based on weight used.

A combination standard containing Aroclor 1016 and 1260 will generate peaks covering the range of all Aroclors of interest. Individual standards for all Aroclors must be created to assist in pattern recognition. The primary stock standards are subsequently diluted to create the intermediate stock standards. Undiluted, opened primary stock standards may be retained for up to six months.

6.2.2 Intermediate Standards: Generally prepared by diluting 1mL of stock standard to 25mL using a Class A volumetric flask and n-hexane. The intermediate stock standard is further diluted to create the calibration standards. Intermediate stock standards may be retained for up to six months.

6.2.3 Calibration Standards: Calibration standards are made daily from intermediate stock standards. Typically, ALSLG-FC prepares a mixture of Aroclor 1016/1260 at a minimum of 5 different concentrations that define the working linear range of the detector. The initial calibration must have a standard at or below the analyte reporting limit. A single point standard for the remaining requested Aroclors should be prepared at the analyte reporting limit. The single point standard will be used for pattern recognition, and to verify the sensitivity of the instrument for each Aroclor.

If the presence of an Aroclor other that 1016/1260 is suspected, a calibration curve containing a minimum of five concentration levels should be prepared for that Aroclor. Create calibration standards by preparing serial dilutions of the intermediate stock standard in n-hexane. A calibration standard at a concentration near the midpoint of the calibration curve will be used as a continuing calibration verification (CCV) standard. See SOP 300 for additional information about standard expiration dates.

6.2.4 Independent Calibration Verification Standard (ICV): Certified and purchased from a vendor or made gravimetrically in-house. Uses a source different from that of the calibration standard so that the accuracy of the calibration standard may be independently verified. Created and analyzed at a concentration level that is near the midpoint of the calibration range. The ICV should be prepared at a level different from the concentration used for the CCV, in order to verify a wider range of the calibration.

6.2.5 Surrogate Spike Solution - Certified and purchased from a vendor or made in-house. Typically, this standard contains 500ng/mL each tetrachloro-m-xylene (TCMX) and decachlorobiphenyl (DCB) in methanol. During preparation, 1.0mL of this standard is spiked into each

sample, standard, and quality control (QC) sample. Other concentrations or solvents may be used as needed (i.e., as defined in the applicable LIMS Program Specification).

6.2.6 Spike Solution - A commercial (i.e., purchased from a vendor) primary standard containing 1,000ppm Aroclor 1016/1260 is used to prepare a 5ppm in methanol solution to be used by the Organics Extractions Group in preparing laboratory control samples (LCS/LCSD) or matrix spiked samples (MS/MSD); typically 1mL of spike solution is added. Other concentrations and/or solvents may be used as appropriate (i.e., as indicated in the applicable LIMS program specification).

NOTE: An internal standard is not currently used for Aroclor analysis. Qualitative identification is determined by pattern recognition and quantitation is accomplished using the external standard method. Dual column confirmation is also routinely performed.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are not chemically preserved and must be collected in amber glass containers (generally 1L) with Teflon-lined lids. Samples should be maintained at 4±2°C and extracted within 7 days of collection. Extracts should also be maintained at 4±2°C and analyzed within 40 days of preparation.

7.3 Solid samples are collected in 250mL widemouth glass containers with Teflon-lined lids. Solid samples are not chemically preserved and should be maintained at 4±2°C. Solid samples should be extracted within 14 days of collection, extracts maintained at 4±2°C, and analyzed within 40 days of extraction.

8. PROCEDURE

8.1 TYPICAL GAS CHROMATOGRAPHIC CONDITIONS

Carrier Gas (He):	1-6mL/min
Make-up Gas (N_2):	20-40mL/min
Purge:	on, 0.75min
Injector Temperature:	205°C
Detector Temperature:	325°C

Oven Temperature Program:

Initial Temperature:	110°C
Oven Ramp:	15°C/min. to 250°C

Oven Ramp A:	20°C/min. to 300°C
Oven Ramp B:	5°C/min. to 270°C
Hold:	5 min

8.2 CHROMATOGRAPHIC MAINTENANCE

8.2.1 Aliquots of solvent may be injected and analyzed to show that the analytical system is free from contamination. They may be injected following samples of unusually high concentration to check the status of the analytical system and to facilitate re-equilibration of the system. Solvent injections may be used to prime the system if it has sat idle for awhile.

8.2.2 Peak tailing for all components will be exacerbated by a dirty injector. Clean per manufacturer's instructions as needed.

8.2.3 ECD detector leak checks are performed semi-annually per the procedures outlined in SOP 016.

8.3 INITIAL CALIBRATION

Prepare calibration standards as discussed above (including addition of surrogate). Typically, a 5-point curve of Aroclor 1016/1260 is prepared and a single-point reporting-limit standard of the remaining Aroclors is prepared. Inject 1-2µL of each standard directly into the GC and analyze. Quantitation is accomplished using 3 to 8 peaks for each Aroclor via the external standard method of quantitation. Where possible, peaks should be chosen that are at least 25% of the height of the largest Aroclor peak. Analyte calibration factors (CFs) are calculated for each peak as follows:

$$CF = \frac{\text{Selected Peak Areas}}{\text{Mass of Aroclor Injected On-Column (ng)}}$$

NOTE: SW-846 8000C also allows for use of concentration instead of mass injected.

If the CFs over the working range of the detector are constant (i.e., ≤20% RSD), then response can be assumed to be invariant and the average (mean) CF may be used to quantitate sample content. Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \frac{\text{Standard Deviation (SD)}}{\text{Average (mean) CF}} \times 100$$

When RSD over the calibration range is ≥20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The type of curve fit applied should be chosen to best represent the data. The

regression calculation will yield a coefficient of determination (r^2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit" with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000C. A quadratic regression should not be used to compensate for detector saturation.

The type of curve fit applied should be chosen to best represent the data.

If the comparison of a sample to a one-point standard suggests that Aroclor 1221, 1232, 1242, 1248, 1262, or 1268 may be present, then a 5-point curve of the appropriate Aroclor standard is prepared. The sample is re-analyzed and quantified using the appropriate 5-point curve.

NOTE: If an initial calibration point is not used for any reason, the analyst must clearly notate why the data point was not used for instrument calibration. "Picking and choosing" among calibration points in order to meet criteria is NOT acceptable. Generally, calibration points are only discarded due to easily demonstratable causes.

The mathematics used in least squares regression have a tendency to favor numbers of larger value over numbers of smaller value. The regression curves that are generated will therefore tend to fit points that are at the upper calibration levels better than those points at the lower calibration levels. To compensate for this, a "weighting" factor which reduces this tendency can be used. The Analyst may weight the curve to either the inverse of the concentration or to the inverse of the square of the concentration.

If regression criteria cannot be met, a new initial calibration must be performed.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

Though not required to be a second source by SW-846 Method 8082, a second source standard (ICV) is run after calibration. The concentration of the ICV should be varied over time and should not be equal to that of the continuing calibration verification (CCV). The acceptance criteria for the ICV are identical to those of the CCV described below. If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The concentration of the CCV is at or near the midpoint of the initial calibration. A CCV check is performed at the beginning (when initial calibration is not performed) and end, of each 12-hour analytical sequence (or batch of 20 samples). While QC samples are counted as part of the number of samples, solvent blanks are not.

NOTE: The CCV frequency given above should be considered a bare minimum, and some clients' LIMS program specifications may require more frequent CCV analysis. Even if this is not the case, a higher CCV frequency is strongly recommended. ALSLG-FC typically analyzes a CCV every 10 samples in order to reduce the amount of repeat injections necessary in the event of CCV failure.

Calculate the percent difference or drift (%D) between the initial and continuing calibration using the equations below:

$$\% \text{ Difference} = \frac{\overline{CF}_I - CF_c}{\overline{CF}_I} x100$$

where:

CF_I = The average calibration factor in the initial calibration

CF_c = Calibration factor for the continuing calibration

$$\%\text{Drift} = \frac{CC - TC}{TC} \times 100$$

where:

CC = Calculated concentration

TC = Theoretical concentration

Note that if a least squares regression is used, the CCV must be evaluated using a percent drift calculation.

If the %D is ≤20%, the CCV is acceptable, and sample analysis may begin. If a compound shows elevated response (> 20%D) and is not present in any samples associated with the CCV, re-analyses of those samples are not necessary.

If any CCV does not meet acceptance criteria, analyses must be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.6 RETENTION TIME WINDOWS

Retention Time Windows (RTWs) are established according to the criteria prescribed by Method SW8000C, Section 11.6. Analyze a mid-level standard in triplicate for each Aroclor, non-consecutively, during a 72-hour period. Calculate the mean and standard deviation (σ) of the three absolute retention times for three to five major peaks in each Aroclor. Each Aroclor's RTW is defined as three times the calculated standard deviation (±3σ) of each major peak, such that the Upper Limit = +3σ and the Lower Limit = -3σ.

8.7 SAMPLE ANALYSIS, CALCULATION AND REPORTING

A constant volume, generally 1µL, of each standard, blank, QC or field sample extract is directly injected into the GC via the automated injector. Sample extracts are diluted to maintain response within the linear range when necessary. All prepared extracts contain the surrogate (see Section 9).

8.7.1 Note that ALSLG-FC employs a sample splitter that facilitates simultaneous dual column injections; therefore, both columns are calibrated in the same manner and either column may serve as the column for quantitation.

8.7.2 Aroclors are identified through pattern recognition. Tentative identification occurs when selected peaks fall within the RTW of one column. If selected peaks also fall within their RTW on the second column, the analyte's presence has been confirmed. Quantitation is calculated from both column responses and the result with the least interference is reported. If both results are of equal quality, the higher result is reported. For the multi-response Aroclors, three to eight peaks are used for identification/quantitation. The same selected peaks must be consistently used for quantitation between the standard and sample set.

8.7.3 Analyst expertise is crucial in identifying and quantitating samples containing multiple Aroclors or Aroclors that are heavily weathered. Weathering of PCBs in the environment and changes resulting from waste treatment processes may alter the PCBs to such an extent that a specific Aroclor pattern is no longer recognizable. Consult the Department Manager for assistance in interpreting complex chromatograms.

8.7.4 Sample analyte concentration is calculated using the equation of the linear curve (i.e., y = mx + b) or average calibration factor generated, which can be represented as:

linear: $A = mC + b$, or $C = (A - b) / m$

average calibration factor: $C = A/R_f$

where:

A = analyte response (area counts)
m = slope of the linear equation
C = concentration present at the instrument
b = the y-intercept of the linear equation
R_f = the average calibration factor from the initial calibration

A concentration is determined for each peak, and the total Aroclor concentration is then determined by averaging the concentrations of the 3 to 8 individual peaks.

8.7.5 Identification of Aroclors may be simplified by comparing standard peak patterns to sample patterns (i.e., RTW of the group of peaks, comparison of peak heights and ratios; software overlays may also be used as desired/possible). Assessment observations may be confirmed using the calculated RTWs. If a minor shift of the entire pattern is observed, the Aroclor may still be positively identified provided that the confirming column result also supports the decision.

8.7.6 Integration between the reference standard and the sample must be consistent. For example, the baseline may be drawn from the start of the first peak in the group to the baseline following the last peak, and lines dropped from peak valleys to baseline for calibration standards and the samples alike.

9. QUALITY CONTROL

9.3 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of samples that are associated with one unique set of batch QC samples and analyzed together. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS) and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specification for additional or alternative requirements.

9.4 METHOD BLANKS

Method blanks are aliquots of matrix (i.e., organic-free water for liquids analyses; Ottawa Sand for solids analyses), which have been prepared and analyzed in the same manner as the associated field samples. To be acceptable, concentrations of analytes of interest detected (if any) in the MB must be below the analyte reporting limit, or as otherwise specified in the LIMS program specification. If this criterion is not achieved, analyses should be halted and the source of the contamination found and corrected.

A reagent or instrument blank is an injection of solvent analyzed to demonstrate that the analytical system is free from contamination. These blanks are typically analyzed following extremely contaminated samples.

9.5 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method and analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.6 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this analysis, either a field sample containing target compound contamination may be analyzed in duplicate, or the laboratory control sample (LCSD) or matrix spike (MSD) analysis can be performed in duplicate. The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD) as shown below. See QC Table for evaluation criteria.

$$\text{RPD} = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.7 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. See QC Table for evaluation criteria. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

Also note that for projects in which the client is to designate MS/MSD samples, an analysis batch may not contain an MS/MSD pair. Where this occurs, a notation will be made in the data package narrative.

9.8 SURROGATE RECOVERY AND ACCEPTANCE CRITERIA

The two surrogates (SUR) used for this procedure are those suggested in SW8081A. Both surrogates are added to all field and quality control samples prior to extraction; recovery is calculated per the recovery formula shown previously for the LCS. The two surrogates used were selected because they respond in a similar manner as the target compounds respond at the detector. Additionally these surrogates are not similar enough chemically to the target compounds to co-elute with the single component targets, nor do they suffer interferences from the multiple component targets. Tetrachloro-m-xylene (TCMX) elutes before any of the target compounds, and decachloro-biphenyl (DCB) elutes after all of the target compounds. However, because the surrogates are not deuterated analogs of targets as in GC/MS methods,

they are not extracted with exactly the same efficiencies as the target compounds. Therefore, surrogate recovery problems are not representative of target analyte recoveries.

Heavy co-extractive non-target compounds generally do not interfere with TCMX; light co-extractive non-target compounds generally do not interfere with DCB. However, some samples may produce matrix effects that cause surrogate recovery to be high or low; because of high concentrations of target and/or non-target compounds, quantification of the surrogates may even be precluded in some samples. Muddy aqueous samples, for example, generally adsorb DCB after spiking and limit recovery to a few percent. High concentrations of heavy hydrocarbons in soils oftentimes have a similar matrix effect on DCB recovery.

The extraction process itself can have an effect on surrogate recovery. An example of this process-caused effect is use of Method SW3520 for extraction of aqueous samples and associated "low" recoveries of DCB. DCB is a heavy molecule and very hydrophobic. When spiked into water, this compound tends to rapidly adsorb to particulates at the liquid-liquid interface and exhibits a low recovery.

For the reasons listed above, ALSLG-FC does not view the evaluation of surrogate recovery in this procedure to be a straightforward process. Therefore, ALSLG-FC observes the following guidance for evaluating surrogate recovery:

- ALSLG-FC's practice is to evaluate and report the recovery of both surrogates. When one or both surrogates are within laboratory control limits, the process is considered to be in control and no further action is taken (unless additional measures are stipulated in the LIMS program specification.

- When, due to elevated target concentrations, an extract requires a dilution of greater than 5X, ALSLG-FC does not consider the surrogate recoveries to have meaning; no further action is required.

- When both surrogates are outside of laboratory control limits (or other limits specified in the LIMS program specification), the extract is re-injected to assure that instrument error was not the cause. If after re-injection the recoveries of both surrogates remain out of control, then re-extraction and re-analysis may be performed as directed by the client. A non-conformance report (NCR; SOP 928) to document the problems is required.

This process of evaluating surrogate recovery is based on several methods and guidance documents and has evolved in particular from Method SW8080 guidance as well as from the National Functional Guidelines for Data Review.

9.9 METHOD DETECTION LIMITS

The MDL study should be performed as needed and at a minimum, annually. See SOP 329 for further guidance.

10. DEVIATIONS FROM METHOD

10.1 This SOP meets the requirements of Method SW8082. The following is the only known deviation from the method: The method allows for single point calibration of Aroclors 1221, 1232, 1242, 1254, 1262 and 1268 using a point near the midpoint concentration of the 1016/1260 curve. ALSLG-FC analyzes a single point for these Aroclors at the reporting limit to assist in pattern recognition as well as to show instrument sensitivity for all the targets. If Aroclor 1221, 1232, 1242, 1254, 1262 or 1268 is detected in the sample, then a calibration curve with at least 5 points is prepared and the sample re-analyzed for that Aroclor following the procedures discussed in this SOP. This more stringent approach is intended to provide more accurate quantitaton for these Aroclors.

Note that ALSLG-FC defines analytical shift (8000C) as per 24hrs, not 12hrs.

10.2 EPA 608: The items discussed in this Section list differences between Methods EPA 608 and SW8082:

10.2.1 EPA 608 states specific extraction methods, chromatographic conditions, etc. to be used in the execution of the method. Some of these materials, apparatus, and conditions have been eclipsed by the more modern technology listed in this SOP. Section 8.1.2. of EPA 608 also states that technological advances are recognized and allowed for use provided that the precision and accuracy requirements put forth by the method can be achieved.

10.2.2 EPA 608 specifies extraction of samples by separatory funnel. ALSLG-FC uses continuous liquid-liquid extractors (CLLEs) or separatory funnels to extract aqueous samples.

10.2.3 EPA 608 specifies that calibration standards be kept in isooctane. ALSLG-FC uses hexane as a solvent for calibration standards.

10.2.4 EPA 608 states that if the RF value over the range demonstrated by the initial calibration is $\leq$10%, the average response factor can be used for calculations. otherwise construct a linear regression curve. ALSLG-FC typically quantifies Aroclors from a linear regression curve.

10.2.5 EPA 608 specifies that a continuing calibration standard be analyzed every 24 hours. ALSLG-FC follows Method SW8082 that specifies a continuing calibration verification be analyzed every 12 hours and every 20 samples thereafter (although ALSLG-FC observes 10 samples between CCVs rather than 20).

10.2.6 The use of surrogate standards is not addressed in EPA 608. ALSLG-FC uses the two surrogates discussed in this SOP.

10.2.7 Because samples from several sites are usually batched together, only one spiking level is used for each compound. Per EPA 608, it is impractical to match each compound's spike amount with the amount of the compound in the samples chosen for spiking, and to match the spike amount to the appropriate regulatory level for each compound. This difference must be stated in the data package narrative for EPA 608 sample analyses.

10.2.8 Section 7.5 of EPA 608 prescribes the use of Florisil columns to remove co-extractives; a sulfuric acid clean up procedure is not discussed in EPA 608. ALSLG-FC routinely performs a Method SW3665A sulfuric acid clean up on all samples analyzed for PCBs only (see SOP 651).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 All flammable compounds must be kept away from ignition sources.

11.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.6 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport. The cylinder must be stored capped and secured at all times.

11.2 WASTE DISPOSAL

11.2.1 Any hexane or other nonhalogenated organic solvents that has not been potentially contaminated with PCBs may be disposed of in the

Acetonitrile/Nonhalogenated Waste.

11.2.2 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.3 The extract vials, associated extracts, and any PCB contaminated debris that may contain PCBs in excess of 50ppm shall be disposed of intact in the PCB Debris Waste.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/5/06: Strengthened LIMS program specification references, analytical columns and consumables used, and chromatographic interpretation. Changed standards storage temperature to -10°C to -20°C from 4±2°C to match practice. Added DOCUMENT REVISION HISTORY. Replacements issued for pages 12 and 16 (corrected RPD formula and updated matrix spike %R formula, updated DOCUMENT REVISION HISTORY).

3/19/09: Revised SUMMARY Section to make it consistent with other similar SOPs. Added Maintenance Section 8.2. Updated CCV discussion in Section 8.5. Updated references to 8000C. Included laboratory's definition of shift in DEVIATIONS Section 10.1.

Analytical Method: SW8082, EPA 608	**Parameter:** Polychlorinated Biphenyls (PCBs)		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point; all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20% (Method SW8082) or ≤10% (EPA 608), use mean CFs to quantitate. If RSD >20% , calculate linear regression (not forced through origin); use for quantitation if coefficient of determination (r^2) is ≥ 0.99.	Evaluate/correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Initial Calibration Verification (ICV); run near midpoint of calibration, but at a different concentration than CCV	With each initial calibration	If ≤20% D analyses may proceed.	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); run at or near midpoint of calibration	Daily prior to sample analyses; brackets each set of 20 field sample analyses (10 sample analyses recommended)	If ≤20% D analyses may proceed.	Evaluate/correct instrument malfunction as needed (e.g., remove 1 meter from the guard column of the GC, prepare a new standard); reanalyze. - If CCV still non-compliant, recalibrate using a new curve. Samples analyzed after a failed CCV will be reanalyzed. - If target(s) in CCV fails high (>20%) and target is not present in samples, re-analyses of samples are not necessary. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW)	Whenever a new column is installed, based on 3 injections throughout a 72-hour period to be more representative of daily operations	Column and compound specific. Window is ±3x the standard deviation of the 3-injection average for the respective column. Note that the ICV and	If SD=zero, then either do additional injections or use a default SD of 0.01 minutes. Experience of analyst weighs heavily in interpretation of chromatograms (refer also to RT Shift).

Analytical Method: SW8082, EPA 608	**Parameter:** Polychlorinated Biphenyls (PCBs)		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
		CCV analyses are also used to monitor RTW shift.	
Retention Time (RT) Shift	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate. Evaluate data based on a comparison with other standards run during the analytical sequence; consider the RTs for the surrogates and spiked compounds analyzed before and after the sample in question:
Method Blank (MB)	1 per each preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are outside the extraction holding time, then complete an NCR and contact PM for sample disposition.
Laboratory Control Sample (LCS)	1 per batch of ≤20 samples of like matrix	See laboratory limits; recoveries for the spiked compounds must be within the laboratory limits or other limits as specified in the LIMS program specification.	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions or analytical preparation was the cause. - if still non-compliant and the samples are within the extraction holding time, then request re-extraction using an NCR, and reanalyze all associated samples for the analyte that does not meet criteria. - if the samples are outside the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration.
Matrix Spike (MS)	1 per batch of samples, not to exceed 20 samples of a given matrix	See laboratory limits; recoveries for the spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.

Analytical Method: SW8082, EPA 608	**Parameter:** Polychlorinated Biphenyls (PCBs)		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Matrix Spike Duplicate (MSD) or Duplicate	1 per batch of samples, not to exceed 20 samples of a given matrix.	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits.	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). If no errors are found and, if analyzed, LCSD RPD is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Surrogate Spike	All extractions including field and laboratory QC samples.	See laboratory limits; recoveries should be within current limits for one or both surrogates; alternative criteria as defined in the LIMS program specifications may apply.	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with both surrogate recoveries outside the recovery limits, with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if both surrogate recoveries in the associated MB are not within limits, and the samples are within the holding time, then re-extract and reanalyze all associated samples. - if samples are outside the holding time, then contact the PM via an NCR. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration.
Method Detection Limit (MDL) Study	As needed and at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If `criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

Must Discard 30 Days from _____ (date printed)

Amendment 7/21/08. Note (and in update) that methanol-extracted QC must be performed where methanol-extracted samples are processed. DAS

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 424 REVISION 12

TITLE: **DETERMINATION OF AROMATIC VOLATILE ORGANICS BY GAS CHROMATOGRAPHY – METHOD SW8021B**

FORMS: 412

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8-11-06

QUALITY ASSURANCE MANAGER _____ DATE 8/11/06

LABORATORY MANAGER _____ DATE 8-11-06

HISTORY: Rev0, 6/23/92; Rev1, 2/5/93; Rev2, PCN #216, 4/12/94; Rev3, PCN #433, 6/27/95; Rev4, 3/22/96; Rev5, 6/10/96; Rev6, 2/12/99, Rev7, 1/24/01; Rev8, 12/9/02; Rev9, 3/6/04; Rev10, 7/26/05; Rev11, 3/13/06; Rev12, 8/11/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references -- SW-846 Method 8021B -- is used to determine the concentration of aromatic volatile hydrocarbons in sludge, solids (tar, asphalt), petroleum products, water and all other aqueous and solid matrices.

The following compounds may be analyzed by this method:

benzene	toluene
chlorobenzene	ethyl benzene
1,2-dichlorobenzene	m- and p-xylene
1,3-dichlorobenzene	o-xylene
1,4-dichlorobenzene	methyl-t-butyl ether (MtBE)

Other compounds may be analyzed if successful method detection limit (MDL) and demonstration of capability (DOC) studies are performed.

2. SUMMARY

Prepared samples are loaded onto a purge and trap device and are subsequently heated and desorbed to a gas chromatograph (GC) containing a sample splitter and two capillary columns of varying selectivity (i.e., dissimilar elution and retention time properties). The target analytes are separated in the columns by temperature programming and detected by two photoionization detectors (PIDs). The PID responses are processed by an electronic integrator and the result is determined using an internal standard quantitation calculation. This chromatography system facilitates tentative identification by one column and confirmation by the other column to be performed simultaneously. Quantified values are reported from the best column for each analyte. The analyst considers performance data

such as separation of interferences, calibration performance and matrix spike results in selecting the quantitation column used for each analyte detected and reported. If results from both columns are comparable, the highest value is reported.

Preparation procedures are based on those described in Method SW5030C. Low/medium concentration samples may be purged and trapped either in neat or diluted form. Full (5mL or 5g) or reduced aliquots of low/medium concentration water or solid samples are heated while sparging (though heated purging of aqueous samples is not required by the method). High concentration aqueous samples may be further diluted using serial dilution techniques. High concentration solid samples are first subjected to methanolic extraction, with an aliquot of extract subsequently analyzed by its addition to 5mLs of reagent water and thus processed as an aqueous sample.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon’s standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Impurities in purge gas and outgassing from organic compounds in the plumbing ahead of the trap account for the majority of potential contamination problems. The analytical system must be demonstrated to be free from contamination under the conditions of the analysis by analyzing laboratory blanks with every batch. Within the purging device, the use of non-PTFE (Teflon) plastic coated sealants or flow controllers with rubber components should be avoided.

4.2 Samples may be contaminated by diffusion of volatile organics (particularly methylene chloride and fluorocarbons) through the septum seal of the sample vial during shipment and storage. A trip blank prepared from organic-free reagent water and carried through sampling, handling and storage protocols can serve as a check on such contamination.

4.3 In this method, syringes are used to introduce the samples, quality control samples (method blank, LCS, MS, etc), and calibration standards into the purge and trap device. The laboratory uses dedicated disposable syringes to prevent cross-contamination. However, contamination by carryover from the trap and lines can occur whenever high-concentration and low-concentration samples are analyzed sequentially. Whenever an unusually concentrated sample is analyzed, it should be followed by the analysis of organic-free reagent water to clean the system and ensure that it is contaminant-free. Frequent bake-out of trap and column is also helpful.

4.4 The laboratory where volatile analyses are performed should be completely free of solvents and the atmosphere must be adequately free of volatile organic compound vapors. The laboratory is sufficiently free of volatile organic interferences if acceptable method blank analyses are routinely accomplished.

4.5 Interferences are also minimized by the use of only high purity reagents.

5. APPARATUS AND MATERIALS

5.1 PURGE AND TRAP AUTOSAMPLER DEVICE
O-I Analytical, Arcon™, Model 4552 automated purge and trap device, or equivalent. Equipped with Supelco™ Trap K #21066-U or equivalent

5.2 GAS CHROMATOGRAPH (GC) / DETECTORS
Hewlett Packard™, Model 5890 Series II GC or equivalent, equipped with dual photoionization detectors (PIDs)

5.3 DATA ACQUISITION AND PROCESSING SYSTEM
Any data acquisition system capable of acquiring, storing and processing chromatographic data (e.g., Hewlett Packard Chem Station™ or equivalent)

5.4 COLUMNS - Equivalent columns/guard columns may also be used

J&W Capillary Column:	DB-624 #200-0113* (30m x 0.53mm ID, 3.0µm film thickness)
J&W Capillary Column:	DB-VRX #200-0015* (30m x 0.45mm ID, 3.0µm film thickness)

* J&W columns are available through Agilent, part numbers are Agilent numbers.

5.5 GASES - only high purity or higher grade gases may be used
Helium - carrier gas

5.6 MEASURING DEVICES
Luer-lock syringes, Becton & Dickinson or equivalent, disposable, 5mL or 25mL (used for sample introduction)

microsyringes, gas-tight, Precision Hamilton or equivalent, 5µL - 1.0mL sizes) (used for spiking)

volumetric flasks, Class A with ground glass stoppers, various sizes

balance (capable of weighing ±0.01g); used for weighing solid samples

5.7 CONSUMEABLES

- Photoionization Lamp - Restek #23020 Model 108 BTEX, or equivalent
- Compact Vespel/Graphite Ferrule - Restek #20264, or equivalent
- Graphite Ferrules - various sizes

6. REAGENTS

6.1 organic-free reagent water, purged with nitrogen per SOP 511

6.2 methanol (CH_3OH, MeOH), JT Baker, #9077-02 or equivalent, purge & trap grade

6.3 Ottawa sand, EMD, #SX0075-3 or equivalent

6.4 STANDARDS

6.4.1 All standards are maintained per PAR SOP 300, which supercedes any guidance in this SOP. Stock standards, in methanol, may either be prepared from pure standard materials (per SW8000B and SW8021B, Section 5.0) or purchased as certified solutions from suitable vendors. Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules, if recommended by the manufacturer. Standards for this procedure must be equilibrated to -10-20°C (stored in freezer) before opening. After opening/initial use, transfer remaining stock standard to a suitable vial (preferably Mininert™) with minimal headspace, and store in freezer (-10-20°C). All opened stock standards must be replaced after 3 months, or sooner, if comparisons with laboratory control samples indicate a problem.

6.4.2 At minimum, two independent sources of target analytes are required. Typically, certified stock standards are purchased from suitable vendors as single analyte solutions (which are later combined in-house) or as mixes. First source materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards. Second source materials are used to create the initial calibration verification (ICV) solution (used to independently verify the accuracy of the initial calibration, ICAL). Non-target analyte surrogate and internal standard stock standards are also prepared or purchased. The surrogate used for this method is 2,3,4-trifluorotoluene. The internal standard used for this procedure is ααα-trifluorotoluene. Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

6.4.3 An appropriate volume of stock standard (target analyte or mix, surrogate, internal standard) is diluted (with methanol) to a specific volume to create an intermediate standard. All dilutions should be performed using microsyringes, Class A volumetric flasks, and purge & trap grade (or higher) MeOH. The surrogate and internal standard are made together as a combined intermediate standard, containing 100µg/mL each of both 2,3,4-trifluorotoluene and α,α,α-trifluorotoluene.

NOTE: BFB (bromofluorobenzene) may also be included in the surrogate/internal standard solution as an additional surrogate, however, this second surrogate is not routinely reported.

The internal standard (IS) component is used to quantitate target analytes detected in samples. The surrogate standard (SS) component is used to monitor system performance and method effectiveness in dealing with each sample matrix. A 1µL nominal aliquot of the 500µg/mL IS/SS spiking solution is added to every sample to yield a final concentration of 100µg/L.

NOTE: If using a system with automated introduction of standards, such as the O-I Arcon™ autosampler, an equipment validation study must be performed to determine the actual volume delivered. The concentration of standard may be adjusted accordingly for the actual volume delivered by the autosampler at the 1µL setting. For example: (1.135µL actual delivery)(441µg/mL IS/SS spiking solution)/5mL = 100µg/L.

6.4.4 The intermediate calibration standards are injected into syringes containing reagent water to create working standards. Working standards (ICAL, ICV, CCV) are prepared on the day of use and documented in the analytical run log (Form 412). These working calibration standards must contain all target analytes, and the surrogate and internal standard. A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.4.5 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples are collected in 40mL glass VOA vials with screw tops and Teflon™-lined septa. Aqueous samples should be headspace-free.

7.3 Where applicable, aqueous samples should be dechlorinated with sodium thiosulfate at time of collection, then acidified with hydrochloric acid (HCl). Typically the addition of 4 drops of concentrated HCl to each 40mL VOA vial is sufficient to bring the pH of the sample to <2.

7.4 If untreated in the field, the Paragon Project Manager may direct that each aqueous sample is tested for residual chlorine upon receipt at the laboratory. Notify the Project Manager immediately if residual chlorine is detected. If the water sample remains unpreserved, the maximum holding time to analysis is 7 days from the date of collection.

7.5 The maximum holding time to analysis for acid-preserved aqueous samples is 14 days from the date of collection.

7.6 All samples are to be kept chilled (4±2°C)

7.7 Solid samples are collected in wide-mouth glass containers with Teflon™-lined lids. Solid samples are not chemically preserved and must be analyzed within 14 days of collection.

8. PROCEDURES

8.1 TYPICAL SYSTEM OPERATING CONDITIONS

Purge & Trap Device

Purge Gas Flow Rate:	45 - 50mL/min
Preheat:	0.01min to 40°C
Purge:	8min
Dry Purge:	2min
Desorb Preheat:	180°C
Desorb:	3min at 250°C
Bake:	4min at 260°C

Gas Chromatograph

Carrier Gas (Helium) Flow Rate:	2 - 6mL/min
Make up Gas (Helium) Flow Rate:	30mL/min
Transfer Line:	120°C
Injector Temperature:	240°C
Initial Oven Temperature:	3min at 40°C
Initial Oven Ramp:	12°C/min to 80°C
Oven Ramp A:	8°C/min to 130°C
Oven Ramp B:	35°C/min to 225°C
Hold:	225°C for 2.5 min
PID Temperature:	260°C

8.2 CHROMATOGRAPHIC MAINTENANCE

8.2.1 Dual columns are connected using a press-fit Y-shaped glass splitter or a Y-shaped fused-silica connector. Reattach the columns after cleanly cutting off at least two loops from the injection port side of the column using a capillary cutting tool or scribe. The accumulation of high boiling residues may change split ratios between dual columns and thereby change calibration factors. Clip a loop from the guard column or replace as necessary.

8.2.2 Columns may be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming.

8.2.3 PID windows may be cleaned if the signal has weakened or annually. Lamps are replaced if signal is unstable or cleaning is ineffective. Replace both lamps at the same time and use equivalent lamps.

8.2.4 Replace trap if consistent MtBE recovery can not be achieved or if other trap performance problems are demonstrated and not alleviated by routine maintenance.

8.3 INITIAL CALIBRATION

8.3.1 Aqueous initial calibration standards are prepared at a minimum of five concentrations by spiking amounts of the prepared analyte (intermediate) standard into syringes containing organic-free reagent water. The range of concentrations of the initial calibration is intended to define the working range of the analytical system. One of the concentrations must be at or below the analyte reporting limit. The O-I Arcon adds the SS/IS mixture is to all non-ICAL samples. However, to facilitate the required multiple concentration levels, the SS is added manually for each ICAL standard, while the IS is added by the O-I Arcon. Typical calibration preparation is depicted below in Table 1.

TABLE 1
CALIBRATION STANDARDS

Level	µL Stock Standard (50µg/mL)	µL Surrogate (100µg/mL)	IS Standard (441µg/mL)	Analyte Concentration (µg/L)
ICAL 8	10	8µL	Added by Arcon	100
ICAL 7	6µL	7µL	Added by Arcon	60
ICAL 6	5µL	6µL	Added by Arcon	50
ICAL 5	4µL	5µL	Added by Arcon	40
ICAL 4	2µL	4µL	Added by Arcon	20
ICAL 3	1µL	3µL	Added by Arcon	10
ICAL 2	(10µL)(@50x)	2µL	Added by Arcon	2
ICAL 1	(2.5µL)(@50x)	1µL	Added by Arcon	1
ICV	Varied	*	*	Varied
CCV	5µL	*	*	50

*Added as mix by O-I Arcon

8.3.2 Solid initial calibration standards are similarly prepared by spiking appropriate amounts of prepared analyte (intermediate) standard onto a 5g aliquot of Ottawa sand that has been measured into a 40mL VOA vial. Then, 5mL of organic-free water (into which the surrogate has

been spiked, see 8.3.1) is added to the 40mL vial, to facilitate purging. The IS is added using the Arcon automated addition feature.

8.3.3 Electronically integrated peak area responses are tabulated and quantitated using internal standard quantitation. Response Factors (RFs) for each compound are calculated as follows:

$$RF = (A_s C_{is}) / (A_{is} C_s)$$

where:

A_s = response for the analyte to be measured

A_{is} = response for the internal standard

C_{is} = concentration of the internal standard (µg/L, µ/Kg)

C_s = concentration of the analyte to be measured (µg/L, µg/Kg)

8.3.4 If RF over the working range is constant (i.e., < 20% RSD), then the response is assumed to be invariant and the average (mean) RF may be used to quantitate sample content. Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \frac{\text{Standard Deviation (SD)}}{\text{Average (mean) CF}} \times 100$$

If more than five calibration concentration levels were acquired and the %RSD (of the RFs) exceeds 20% because one of the calibration injections is seen to have been ineffective, that one data point may be deleted from the initial calibration and the %RSD recalculated. The recalculated %RSD must meet acceptance criteria.

NOTE: A minimum of five (5) points must be used for the initial calibration. If more than one calibration point must be discarded to meet the % RSD criteria, the initial calibration is judged to be invalid and a new initial calibration must be generated.

If an initial calibration point is not used for any reason, the analyst must clearly notate why the data point was not used for instrument calibration.

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be $\geq$0.99 to be used for sample quantitation. Note that

the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000. A quadratic regression should not be used to compensate for detector saturation.

Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

If regression criteria cannot be met, a new initial calibration must be performed.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source (ICV) standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration. Acquire a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

NOTE: Method SW8000B Section 7.7 allows up to 12 hours of analysis (approximately 20 injections) between CCVs. Paragon commonly analyzes 10 samples between CCVs to reduce the amount of repeat injections.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when all compounds are within 15%D or when the average of the %Ds for all compounds is $\leq$15% (individual compounds that exceeded 15% are noted in the data package narrative). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the

CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.6 RETENTION TIME WINDOWS

For GC methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (σ) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time $\pm 3\sigma$, such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time drift). Sample matrices may cause drift that requires further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system.

8.7 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)

Samples are introduced to the GC via purge and trap. Sample introduction techniques (i.e., choice of sample size or dilution) are chosen to maintain response within the linear quantitation range. QC samples (LCS, MS, etc.) are prepared in a manner similar to that of standards described above. A discussion of quantitation follows.

8.7.1 Note that Paragon employs a sample splitter that facilitates simultaneous dual column injections; therefore, both columns are calibrated in the same manner and either column may serve as the column for quantitation.

8.7.2 Tentative identification occurs when a sample peak falls within the RTW of one column. If the peak also falls within the RTW of the second column, then the analyte's presence has been confirmed. Quantitation is calculated from both column responses and the best result is reported. The analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the quantitation column for each analyte detected and reported. If there are interferences present on one column, these need to be documented by printouts of that region of the chromatogram; the lower (i.e., other column's) results may be reported

in this case. If results from both columns are of comparable quality, the higher concentration is reported (per SW8000B).

8.7.3 The following equation is used to quantify sample concentration when RF (or mean RF) is employed:

$$\text{Concentration } (\mu g/L \text{ or } Kg) = \frac{[(A_x)(C_{is})(DF)]}{(A_{is})(\text{mean RF})(V_s \text{ or } W_s)}$$

where:

A_x	=	analyte response (area units)
C_{is}	=	amount of internal standard added (ng)
DF	=	Dilution Factor (if applicable); if no dilution was made, DF = 1 (dimensionless)
A_{is}	=	internal standard response (area units)
RF or mean RF	=	standard response (area units)
Vs or Ws	=	(volume or weight) of sample analyzed (mL or g)

Where linear regression is employed, quantitation of sample concentration is based on the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte

y = analyte instrument response (area units)

b = calculated intercept

m = calculated slope of the line

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried

through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method Blanks (MBs) are aliquots of matrix (i.e., organic-free water for liquids, Ottawa sand for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and corrected.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. Percent Recovery (%R) for spiked analytes is calculated as follows (See QC Table for evaluation criteria:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right) (100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 SURROGATE RECOVERY

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. If the recovery is outside QC limits, the sample is reanalyzed to verify that analytical error was not the problem. If after re-injection the recovery is still out-of-control, initiate an NCR (SOP 928) and apply the decided upon action. Typically, matrix effect is cited as the cause and the occurrence is narrated. However, the client may direct that the sample be re-extracted and reanalyzed (holding time is a consideration).

9.7 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW8021B and the preparatory procedures described in SW5030C. It should be noted, however, that Paragon may use a heated purge for aqueous samples, which rigorous but not required by SW5030C. SW5030C(mod) is the cited reference for solid sample preparation. Solid samples are prepared and analyzed taking guidance from SW5030C (Purge & Trap for Aqueous Samples) and SW5035A (Closed System Purge & Trap and Extraction of Solid Samples). Currently Paragon's analysis is not conducted on a closed system, hence the SW5035A method citation is not used. There are no other known deviations from the methods.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Solvent wastes must be disposed of in the appropriate waste containers.

11.2.2 Any rinse waters used for rinsing syringes or other devices prior to sample contact may be disposed of in the Aqueous Lab Waste.

11.2.3 Any methanol, hexane or other nonhalogenated organic solvents that has not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

Analytical Method: SW8021B	**Parameter:** Aromatic Volatile Organics (AVOs)		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5-point, all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitate Calculate linear regression (not forced through origin); use for quantitation if correlation coefficient (r) ≥0.995 or Calculate quadratic regression (minimum of six points required); use for quantitation if COD (r^2) ≥0.99	Evaluate/correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Initial Calibration Verification (ICV); conc. not equal conc. to midpoint of calibration curve; second source	After each ICAL	≤15%D of each compound or mean %D ≤15% or as otherwise specified in applicable LIMS program specification	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8121B allows bracketing of 20 field sample analyses)	≤15%D of each compound or mean %D ≤15% or as otherwise specified in applicable LIMS program specification	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of	Whenever a new column is installed	Column and compound specific Window is ±3x the standard deviation of the 3-injection average for the respective column	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms

QC Check	Frequency	Acceptance Criteria	Corrective Action
variation		Note that the ICV and CCV analyses are also used to monitor RT drift	(refer also to RT Shift).
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition.
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the

Analytical Method: SW8021B	**Parameter:** Aromatic Volatile Organics (AVOs)		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries RPDs should be within advisory limits	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Surrogate Spike	All field and laboratory QC samples	See laboratory limits; recoveries should be within current limits alternative criteria as defined in the LIMS program specifications may apply	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if surrogate recovery in the associated MB is not within limits and the samples are within the

TITLE: **ANALYSIS OF TOTAL VOLATILE PETROLEUM HYDROCARBON (TVPH) GASOLINE RANGE ORGANICS (GRO) BY GAS CHROMATOGRAPHY -- METHODS SW 8015B and CAL-LUFT**

FORMS: **412 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8.31.06

QUALITY ASSURANCE MANAGER _____ DATE 8/31/06

LABORATORY MANAGER _____ DATE 8-31-06

HISTORY: NEW, Rev 0, 11/8/92; Rev1, 2/5/93; Rev2, PCN #214, 4/11/94; Rev3, PCN #434, 6/27/95; Rev4, 4/23/98; Rev5, 2/15/99; Rev6, 2/17/00; Rev7, 1/15/02; Rev8, 3/01/02; Rev9, 3/14/03; Rev10, 4/16/04; Rev11, 3/13/06; Rev12, 8/24/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- SW8015B and CAL-LUFT -- are used to determine the concentration of Gasoline Range Organic (GRO) compounds in aqueous and solid/sludge samples.

Method SW8015B defines the alkane range corresponding to GRO as approximately C_6 through C_{10} boiling point, with the approximate boiling points ranging from 60°C to 170°C. State-specific or client-specific fuels analysis protocols may require analysis of a modified carbon range.

Gasoline is identified by pattern recognition; however, certain volatile aromatic compounds (e.g., benzene, xylenes, MtBE) are detectable as target analyte indicators. Analyst expertise is crucial to this method as multiple patterns may be present in a sample. Also, pattern responses in environmental samples may differ from textbook characterizations because of weathering. Any peak(s) present in the current GRO retention time window will be integrated and reported as GRO.

2. SUMMARY

Sample aliquots are introduced onto a purge and trap device and are subsequently desorbed onto a gas chromatograph (GC). The GC is temperature programmed to facilitate separation of surrogate standards, to produce a good GRO pattern and to resolve the early diesel elution pattern. Analytes of interest are detected using a photoionization detector (PID) in series with a flame ionization detector (FID). The PID output is used to monitor the internal standard and surrogate standard retention times and areas. Standard areas are subtracted from the FID/GRO area to achieve a valid total GRO response. Detector responses are recorded by an electronic data system. The sample response is

compared to the GRO response, of reference standards, using the internal standard method of quantitation to quantitatively determine GRO.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 High levels of heavier petroleum products (e.g., diesel fuels) may contain some volatile compounds that elute within the retention time range of GRO. Other organic compounds including halogenated solvents, ketones, and ethers are also measurable. As defined in the methods, GRO quantitation includes these compounds.

4.2 Samples may become contaminated by diffusion of volatile organic compounds (VOCs) through the sample container septum during shipment and storage. A trip blank prepared from reagent water and carried through sampling and subsequent storage and handling can serve as a check on such contamination. Weekly checks

for possible sample storage refrigerator contamination are performed per SOP 512.

4.3 In this method, syringes are used to introduce aqueous samples, soil extracts, or an additional aliquot of organic-free water into the purge and trap device. The laboratory uses dedicated disposable syringes to prevent cross-contamination. However, contamination by carryover within the analytical system can occur whenever high-concentration and low-concentration samples are analyzed sequentially. Samples analyzed in an autosampler run after high concentration samples may need to be re-analyzed if carryover contamination is suspected. Autosampler cleaning is addressed in Section 8.

4.4 Glassware must be scrupulously cleaned, details are provided in SOP 334. Purge tubes are scrubbed with a brush and hot water, rinsed with hot tap water and baked dry at 125°C (±25°C).

5. APPARATUS AND MATERIALS

5.1 PURGE AND TRAP AUTOSAMPLER DEVICE

OI MPM-16 autosampler equipped with pocket heaters and OI Model 4560 concentrator and Supelco Trap J #24939, or equivalents

or

OI Model 4552 Archon automated sampler with concentrator (i.e. Tekmar 3000) device equipped with Supelco Trap K #21066-U, or equivalent

5.2 GAS CHROMATOGRAPH (GC) AND DETECTORS
Hewlett Packard 5890 Series II GC or equivalent equipped with a photoionization (PID) and flame ionization detector (FID) in series

NOTE: An FID must be used for GRO quantitation because its response is similar for all hydrocarbons; other detectors will not produce accurately quantitated total GRO results.

5.3 GC COLUMNS - Equivalent columns/guard columns may also be used

J&W Capillary Column:	DB-624 # 21512-304 *	(30m x 0.53mm ID, 3.0µm film thickness)
J&W Capillary Column:	DB-VRX # 21512-270 *	(30m x 0.45mm ID, 2.55µm film thickness)

*J&W columns are available through VWR, part numbers listed are VWR numbers.

NOTE: The minimum acceptable column resolution should provide separation of MtBE from the methanol solvent front and ethylbenzene from m/p-xylenes in standards.

5.4 CHROMATOGRAPHIC DATA SYSTEM
Hewlett Packard ChemStation (Enviroquant™) or equivalent

5.5 GASES - use only ultra high purity (99.999%)
Helium (purge and carrier gas)
Hydrogen (flame FID detector gas)
Compressed Air (flame FID detector gas)

5.6 MEASURING DEVICES
5.6.1 Luer-lock syringes, Becton & Dickinson or equivalent, disposable, 5mL or 25mL (used for sample introduction)

5.6.2 microsyringes, gas-tight, Precision Hamilton or equivalent, 5µL - 1.0mL sizes (used for spiking)

5.6.3 balance, capable of weighing ±0.01g (used for weighing solid samples)

5.6.4 volumetric flasks, Class A with ground glass stoppers, various sizes

5.7 CONSUMEABLES
5.7.1 Photoionization Lamps, Restek Model 108 #23020 BTEX or equivalent (GRO 8015B or BTEX 8021B); also, Restek Model 108 #20675 or equivalent (GRO 8015B-only)

5.7.2 Compact Vespel/Graphite Ferrules, Restek #20264 or equivalent

5.7.3 Graphite Ferrules, various sizes

5.7.4 Purge Tube (19x150mm), Fisher Scientific Kimbal #14-925K or equivalent

5.7.5 VOA vials, unpreserved, 40mL

6. REAGENTS

6.1 organic-free water, carbon-filtered, heated and purged with helium prior to use (SOP 511)

6.2 Ottawa sand, EMD #SX0075-3 or equivalent

6.3 Methanol (CH_3OH, MeOH), purge and trap grade or higher, Burdick and Jackson #230-4 or JT Baker #9077-02 or equivalent

6.4 STANDARDS
6.4.1 All standards are maintained per PAR SOP 300, which supercedes any guidance in this SOP. Two independent sources of commercial stock standards, in methanol, are required for GRO. The stock standards are purchased as certified solutions from suitable vendors. Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules, if recommended

by the manufacturer. Standards for this procedure must be equilibrated to -10--20°C (stored in freezer) before opening. After opening/initial use, transfer remaining stock standard to a suitable vial (preferably Certan™) with minimal headspace, and store in a freezer (-10--20°C). All opened stock standards must be replaced after 3 months from date opened, or sooner, if comparisons with laboratory control samples indicate a problem.

6.4.2 First source materials are used to create calibration and continuing calibration verification (CCV) standards. Second source materials are used to create the initial calibration verification (ICV) solution. Spike standards may be from either source (the second source is most commonly used for spiking).

Paragon typically uses a commercial gasoline component standard, labeled as Wisconsin GRO mix, as the GRO target stock standard. This Wisconsin GRO mix is typically 10,000-20,000µg/mL total concentration, encompassing a carbon range from C_6 to C_{10}. It typically contains 1,000 to 2,000µg/mL each of benzene, ethylbenzene, methyl-t-butyl ether (MtBE), toluene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, o-xylene, m-xylene, p-xylene and naphthalene (the GRO retention time window is set from this mix using MtBE and naphthalene elution times). Specific commercial gasolines or neat blended gasolines are not typically used.

Non-target analyte internal standard (IS) and surrogate (SS) stock standards are also purchased. The IS is used to quantitate GRO detected in samples. The SS is used to monitor system performance and method effectiveness in dealing with each sample matrix. The IS used for this procedure is α,α,α-trifluorotoluene; the SS used for this procedure is 2,3,4-trifluorotoluene. Each of the standards is purchased typically at a concentration of 2,000µg/mL. Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

NOTE: BFB (bromofluorobenzene) may also be included as an additional surrogate, however, this second surrogate is not routinely reported.

6.4.3 An appropriate volume of stock standard is diluted, with methanol, to a specific volume to create intermediate standards. All dilutions should be performed using microsyringes, Class A volumetric flasks, and purge & trap grade (or higher) MeOH.

A 500µL aliquot of the GRO 10,000µg/mL stock standard is spiked into a 10mL Class A volumetric flask and diluted to the mark using methanol, to create a 500µg/mL total (50µg/mL each component) intermediate calibration standard. The second source GRO stock standard is likewise diluted to create a 500µg/mL ICV intermediate standard.

Because the IS and SS may be added manually or automatically, also separately or together, several intermediate standards are made:

- Use of separate IS and SS standards facilitates surrogate addition at the varied concentration levels required for the ICAL (see Table 1).
- Manual addition is used when the OI MPM-16 purge & trap autosampler device is employed; automated addition is used when the OI Model 4552 Archon purge & trap autosampler device is employed.
- For manual addition, a larger volume (e.g. 5µL) of a 100µg/mL intermediate standard is spiked; for automated addition, a smaller volume (e.g. 1µL) of a 500µg/mL intermediate standard is spiked.
- The separate IS and SS 100µg/mL intermediate standards are prepared by diluting the 2,000µg/mL stock standards 20X using methanol (i.e., a 250µL aliquot of the stock standard is placed into a 5mL Class A volumetric flask and diluted to the mark using methanol).
- The combined IS/SS 500µg/mL intermediate standard is prepared by placing a 50µL aliquot of each of the IS and SS stock standards into a 5mL Class A volumetric flask and diluting to the mark using methanol.

All intermediate standards must be prepared monthly. Standards may be replaced sooner if laboratory quality control analyses or other factors indicate deterioration.

6.4.4 The intermediate GRO calibration standard is injected into syringes containing reagent water to create calibration working standards. Working standards (ICAL, ICV, CCV) are prepared on the day of use and documented in the analytical run log (Form 412). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.4.5 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples are collected in 40mL glass VOA vials with screw tops and Teflon™-lined septa. Aqueous samples should be headspace-free. It is recommended that a minimum of three vials should be collected for each field sample. For a designated MS/MSD, the client may need to provide as many as six vials.

7.3 Where applicable, aqueous samples should be dechlorinated with sodium thiosulfate at time of collection. Aqueous samples are acidified to pH<2 with hydrochloric acid (HCl). Typically the addition of 4 drops of concentrated HCl to each 40mL VOA vial is sufficient to bring the pH of the sample to <2.

The Paragon Project Manager may direct that each aqueous sample is tested for residual chlorine upon receipt at the laboratory. Notify the Project Manager immediately if residual chlorine is detected.

The pH of an aqueous aliquot for each sample is measured and recorded immediately before analysis. Notify the Project Manager if the pH of the sample is greater than 2.

7.4 All samples are to be kept chilled (4±2°C).

7.5 The maximum holding time to analysis for acid-preserved aqueous samples is 14 days from the date of collection. If the water sample is unpreserved, the maximum holding time to analysis is 7 days from date of collection.

7.6 Closed vessel purging by SW5035 is not required. If SW5035 direct purge is requested, solid samples must be collected in Encore™ tubes, however, Paragon is not presently performing low-level SW5035 analysis. Otherwise, for SW5035 methanolic extractions or SW5030 direct purge preparation, solid samples may be collected in 125mL wide-mouth glass containers with Teflon™-lined lids. Solid samples are not chemically preserved and must be analyzed within 14 days of collection.

8. PROCEDURE

8.1 TYPICAL PURGE & TRAP DEVICE SETTINGS (OI Model 4560 concentrator)

Purge Gas Flow (He)Rate:	approximately 40mL/min
Preheat to 40°C:	1-2min
Purge:	8min
Dry Purge:	1min
Desorb Preheat:	none
Desorb:	2min at 255°C
Bake:	13min at 255°C
Valve:	120°C
Transfer Line:	120°C
Sample Heaters:	40°C

NOTE: It is recommended to use the trap manufacturer's temperature parameters. Also note that the dry purge time will remove water vapor and methanol from the injection; however, if the dry purge is overextended, it may cause breakthrough and limited recovery of lighter molecular weight target compounds.

Though not required by any of the referenced methods, Paragon typically applies a heated purge to both aqueous and solid samples. The heated purge will increase purge efficiency or have no effect given complete purge efficiency.

8.2 TYPICAL GC OPERATING CONDITIONS - Conditions may be altered to improve resolution of GRO compounds.

Purge and Carrier gas (He) Flow Rate:	30-50mL/min
FID H_2 Flow Rate:	30mL/min
FID Air Flow Rate:	350mL/min
FID Temperature	260°C
PID Temperature:	300°C
Injector Temperature:	180°C
Initial Oven Temperature:	3min at 35°C
Initial Oven Ramp:	10°C/min to 120°C
Oven Ramp A:	25°C/min to 220°C
Hold:	220°C for 2min

8.3 AUTOSAMPLER CLEANING

After use, each purge tube is removed from the autosampler, washed and regenerated per SOP 334. Additionally, each purge needle is flushed with organic-free DI water (note that the purge tube is rinsed in place, as part of the system program, if using the OI Archon autosampler), then the exterior is wiped with a KimWipe™ and MeOH.

8.4 CHROMATOGRAPHIC MAINTENANCE

8.4.1 Bake out the trap and column. Extra blanks may be necessary to achieve an adequate baseline if carryover is observed. Replace trap if performance problems are demonstrated and cannot be alleviated by routine maintenance.

8.4.2 If trap and front end are clean and functioning properly, clip a loop from the column or replace as necessary.

8.4.3 Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming. If a column is oxidized, replacement may be necessary.

8.4.4 The PID window may be cleaned if the signal has weakened or annually. Lamps are replaced if signal is unstable or cleaning is ineffective.

8.4.5 Standards may be purged and analyzed to ensure that the system is stable prior to acquisition of an ICAL or CCV (i.e., priming may be performed).

8.5 INITIAL CALIBRATION

8.5.1 The GRO initial calibration (ICAL) includes a minimum of 5 concentrations of calibration standards (typically 8 are used), defining the linear range of the detector, typically 50-6000 µg/L. The lowest concentration standard shall be at a level at or below the reporting limit (RL) of each analyte (GRO or component); not all compounds can be detected at the lowest levels of the calibration. Each ICAL standard must include the surrogate, at a level similar to the target analytes; each ICAL must also include the internal standard.

8.5.2 The calibration standards are prepared on the day of use by spiking amounts of intermediate calibration standard into a syringe containing

5mL of organic-free reagent water. Calibration standards are typically prepared as follows:

TABLE 1
GRO INITIAL CALIBRATION STANDARDS

Level	µL GRO Standard (500 µg/mL)	µL Surrogate (100µg/mL)	µL Internal Standard *	Final Volume (5mL)	Final GRO Conc. (µg/L)
ICAL 1	0.5	20	5 (manual), 1 (automated)		50
ICAL 2	1	40	5 (manual), 1 (automated)		100
ICAL 3	2	60	5 (manual), 1 (automated)		200
ICAL 4	5	80	5 (manual), 1 (automated)		500
ICAL 5 (CCV)	10	100	5 (manual), 1 (automated)		1000
ICAL 6	20	120	5 (manual), 1 (automated)		2000
ICAL 7	40	140	5 (manual), 1 (automated)		4000
ICAL 8	60	160	5 (manual), 1 (automated)		6000
ICV (varied)	15	120	5 (manual), 1 (automated)		1500

NOTES: Lower concentration standards may be analyzed, particularly if 8021B analysis is performed simultaneously.

* Concentration of intermediate standard for manual injection is 100 µg/mL, concentration of intermediate standard for automated injection is 500 µg/mL

Where automated injection is accomplished, an equipment validation study must be performed to determine the actual volume delivered. The concentration of standard may be adjusted accordingly for the actual volume delivered by the autosampler at the 1µL setting. For example: (1.135µL actual delivery)(441µg/mL IS/SS spiking solution)/5mL = 100µg/L.

8.5.3 Solid initial calibration standards are similarly prepared by spiking appropriate amounts of intermediate standard onto a 5g aliquot of Ottawa sand that has been measured into a purge tube that contains a small amount of glass wool at the bottom. Then, 5mL of organic-free water is added to facilitate purging.

8.5.4 Electronically integrated peak area responses are tabulated and quantitated using internal standard quantitation. Response Factors (RFs) for individual compounds are calculated as shown below. For

GRO, a 'fingerprint' of peaks within an established retention time range is used for quantitation of analyte concentration (Cs), calculated as shown below:

$RF = (A_x C_{is}) / (A_{is} C_s)$ when using average response factor

$C_s = [(As/Ais - b] [C_{is}/m]$ when using linear curve fit

where:

A_s = response for the analyte to be measured

A_{is} = response for the internal standard

C_{is} = concentration of the internal standard (µg/L, µ/Kg)

C_s = concentration of the analyte to be measured (µg/L, µg/Kg)

b = The intercept of the linear equation

m = The slope of the linear equation

8.5.5 If RF over the working range is constant (i.e., < 20% RSD), then the response is assumed to be invariant and the average (mean) RF may be used to quantitate sample content. Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \frac{\text{Standard Deviation (SD)}}{\text{Average (mean) RF}} \times 100$$

If more than five calibration concentration levels were acquired and the %RSD (of the RFs) exceeds 20% because one of the calibration injections is seen to have been ineffective, that one data point may be deleted from the initial calibration and the %RSD recalculated. The recalculated %RSD must meet acceptance criteria. If an initial calibration point is not used for any reason, the analyst must clearly notate why the data point was not used for instrument calibration.

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be $\geq$0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000. A quadratic regression should not be used to compensate for detector saturation.

Linear (most often) and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

8.6 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of the CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.7 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration. A CCV must be analyzed and reviewed daily prior to the analysis of samples (unless the sequence starts with an ICAL/ICV), after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

NOTE: Method SW8015B allows for up to 12 hours of analysis between CCVs. Paragon commonly analyzes 10 samples between CCVs (less than 12 hours) to reduce the amount of repeat injections.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculate d concentrat ion}) - (\text{expected concentrat ion})}{\text{expected concentrat ion}} \right] (100)$$

Calibration is verified when all compounds are within 15%D or when the average of the %Ds for all compounds is $\leq$15% (individual compounds that exceeded 15% are noted in the data package narrative). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.8 RETENTION TIME WINDOWS

The GRO retention time window (RTW) is set to include the C_6-C_{10} range (MtBE through naphthalene). The RTW is checked to ensure that it is sufficiently wide to include these compounds throughout each analytical batch (i.e., MtBE and naphthalene must be within the RTW for each CCV in the batch).

8.9 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)
Samples are introduced to the GC via purge and trap. Sample introduction techniques (i.e., choice of sample size or dilution) are chosen to maintain response within the linear quantitation range. QC samples (LCS, MS, etc.) are prepared in a manner similar to that of standards described above. A discussion of sample preparations and quantitation follows:

8.9.1 LOW/MEDIUM-LEVEL ANALYSIS

8.9.1.1 Per SW5030B, the nominal sample size is 5mL or 5g. Smaller soil aliquots (i.e., down to 1g) may be used to achieve dilutions up to 5X. Do not use soil sample sizes less than 1g, as smaller soil sample aliquots are likely to yield poor representativeness.

NOTE: See Subsampling for Soil and Sediments (workorder review\QA Info\Guidance Documents) for a discussion of representative soil sampling.

8.9.1.2 Add an appropriate aliquot of aqueous sample to a clean 5mL Luer-lock injection syringe.

When performing an in-syringe dilution (aqueous samples, dilutions >5X), allow enough headspace in the syringe for addition of the sample. Document the dilution on the run log (Form 412).

If the Archon automated injector is not used, spike the sample syringe with 5µL of 100 µg/mL internal standard/surrogate solution. Inject the prepared sample syringe into a purge tube.

8.9.1.3 For solid matrix samples, weigh 1g (nominal) of sample into a 25mL purge tube containing a small amount of glass wool at the bottom. Use a balance that has been verified per SOP 305. Record the exact weight of sample in the preparations logbook.

Attach the purge tube to the autosampler.

Measure 5mL organic-free water into a syringe. If the Archon automated injector is not used, spike the sample syringe with 5µL of 100 µg/mL of internal standard/surrogate solution. Inject the prepared water into the 25mL purge tube containing the measured sample.

8.9.1.4 Make sure the sample valves are placed on the 'purge' position. Analyze.

8.9.1.5 Samples with responses that exceed the calibration range require dilution. In instances where a sample response is out of range, investigation must be performed to ensure that ensuing sample results are not biased by carryover. Investigation includes reanalysis of the contaminated sample and the subsequent samples until confirmation of results demonstrates the lack of bias from carryover.

When high levels analytes are observed on a multi-position autosampler, a dry tube is installed on that position and purged on the next pass to demonstrate fitness of use for that position. In the case of autosampler runs, re-analyze a sample with positive results that follows an over-range sample.

8.9.2 METHANOL-EXTRACTED SAMPLES

8.9.2.1 Obtain solid sample to be extracted from refrigerator and allow it to warm to room temperature. Return sample to refrigerator once a suitable aliquot has been obtained.

8.9.2.2 A 5g to 5mL of methanol extraction is performed in accordance with SW5035. Weigh a minimum of 5.0g of sample into a 20mL VOA vial. Record the weight to 2 decimal places. Add 5.0mL of methanol, cap shake and centrifuge for two minutes at 1400RPM or allow the extract to settle until the methanol solution appears to be free of particles.

8.9.2.3 A maximum of 100µL of methanol extract may be injected so as to not overload the trap. Inject an aliquot of methanol extract into a syringe containing approximately 5mL of organic-free reagent water. If the Archon automated injector is not used, also spike the syringe with 5µL of internal standard/surrogate solution. Inject the prepared water into a purge tube and analyze.

The remaining methanol extract may be transferred to a suitable vial with a Teflon™-lined cap and stored with other extracts in the refrigerator.

8.9.2.4 A methanolic reagent blank (100µL methanol to 5mL organic free water) must also be analyzed.

8.9.2.5 Methanolic extracts must be analyzed within 14 days of sample collection, regardless of when the extraction was performed.

8.9.3 GRO IDENTIFICATION

Concentration of GRO in the sample is calculated using the sum of all peak responses (excluding internal standard and surrogates) from within the C_6 to C_{10} RTW.

8.9.4 LOW/MEDIUM-LEVEL QUANTITATION

The following internal standard quantitation formula is employed where RFs or CFs were used for calibration:

$$\text{Sample GRO}_{\mu g/L \text{ or } \mu g/ Kg} = \frac{(A_x)(DF)}{(\text{mean RF})(V_s \text{ or } W_s)}$$

where:

A_x = Summed GRO peak response in sample, in area units

DF = Dilution factor (if applicable); if no dilution was made, D=1 (dimensionless)

mean RF = Average (mean) RF from latest initial calibration, mg/area

V_s or W_s = Volume or Weight of sample purged, L or Kg

8.9.5 METHANOL-EXTRACTED SAMPLE QUANTITATION

The following internal standard quantitation formula is employed where RFs or CFs were used for calibration:

$$\text{Sample GRO}_{\mu g/L \text{ or } \mu g/Kg} = \frac{(A_x)(V_t)(DF)}{(\text{mean RF})(V_s \text{ or } W_s)(V_i)}$$

where:

A_x = Summed GRO peak response in sample, in area units

DF = Dilution factor (if applicable); if no dilution was made, D=1 (dimensionless)

mean RF = Average (mean) RF from latest initial calibration, mg/area

V_s or W_s = Volume or Weight of sample purged, L or KG

V_t = Total volume of methanol extract, mL

V_i = Volume of extract used for purging, mL

8.9.6 QUANTITATION WHERE CALIBRATED BY LINEAR REGRESSION

Where linear regression is employed, quantitation of sample concentration is based on the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte

y = analyte instrument response (area units)

b = calculated intercept

m = calculated slope of the line

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method Blanks (MBs) are aliquots of matrix (i.e., organic-free water for liquids, Ottawa sand for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and corrected.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results

of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$\text{RPD} = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. Percent Recovery (%R) for spiked analytes is calculated as follows (see QC Table for evaluation criteria):

$$\%\text{R} = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 SURROGATE RECOVERY

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. If the recovery is outside QC limits, the sample is reanalyzed to verify that analytical error was not the problem. If after re-injection the recovery is still out-of-control, initiate an NCR (SOP 928) and apply the decided upon action. Typically, matrix effect is cited as the cause and the occurrence is narrated. However, the client may direct that the sample be re-extracted and reanalyzed (holding time is a consideration).

9.7 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the sensitivity limit of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM THE METHOD

10.1 This SOP meets the requirements of SW-846 Method 8015B and CAL-LUFT. Paragon notes that the suggested carbon range for gasoline (C_6-C_{10}) in SW-846 may be modified to meet our client's requirements. The spike mixture used in

this procedure contains a mixture of pure compounds whose straight-chain carbon equivalent numbers range from C_6 to C_{12}. These pure compounds (in their mixture) define the chromatographic retention time region used to identify and quantitate the gasoline components in the samples and allow for the application of an extended range analysis to C_{12} upon client request.

10.2 Heated purge of aqueous samples is not required by SW5030. Paragon may perform heated purging of aqueous samples. The heated purge of a water increases the purging efficiency or has no effect on a complete purge and will not adversely bias the results.

10.3 CAL-LUFT specifies a %D criterion of ±10% for daily calibration verification. Paragon defaults to the criteria listed in Method 8015B of ±15%D unless otherwise required by client or project specific needs (as indicated in the LIMS Project Specification).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.5 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.2 WASTE DISPOSAL

11.2.1 Any methanol, hexane, acetone, or other non-halogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste stream.

11.2.2 Any rinse waters used for rinsing syringes or other devices prior to contact with samples must be disposed of in the Aqueous Lab Waste.

11.2.3 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.4 The extract vials, associated extracts, and any PCB contaminated debris that may contain PCBs in excess of 50ppm shall be disposed of intact in the PCB Debris Waste stream.

11.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be removed or defaced prior to disposal.

DOCUMENT REVISION HISTORY

8/24/06: LIMS program specification language strengthened. Standards and Analysis sections re-organized. Form attached. DOCUMENT REVISION HISTORY section added.

Analytical Method: SW8015B	**Parameter:** Total Volatile Petroleum Hydrocarbons		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5-points, all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitate, If RSD ≥20%, calculate linear regression (not forced through origin); use for quantitation if correlation coefficient (r) ≥0.995 or calculate quadratic regression (minimum of six points required); use for quantitation if COD (r^2) ≥0.99	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Initial Calibration Verification (ICV); conc. not equal to midpoint of calibration curve; second source	After each ICAL	≤15%D of each compound or mean %D ≤15% or as otherwise specified in applicable LIMS program specification	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8015B requires minimum of once per 12 hour shift)	≤15%D of each compound or mean %D ≤15% or as otherwise specified in applicable LIMS program specification	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed before and after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV (bracketed by acceptable CCVs) will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.

Analytical Method: SW8015B	**Parameter:** Total Volatile Petroleum Hydrocarbons		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Retention Time Window (RTW); The retention time range for GRO includes MtBE through naphthalene, window is checked against CCV for each batch.	Whenever a new column is installed; and checked with each batch	Note that the ICV and CCV analyses are also used to monitor RT drift	Width of GRO window should include MtBE and naphthalene of bracketing CCVs.
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix NOTE: Methanol extracts additionally require a methanol MB.	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze

Analytical Method: SW8015B	**Parameter:** Total Volatile Petroleum Hydrocarbons		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Sample (LCS)	matrix	limits as specified in the LIMS program specification	to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits.	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers. Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed)

Analytical Method: SW8015B	**Parameter:** Total Volatile Petroleum Hydrocarbons		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Surrogate Spike	All extractions including field and laboratory QC samples	See laboratory limits; recoveries should be within current limits alternative criteria as defined in the LIMS program specifications may apply	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the most likely cause. However, any samples with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if surrogate recovery in the associated MB is not within limits and the samples are within the holding time, then re-extract and reanalyze all associated samples - if samples are beyond the holding time, then contact the PM via an NCR. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration.
Internal Standard	Each batch	50-200%	Investigate and correct standard or instrument
Method Detection Limit (MDL) Study	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 434 REVISION 8

TITLE: **ANALYSIS OF CHLORINATED HERBICIDES BY GAS CHROMATOGRAPHY -- METHODS SW8151A, EPA 615 AND EPA 515.1**

FORMS: **530 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER Dan Sherman DATE 7/24/06
QUALITY ASSURANCE MANAGER Deb Schaut DATE 7/21/06
LABORATORY MANAGER [signature] DATE 7-21-06

HISTORY: Rev0, PCN #254, 8/15/94; Rev1, 1/17/96; Rev2, 2/27/96; Rev3, 6/24/99; Rev4, 3/6/02; Rev5, 8/5/02; Rev6, 2/13/04; Rev7, 3/9/06; Rev8, 7/24/06. re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operation Procedure (SOP) and the methods it references, SW8151A, EPA 615 and EPA 515.1, are used to determine the concentration of chlorinated herbicides in liquid (all) and solid matrices (SW8151A). The following compounds typically comprise Paragon's target analyte list:

Dalapon	Silvex
Dicamba	2,4,5-T
MCPP	2,4-DB
MCPA	Dinoseb
Dichloroprop	2,4-Dichlorophеylacetic acid
2, 4-D	

Other compounds may be analyzed if successful method detection limit (MDL) and demonstration of capability (DOC) studies are performed.

2. SUMMARY

The target herbicides are commonly applied as either an amine salt (usually trimethyl amine) or one of many esters of the base compound. These are easier to handle than the free acids. Hydrolysis, to covert any esters to free acids, is included in the sample preparation process. Samples are extracted, esterified and the extracts concentrated and solvent exchanged using appropriate Paragon Analytics (PAR) SOPs (i.e., 664, 607, 637). The extracts are injected into a gas chromatograph (GC) containing a sample splitter and two columns of varying selectivity (i.e., dissimilar RT elution properties). The target analytes are separated in the columns and detected by two electron capture

detectors (ECDs). This chromatography system allows tentative identification by one column and confirmation by the other column to be performed simultaneously. Quantitation is performed using the best column for each analyte. The analyst considers performance data such as separation of analytes and interferences, calibration performance and matrix spike results in selecting the quantitation column for each analyte detected and reported. If results from both columns are comparable, the highest result is reported.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Method interferences may be caused by contaminants in solvents, reagents, glassware, or other sample processing hardware that lead to discrete artifacts or elevated baselines in gas chromatograms. Only high purity solvents and reagents are used; prescriptive measures for cleaning glassware are detailed in SOP 334. All of these materials must be routinely demonstrated to be free from

interferences under the conditions of the analysis as evidenced by the analysis of interference-free reagent blanks.

4.2 The target herbicides are strong organic acids that react readily with alkaline substances and may be lost during sample preparation steps.

4.3 Matrix interferences may be caused by contaminants that are co-extracted from the sample. The extent of matrix interferences will vary considerably from waste to waste, depending upon the nature and diversity of the waste being analyzed.

4.4 Organic acids, especially chlorinated acids, cause the most direct interference (due to reaction products formed in the methylation sample preparation step). Phenols, including chlorophenols, may also interfere.

4.5 Sample extracts must be free of water prior to methylation or poor recoveries will be obtained. The sodium sulfate drying agent must be acidified before use.

4.6 Alkaline hydrolysis and subsequent extraction of the basic solution removes many chlorinated hydrocarbons and phthalate esters that might interfere with the electron capture analysis. However, hydrolysis might result in limited recovery of dinoseb (cleavage of alkyl group) and dalapon (hydrolysis to pyruvic acid).

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH, AUTOSAMPLER, DETECTORS
Hewlett Packard (HP) 5890 Series II GC equipped with HP7673A autosampler and dual electron capture detectors (ECDs), or equivalents

5.2 CHROMATOGRAPHIC DATA ACQUISITION/PROCESSING SYSTEM
Hewlett Packard ChemStation (Enviroquant™) or equivalent

5.3 COLUMNS - Equivalent columns may also be used

Restek Pesticide Column:	RTX-CLPesticides	#11123	(30m, 0.25mm ID, 0.5µm film)
Restek Pesticide (Guard) Column:	RTX-CLPesticides2	#11323	(30m, 0.25mm ID, 0.5µm film)
Restek Pesticide Column:	RTX-CLPesticides	#11139	(30m, 0.32mm ID, 0.25µm film)
Restek Pesticide (Guard) Column:	RTX-CLPesticides2	#11324	(30m, 0.32mm ID, 0.25µm film)

5.4 GASES - ultra high purity (99.999%)
Helium - carrier gas
Nitrogen - make-up gas

5.5 MEASURING DEVICES
Syringes - 10-1000µL
Volumetric flasks, Class A with stoppers, 10-100mL

5.6 GC CONSUMABLES

- Vials - National Scientific C4011-1, or equivalent
- Caps - National Scientific C4000-51B, or equivalent
- Inlet Seals - dual Vespel ring, 0.8mm, Restek #21243, or equivalent
- Septa - 11mm, Restek #20365, or equivalent
- O-ring - graphite, 6.5mm, Restek #20299, or equivalent
- O-ring - Viton™, Restek #20377, or equivalent
- Liner - splitless, 4mm ID, Restek #20799-214.5, or equivalent
- Glass Wool - deactivated, Restek #20789, or equivalent
- Gold Seal - Restek #21306, or equivalent
- Universal Presstight Y - Restek #20469, or equivalent
- Vespel/Graphite Ferrule (detector) - Restek #20221, or equivalent
- Compact Vespel/Graphite Ferrule - Restek #20249, or equivalent
- Graphite ferrules - various sizes
- Split Vent Trap (SW8081) - Agilent RDT-1023, or equivalent

6. REAGENTS

6.1 SOLVENTS - Only pesticide grade solvents may be used!

Methanol (CH_3OH, MeOH) - Burdick and Jackson #230-4, or equivalent

n-Hexane (C_6H_{14}) - Burdick and Jackson #216-4, or equivalent

Diethyl ether ($C_2H_5OC_2H_5$) - Burdick & Jackson #106-4, or equivalent. Must be peroxide-free. If preserved, stabilized with BHT (not ethanol), or unpreserved.

Methyl tert butyl ether $(CH_3)_3COCH_3$, MTBE - JT Baker #9043-02, or equivalent -- Method EPA 515.1 only

6.2 STANDARDS

6.2.1 Storage and Documentation - All standards are maintained per SOP 300, which supercedes any guidance in this SOP. Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules, if recommended by the manufacturer. Generally after opening ampules, the standards for this procedure are stored in the freezer (-10--20°C), in PTFE-capped, or equivalent, vials. Opened stock standards and intermediate standards expire six months from opening (preparation) or per the manufacturer's expiration date (whichever is sooner). Standards may be replaced sooner if laboratory quality control (QC) analyses or other factors indicate deterioration.

6.2.2 Calibration and Spike Standards - At minimum, two independent sources (first, second) of commercial stock standards are needed for target analytes. These certified stock standards are purchased from suitable vendors as free acid mixes (first source) and methyl esters

(second source). First source materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards. Second source materials are used to create the initial calibration verification (ICV) solution (used to independently verify the accuracy of the initial calibration, ICAL). Where commercially-derivatized methyl esters are used to prepare standards, the concentrations must be corrected back to the free acid form. A (non-target analyte) surrogate stock standard is also purchased. The surrogate used for this method is 2,4-dichlorophenylacetic acid (DCAA). Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

An appropriate volume of stock standard is diluted (in hexane) to a specific volume to create intermediate standards (the QC sample and surrogate spike standards, used by the Organics Extraction Group, are intermediate standards). The intermediate calibration standards are further diluted to volume using an appropriate solvent to create working standards. Working standards are prepared on the day of use and documented in the analytical run log (Form 530). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.2.3 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory **D**epartment.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING, HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are generally not chemically preserved for SW8151A analysis and must be collected in amber glass containers (generally 1000mL) with Teflon™-lined lids. Samples must be maintained at 4±2°C and extracted within 7 days of collection (14 days for EPA 515.1). Sodium thiosulfate ($Na_2S_2O_3$) may be used to dechlorinate liquid samples such as drinking water or chlorinated wastewater. This should be accomplished by the client in the field. The Project Manager may designate the need for residual chlorine check of the sample upon receipt. Additionally, samples for EPA Method 608 may need to have pH adjusted upon receipt.

7.3 Solid samples are collected in wide-mouth glass containers with Teflon™-lined lids. Solid samples are not chemically preserved and must be maintained at 4±2°C. Solid samples must be extracted within 14 days of collection.

7.4 Extracts, from liquid or solid samples, must be maintained between ⁻10 and ⁻20°C and analyzed within 40 days of preparation.

8. PROCEDURE

8.1 TYPICAL GAS CHROMATOGRAPHIC CONDITIONS

Carrier gas (He):	2.2 mL/min
Make-up gas (N_2):	20-40 mL/min
Injection port temperature:	205°C
Injection volume:	1-2µL, splitless
Detector temperature:	325°C
Initial oven temperature:	50°C, hold 4min
Oven ramp A:	15°C/min to 130°C
Oven ramp B:	7°C/min to 190°C, hold 3.0min
Oven ramp C:	20°C/min to 320°C, hold 7.0min

The conditions used for sample analysis must be the same as the conditions used during initial calibration**.**

8.2 SYSTEM MAINTENENANCE AND PREPARATION

Because of the low concentrations injected on a GC/ECD, column adsorption (active sites) may be a problem when the GC has not been used for a day or more. Therefore, the GC column may need to be conditioned by injecting a suitable prime, such as mid to high concentrations of expired standards, prior to calibration. Solvent blanks are typically injected following the priming to demonstrate that the system is free from carryover.

8.3 INITIAL CALIBRATION

8.3.1 Prepare a minimum of 5 concentrations of calibration standards (generally six are used), defining the linear range of the detector (SW8151A). Fewer calibration levels are required by EPA 615 and 515.1, but the use of six calibration levels is recommended. The lowest concentration standard shall be at a level at or below the reporting limit (RL) of each analyte. Create calibration standards by diluting aliquots of the intermediate calibration standard using hexane. The mid-range calibration standard is used for continuing calibration verification (CCV). For herbicides analysis, the calibration range varies contingent upon the target analyte. Calibration standards are prepared with surrogate standards at similar levels to target analytes. A typical

calibration sequence and preparation steps are shown below in Table 1.

TABLE 1
CALIBRATION STANDARDS

Working Standard	Hexane (µL)	Intermediate Standard (µL)	Standard Concentration (ng/mL)
ICAL Level 6 (30%)	700	300	varies per analyte
ICAL Level 5 (25%)	750	250	varies per analyte
ICAL Level 4 (20%)	1000	250	varies per analyte
ICAL Level 3 (10%)	900	100	varies per analyte
ICAL Level 2 (5%)	950	50	varies per analyte
ICAL Level 1 (2.5%)	975	25	varies per analyte
2nd source ICV (10%)	900 varied over time	100 varied over time	varies per analyte
CCV (20%)	1000	250	varies per analyte

8.3.2 Inject and analyze 1µL of each calibration standard. Each data file quantitation is accomplished via the external standard method of quantitation. Analyte Response Factors (RFs) are calculated as follows:

$$RF = \frac{\text{integrated peak area of analyte}}{\text{analyte concentration}}$$

If the RFs over the working range of the detector are constant (i.e., $\leq$20% RSD), then response can be assumed to be invariant (linear through zero) and the average (mean) RF may be used to quantitate sample concentration.

8.3.3 Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean response factor}} \right)(100)$$

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be $\geq$0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. Non-linear (quadratic)

regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000. A quadratic regression should not be used to compensate for detector saturation.

Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is injected after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of the CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated. Exception: Paragon has noted a consistent comparative elevated response for dinoseb and subdued response for dalapon between the first and second source vendor standards used. Paragon narrates this occurrence in the data package narrative.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. After a valid CCV is achieved, up to 10 samples may be analyzed. After the 10th sample, a CCV must be analyzed and the percent difference (drift) calculated (see equation below). QC samples are counted as part of the number of injections, instrument blanks are not.

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

NOTE: Method SW8151A allows 20 samples to be analyzed between CCVs. Paragon commonly analyzes 10 samples between CCVs to reduce the amount of repeat injections.

Method 515.1 provides guidance that the concentration of calibration checks should be varied with one below the midpoint and one above the midpoint of the calibration range.

Calibration is verified when all compounds are within 15%D or when the average of the %Ds for all compounds is ≤15% (individual compounds that exceeded 15% are noted in the data package narrative). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples

injected since the last compliant CCV must be reanalyzed. As long as CCV analyses are compliant (±15 %D), the run sequence may continue.

8.6 RETENTION TIME WINDOWS

For GC methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (equation given previously) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time ±3σ, such that the Upper Limit = +3σ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time drift). Sample matrices may cause drift that requires further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system.

8.7 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)

A constant volume, generally 1µL of each standard, blank, QC or field sample extract is directly injected into the GC via the automated injector. Sample extracts are diluted to maintain response within the linear range when necessary. All prepared extracts contain the surrogate (see Section 9). Extract and sample concentration are determined as discussed below.

8.7.1 Note that Paragon employs a sample splitter that facilitates simultaneous dual column injections; therefore, both columns are calibrated in the same manner and either column may serve as the column for quantitation.

8.7.2 Tentative identification occurs when a peak from a sample extract falls within the RTW of one column. If the peak also falls within the RTW of the second column, then the analyte's presence has been confirmed. Quantitation is calculated from both column responses and the best result is reported. The analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the quantitation column for each analyte detected and reported. If there are interferences present on one column, these need to be documented by printouts of that region of the

chromatogram; the lower (i.e., other column's) results may be reported in this case. If results from both columns are of comparable quality, the higher concentration is reported (per SW8000).

8.7.3 Sample concentration is calculated using the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte

y = analyte instrument response (area units)

b = calculated intercept

m = calculated slope of the line

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

If the average CF is used for quantitation, the sample concentration is calculated using the following equation:

$$\text{Concentration}_{(ug/L,\ ug/kg)} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(V_s \text{ or } W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition,

batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

MBs are aliquots of matrix (i.e., organic-free water for liquids and acidified boiling chips for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and corrected. As the analyst deems necessary, aliquots of solvent may be injected to clean the analytical system and demonstrate that it is free from contamination.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix

on target analyte detection and recovery. See QC Table for evaluation criteria. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right) (100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 SURROGATE RECOVERY

The %R of the surrogate is calculated (see equation shown for LCS recovery above) for all field and QC samples. If the recovery is outside QC limits, the sample is reanalyzed to verify that analytical error was not the problem. If after re-injection the recovery is still out-of-control, initiate an NCR (SOP 928) and apply the decided upon action.

9.7 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at a minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Methods SW8151A, EPA 615 and EPA 515.1. Performance data substantiating the use of Soxhlet extraction as an appropriate preparative technique for solid samples is on file with Paragon's Quality Assurance Department.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.5 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.2 WASTE DISPOSAL

11.2.1 Any hexane, acetone, or other nonhalogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste stream.

11.2.2 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.3 The extract vials, associated extracts, and any PCB contaminated debris that may contain PCBs in excess of 50ppm shall be disposed of intact in the PCB Debris Waste stream.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be removed or defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/14/06: LIMS program specification references strengthened; dual column use and results interpretation clarified; curve fit criteria discussion augmented; referenced Soxhlet Extraction of Herbicide in Soils technical report. DOCUMENT REVISION HISTORY added. Replacements for pages 11, 12, 14 issued 7/31/06 (corrected RPD and updated MS %R formulas, updated DOCUMENT REVISION HISTORY).

Analytical Method: SW8151A, EPA 615 & 515.1	**Parameter:** Analysis of Chlorinated Herbicides by Gas Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5-points, all analytes (SW 8151A); Methods EPA 615 & 515.1 do not require 5-points	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitate Calculate linear regression (not forced through origin); use for quantitation if correlation coefficient (r) ≥0.995 or Calculate quadratic regression (minimum of six points required); use for quantitation if COD (r^2) ≥0.99	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Initial Calibration Verification (ICV); conc. not equal to midpoint of calibration curve; second source	~~Once~~ After each ICAL	≤15%D of each compound or mean %D ≤15% or as otherwise specified in applicable LIMS program specification	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses; (SW8151A allows bracketing of 20 field sample analyses)	≤15%D of each compound or mean %D ≤15% or as otherwise specified in applicable LIMS program specification	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections	Whenever a new column is installed	Column and compound specific. Window is ±3x the standard deviation of the 3-injection average for the respective column	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound.

Analytical Method: SW8151A, EPA 615 & 515.1	**Parameter:** Analysis of Chlorinated Herbicides by Gas Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
throughout at least a 72-hour period to be representative of variation		Note that the ICV and CCV analyses are also used to monitor RT drift	Experience of analyst weighs heavily in interpretation of chromatograms (refer also to RT Shift).
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL		Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of $\leq$20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at $\geq$10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS);	1 per each preparation	See laboratory limits; recoveries	Check calculations and spike

Analytical Method: SW8151A, EPA 615 & 515.1	**Parameter:** Analysis of Chlorinated Herbicides by Gas Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Laboratory Control Sample (LCS)	batch of ≤20 samples of like matrix	for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions was the cause. - if still non-compliant and the samples are within the extraction holding time, then request re-extraction using an NCR, and reanalyze all associated samples for the analyte that do not meet criteria - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per batch, not to exceed 20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per batch ~~of samples~~, not to exceed 20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits.	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Surrogate Spike	All extractions including field and laboratory QC samples	See laboratory limits; recoveries should be within current limits ~~for one or both surrogates~~; alternative criteria as defined in the LIMS program specifications may apply	Check calculations and spike preparation for documentable errors. - if no errors are found and the surrogate recoveries in the MB and LCS are within limits, then sample matrix effects are the

Analytical Method: SW8151A, EPA 615 & 515.1	**Parameter:** Analysis of Chlorinated Herbicides by Gas Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			most likely cause. However, any samples with ~~both~~ surrogate recovery outside the QC limits with no visible chromatographic cause, should be re-injected to determine if an injection error was the cause for the low recovery. - if ~~both~~ surrogate recovery in the associated MB and LCS is not within limits and the samples are within the holding time, then re-extract and reanalyze all associated samples - if samples are beyond the holding time, then contact the PM via an NCR. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration.
Method Detection Limit (MDL) Study	As needed, ~~and~~ at minimum, annually	Positive result < the analyte reporting limit (RL)	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

LABORATORY MANAGER _____ DATE 8-13-07

HISTORY: New, Rev0, 5/15/97; Rev1, 2/18/99; Rev2, 8/18/99; Rev3, 1/23/02; Rev4, 3/2/02; Rev5, 3/14/03; Rev6, 4/16/04; Rev7, 11/22/04; Rev8, 3/9/06; Rev9, 8/4//06; Rev10, 8/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- Methods EPA 504.1 and SW8011 -- are used to determine the concentration of 1,2-dibromoethane (EDB) and 1,2-dibromo-3-chloropropane (DBCP) in water. A third compound, 1,2,3-trichloropropane (1,2,3-TCP) may also be analyzed by this procedure, but this compound is not typically part of Paragon's target analyte list.

2. SUMMARY

A 6g portion of salt (NaCl) is added to a 40mL VOA vial containing approximately 35mLs of standard or sample (actual volume determined gravimetrically). Then, 2mLs of n-hexane (extraction solvent) is added to the vial, which is capped and shaken vigorously for 1min (manually micro-extracted). After the contents of the vial are allowed to settle (phase separation), 1µL of hexane extract is injected into a gas chromatograph (GC) that is equipped with a sample splitter, two dissimilar columns, and dual electron capture detectors (ECDs). Each column separates the target analytes, and an electronic integrator processes ECD peak response. Target compound concentration is calculated using an external standard method of quantitation. This dual column chromatography allows tentative identification by one column and confirmation by the other column to be performed simultaneously.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of

Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Trip blanks should be received with each sample submission for evaluation of possible contamination during shipment. Inform the Project Manager if no trip blank is received.

4.2 Contaminants in reagents such as the hexane extraction solvent, from glassware or carried over from within the analytical system, may cause the appearance of discrete artifacts or elevated baselines. Use of high purity reagents, scrupulously cleaned glassware and frequent maintenance of the analytical system minimizes these interferences. The absence of significant peak tailing is a good indication of proper system performance.

4.3 If present in very high concentrations, the common chlorination by-product, dibromochloromethane (synonym chlorodibromomethane), may mask low levels of EDB.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH (GC), AUTOSAMPLER AND DETECTORS
Hewlett Packard (HP) 5890 Series II GC equipped with dual on-column injection and electron capture detectors (ECDs), with Hewlett Packard 7673 Autosampler or equivalents

5.2 CHROMATOGRAPHIC DATA ACQUISITION AND PROCESSING SYSTEM
Hewlett Packard ChemStation (Enviroquant™), or equivalent

5.3 COLUMNS - Equivalent columns/guard columns may also be used

Restek Pesticide Column:	RTX-CLPesticides	#11123	(30m, 0.25mm ID, 0.5µm film)
Restek Pesticide Column:	RTX-CLPesticides2	#11323	(30m, 0.25mm ID, 0.5µm film)
Restek Pesticide Column:	RTX-CLPesticides	#11139	(30m, 0.32mm ID, 0.25µm film)
Restek Pesticide Column:	RTX-CLPesticides2	#11324	(30m, 0.32mm ID, 0.25µm film)

5.4 GASES - **Only high or ultra-high purity gases shall be used**
Helium (carrier/detector gas)
Nitrogen (makeup gas)

5.5 MEASURING DEVICES
Precision Hamilton™ microsyringes, or equivalent, in 10, 25, 100µL and 2.0mL sizes
Volumetric flasks, Class A with ground glass or PTFE stoppers, 10mL and 25mL sizes
Top-loading laboratory balance, with ±0.01g sensitivity

5.6 GC CONSUMABLES

- Vials - National Scientific C4011-1, or equivalent
- Caps - National Scientific C4000-51B, or equivalent
- Inlet Seals, dual Vespel ring - Restek 0.8mm #21243, or equivalent
- Septa, 11mm - Restek #20365 or equivalent
- O-ring, graphite, 6.5mm - Restek #20299, or equivalent
- O-ring, Viton - Restek #20377, or equivalent
- Liner, splitless, 4mm ID - Restek #20799-214.5, or equivalent
- Glass Wool, deactivated - Restek #20789, or equivalent
- Gold Seal - Restek #21306, or equivalent
- Universal Presstight Y - Restek #20469, or equivalent
- Vespel/Graphite Ferrule (detector) - Restek #20221, or equivalent
- Compact Vespel/Graphite Ferrule - Restek #20249, or equivalent
- Graphite Ferrules - various sizes
- Split Vent Trap (SW8081) - Agilent RDT-1023, or equivalent

5.7 Autosampler vials, with caps

5.8 Transfer pipets, disposable

6. REAGENTS - Only chemicals that are reagent grade or higher shall be used

6.1 Sodium chloride (NaCl), VWR, Cat. #VW6430-7 or equivalent: Prepare by pulverizing a batch of NaCl and placing it in a muffle furnace at room

temperature. Increase the temperature of the muffle furnace to 400°C for 0.5 to 6 hours. Remove the NaCl, allow to cool, place in a storage bottle and cap.

6.2 Deionized (DI) reagent water; obtained from Paragon's DI water system

6.3 SOLVENTS - **Only pesticide residue grade or equivalent may be used!**
Hexane (C_6H_{14}), Burdick and Jackson #216-4, or equivalent
Methanol (CH_3OH, MeOH), Burdick and Jackson #230-4, or equivalent

6.4 STANDARDS

6.4.1 All standards are maintained per PAR SOP 300, which supercedes any guidance in this SOP. Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules, if recommended by the manufacturer. Generally after opening ampules, the standards for this procedure are stored in the freezer (-10--20°C), in PTFE-capped, or equivalent, vials.

Opened stock standards and intermediate standards expire six months from opening (preparation) or per the manufacturer's expiration date (whichever is sooner). Standards may be replaced sooner if laboratory quality control (QC) analyses or other factors indicate deterioration.

6.4.2 Two independent sources of commercial stock standards are required for target analytes. These certified stock standards are purchased from suitable vendors. First source materials are used to create calibration and continuing calibration verification (CCV) standards. Second source materials are used to create the initial calibration verification (ICV) solution and the QC sample (i.e., LCS/LCSD, MS/MSD) spike standard. Section 9 of this SOP gives definitions and uses of batch QC samples. Per SW8011, Paragon does not utilize a surrogate for this procedure.

For this procedure, aliquots of primary stock standard are spiked directly into an approximate volume of 35mLs of DI water (actual volume determined gravimetrically) to create the uppermost three instrument calibration standards. The stock standard is also diluted 10-fold (with methanol) to create an intermediate standard, from which aliquots are spiked directly into approximate volumes of 35mLs of DI water to create the lower three instrument calibration standards, as well as the CCV. Second source materials are diluted with methanol to create an intermediate ICV (used by the analyst) and QC sample (used by the Organics Extraction Group) spike standard.

All working standards (i.e., those prepared in DI water) are made on the day of use. Microextractions are documented on Form 532; analyses are documented on run log Form 530. A detailed description regarding calibration standards can be found in Section 8 of this SOP.

6.4.3 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Samples must be collected in analyte-free 40mL screw-cap vials with Teflon™ septa. Note that samples are micro-extracted in their original containers.

7.3 Sodium thiosulfate ($Na_2S_2O_3$) may be used to dechlorinate liquid samples that contain residual chlorine. This should be accomplished by the client in the field. One of two preservation procedures may be used: Either sample containers may be prepared by adding 3.0mg of $Na_2S_2O_3$ crystals, or, samples may be preserved in the field via the addition of 75µL of freshly prepared $Na_2S_2O_3$ solution (40mg/mL concentration). The Paragon Project Manager may designate the need for residual chlorine check of the sample upon receipt.

7.4 Samples must be maintained at 4±2°C and extracted within 14 days of collection. Analysis must occur within 24hrs of extraction (EPA 504.1).

8. PROCEDURE

8.1 TYPICAL GC OPERATING CONDITIONS

Carrier gas:	1.5mL/min (constant flow mode 9.3psi)
Make-up gas:	20-40mL/min
Injector Temperature:	200°C
Initial Oven Temperature:	60°C
Initial Hold:	0.5min
Oven Ramp A:	10°C/min to 120°C
Oven Ramp B:	30°C/min to 210°C
Hold:	0.5 min
Detector Temperature:	325°C

8.2 CHROMATOGRAPHIC MAINTENANCE

8.2.1 Dual columns are connected using a press-fit Y-shaped glass splitter or a Y-shaped fused-silica connector. Reattach the columns after cleanly cutting off at least two loops from the injection port side of the column using a capillary cutting tool or scribe. The accumulation of high boiling residues may change split ratios between dual columns and thereby change calibration factors. Clip a loop from the guard column or replace as necessary.

8.2.2 Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming.

8.2.3 Peak tailing for all components is exacerbated by dirty injectors, dirty guard columns, and dirty glass Y's.

8.2.4 Prime is needed to fill the GC system's active sites and to stabilize instrument response. A standard, at a level approximately twice that of the CCV, is injected repeatedly until reproducible peak areas are observed (usually three injections). If the system remains unstable, additional maintenance must be performed to correct the problem prior to continuing with the analysis.

8.3 INITIAL CALIBRATION

8.3.1 Prepare a minimum of 5 concentrations of calibration standards to define the linear range of the detector. For this procedure, the working calibration standards are created by adding aliquots of a 200µg/mL stock standard to a VOA vial of reagent water, for a total volume of 35mLs (actual volume is determined gravimetrically and recorded). A 6g portion of salt is then added to each VOA vial followed by the addition of 2mLs of hexane. After manually shaking (micro-extraction) and allowing the vial's contents to settle, a 1µL volume of hexane extract is directly injected into the GC for analysis.

NOTE: For EPA 504.1 analysis, if the samples were treated with sodium thiosulfate ($Na_2S_2O_3$) to remove residual chlorine, the calibration and calibration check standards must also be prepared with an amount of $Na_2S_2O_3$ equal to that used to treat the samples.

Each ICAL standard must include all target analytes. The lowest concentration standard shall be at a level at or below the analyte

reporting limit (RL). A typical calibration sequence and preparations are shown below in Table 1.

Table 1
CALIBRATION STANDARDS

Calibration Level	Amount of Standard (µL)	Final Volume H_20 (mL)	Final Concentration (µg/L)
ICAL 6	70 (primary)	35	0.4
ICAL 5	35 (primary)	35	0.2
ICAL 4	17.5 (primary)	35	0.1
ICAL 3	70 (intermediate)	35	0.04
ICAL 2	35 (intermediate)	35	0.02
ICAL 1	17.5 (intermediate)	35	0.01
CCV	17.5 (primary)	35	0.1
ICV	17.5 (primary, 2nd source)	35	0.1

8.3.2 Inject and analyze 1µL of each calibration standard. Each data file quantitation is accomplished via the external standard method of quantitation. Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{Peak Area}}{\text{Amount of analyte injected}}$$

If the CFs over the working range of the detector are constant (i.e., ≤20% RSD), then response can be assumed to be invariant (linear through zero) and the average (mean) CF may be used to quantitate sample content.

8.3.3 Relative Standard Deviation (RSD) is calculated as:

$$\text{RSD (\%)} = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean response factor}} \right)(100)$$

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first (minimum of 5 ICAL points used, r) or second (minimum of 6 ICAL points used, r^2) order regression curve fit that does not pass through zero (e.g., least squares method) may be constructed. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000B. A quadratic regression should

not be used to compensate for detector saturation. Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

If a first order regression fit is applied, the correlation coefficient (r) value yielded must be $\geq$0.995. If a second order regression fit is applied, the coefficient of determination (COD, r^2 value) yielded must be $\geq$0.99. Note that the curve fit value expresses "goodness of fit", with perfect fit being a value of 1.0.

If the curve fit value does not meet criteria, check that the calibration standards were prepared properly, reanalyze and generate a new initial calibration curve.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The acceptance criteria for the ICV is the same as for the CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated. See QC Summary Table for further details.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration (0.1µg/L). Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

NOTE: Method SW8011 allows 20 samples to be analyzed between CCVs. Paragon commonly analyzes 10 samples between CCVs to reduce the amount of repeat injections.

The percent difference (%D) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when responses for all analytes are within $\leq$30%D for EPA 504.1 and $\leq$40%D for SW8011. If a CCV does not meet acceptance criteria, reanalyze the CCV. See QC Summary Table for further details and corrective action to be taken should the CCV still fail.

8.6 RETENTION TIME WINDOWS

For GC methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used to compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (σ) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time $\pm 3\sigma$, such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time shifts). Sample matrices may cause RT differences that require further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system.

8.7 SAMPLE MICROEXTRACTION, ANALYSIS, CALCULATIONS, REPORTING

8.7.1 Remove samples from storage and allow them to come to room temperature before starting preparation.

8.7.2 Uncap a 40mL sample vial and pour off approximately 5mL.

8.7.3 Recap the sample vial, weigh to the nearest 0.01g, record on benchsheet (Form 532).

8.7.4 Remove cap and add 6g prepared NaCl. Recap and shake container until dissolved.

8.7.5 Remove cap. If sample is to be used as a QC sample, spike with appropriate amount of QC spike solution. Use a syringe to add 2mLs n-hexane. Recap and shake vigorously for 1min.

8.7.6 Set vial aside and allow phases to separate.

NOTE: If stored at this stage, *keep container upside down initially*. Turn bottles upright after several hours.

8.7.7 Remove cap. Using a clean transfer pipette, carefully transfer an aliquot of the n-hexane layer to a clean autosampler vial and cap the vial. Place in automated sampler for subsequent analysis.

NOTE: The remaining hexane phase (being careful not to include any of the water phase) may be transferred into a second autoinjector vial, capped, and stored at 4±2°C as a reserve for reanalysis if needed. However, the extract holding time is only 24 hour.

8.7.8 Discard the remaining contents of the 40mL container into the appropriate waste stream for mixed aqueous/non-halogenated solvent. Rinse with water and shake empty vial briskly to remove any liquid that is still clinging. Recap and weigh to the nearest 0.01g and record on benchsheet. The net weight (g) is equivalent to the sample volume (mL) extracted.

8.7.9 A constant volume, generally 1µL of each standard, blank, QC or field sample extract is directly injected into the GC via the automated injector. When necessary, sample extracts are diluted (with hexane) to maintain response within the linear range.

8.7.10 Note that Paragon employs a sample splitter that facilitates simultaneous dual column injections. Both columns are calibrated in the same manner and either column may serve as the column for quantitation.

Tentative identification occurs when a peak falls within the RTW of one column. If the peak also falls within the RTW of the second column, then the analyte's presence has been confirmed. Quantitation is calculated from both column responses, and the best result is reported. The analyst considers performance data such as separation of interferences, calibration performance and matrix spike results in selecting the quantitation column for each analyte detected and reported. If there are interferences present on one column, these need to be documented by printouts of that region of the chromatogram; the lower column's results may be reported in this case. If results from both columns are of comparable quality, the higher concentration is reported (per SW8000).

8.7.11 Sample concentration is calculated using the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m(W_s)}$$

where:

x = concentration of the analyte

y = analyte instrument response (area units)

b = calculated intercept

m = calculated slope of the line

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

W_s = volume or weight of sample extracted (g)

If the average CF is used for quantitation, the sample concentration is calculated using the following equation:

$$\text{Concentration}_{(ug/L,\ ug/kg)} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor

W_s = weight of sample extracted (g)

Linear regression is the preferred method of quantification for this procedure.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method Blanks (MBs) are aliquots of DI water that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the reagents, glassware and the analytical system are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and corrected. See QC Summary Table for further information. As the analyst deems necessary, aliquots of solvent may be

injected to clean the analytical system and demonstrate that it is free from contamination.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

See QC Summary Table for evaluation criteria.

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below:

$$RPD = \left[\frac{(concentration\ sample - concentration\ duplicate)}{1/2(concentration\ sample + concentration\ duplicate)} \right](100)$$

See QC Summary Table for evaluation criteria.

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

See QC Summary Table for evaluation criteria.

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement is to perform these analyses is waived, and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM THE METHOD

Section 7.19 of EPA 504.1 discusses the use of dichlorophenylacetic acid (DCAA) as a surrogate. Per SW8011, Paragon does not utilize a surrogate for this procedure.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.5 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.2 WASTE DISPOSAL

11.2.1 Any rinse waters used for rinsing syringes or other devices prior to sample contact may be disposed of in the Aqueous Lab Waste.

11.2.2 Any hexane, acetone, or other nonhalogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste stream.

11.2.3 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be removed or defaced prior to disposal.

DOCUMENT REVISION HISTORY

8/4/06: LIMS program specification language augmented. Dual column identification and interpretation of results clarified. List of consumables added. DOCUMENT REVISION HISTORY section added.

8/12/07: Calibration discussion further clarified, Section 8.3.3 and QC Table.

Analytical Method: SW8011, EPA504.1	**Parameter:** EDB & DBCP		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5-points, all analytes	As needed (i.e., when daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean CF to quantitate Calculate linear regression (not forced through origin); use for quantitation if COD (r^2) ≥0.99 or Calculate quadratic regression (minimum of six points required); use for quantitation if COD ≥0.99	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Initial Calibration Verification (ICV); second source	After each ICAL	70-130% (EPA 504.1) 60-140% (EPA SW8011) Other client-specific criteria may apply, consult applicable LIMS program specification	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at midpoint of calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses	70-130% (EPA 504.1) 60-140% (EPA SW8011) Other client-specific criteria may apply, consult applicable LIMS program specification	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of	Whenever a new column is installed	Column and compound specific Window is ±3x the standard deviation of the 3-injection average for the respective column	Wider windows can be used to screen for compounds; If zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms

Analytical Method: SW8011, EPA504.1	**Parameter:** EDB & DBCP		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
representative of variation		Note that the ICV and CCV analyses are also used to monitor RT drift	in interpretation of chromatograms (refer also to RT Shift).
Retention Time Shift	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	one per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	one per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions was the cause.

Analytical Method: SW8011, EPA504.1	**Parameter:** EDB & DBCP		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			- if still non-compliant and the samples are within the extraction holding time, then request re-extraction using an NCR, and reanalyze all associated samples for the analyte that do not meet criteria - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	one per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits, as prescribed in the applicable LIMS program specification	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	one per preparation batch of ≤20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits, as prescribed in the applicable LIMS program specification	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers.
Method Detection Limit (MDL) Study	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

HISTORY: DRAFT, Rev0, 4/27/00, Rev1, 12/31/01; Was retired then reinstated, Rev2, 3/15/04; Rev3, 3/9/06; Rev4, 9/1/06; Rev5, 2/8/07.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- CRREL 89-35 and SW-846 Method 8000B -- are used to determine the concentration of nitroguanidine and related compounds such as guanidine nitrate in aqueous and solid matrices. **All procedures must be conducted with care as the analytes of interest may present an explosion hazard. Nitroguanidine is a primary component of U.S. Army triple-base propellants, which also contain nitrocellulose and nitroglycerin.**

2. SUMMARY OF METHOD

Aqueous samples are analyzed by direct injection. Turbid aqueous samples may be filtered with 0.45µm nylon filters. Solid matrix samples are extracted with water, allowed to settle, and filtered. An aliquot of prepared sample extract is then injected into a high performance liquid chromatograph (HPLC) containing an Ultra IBD chromatography column (or equivalent). An isocratic flow condition is used to elute the target compound from the column. The target analytes are then detected by an ultraviolet (UV) detector at two wavelengths (263nm, 215nm). Responses of the analyte are recorded and calculated by a data acquisition system, using an external standard method of quantitation. Identification is confirmed by the presence of a peak at both wavelengths within the appropriate retention time. No surrogate standard is utilized due to the lack of an established representative surrogate compound and because water samples are directly injected (essentially no preparation variables).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of

Supervisory/training review, by the results of precision and accuracy tests performed, or by other suitable means.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the analytical review sheet and the case narrative indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action by the reviewer or analyst. Corrective actions may include re-analysis or correcting errors in logbooks or on chromatograms or in associated electronic records.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Contaminants in reagents, from glassware or within the analytical system may cause the appearance of discrete artifacts or elevated baselines. Use of high purity reagents, scrupulously cleaned glassware (SOP 334) and frequent maintenance of the analytical system minimizes these interferences.

4.2 Interferences introduced from the sample matrix will vary considerably from source to source.

4.3 Degradation of nitroguanidine is accelerated by exposure to light. Light exposure should be limited during sample storage, extraction and analysis.

5. APPARATUS AND MATERIALS

5.1. HPLC SYSTEM

A Hewlett-Packard (HP) 1090 or equivalent HPLC equipped with a system controller, column oven, autosampler, diode array uv-vis detector or other multi-wavelength uv-vis detector.

5.2. DATA SYSTEM

Data acquisition system capable of acquiring, storing and processing HPLC data

(e.g., LC ChemStation™ or equivalent).

5.3. MEASURING DEVICES
microsyringes, glass, various µL sizes
volumetric flasks, Class A with ground glass or Teflon™ stoppers, 10-100mL sizes

5.4 COLUMN - equivalent column may be used

Restek Ultra IBD (intrinsically base deactivated) # 9175565 150 x 4.6mm, 5µm

5.5. CONSUMABLE SUPPLIES

- PTFE syringe filters, 0.45µm
- extraction vials
- autosampler vials
- glass pipettes, 5mL
- centrifuge tubes, plastic
- Ottawa sand (if solid matrix samples are to be analyzed)

5.6. sonicator

5.7. vortex mixer

6. REAGENTS - Only UV, HPLC grade solvents may be used!

6.1 SOLVENTS
acetonitrile (ACN; CH_3CN), Burdick & Jackson #015-4 or equivalent
methanol (MeOH, CH_3OH), Burdick and Jackson 230-4 or equivalent
HPLC (reagent water), Burdick and Jackson 365-4 or equivalent

6.2 STANDARDS

6.2.1 All standards are maintained per PAR SOP 300. Target analyte stock standards, typically 1,000µg/mL, are generally purchased as a certified solution, but may be prepared from pure standard material dissolved in MeOH or ACN. Two independent sources (first, second) of target analyte stock standards are needed.

Intermediate standards are made by diluting an appropriate aliquot of stock standard to a specific volume using acetonitrile, and are stored in Teflon™-sealed vials. Typically, a 100-fold dilution is made, thus creating intermediate standards at a concentration of 10µg/mL. First source target analyte materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards (used by the Organics Extraction Group). Second source target analyte materials are used to create the initial calibration verification (ICV)

solution. Section 9 of this SOP gives definitions and uses of QC (i.e., LCS/LCSD, MS/MSD) samples.

Unopened stock standards are valid until the manufacturer's expiration date and are stored in accord with manufacturer's guidelines. Transfer remainders of opened stock standards to Teflon™-sealed vials for storage. Stock standards are stored in the freezer (i.e., dark, -10 to -20°C). Opened stock or prepared intermediate standards expire 30 days from opening (preparation), or per the manufacturer's expiration date (whichever is sooner). All intermediate standards must be stored in the dark (i.e., refrigerator, 4±2°C) and may be retained for 30 days. Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

6.2.2 The intermediate target analyte standards are further diluted with reagent water to create working standards. These working standards (ICAL, ICV, CCV) are prepared on the day of use. Calibration standards are documented in the analytical run log (Form 410). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 8 of this SOP.

6.2.3 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are not chemically preserved and must be collected in amber glass containers (generally 40mL VOA vials) with Teflon™-lined lids. Samples must be maintained in the dark, and chilled (i.e., 4±2°C).

7.3 Solid samples are collected in wide-mouth glass containers, preferably amber, with Teflon™-lined lids. Solid samples are not chemically preserved and must be maintained in the dark, chilled (i.e., 4±2°C).

7.4 Aqueous samples must be analyzed within 14 days of collection. Solid samples must be extracted within 14 days of collection, extracts must be maintained in the dark at 4±2°C, and analyzed within 14 days of preparation.

8. PROCEDURE

8.1 TYPICAL ISOCRATIC HPLC CONDITIONS

Mobile Phase Flow Rate:	1.0mL/min
Mobile Phase Composition:	100% water (HPLC)
Column Temperature:	40°C (held constant throughout run)
UV Detector:	215 and 263nm
Injection Volume:	100µL

NOTE: If a diode array detector is used, data should be collected between 210 and 300nm for spectral identification.

8.2 ROUTINE MAINTENANCE AND PRE-RUN CHECK

Prior to analyzing samples or establishing calibration curve, the following suggested maintenance may be performed to aid in achieving more consistent results:

- Change the column frits as needed (i.e., if pressure increase is observed).
- Change the cartridge on the guard column as necessary (i.e., pressure increase or poor chromatography).
- Install fresh HPLC water for every run.
- Restart the computer and instrument before starting equilibration and analysis.
- Minimize air currents blowing on the instrument and vials loaded on the autosampler tray.
- Replace UV lamp at 2yr or upon observation of degraded signal.
- Major repairs on contract (by Full Spectrum or equivalent).
- Ensure that instrument is equilibrated, may be primed with one or more injections of the CCV solution prior to initiation of the CCV for the acquisition sequence.

8.3 INITIAL CALIBRATION

8.3.1 Prepare a minimum of 5 concentrations of calibration standards as shown below in Table 1 or as required for each sample set, to define the linear range of the detector. The lowest standard's concentration standard shall be at or below the reporting limit (RL).

TABLE 1
CALIBRATION STANDARDS

Volume of 10µg/mL Nitroguanidine Standard (µL)	Final Volume in Water (mL)	Working Standard Concentration (µg/mL)
500	1.0	5.0
250	1.0	2.5
125	1.0	1.25
100 (CCV, ICV-Level)	1.0	1.0
50	1.0	0.50
20	1.0	0.20

8.3.2 Inject 100µL of each calibration standard into the HPLC and acquire data. Quantitation is accomplished using the external standard method. Analyte Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{integrated peak area of analyte}}{\text{analyte concentration } (ng/mL)}$$

If the CFs over the working range of the detector are constant (i.e., ≤20% RSD), then response can be assumed to be invariant (linear through zero) and the average (mean) CF may be used to quantitate sample concentration.

8.3.3 Relative Standard Deviation (RSD) is calculated as:

$$RSD\ (\%) = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean calibration factor}} \right)(100)$$

When the RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be ≥0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit" with perfect fit being a value of 1.0.

Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000. A quadratic regression should not be used to compensate for detector saturation.

The type of curve fit applied should be chosen to best represent the data. Strong linearity is expected for this method. If other response is observed, check for poor peak shape or other system problems.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The acceptance criteria for the ICV is the same as for the CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated. See QC Summary Table for further details.

8.5 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when responses for all analytes are within $\leq$15%. If a CCV does not meet acceptance criteria, reanalyze the CCV. See QC Summary Table for further details and corrective action to be taken should the CCV still fail.

So long as CCV analyses yield compliant results, and other QC samples are analyzed as required, the series of ten sample analyses bracketed before and after by successful CCV analyses may continue as long as the reserve of solvents lasts.

8.6 RETENTION TIME WINDOW

For chromatographic methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used to compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (σ) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time $\pm 3\sigma$, such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time shifts). Sample matrices may cause RT differences that require further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target compounds are not missed by the data system

8.7 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATION, REPORTING)

8.7.1 Solid matrix samples are extracted by mixing 2g of air-dried sample with 40mL of water in centrifuge tube. The centrifuge tube is then vortex mixed for 30 seconds and sonicated in a ultrasonic bath for 2hrs. The solution is then allowed to settle for 0.5hr and/or filtered with 0.45µm nylon syringe filter. Filtering is helpful to maintain consistent HPLC performance.

8.7.2 Where necessary, reduced aliquots of aqueous sample are analyzed or diluted (HPLC water) sample extracts are analyzed to keep target analyte response within the detectors' linear range.

8.7.3 Tentative identification occurs when 263nm response falls within the RTW for the IBD column. Confirmation occurs when 215nm response for the analyte also falls within the RTW for the IBD column. Optionally, spectral matching can also be used to determine presence or absence of nitroguanidine.

8.7.4 If the average CF is used for quantitation, the sample concentration is calculated as follows:

$$\text{Concentration}_{(ug/L,\ ug/kg)} = \frac{(A_x)(V_t)(DF)}{(\text{Average CF})(V_s \text{ or } W_s)}$$

where:

A_x = analyte response (area units)

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Average CF = average calibration factor (area/concentration in mg/mL)

V_s or W_s = volume or weight of sample extracted (L or kg)

8.7.5 Sample concentration, in ppb (µg/L or µg /kg), may also be calculated using the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\ (V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte (nitroguanidine, ppb)
y = intercept for analyte instrument response (area)
b = calculated intercept (area)
m = calculated slope of the line (area/concentration in ng/mL)
V_t = total volume of concentrated extract (mL)
DF = Dilution Factor (if applicable); if no dilution, then DF = 1
V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples of like matrix that is associated with one unique set of QC samples and processed together as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS) and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Check LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

MBs are aliquots of matrix (i.e., HPLC water for liquids analyses; Ottawa sand for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is processed, or there is a change in reagents, an MB must be prepared. Concentrations of target analytes, if any, must be less than the analyte reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this requirement is not met, analyses must be halted and the source of the contamination found and corrected.

Carryover blanks are aliquots of contaminant-free matrix that are analyzed to clean the analytical system. There are no acceptance criteria associated with these blanks other than the qualitative observation that all significant carryover has been alleviated.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

See QC Table for evaluation criteria.

9.4 LABORATORY DUPLICATE

A duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this, the matrix spike analysis is typically performed in duplicate (MSD). Relative percent difference (RPD) for each analyte of the duplicate pair is calculated as follows:

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.4 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. See QC Table for evaluation criteria. Percent Recovery (%R) for spiked analytes is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right)(100)$$

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.5 METHOD DETECTION LIMIT (MDL) STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses for each target analyte at a concentration level near to the capabilities of the method. The MDL study should be performed as needed and at a minimum, annually (SOP 329).

10. DEVIATIONS FROM THE METHOD

The method is this SOP contains proprietary techniques developed by Paragon Analytics.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 **Samples containing explosive material may under no circumstances be heated in any fashion (e.g., boiling a solution;**

drying in an oven). Also, all operations in the sonic bath must be performed with the cooling coil in place and operational along with the cold water turned on.

11.1.2 **Solid samples with explosive residue content as high as 2% may be safely homogenized using a mortar and pestle. Visual observation of the sample is important. Lumps of material that have a chemical appearance should not be ground. Explosives are generally a very finely ground grayish-white material.**

11.1.3 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

11.1.4 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.5 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.6 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

11.1.7 Any non original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Any rinse waters used for rinsing syringes or other devices prior to sample contact may be disposed of in the Aqueous Lab Waste.

11.2.2 The ACN-Water HPLC waste may be discarded into the ACN Waste Stream (Nonhalogenated Waste) container.

11.2.3 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.4 The extract vials, associated extracts, and any PCB-contaminated

debris that may contain PCBs in excess of 50ppm, shall be disposed of intact in the PCB Debris Waste.

11.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 444 REVISION 1

TITLE: **EXTRACTION AND DETERMINATION OF GLYCOLS BY GAS CHROMATOGRAPHY -- METHOD SW8015B**

FORMS: **531 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-21-06

QUALITY ASSURANCE MANAGER _____ DATE 11/21/06

LABORATORY MANAGER _____ DATE 11-21-06

HISTORY: Rev0, 11/11/02 and 7/8/05; Rev1, 11/20/06. re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references, SW-846 8015B, are used to extract and determine the concentration of glycols in aqueous and solid matrices. The following substances are currently analyzed at Paragon using this procedure:

ethylene glycol propylene glycol

Other compounds may be analyzed using this procedure, if successful MDL studies and initial demonstration of capability are performed. At present, no second column confirmation can be performed, as Paragon is unaware of an alternative column phase that is suitable for this test.

2. SUMMARY

Aqueous samples are analyzed by direct injection onto a gas chromatograph. Solid samples are extracted with deionized water and the aqueous extract is injected onto a gas chromatograph. Both water samples and the aqueous extracts from soils are mixed with acetone prior to injection to improve retention time stability and reproducibility of the injections. The GC is temperature programmed to facilitate separation and identification of target compounds. The analytes are detected by a flame ionization detector (FID). Detector responses are recorded by a data acquisition system to facilitate processing of data. Quantitation is accomplished using the external standard method. Reporting limits are at or above the low standard incorporated into the calibration curve.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of

Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Interferences from phthalate esters can be minimized by using plasticizer-free solvent containers and scrupulously cleaned glassware (SOP 334) that has been solvent rinsed prior to use.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH, AUTOSAMPLER AND DETECTOR SYSTEM
Hewlett Packard 5890 Series II GC, equipped with a Hewlett Packard 7673 Automated Injection System, and a flame ionization detector (FID) or equivalent system.

5.2 CAPILLARY COLUMN
Restek Stabilwax 30m, 0.32mm ID, 1µm film thickness or equivalent.

5.3 CHROMATOGRAPHIC DATA ACQUISITION AND PROCESSING SOFTWARE
Any data acquisition system capable of acquiring, storing and processing chromatographic data (e.g., Hewlett Packard ChemStation™ or equivalent).

5.4 GASES - **Use only high purity gases!**
Helium - carrier gas
Hydrogen - to supply FID

Compressed Air - to supply FID

5.5 MEASURING DEVICES

5.5.1 Microsyringes, Hamilton Precision™ or equivalent, various sizes (e.g., 5µL-1.0mL)

5.5.2 Top loading balance, capable of weighing to ±0.01g (sample preparation)

5.5.3 Top loading balance capable of weighing to ±0.0001g (standard preparation).

5.5.4 Volumetric flasks, Class A with ground glass or PTFE stoppers, 10mL and 25mL sizes, or other sizes as appropriate

5.6 CONSUMABLES

septa	preconditioned, 11mm, Agilent 5183-4759 or equivalent
inlet liner	open-top Uniliner, Restek 20843-205 or equivalent
gold seal	0.8mm ID, Restek 21317 or equivalent
ferrules	graphite, 0.8mm, Restek 20251 or equivalent
o-ring	6.5mm ID, Restek 20299 or equivalent
glass wool	Siltek deactivated, Restek 21100 or equivalent
filter	Whatman 6890-2507 0.7µm GD/X or equivalent

6. REAGENTS

6.1 SOLVENTS - **Only chromatography grade or higher quality solvents may be used**

acetone

organic-free reagent water, laboratory deionized (DI) water is suitable for use

6.2 STANDARDS

6.2.1 Details pertaining to standard preparation and storage procedures are documented in SOP 300.

6.2.2 Two independent sources (first, second) of target analyte standards are required. Pure compounds may be purchased and primary standards prepared gravimetrically from the neat compounds. Alternatively, solutions containing the compounds of interest may be purchased from commercial vendors and utilized as primary standards.

First source materials are used to create calibration and continuing calibration verification (CCV) standards. Second source materials are used to create the initial calibration verification (ICV) solution.

6.2.3 No surrogate or internal standards are used in this procedure.

6.2.4 Laboratory Control Sample (LCS) and Matrix Spike (MS) spike standards may be from either source (the second source is most commonly used).

6.2.5 Secondary standards are prepared by dilution of the primary standards using an appropriate solvent. These standards can generally be stored for six months when prepared in organic solvents.

6.2.6 Unopened stock (primary) standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules or other container as recommended by the manufacturer.

6.2.7 Working standards are prepared fresh daily. This category of standards includes those to be injected on the GC.

7. SAMPLE COLLECTION, PRESERVATION, AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples are collected in 40mL glass VOA vials with screw tops and Teflon-lined septa; amber glass is preferred. Where applicable, aqueous samples should be dechlorinated with sodium thiosulfate at time of collection. The Paragon Project Manager may direct that each aqueous sample is checked for residual chlorine upon receipt at the laboratory. Notify the Project Manager immediately if residual chlorine is detected.

No acidification is required.

7.3 Soil samples are collected in wide-mouth glass (amber preferred) containers with Teflon-lined lids.

7.4 All samples (and extracts) must be maintained chilled (4±2°C).

7.5 Aqueous samples must be analyzed within 7 days from collection, or 14 days from preparation by mixing with acetone. Solid samples must be extracted within 14 days from collection, and must be analyzed within 14 days following mixing with acetone.

8. PROCEDURE

8.1 TYPICAL GC OPERATING CONDITIONS

Carrier Gas Flow Rate:	3-5mL/min
FID H_2 Flow Rate:	30mL/min
FID Air Flow Rate:	350mL/min

Injector Temperature:	210°C
Initial Oven Temperature:	100°C for 1.5min
Oven Ramp:	15°C/min to 200°C
Hold:	200°C for 2min
FID Temperature:	225°C

Purge Off for entire analytical time

8.2 CHROMATOGRAPHIC MAINTENANCE

8.2.1 Bake out the column. Extra blanks may be necessary to achieve an adequate baseline if carryover is observed. Clean injector, cut or replace column as necessary to maintain adequate peak shape and response.

8.2.2 Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming. If a column is oxidized, replacement may be necessary.

8.3 INITIAL CALIBRATION

8.3.1 Prepare calibration standards, in DI water, at suitable concentrations. A minimum of five levels must be used. Note that the aqueous calibration standards are mixed with an equal volume of acetone prior to analysis.

Concentration (µg/mL)	10	25	50	100	200

Typically 1µL of standard or field or QC sample extract is injected by automated injector for analysis. Analyze the initial calibration and process using the data processing software.

8.3.2 Peak area responses are tabulated by the data acquisition system. Quantitation is accomplished using an external standard approach, typically using linear regression (not forced through the origin).

If average response factor calibration is employed, then a calibration factor (CF) for each standard is calculated as follows:

$$Calibration\ factor\ (CF) = \frac{peak\ area}{analyte\ concentration}$$

8.3.3 If the CFs over the working range are constant (i.e., <20% RSD), then response can be assumed to be invariant and the average (mean) CF may be used to quantify sample concentrations.

Relative Standard Deviation (RSD) is calculated as follows:

$$RSD = \frac{\text{Standard deviation}}{\text{mean CF}}\ (100)$$

If the RSD is >20%, then a form of calibration other than average response factor must be employed. Linear regression is typically utilized even when the RSD is less than 20%. The regression calculation will yield a correlation coefficient (r^2) that must be $\geq$0.99 to be used for sample quantitation. Note that the correlation coefficient is an expression of "goodness of fit" with perfect fit being a value of 1.0. Non-linear curve fitting is allowed with minimum of 6 points following guidelines in SW-846 Method 8000B.

8.3.4 INITIAL CALIBRATION VERIFICATION (ICV)
Before samples may be analyzed, an ICV must be analyzed to verify the working calibration curve. The ICV should be analyzed at a concentration different from the continuing calibration verification standards to ensure the curve is valid over much of the range of the initial calibration. Refer to QC Table for acceptance criteria.

8.4 DAILY CALIBRATION VERIFICATION

8.4.1 Consistent detector response during a run sequence is verified by the analysis of a Continuing Calibration Verification (CCV) standard. The calibration verification standard does not need to always be performed at or near the midpoint of the initial calibration. Levels above and below the mid-range should be analyzed over time.

8.4.2 After an initial calibration and acceptable ICV are analyzed, up to ten samples, blanks or quality control (QC) samples may be analyzed. After the tenth injection, a CCV must be analyzed and the Percent Difference (%D) calculated:

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}}\right](100)$$

The analytical sequence of 10 injections, CCV, 10 injections, CCV, etc., may continue so long as the CCVs yielded are acceptable (±15%D). Refer to QC Table for appropriate corrective measures.

8.5 RETENTION TIME WINDOWS

8.5.1 RTWs are used to define the integration envelope for quantifying various compounds in samples. The retention time window (RTW) is determined by making a minimum of three injections of the appropriate standard throughout the course of at least a 72-hour period. Serial injections over less than a 72-hour period result in RTWs that are too tight. Guidelines are given in Method SW8000B.

8.5.2 Calculate the mean and standard deviation of the start time and end time of the RTW for the analyte. Multiply by three, add, and subtract from the means to generate windows.

8.5.3 Integration of peak areas is performed by the chromatographic data processing system, but can be manually performed by the analyst following the guidelines of SOP 939.

8.5.4 The experience of the analyst weighs heavily in interpretation of the chromatogram. Environmental samples may contain more than one type or class of compound.

8.6 SAMPLE PREPARATION, ANALYSIS, QUANTITATION, REPORTING

8.6.1 Aqueous samples are not extracted in preparation for analysis. All aqueous samples are mixed with an equal volume of acetone prior to injection (as are the calibration standards). The addition of acetone yields more reproducible injections and retention times than when direct aqueous injection is used.

8.6.2 Solid samples (soils, sediments, waste or other solids) are extracted with deionized water for two hours in an ultrasonic bath prior to analysis. Typically, extraction is accomplished in 40mL VOA vials or 4oz. glass jars, using 20g aliquots of sample with 30mL of DI water added.

The samples are removed from the ultrasonic bath after 2hrs and a portion of the aqueous extract is removed and centrifuged or filtered with an appropriate 0.7µm filter.

A portion of the filtered extract is then mixed with an equal volume of acetone before injection on the GC.

8.6.3 Standard and sample preparations are introduced onto the GC via an automated injector. Typically a 1µL aliquot of standard, prepared aqueous sample, extract, or QC sample is injected. The volume of the injection must be the same for standards and samples.

Once successful calibration has been achieved (Section 8.3), the automated injector is staged to continue in a CCV, 10 injections, CCV, etc. sequence (as described in Section 8.4), so long as samples require analysis and CCVs yield acceptable performance (refer to QC Table).

8.6.4 Make sure all gas and rinse solvents are adequate to last throughout the automated run.

8.6.5 Where necessary, dilute samples or extracts to keep response within the calibration range.

8.6.6 Concentration of targets in the sample is calculated using the integrated peak areas at the correct retention time.

If the average CF is used for quantitation, the extract concentration (µg/mL) is calculated as follows:

$$extract\ conc. = \frac{area}{mean\ CF}$$

where:

area = integrated peak response in sample

mean CF=average CF from the multipoint calibration

Where linear regression is employed, quantitation of sample concentration is based on the equation of the linear curve generated during initial calibration (i.e., y = mx + b):

$$x = \frac{(y - b)\,(V_t)(DF)}{m(V_s \text{ or } W_s)}$$

where:

x = concentration of the analyte

y = analyte instrument response (area units)

b = calculated intercept

m = calculated slope of the line

V_t = total volume of concentrated extract (mL)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

V_s or W_s = volume or weight of sample extracted (mL or g)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method Blanks (MBs) are aliquots of matrix (i.e., organic-free water for liquids, typically Ottawa sand for solids) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. If this criterion is not achieved, then analyses must be halted and the source of the contamination found and corrected.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). A field sample may also be analyzed in duplicate. The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. Percent Recovery (%R) for spiked analytes is calculated as follows (see QC Table for evaluation criteria):

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right) (100)$$

NOTE: Typically, one MS and MSDuplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

9.6 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the sensitivity limit of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of SW-846 Method 8015B.

11. SAFETY HAZARDS AND WASTE

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.6 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.1.7 Food and drink are prohibited in all lab areas..

11.2 WASTE DISPOSAL

11.2.1 Solvent wastes must be disposed of in the appropriate waste containers.

11.2.2 Any rinse waters used for rinsing syringes or other devices prior to contact with samples must be disposed of in the Aqueous Lab Waste stream.

11.2.3 Any methanol or other nonhalogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/ Nonhalogenated Waste stream.

11.2.4 The extract vials and associated extracts that contain methanol or other organic solvent but not PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

11.2.5 The extract vials, associated extracts, and any PCB contaminated debris that may contain PCBs in excess of 50ppm shall be disposed of intact in the PCB Debris Waste.

11.2.6 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

Analytical Method SW8015B	**Parameter:** Glycols		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration (ICAL); minimum 5 points; all analytes	As needed (i.e., when the daily calibration verification does not meet criteria)	When RSD ≤20%, may use mean RF to quantitated. If RSD ≥20%, calculate linear regression (not forced through origin); use for quantitation if coefficient of determination (r^2) ≥0.99 or calculate quadratic regression (minimum of six points required); use for quantitation if COD ≥0.99	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Initial Calibration Verification (ICV); all analytes	After each ICAL	≤15%D of each compound or mean %D ≤15%	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); all analytes	Run at start of sequence if ICAL not performed; brackets each set of 10 injections; (SW8015B requires minimum of once per 12 hour shift)	≤15%D of each compound or mean %D ≤15%	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed before and after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV (bracketed by acceptable CCVs) will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on 3 injections throughout a 72-hour period to be more representative of daily operations	Whenever a new column is installed,	Column and compound specific. Window is ± 3x the standard deviation of the 3-injection average for the column Note that the ICV and CCV analyses are also used to monitor RTW drift	If zero, substitute window of close-eluting similar compound. Wider windows can be used to screen for compounds; experience of analyst should weigh heavily in interpretation of chromatograms (refer to RT Shift).
Retention Time (RT) Shift; RT of analyte in CCV is evaluated against the midpoint of the ICAL or the preceding CCV	Each CCV	Column and compound specific, varies with each initial calibration	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate. Evaluate data based on a comparison with other standards run during the analytical sequence; consider the RTs for spiked compounds analyzed before and after the

QC Check	Frequency	Acceptance Criteria	Corrective Action
			sample in question: - expand RTW to encompass the shift in compound location - if no peaks are found in the expanded window, report the compound as non-detect
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike Duplicate (MSD) or Laboratory Control Sample Duplicate (LCSD)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; see Matrix Spike information above for MSD recoveries. RPDs should be within advisory limits.	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and

Analytical Method SW8015B	**Parameter:** Glycols		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
			spike preparation). Check unspiked sample results and surrogate recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers. Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. If still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed)
Method Detection Limit (MDL) Study; run at analyte concentrations near to the minimum detection capabilities of the method	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

STANDARD OPERATING PROCEDURE 446 REVISION 2

TITLE: **ANALYSIS OF CRYSTAL VIOLET IN WATER BY HPLC**

FORMS: **410, 611** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3-26-09

QUALITY ASSURANCE MANAGER _____ DATE 3/20/09

LABORATORY MANAGER _____ DATE 4-8-09

HISTORY: Rev0, 1/28/05; Rev1, 7/24/06; Rev2, 3/19/09.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) is used to determine the concentration of crystal violet in aqueous samples. Crystal violet, also known as gentian violet or hexamethyl-pararosanilinen chloride, is used to control fungi and has various purposes in human and veterinary medicine. This compound belongs to the group of triphenylmethane dyes, which are linked to an increase in health risks. This procedure was developed at ALSLG-FC from literature references. The direct aqueous injection of waters is modified from SW-846 Method 8330. The HPLC conditions are adapted from available literature references.

Analyte (IUPAC Name)	**CAS #**
Methyl Violet 2B	8004-87-3

2. SUMMARY

Aqueous samples are prepared for analysis by dilution with solvent (acetonitrile with C18 column, or methanol with cyano column). The diluted sample is injected into a high performance liquid chromatograph (HPLC). The target analyte is separated under gradient or isocratic mobile phase flow conditions, as detailed in Section 9. The target analyte is then detected by an ultraviolet (UV/Vis) detector, using the absorption maxima of crystal violet at 588nm and 300nm. Responses of the analyte are recorded and calculated by a data acquisition system, using an external standard method of quantitation. Identification is confirmed by the presence of a peak at both wavelengths at the expected retention time. No surrogate is utilized because water samples are directly injected (essentially no preparation variables) and due to the lack of a representative surrogate compound.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review or results of precision and accuracy tests performed.

3.3 ALSLG-FC 's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede ALSLG-FC standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the appropriate review sheets and case narrative indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work, and documentation of measures taken to correct the problem.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Contaminants in reagents from glassware or within the analytical system may cause the appearance of discrete artifacts or elevated baselines. Use of high purity reagents, scrupulously cleaned glassware and frequent maintenance of the analytical system minimizes these interferences.

4.2 Interferences from the sample matrix may vary considerably from source to source. If significant interferences are observed, these are reported in the results narrative.

5. APPARATUS AND MATERIALS

5.1 HPLC SYSTEM

Hewlett-Packard (HP) 1050 or 1090 or equivalent HPLC equipped with a degassing system (helium sparge or vacuum degasser), system controller, column oven, autosampler, diode array UV-Vis or other adequate UV-Vis detector.

NOTE: If the HP 1050 is used, two separate acquisition methods are required, one using 588nm and another for 300 nm.

5.2 DATA SYSTEM

Any data acquisition system capable of acquiring, storing and processing HPLC data (e.g., LC ChemStation™ or equivalent).

5.3 MEASURING DEVICES

- Pipettes – air displacement/conical tip, or equivalent, various µL ranges
- Volumetric Flasks, Class A, various sizes

- Graduated cylinders, glass, 5 to 1000mL, or equivalent
- Analytical Balance, capable of reading +0.0001g.

5.4 HPLC COLUMNS - Equivalent columns may also be used

C_{18} column:	Zorbax Extend™ C18; 3.0x 100mm, 3.5µm 80Å
Cyano column:	Develosil™ CN-UG 5µm (250 X 4.6mm) or equivalent

NOTE: Either of these two columns may be used with dual wavelength confirmation.

5.5 CONSUMABLE SUPPLIES

- solvent inlet filter frit-1/4", 4.6mm, 2µm, Restek #25071 or equivalent
- HPLC pump maintenance kit, Restek #25270 or equivalent
- autosampler maintenance kit, Restek #25259 or equivalent
- PTFE syringe filter, 0.45µm (see note below)
- autosampler vials and caps
- glass pipets, disposable

NOTE: Do not filter water samples prior to addition of solvent. Loss to filters has been documented prior to solvent addition. Allowing the sample to settle or use of a centrifuge may be preferable. Also, glass contact surfaces (test tubes, autosampler vials, standards storage vials), are preferable to HDPE. Crystal violet is attracted to HDPE surfaces.

6. REAGENTS

6.1 SOLVENTS - **Only HPLC grade solvents with acceptable UV cutoffs may be used.**

methanol (CH_3OH), Burdick and Jackson 230-4 or equivalent

6.2 REAGENTS

- reagent water (H_2O), Burdick and Jackson 365-4 or Millipore filtered water or equivalent
- glacial acetic acid, VWR VW0125-3 or equivalent
- ammonium hydroxide, EM Science AX1303-3 or equivalent
- Cyano Column Buffer: approximately 0.02M acetate buffer - adjusted to pH 4 with ammonium hydroxide (2.87mL glacial acetic acid + 1mL ammonium hydroxide brought to 1000mL with reagent water)
- C18 Column Buffer: approximately 50mM ammonium acetate; 7.5g of ammonium acetate to 2.0 L of reagent water, pH to 4.00 with acetic acid.

6.3 STANDARDS

6.3.1 All standards are maintained per SOP 300. Target analyte stock standards, typically 100µg/mL, are prepared from pure standard reference materials dissolved in a small aliquot of MeOH and/or ACN and brought to final volume in reagent water. For neat standards or standard materials

of a purity <95%, adjust concentration for purity when calculating standard concentration. Two independent sources (first, second) of target analyte stock standards are required. No surrogate is required in association with this method because water samples are directly injected (essentially no preparation variables) and due to the lack of a representative surrogate compound.

Intermediate standards are made by diluting an appropriate aliquot of stock standard to a specific volume using reagent water, and are stored in Teflon™-sealed vials. Typically, a 10-fold dilution is made, thus creating intermediate standard at a concentration of 10µg/mL. A 500µg/L intermediate is also typically prepared to facilitate preparation of calibration standards. First source target analyte materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards (used by the Organics Extraction Group). Second source target analyte materials are used to create the initial calibration verification (ICV) solution.

All stock and intermediate standards are stored in the freezer (i.e., dark, -10 to -20°C). Stock standards expire 1 year from the date of preparation, or per the manufacturer's expiration date (whichever is sooner). Intermediate standards expire one week from preparation. Standards may be replaced sooner if laboratory QC analyses or other factors indicate deterioration.

NOTE: Standards must be equilibrated to room temperature, sonicated and vortex mixed prior to diluting to avoid low recovery from solution.

6.3.2 The intermediate target analyte standards are further diluted to create working standards. These working standards (ICAL, ICV, CCV) are prepared on the day of use, directly in analysis vials, using aliquots of intermediate and diluent to create sufficient standard volume for analysis. Calibration standards are documented in the analytical run log (Form 410). A detailed description of the concentration of the calibration standards and how they are used can be found in Section 9 of this SOP.

6.3.3 All stock and intermediate standards are documented in ALSLG-FC's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are not generally chemically preserved and must be collected in glass containers (generally 40mL) with Teflon-lined lids. Samples must be maintained at 4±2°C and prepared for analysis within 7 days of collection. Prepared aqueous samples must be maintained in the dark at 4±2°C and analyzed within 7 days of preparation. Preparation of aqueous samples consists of mixing with acetonitrile (C18 chromatography) or methanol (cyano chromatography).

8. SAMPLE PREPARATION

Aqueous samples are prepared by mixing 5mL of sample with 1mL of acetonitrile (if analyzed on the C18 column) or 1mL methanol (if analyzed on the cyano column). Samples are allowed to settle or a centrifuge may be used if sediments are present in the sample. If filters are used, solvent must be added first and recovery of crystal violet from the filer should be demonstrated.

9. ANALYTICAL PROCEDURE

9.1 TYPICAL HPLC ANALYSIS CONDITIONS FOR C18 COLUMN

Flow rate: 0.5mL/min

Gradient:

Time (min.s)	% A (Water)	%B (Acetonitrile)
0	60	40
9	10	90
10	10	90
11	60	40
14	60	40

Post Time (for further equilibration): 4 minutes

Oven temperature: 32°C

Injection volume (C18): 80µL (within an acquisition, injection-volume is held constant)

9.2 TYPICAL HPLC ANALYSIS CONDITIONS FOR CYANO COLUMN

Flow rate: 1.0mL/min

Solvent: isocratic 75% methanol, 25% acetic acid buffer

Oven temperature: 32°C

Injection volume (cyano): 100µL (within an acquisition, injection-volume is held constant)

9.3 Routine maintenance is performed prior to the initiation of each run. This includes ensuring that the mobile phase is within expiration and sufficiently degassed, that no

leaks are observed upon initiation of flow, and that system pressure and baseline are consistent prior to the start of the acquisition.

If the instrument has sat idle for a period of time, it may be necessary to condition the column with one or more injections of the CCV prior to analysis of the CCV for the acquisition sequence.

9.4 INITIAL CALIBRATION

9.4.1 Intermediate Standards for Preparation of Calibration Standards: A 5 parts reagent water plus 1 part solvent diluent solution is first prepared. For example aliquot 10mL of reagent water to a vial and then add 2.0mL of solvent (acetonitrile if C18 column is to be used; methanol if cyano column is to be used).

Conc. of Solution Diluted	**Volume of Solution Diluted** (µL)	**Volume of Diluent** (µL)	**Concentration of Intermediate Solution** (µg/L)
100 µg/mL	100	900	10,000
10,000 µg/L	50	950	500

9.4.2 The linear range of the analytical system is defined using a minimum of five different concentrations. The lowest concentration standard shall be at a level at or below the analyte reporting limit. A typical set of calibration standards is depicted below:

ICAL Dilutions for Use with C18 Column

Diluent (µL)	**µL of Intermediate Standard**	**Final Conc. (µg/L)**
850	150µL of 500µg/mL	75
900	100 µL of 500µg/mL	50
920	80µL of 500µg/mL	40
940	60µL of 500µg/mL	30*
960	40µL of 500µg/mL	20
970	30µL of 500µg/mL	15
980	20µL of 500µg/mL	10
990	10µL of 500µg/mL	5

*Recommended CCV and ICV level.

ICAL Dilutions for Use with Cyano Column

MeOH (µL)	Reagent Water (µL)	µL of Intermediate Standard	Final Conc. (µg/L)
1000	4750	250µL of 10µg/mL	416
1000	4900	100µL of 10µg/mL	167
1000	4950	50µL of 10µg/mL	83
1000	4875	125µL of 2µg/mL	42
1000	4950	50µL of 2µg/mL	16.7
1000	4975	25µL of 2µg/mL	8.3
1000 (ICV)	4875	125µL of 10µg/mL (2^{nd} source)	208
1000 CCV	4900	100µL of 10µg/mL	167

9.4.3 Inject and analyze 80µL (C18 column) or 100µL (cyano column) of each calibration standard and sample. Each data file quantitation is accomplished via the external standard method of quantitation. Analyte Response Factors (CFs) are calculated as follows:

$$CF = \frac{\text{integrated peak area of analyte}}{\text{analyte concentration}}$$

Relative Standard Deviation (RSD) is calculated as:

$$RSD\,(\%) = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean response factor}}\right)(100)$$

When RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. Non-linear (quadratic) regression curve fitting is also allowed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000. A quadratic regression should not be used to compensate for detector saturation.

Linear and 2nd order regressions are used almost exclusively with this procedure. The type of curve fit applied should be chosen to best represent the data.

9.5 INDEPENDENT CALIBRATION VERIFICATION

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of the CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

9.6 CONTINUING CALIBRATION VERIFICATION

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration. Inject a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when all compounds are within 15%D or when the average of the %Ds for all compounds is $\leq$15% (individual compounds that exceeded 15% are noted in the data package narrative). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

9.7 RETENTION TIME WINDOWS

For chromatographic methods, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed, and are used compensate for minor RT shifts. It is important to establish valid RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures normal system variation). Calculate the standard deviation (equation given previously) of the absolute retention time yielded for each analyte for the set of analyses used for the RTW study. Define each analyte's RTW as the mean retention time $\pm 3\sigma$, such that the Upper Limit = $+3\sigma$ and the Lower Limit = -3σ.

Per SW-846 Method 8000B, RTWs may be centered on the midpoint standard if applied to samples run immediately after an initial calibration, or centered on the CCV for subsequent application (corrects for minor retention time drift). Sample matrices may cause drift that requires further analyst interpretation. RTWs and integration parameters should be set to err on the side of false positives, so target

compounds are not missed by the data system.

Tentative identification occurs when a peak response falls within the RTW at primary wavelength (588nm) on the cyano column. Confirmation occurs when the peak's response also falls within the RTW for the confirmation wavelength (300nm) on the cyano column. Diode array spectral confirmation may also be used on a project and client specific basis.

9.8 QUANTITATION

Sample analyte concentration is calculated using the equation of the linear curve generated (i.e., y = mx + b), which can be represented as:

$$A = mC + b$$

where:

A = analyte response (area counts)
m = slope of the linear equation
C = concentration present at the instrument
b = the y-intercept of the linear equation

10. QUALITY CONTROL

10.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or less field samples of like matrix that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS) and matrix spike and duplicate (MS/MSD). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

10.2 BLANKS

MBs are aliquots of matrix (i.e., HPLC reagent water) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that Interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is prepared, analyzed, or there is a change in reagents, a MB must be processed.

To be acceptable, concentration of the analyte of interest detected (if any), in the MB must be below the analyte reporting limit or as otherwise prescribed in the LIMS program specification. If this criterion is not met, analyses must be halted and the source of the contamination found and corrected.

10.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. The LCS is similar to the matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS). Percent recovery is calculated as follows:

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right) (100)$$

See QC Table for evaluation criteria.

10.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this, the matrix spike analysis is performed in duplicate (MSD). Precision is evaluated as Relative Percent Difference (RPD) for each analyte of the duplicate pair, and is calculated as follows:

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right) (100)$$

See QC Table for evaluation criteria.

10.5 MATRIX SPIKE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection. Analyte recovery is calculated as shown below:

$$\%R = \left(\frac{\text{concentration detected} - \text{conc. sample}}{\text{concentration spiked}} \right) (100)$$

where:

$Conc_{found}$ = analyte concentration found in the MS or MSD sample

$Conc_{sample}$ = analyte concentration found in the field sample

$Conc_{target}$ = target (anticipated) analyte conc. based on amount spiked

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation is made in the data package narrative.

10.6 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

11. DEVIATIONS FROM THE METHOD

This SOP documents procedures developed at ALSLG-FC and as such, is **proprietary information**.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

12.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

12.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.5 All flammable compounds must be kept away from ignition sources.

12.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

12.1.7 Food and drink are prohibited in all lab areas.

12.2 WASTE DISPOSAL

12.2.1 Any rinse waters used for rinsing syringes or other devices prior to sample contact may be disposed of in the Aqueous Lab Waste.

12.2.2 The methanol-water HPLC waste may be discarded into the ACN Waste Stream container.

12.2.3 The extract vials and associated extracts that do not contain PCBs greater than 50ppm may be disposed of intact in the Discarded Extract Vial Waste.

12.2.4 The extract vials, associated extracts, and any PCB-contaminated debris that may contain PCBs in excess of 50ppm, shall be disposed of intact in the PCB Debris Waste.

12.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

7/24/06: Augmented RESPONSIBILITIES, added FORMS and DOCUMENT REVISION HISTORY.

3/19/09: Added analyte Table to Scope and Section 9. Updated standard preparation and management practices. Added recent literature reference.

Analytical Method: In-house Procedure	**Parameter:** Crystal Violet by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point; all analytes	As needed (i.e., at on-set of analyses or when calibration verification does not meet criteria)	When RSD ≤20%, may use mean CF to quantitated Calculate linear regression (not forced through origin); use for quantitation if correlation coefficient (r^2) ≥0.99 or Calculate quadratic regression (minimum of six points required); use for quantitation if COD ≥0.99	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Independent Calibration Verification (ICV); run above or below midpoint of calibration	After each ICAL	≤20 %D	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); run at midpoint of calibration	Run at start of sequence if ICAL not performed; brackets each set of 10 field sample analyses	≤20 %D	Evaluate/correct instrument malfunction as needed (e.g., rinse or change liner, remove some of the guard column); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed. - If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of variation	Whenever a new column is installed	Column and compound specific Window is ±3x the standard deviation of the 3-injection average for the respective column	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms (refer also to RT Shift).

Analytical Method: In-house Procedure	**Parameter:** Crystal Violet by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
		Note that the ICV and CCV analyses are also used to monitor RT drift	
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question.
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition
Blank Spike (BS); Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix	See laboratory limits; recoveries for spiked compounds must be within laboratory limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions was the cause. - if still non-compliant and the samples are within the extraction holding time, then request re-extraction using an NCR, and reanalyze all associated samples for the analyte that do not meet criteria - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration

Analytical Method: In-house Procedure	**Parameter:** Crystal Violet by HPLC		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Matrix Spike (MS)	1 per batch, not to exceed 20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (MS)	1 per batch, not to exceed 20 samples of like matrix	See laboratory limits; recoveries for spiked compounds should be within advisory limits	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated BS (LCS) is within limits, then sample matrix effects are the most likely cause. Note in narrative.
Method Detection Limit (MDL) Study	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 447 REVISION 0

TITLE: **DETERMINATION OF HEXAVALENT CHROMIUM IN AIR BY ION CHROMATOGRAPHY**

FORMS: **413, 414** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 12/8/06

QUALITY ASSURANCE MANAGER _____ DATE 12/8/06

LABORATORY MANAGER _____ DATE 12-12-06

HISTORY: NEW, Rev0, 12/7/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- NIOSH 7605 and OSHA ID215 -- are used to determine exposure to hexavalent chromium, in the workplace, through determination of the concentration of hexavalent chromium [CrO_4^{-2}/diphenylcarbazide (DPC) complex; Cr(VI)] in airborne particulates collected on PVC air sampling filters. Filters are extracted and the extract is analyzed using HPLC/post-column derivatization and UV detection at 540nm.

2. SUMMARY

Sampling is performed, in the field, by pumping a controlled and measured volume of air from the source of interest through a 5.0µm PVC membrane filter. The filter is then sent to the laboratory (either in cassette or in a vial) where it is extracted and analyzed to determine the total hexavalent chromium content. Sample preparation procedures are based on those described in the NIOSH 7605 and OSHA ID215 methods. Hexavalent chromium is extracted from particulates collected on 5.0µm PVC membrane filters by transferring each sample filter to a 50mL disposable centrifuge tube, wetting with precipitation reagent (phosphate buffer and magnesium sulfate), and extracting with NaOH- Na_2CO_3 solution on a heated water bath set at 100°C for 45minutes to one hour with periodic mixing. The precipitate is removed through centrifugal separation and filtering and the final volume is taken to 10mL with ASTM Type II water. An aliquot is then analyzed by ion chromatography.

A 100uL sample is introduced to the ion chromatograph and anion exchange separation is performed prior to post column complexation with 1,5-diphenylcarbazide (DPC) and UV detection at 540nm. Detector responses are processed using an electronic integrator and the result is determined using an external standard quantitation calculation.

Dual column confirmation is not required because the anion exchange separation and relatively unique detection characteristics of the complex at 540nm provide sufficient selectivity to support quantitative determination of hexavalent chromium.

The concentration of hexavalent chromium in the air trapped by the filter is then calculated based on the field data. Both the weight of hexavalent chromium per filter and the concentration in the volume of air sampled are typically reported.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Reducing metal species, primarily Fe(II), may interfere with the determination of Cr(VI) by reducing the Cr(VI) to Cr(III).

4.2 Colored compounds, metals and organic compounds that react with 1,5-diphenyl carbazide such as copper, lipids and ketones are separated from hexavalent chromium. The anion exchange separation provides greater selectivity than the spectrophotometric method.

4.3 Method OSHA ID215 provides the procedure for use of magnesium sulfate/phosphate buffer (PBE) to precipitate potential metal interferences. The

basic extraction/digestion solution also serves to retard the rate of Cr(VI) reduction relative to a less basic solution.

4.4 Interferences are also minimized by the use of high purity reagents.

5. APPARATUS AND MATERIALS

5.1 HPLC, AUTOSAMPLER, DETECTORS

Hewlett-Packard (HP) 1050 (or equivalent) HPLC equipped with:

- gradient or isocratic pumping system
- autosampler
- system controller
- column oven (method runs at ambient temperature)
- post-column reagent pump
  (capable of pumping 0.7 mL/min at 400-1000 PSI)
- heated mixing loop: 2.2m PEEK at 30 ± 3 ºC or equivalent
- ultraviolet (UV) detector

5.2 DATA SYSTEM

Any data acquisition system capable of acquiring, storing and processing HPLC data (e.g., LC ChemStation™ or equivalent)

5.3 COLUMNS - Equivalent columns may also be used

Guard Column: Dionex NG1 4x35mm PN039567
Analytical Column: Dionex Ion Pak 4x250mm PN035393

5.4 MEASURING DEVICES

Pipettes – air displacement/conical tip, or equivalent, various µL ranges

Graduated cylinders – 5 to 1000mL glass or polymer (translucent plastic, PMP), or equivalent

Beaker (with stir bar and stir plate for reagent preparation)

Analytical balance, 0.0001g sensitivity (for preparation of standards)

Top-Loader Balance, 0.01g sensitivity

5.5 CONSUMABLES

- Filter for Mobile Phase and Derivatization Reagent: VWR Vacuum filtration system PES 0.45µm #87006-070 or equivalent.
- Filter (matrix) for Laboratory Blank and LCS/LCSD: 37mm, 5.0µm PVC; SKC Inc. #225-8-01-1 or equivalent
- See Guard Column (above 5.3)
- Solvent Inlet Filter Frit-1/4” 4.6mm, 2µm, Restek #25071

- Pump Maintenance Kit -Agilent 1050 HPLC, Restek #25270
- Autosampler Maintenance Kit -Agilent 1050 HPLC, Restek #25259
- Plastic test tubes (for mixing standards)
- Disposable plastic sample cups
- Disposable transfer pipettes-SAMCO #202 or equivalent
- 50 mL disposable centrifuge tubes-Falcon #35720 or equivalent
- Syringe Filter-Restek 25mm, 0.22µm PTFE #26146 or equivalent
- Autosampler vials and caps

6. REAGENTS

6.1 Mobile Phase: 250mM ammonium sulfate; 100mM ammonium hydroxide (Expiration-2 months)

6.1.1 ASTM Type II or Millipore water.

6.1.2 ammonium sulfate, Mallincrodt ACS or equivalent

6.1.3 ammonium hydroxide, EM Science AX1303-3 or equivalent

Dissolve 33g of ammonium sulfate in about 500mL of deionized water, add 6.5mL ammonium hydroxide, bring to a final volume of 1.0L with ASTM Type II water. Filter (0.45µm).

6.2 Post Column Derivatization Reagent: 2.0mM DPC; 10% methanol; 1N sulfuric acid (Expiration-4 days ambient, 1 week refrigerated)

6.2.1 1,5-diphenyl carbazide (DPC), Aldrich ACS or equivalent; avoid inhalation or exposure to skin, and eyes.

6.2.2 Methanol (CH_3OH; MeOH), Burdick & Jackson #230-4, or equivalent; TWA 200ppm, STEL 250ppm

6.2.3 Sulfuric acid (H_2SO_4), EM trace metals grade or equivalent; TWA 1mg/m^3 (0.25ppm); STEL 3mg/m^3 (0.75ppm); corrosive causes severe burns to skin and all body tissue.

Dissolve 500mg of DPC in 100mL methanol; stir and add 500 mL of water with 28mL of concentrated sulfuric acid bring to a final volume of 1.0L with ASTM Type II or Millipore water. Filter (0.45µm).

6.3 Water, ASTM Type II or Millipore water is used for **all** applicable reagents and system washes.

6.4 Magnesium Sulfate Solution (Expiration-2 months): Dissolve and bring 9.9g of ACS magnesium sulfate ($MgSO_4$) to a final volume of 100mL water.

6.5 Phosphate Buffer Solution (Expiration-2 months):

6.5.1 68g of potassium phosphate, monobasic (KH_2PO_4); ACS

6.5.2 87.1g of potassium phosphate, dibasic (K_2HPO_4); ACS

Dissolve and bring to final volume of 1.0L in ASTM Type II or Millipore water.

6.6 Precipitation Reagent (Expiration-4 hours): Combine 50mL of phosphate buffer solution with 25mL of magnesium sulfate solution.

6.7 Filter Extraction Solution: 2% Sodium hydroxide; 3% sodium carbonate (Expiration-2 months)

6.7.1 Sodium hydroxide VWR ACS or equivalent; TLV 2 mg/m, corrosive, may cause severe burns.

6.7.2 Sodium carbonate (Na_2CO_3) ACS

Dissolve 20g sodium hydroxide and 30g sodium carbonate in ASTM Type II water and bring to a final volume of 1.0L in ASTM Type II water.

6.7.3 For standards dilution, dilute 1:5 in ASTM Type II or Millipore water (Expiration-2 months).

6.8 Potassium dichromate ($K_2Cr_2O_7$) ≥99%; OSHA PEL (as CrO_3): C 0.1 mg/m^3 (0.01ppm) Chromium (VI) is a known carcinogen (cancer hazard), take precautions when handling including use of safety glasses, gloves and good ventilation. Treat as a carcinogen

6.9 STANDARDS

6.9.1 All standards are maintained and documented per PAR SOP 300. Certificates of Analysis are maintained by the applicable laboratory Department. Stock standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer.

6.9.2 At minimum, two independent sources of target analyte are required. First source materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards. Second source materials are used to create the initial calibration verification (ICV) solution (used to independently verify the accuracy of the initial calibration, ICAL)

6.9.3 A 500mg/L hexavalent chromium stock solution is prepared by dissolving 0.1414g of potassium dichromate ($K_2Cr_2O_7$) in ASTM II or Millipore

water. The solution is brought to a final volume of 100mL in ASTM II or Millipore water.

6.9.4 A 10mg/L intermediate standard solution is prepared by diluting 2.0mL of the 500mg/L hexavalent chromium stock solution to 100mL in ASTM II or Millipore water.

6.9.5 An appropriate volume of stock standard (10mg/L) is diluted in 1:5 filter extraction solution to a specific volume to create working standards. All dilutions should be performed using calibrated pipettes (SOP 321). A one-week expiration is assigned to standards diluted from stock.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected in accord with NIOSH or OSHA standards. Air sampling is performed by the client in the field. NIOSH 7605 specifies sampling flows from 1-4L/min. and sampling volumes from 1-400L.

7.2 Samples are collected on 37mm, 5.0µm PVC membrane filter cartridges and may be shipped at ambient or cooler temperatures.

7.3 Filter samples are shipped in the original cassettes or removed from the cassette and shipped in a vial. NIOSH 7605 recommends shipping with bagged refrigerant.

7.4 Samples may be held, prior to extraction, for 2 weeks at ambient temperature and for 4 weeks refrigerated (4±2°C).

7.5 Sample extracts may be held for up to 1 week.

7.6 All samples are to be to be kept chilled (4±2°C).

8. PROCEDURES

8.1 TYPICAL SYSTEM OPERATING CONDITIONS

HPLC DEVICE

Flow Rate (mobile phase):	1 mL/min
Injection Volume:	100µL
Column Temperature:	Ambient to 30°C
Post-Column Mixing Temperature:	32°C
Post Column Derivative Flow:	0.7 mL/min
Detector Wavelength	540nm

8.2 HPLC MAINTENANCE

Prior to analyzing samples or establishing calibration curves, the following suggested maintenance can be performed to aid in achieving more consistent results:

- Restart the instruments and computer prior to beginning equilibration and analysis.
- Ensure that mobile phase and derivatizing reagent have not expired prior to initiating each run.
- Run several primes (1:5 DI extraction solution) before each run until baseline has stabilized. Run curve from high to low to avoid minor effects from active sites on the analytical column.
- Test the total flow prior to each run. The total flow should be 1.6-1.9mL/minute. Also ensure that each pump's pressure is steady and that the solvent effluent rate is steady.
- Change the column frits as needed (i.e., if pressure increase is observed). At the time of method draft, the observed pressures are 180-195bar for mobile phase (1.0mL/min) and approximately 600PSI (0.7mL/min) for the post column derivative pump.
- Change the guard column as necessary (i.e., pressure increase or poor chromatography).
- Inject ASTM type II or Millipore water, at the end of each run to rinse the injector. Then flush the entire analytical system (including the columns) with DI water after each use (a water method may be used to inject water and to flush the system). Remove column after flushing with water.
- When pumps fail to produce acceptable flow, flush system with water, remove and cap column. Then isopropyl alcohol (IPA) may be pumped. Pumping IPA helps to seat the pump seals, clean and seat check valves and to clean the detector window (remove column prior to pumping IPA). IPA is then removed by pumping water. If the problem persists clean pump heads. Check inlet frits and in-line filter, and mobile phase filter.
- **IMPORTANT:** Ensure that system is effectively purged with water prior to allowing IPA to be pumped. It is crucial to prevent a precipitation event and serious damage to the system.

  Flush system with DI water prior to and after IPA use!

- Major repairs are contracted (see Manager regarding applicable service contacts).

8.3 INITIAL CALIBRATION

Initial calibration standards are prepared in 1:5 extraction solution (6.7.4), at a minimum of six concentrations. The range of concentrations of the initial calibration is intended to define the working range of the analytical system. One of the concentrations must be at or below the analyte-reporting limit. The working standards are assigned a 1-week expiration period.

TABLE 1
CALIBRATION STANDARDS

Level	Analyte Concentration (µg/L)	Standard Diluted	Standard Added (µL)	Final Volume (mL)
ICAL 7 (Optional)	2000	10mg/L Stock	2000	10
ICAL 6	1000	10mg/L Stock	1000	10
ICAL 5	250	ICAL 6 (1000)	250	1.0
ICAL 4	100 (CCV-level)	10mg/L Stock	1000	100
ICAL 3	50	ICAL 4 (100)	500	1.0
ICAL 2	25	ICAL 4 (100)	250	1.0
ICAL 1	5	ICAL 4 (100)	250	5.0
ICV	1000	10mg/L ICV Stock	1000	10
Dilution Blank	0.0	N/A	1:5 Standard Dilution Solution	N/A

8.3.1 Inject 100µL of each calibration standard into the HPLC and acquire data. Quantitation is accomplished using the external standard method. Analyte Calibration Factors (CFs) are calculated as follows:

$$CF = \frac{\text{integrated peak area of analyte}}{\text{analyte concentration (µg/L)}}$$

If the CFs over the working range of the detector are constant (i.e., $\leq$20% RSD), then response can be assumed to be invariant (linear through zero) and the average (mean) CF may be used to quantitate sample concentration.

8.3.2 Relative Standard Deviation (RSD) is calculated as:

$$\text{RSD (\%)} = \left(\frac{\text{standard deviation of the analyte's response factors}}{\text{mean calibration factor}} \right)(100)$$

8.3.3 When the RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points (e.g., least squares method) may be constructed. The curve is not to be forced through zero. A zero point may be included if using a quadratic fit provided that a zero point is acquired and that no interference is present. The regression calculation will yield a coefficient of determination (r^2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit" with perfect fit being a value of 1.0.

Non-linear (quadratic) regression curve fitting is allowed, with a minimum of 6 points. A quadratic regression should not be used to compensate for detector saturation.

The type of curve fit applied should be chosen to best represent the data.

NOTE: A minimum of five (5) points must be used for the initial calibration. A minimum of five calibration points must be used to meet the %RSD criteria, or the initial calibration is judged to be invalid and a new initial calibration must be generated.

If an initial calibration point is not used for any reason, the analyst must clearly notate why the data point was not used for instrument calibration.

If regression criteria are not met, a new initial calibration must be performed.

8.4 INITIAL CALIBRATION VERIFICATION (ICV)

A second source (ICV) standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of CCV (described below). If the below criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.5 PREPARATION OF SAMPLE EXTRACT

8.5.1 Prepare one blank sample with the same filter lot to be used for the LCS/LCSD.

8.5.2 Label two centrifuge tubes LCS and LCSD. Add one unused filter to each tube. Record the tare weight of the original tube plus sample filter.

8.5.1.1 Add 1.5mL of precipitation reagent to each tube. Add 100uL of 10mg/L Cr^6 standard to each LCS. Ensure that each filter is effectively wetted with the precipitation reagent to control possible interferences.

8.5.1.2 Add 5.0mL of filter extraction solution (Reagent 6.7) to each. The formation of a precipitate should be observed upon addition of the filter extraction solution.

8.5.3 Remove tape from outside of each sample cassette. Open each cassette.

8.5.4 Handle the filters carefully, loss of particulates will cause a low bias. Remove the filter (omitting/discarding the backup pad) from the cartridge and transfer it to the centrifuge tube for extraction.

8.5.5 A second filter is moistened with precipitation reagent and used to wipe the cassette casing associated with the filter surface (specified by OSHA for welding operation samples). Filters are placed in the centrifuge tube with the samples surfaces on the outside to facilitate contact with the extraction solution.

8.5.6 Record the tare weight of the tube and filters. Add 1.5mL of precipitation reagent and ensure that the filter surfaces are contacted.

8.5.7 Add 5.0mL of extraction solution to each centrifuge tube. The formation of a precipitate should be observed upon addition of the filter extraction solution.

8.5.8 Heat tubes, with regular agitation, for 55 to 65 minutes in a hot water bath (set to 95 ± 10°C).

8.5.9 Remove tubes from heat. Adjust the final volume to 10mL by adding ASTM II or Millipore water to achieve a final weight equal the tare weight plus 10.49 g. Note: 1.5mL of precipitation reagent plus 5.0mL of extraction solution brought to a final volume of 10.0mL with ASTM Type II or Millipore water weighs 10.49g.

8.5.10 Spin the samples, in a centrifuge, at 3200rpm for 20-30 minutes. Additional filtration of the supernatant using a syringe filter (Restek 25mm, 0.22µm PTFE #26146 or equivalent) is recommended. Note: The precipitate particles increase in size over time.

8.5.11 It is important to omit particulates during transfer to the autosampler vial (ASV). An aliquot of supernatant or filtered supernatant is transferred to an ASV, capped and analyzed. The extracts should be analyzed within one week of extraction.

8.5.12 *Ensure that no visible precipitate remains in each ASV prior to initiating HPLC injection.*

8.6 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is within the quantitation range of the method. Acquire a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when all compounds are within 15%D or when the average of the %Ds for all compounds is $\leq$15% (individual compounds that exceeded 15% are noted in the data package narrative). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.7 RETENTION TIME WINDOWS

Evaluate bracketing standards and set the retention time window (RTW) to include the hexavalent chromium peak. Ensure that the RTW is sufficiently reproducible to support proper evaluation of samples.

RTWs are used to define the integration envelope for quantifying various products in samples. Peak area integration will begin immediately prior to elution of the hexavalent chromium peak and will stop after the peak has attained baseline response.

8.8 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)
Samples are extracted with warm extraction solution and brought to a final volume of 10mL. QC samples (LCS, MS, etc.) are prepared in a manner similar to that of standards described above. A discussion of quantitation follows.

8.8.1 Dual column confirmation is not required because the separation and detection of the method provides a high level of selectivity. The anion exchange separation together with the relatively unique detection characteristics of the DPC complex (detection at 540nm) provide highly selective method performance.

8.8.2 The following equation is used to quantify sample concentration when CF (or mean CF) is employed:

$$\text{Concentration } (\mu g/L) = \frac{(A_x)(DF)}{(\text{mean CF})(V_s \text{ or } W_s)}$$

where:

A_x	=	analyte response (area units)
DF	=	dilution factor (if applicable); if no dilution was made, DF = 1 (dimensionless)
CF or mean CF	=	standard response (area units/concentration)
Vs	=	volume of sample analyzed (L)

NOTE: The final volume is 10mL. The final volume in mL is entered into LIMS.

8.8.3 Where linear regression is employed, quantitation of sample concentration is based on the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m}$$

where:

x = concentration of the analyte (µg/filter)

y = analyte instrument response (area units)

b = calculated intercept (area units)

m = calculated slope of the line (area/conc. in µg/L)

V_t = total volume of concentrated extract (L)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

Calculation of $\mu g/m^3$: x/air volume sampled in m^3

Reporting Limit: LIMS default in µg/filter (based on MDL study)

Limit Associated with Volume Sampled: (µg/filter)/(Volume Sampled in m^3)

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS) and laboratory control sample duplicate (LCSD). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method Blanks (MBs) are aliquots of matrix (i.e., PVC air-sampling filters) that have been prepared and analyzed in the same manner as the associated field samples. Blank filter media should be submitted, by the client, with the samples. MBs are analyzed to demonstrate that interferences from the analytical system, media, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification. NIOSH 7605 specifies that blank correction be performed if interferences are observed. Report any observed blank positives to Supervisor.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. An LCS is similar to a matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE
Not required for air sampling since the LCS is a spike of the PVC filter (matrix spike).

9.6 SURROGATE RECOVERY
Not applicable, no surrogate standard is required in association with this method.

9.7 METHOD DETECTION LIMIT STUDY
A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

10.1 This SOP meets the requirements of NIOSH 7605. A minor modification of NIOSH 7605 is specified to facilitate improved sensitivity by using a final volume of 10.0mL. This step is validated in OSHA ID215.

10.2 Method NIOSH 7605 specifies that precipitation may be performed to remedy interferences. Since various sources of PVC filters are known to provide varying background levels of interference for hexavalent chromium, the precipitation step has been included. No blank interferences were observed during method validation.

10.3 Extraction solution is per NIOSH 7605 and varies from that specified in OSHA ID215.

10.4 Paragon policy does not call for the use of blank subtraction. If blank interference is observed, it is reported.

10.5 NIOSH 7605 specifies 1.0 mL/min mobile phase and 0.7mL/min. derivatization reagent. OSHA specifies 0.9 and 0.6 mL/min flows respectively. Both flow rates appear to function well. This method calls for 1.0mL/min mobile phase and 0.7mL/min derivatization -reagent flow.

10.6 Holding Times and sample storage, specified in this method, are in accord with NIOSH 7605, OSHA ID215 has additional specifications for samples from various sources. The LIMS Program Specification may be used to specify project-specific requirements.

10.7 Standards are diluted in a 1:5 dilution of sample extraction solution. The precipitation reagent is not included. Method development data demonstrates that accurate results are achieved with this matrix-matching strategy.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with safety showers, eye wash stations, fire extinguishers, fire blankets, and first aid kits. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time. Potassium dichromate, sulfuric acid, ammonium hydroxide, sodium hydroxide and diphenyl carbazide are utilized in this procedure, familiarity with the associated hazards is important.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area. Gloves and safety glasses are important at the HPLC due to the use of strong base and strong acid mobile phase and derivatization reagent.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Reagent preparation, for this method, should be performed in a hood.

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport (compressed gas is used for the Agilent 1050's pneumatic system).

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Mobile phase waste is collected and disposed of in accord with SOPs 003 and 015.

11.2.2 Hexavalent chromium standards and sample vials are emptied and added to the mobile phase waste (11.2.1).

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

STANDARD OPERATING PROCEDURE 448 REVISION 1

TITLE: **DETERMINATION OF PERCHLORATE IN LIQUIDS AND SOLIDS USING HIGH PERFORMANCE LIQUID CHROMATOGRAPHY, ELECTROSPRAY IONIZATION TANDEM MASS SPECTROMETRY (LC/MS/MS)**

FORMS: **415** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1-5-09

QUALITY ASSURANCE MANAGER _____ DATE 1/5/09

LABORATORY MANAGER _____ DATE 1/5/09

HISTORY: NEW Rev0, 3/20/08; Rev1, 12/31/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references – EPA SW6850 (multi-matrix), DoD Perchlorate Handbook, and Method 331.0 (drinking water matrix), are used to determine the concentration of perchlorate in liquid and solid samples.

Analyte	CAS #
Perchlorate ClO_4^-	14797-73-0

2. SUMMARY

Water samples are filtered prior to analysis, soil samples are extracted with reagent water then filtered prior to analysis. An internal standard (IS) is added to the sample/extract, which is then well-mixed, before being filtered and analyzed. Samples/extracts may be subjected to a C_{18} or ion exchange cleanup prior to HPLC separation with subsequent multi-reaction monitoring (MRM) analysis by LC/MS/MS, with electrospray ionization and isotope dilution quantitation. Data is captured via an integrator, and instrument operation and data processing are assisted by a personal computer (PC).

NOTE: Cleanup removes high hydrocarbon level interferences and discoloration. The ion chromatography versions of this method use multiple cleanup procedures via filter technology, such as Hydronium (–H) for carbonate, silver (-Ag) for chloride, and barium (Ba^{2+}) for sulfate. Method validation showed that such cleanup is usually unnecessary when using the K' column and solvent diversion valve. Two barium cartridges with one hydronium cartridge in parallel or a combined bed cartridge may be used to remedy extreme matrix challenges.

A 100uL sample (including added acetonitrile and acetic acid) is introduced into the

HPLC. Perchlorate (ClO_4^-) is separated chromatographically from the sample/extract matrix. Early eluting interferences may be diverted to waste prior to introducing the HPLC stream to the ion source. The HPLC is connected to the ion source of the MS/MS, where electrospray ionization is performed. Perchlorate ions m/z 99 ($^{35}ClO_4$), 101($^{37}ClO_4$) and 107 ($^{35}Cl^{18}O_4$) are selectively filtered to the collision cell by the first quadrupole mass filter, where perchlorate is partially fragmented via collisionally induced dissociation. Multiple reaction monitoring (MRM) is performed and fragment ions m/z 83 ($^{35}Cl0_3^-$), 85 ($^{37}ClO_3^-$) and 89 ($^{35}Cl^{18}O_3^-$) are selectively detected. Detector responses are processed by an electronic integrator and the result is determined using an internal standard quantitation calculation. Since the internal standard used is an isotopically labeled version of the analyte and is added at the start of the sample preparation process, this is an isotope dilution method with recovery correction included.

This technique is highly sensitive and selective. Perchlorate presence, confirmed by MS/MS MRM products, has a high level of certainty.

Precursor Ion (m/z)	**Fragment Lost (m/z)**	**Product Ion (m/z)**
$^{35}ClO_4$ (99) quant. ion	^{16}O (16)	$^{35}Cl0_3^-$ (83)
$^{37}ClO_4$ (101) conf. ion	^{16}O (16)	$^{35}Cl0_3^-$ (85)
$^{35}Cl^{18}O_4$ (107) IS ion	^{18}O (18)	$^{35}Cl^{18}O_3^-$ (89)

Please note that as stated in Section 10, the requirements prescribed in this SOP meet or exceed the requirements set forth in EPA SW6850. A summary of QC parameters and associated corrective actions is provided as a Table at the end of the SOP. Note also (Section 3.2) that these requirements may be superceded by the requirements prescribed via a specific client program specification. Consult the individual program specification for client-specific criteria and corrective actions.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for

client-specific requirements prior to initiating handling of samples or data.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented as prescribed in SOP 928.

4. INTERFERENCES

4.1 Sulfate has essentially the same parent mass as perchlorate. However, sulfate cannot form the collision products that are monitored from perchlorate, and sulfate is well separated from perchlorate by the K' RP column.

4.2 Carbonate, chloride and other anions and eluting ions may also interfere if present at sufficiently high concentrations.

4.3 Co-eluting entities can cause ion suppression. Absence of ion suppression as a problem below 4500mg/mL challenge (31,200µS/cm) was demonstrated during validation of EPA Method 6850 and is documented as shown in Table 3 below:

Table 3
Matrix Challenge Study Results

Conc. Suppressors (mg/mL)	Conductivity (µS/cm)	Suppression Observed	RT Drift
500	5000	No	Within Divert
2000	16620	No	Within Divert
4000	28500	No	Exceeds Divert
4500	31200	No	Exceeds Divert
5000	34000	IS < 50%	Exceeds Divert
5500	36700	IS < 50%	Exceeds Divert

NOTE: $^{35}ClO_3^-$ (m/z83)/ $^{35}ClO_3^-$(m/z85) ratio acceptable throughout study range.

A study to determine the maximum tolerable concentration of known ion suppressors bicarbonate, carbonate, chloride and sulfate was performed. This study included no divert event. Diversion of the HPLC effluent prior to elution of perchlorate may be used to protect the instrument from contamination. However,

as sample conductivity increases, perchlorate retention decreases, and perchlorate will go to divert at conductivity beyond about 17000 µS/cm. For this reason, 16620uS/cm (2000 mg/mL) is the level selected for the matrix conductivity threshold (MCT).

In light of retention time drift, samples with sufficiently high conductivity to cause perchlorate to be diverted from the mass spectrometer must be diluted for analysis (assuming required reporting limit can be met), subjected to cleanup, or analyzed without divert. Dilution may be performed routinely, provided that the required sensitivity is achieved.

An Interference Check Sample (ICSL), may be analyzed to verify method performance for perchlorate, at the RL, in the MCT solution. Refer to QC Table at the end of this SOP or information given in the specific client program specification for ICSL acceptance criteria.

4.4 Additional cleanup procedures may be used. SPE C_{18} (for organic contamination) and/or cartridge cleanups such as Ba^{2+} (for sulfate), -H (for carbonate), and Ag (for chloride), may be used if removal of these interferences is appropriate. Two barium and one hydronium cartridge in series have been shown to be effective in removal of high sulfate and carbonate interferences. If cleanup columns are used, associated QC samples must be prepared in the same manner as the batch sample(s).

4.5 Interferences are also minimized by the use of high purity reagents.

5. APPARATUS AND MATERIALS

5.1 HPLC, AUTOSAMPLER, DETECTORS

Shimadzu Prominence (or equivalent) binary HPLC equipped with:

- gradient pumping system
- autosampler
- system controller – interface to MS data system
- column oven

Tandem mass spectrometer

- Applied Biosystems API 3200 MS/MS or equivalent

5.2 DATA ACQUISITION

Any data acquisition system capable of acquiring, storing and processing HPLC/ mass spectrometry data (e.g., Analyst™ or equivalent) to support qualitative and quantitative requirements may be used.

5.3 COLUMNS - Equivalent columns may also be used

Guard Column: Optional; guard must not undermine system performance
Analytical Column: K' Technologies, Inc. RP HPLC 4x250mm KPRPP-X250

5.4 MEASURING DEVICES

- Pipettes – air displacement/conical tip, or equivalent, various µL ranges; operated as prescribed in SOP 321
- Volumetric Flasks (Class A) – various sizes
- Graduated cylinders – 5 to 1000mL glass or polymer (translucent plastic, PMP), or equivalent
- Analytical Balance (for preparation of standards and matrix challenge solution); operated as prescribed in SOP 305
- Top-Loader Balance: to 0.01g (for sample aliquot prior to extraction extraction) ; operated as prescribed in SOP 305
- VWR Conductivity Meter Model 23226-523 or equivalent

5.5 CONSUMABLES

- Filter for Mobile Phase: Filter the mobile phase using vacuum filtration with a 0.45µm nylon membrane filter; 47mm (Whatman 7404-004) or equivalent
- Disposable 50mL centrifuge tubes, Falcon #35720 or equivalent
- Disposable transfer pipettes, SAMCO #202 or equivalent
- Syringe Filter, Restek 25mm, 0.22µm PTFE #26146, 0.45µm or equivalent
- Autosampler vials and caps
- C_{18} Solid Phase Extraction (SPE) Cartridges (optional cleanup)
- Ion exchange cartridges: Ba^{2+}, –H and/or Ag (optional cleanup)

NOTE: **High Density Polyethylene** (HDPE) instead of glass is acceptable for perchlorate per EPA 331.0.

6. REAGENTS - All reagents must be HPLC grade or better

6.1 Mobile Phase: 50:50 Acetonitrile (ACN): HPLC H_2O, with 0.1% Acetic Acid (HOAc) – Make by mixing 500mL HPLC reagent water and 500mL ACN, add 1.0mL of acetic acid. Filter as per Section 5.5.

6.2 Internal Standard (IS) Stock Solution
Isotopically labeled perchlorate ($^{35}Cl^{18}O_4$) as neat salt or in HPLC water (concentration as received from manufacturer)

6.3 Working Internal Standard Solution (WIS)
Typically the concentration of the WIS is 50µg/L of isotopically labeled perchlorate ($^{35}Cl^{18}O_4$) in HPLC water (final IS concentration in samples is

0.5µg/L). The absolute concentration is not critical as long as all samples and standards are spiked equivalently.

6.4 Acetonitrile/Acetic Acid Solution: ACN + 0.1% HOAc.

6.5 Solid phase column activation (optional cleanup)
Methanol, HPLC grade

6.6 Ottawa sand

6.7 STANDARDS
All standards are maintained per SOP 300. In the event of a conflict, the specific guidance in this SOP shall supercede that of SOP 300. All stock and intermediate standards are documented in the laboratory's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Certificates of Analysis from vendor materials are maintained by the applicable laboratory Department.

6.7.1 At minimum, two independent sources of target analyte are required. First source materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards. Second source materials are used to create the initial calibration verification (ICV) solution (used to independently verify the accuracy of the initial calibration, ICAL).

6.7.2 An appropriate volume of commercial stock standard is diluted to a specific volume to create both Intermediate and Working Standards; these dilutions are shown below. Perform all dilutions using calibrated pipettes (SOP 321). Do not use standards beyond their expiration date. EPA 6850 specifies a one-year expiration period for intermediate perchlorate standards. This applies to labeled internal standard as well as native perchlorate standards.

Intermediate standards are prepared from 1000µg/mL perchlorate stock (first source for calibration standards, second source for ICV) as follows:

Intermediate Perchlorate Solution A:
500µg/L (50µL of 1000µg/mL perchlorate to 100mL HPLC water)

Intermediate Perchlorate Solution B:
5µg/L (100µL of A to 10mL HPLC water)

TABLE 4
CALIBRATION STANDARDS

Level	Analyte Conc. (µg/L)	Standard Diluted (Intermediate Solutions Above)	Standard Added (µL)	Final Volume (mL)
ICAL 9	100	A: 500 µg/L Stock	2000	10.0
ICAL 8	50	A: 500 µg/L Stock	1000	10.0
ICAL 7	10	A: 500 µg/L Stock	200	10.0
ICAL 6	5.0	A: 500 µg/L Stock	100	10.0
ICAL 5	1.0	B: 5.0 µg/L	2000	10.0
ICAL 4	0.5	B: 5.0 µg/L	1000	10.0
ICAL 3	0.1	B: 5.0 µg/L	200	10.0
ICAL 2	0.05	B: 5.0 µg/L	100	10.0
ICAL 1	0.01	B: 5.0 µg/L	20	10.0
ICV	1.0	B: 5.0 µg/L (2^{nd} source)	2000	10.0

NOTE: Alternate equivalent dilution schemes may be used as appropriate.

NOTE: The ICV is to be utilized at the midpoint of the calibration curve. Based on a logarithmic (i.e., order-of-magnitude) view of the calibration, the ICV has currently been established as 1.0ug/L, which is two orders of magnitude above the low standard and two orders of magnitude below the high standard. This interpretation provides for the best quantitation of perchlorate, particularly because it retains focus at a concentration level most likely to be of primary interest regarding environmental perchlorate samples.

6.8 Interference Check Solution Stock (ICSS) 20mg/mL of each ion: Cl^-, SO_4-, CO_3^-, and $HCO_3^=$. Make by weighing 3.30g NaCl; 2.96g Na_2SO_4; 3.53g Na_2CO_3; and 2.76g $NaHCO_3$ and bring to 100mL with HPLC water. Mix thoroughly, then filter solution through a 0.45µm filter.

6.9 Interference Check Standard for LC/MS (ICSL). For 2000ppm of each anion and 0.05µg/L perchlorate, add 1mL ICSS and 100µL Intermediate Perchlorate Solution B (5µg/L) and bring to 10mL with HPLC water.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Water samples are collected in 125mL sterile HDPE bottles; solid samples are collected in a 4oz amber glass jar. Headspace (one third of total volume) **should** be present to minimize anaerobic biodegradation.

7.3 Store samples at 4±2°C.

7.4 Liquid samples must be analyzed within 28 days of collection. Extracts must be generated from solid samples, within 28 days of collection; the extracts must then be analyzed within 28 days thereafter. A Q flag is appended if samples are out of holding time when received by the laboratory.

8. PROCEDURES

8.1 TYPICAL SYSTEM OPERATING CONDITIONS

HPLC DEVICE

Flow Rate (mobile phase):	0.5 mL/min
Auto Sampler Temperature	15°C
Injection Volume:	100 µL
Column Temperature:	30°C
Run Time:	16 min. (2 min. beyond peak tail)
Ionization Mode:	Turbo Spray (ESI)
Polarity:	Negative

8.2 LCMS-MS MAINTENANCE

Prior to analyzing samples or establishing calibration curves, the following suggested maintenance may be performed/documented to aid in achieving more consistent results:

- Change the column frits as needed (i.e., if pressure increase is observed).
- Ensure that mobile phase provides expected chromatography for perchlorate.
- Flush the entire analytical system and back-flush the column with 50:50 ACN:H2O after each use with this method.
- Clean the K' column by pumping 90:10 ACN:Water. Store the column in the same solution.

  NOTE: The column should be flushed with cleaning solution every 2 months if storing for longer than 2 months.

- Clean or change inlet or outlet valves as appropriate to maintain acceptable flow and accurate flow rate.
- Clean the curtain plate. **CAUTION - source housing and curtain plate may be extremely hot!** Remove the ion source (not necessary to break vacuum); carefully remove the curtain plate and clean on a dust-free surface. Use a dust-free wipe with HPLC water and methanol or 1:1 HPLC

water:ACN with 0.1% formic acid. Carefully reassemble.

8.3 INSTRUMENT MASS CALIBRATION AND TUNING; ANALYTE OPTIMIZATION

The LCMS-MS must have valid mass calibration and tuning, and analyte optimization prior to the performance of any sample analysis.

8.3.1 Mass Calibration and Tuning

Mass calibration ensures that mass peaks are assigned the correct mass-to-charge values. Tuning is the adjustment of the instrument's resolution off-sets to ensure the best peak response. Mass calibration and tuning are performed per manufacturer's instructions.

- The calibration is updated on an as needed basis (i.e., when QC failures are observed, ion masses show large deviation from known masses, major instrument maintenance is performed, or if the instrument is moved).
- If problem is suspected, check calibration with polypropylene glycol (PPG) infusion per manufacturer's recommendation. Adjust as necessary or appropriate.
- Acceptance Range: 0.7 +/- 0.1 (unit resolution)

8.3.2 Analyte Optimization - Analyte optimization considerations consist of both Compound Dependent Parameters and Source Dependent Parameters.

Compound Dependent Parameters:

Declustering Potential (DP)

Entrance Potential (EP)

Pressure of the collision gas during MS/MS scan (CAD gas)

Collision Energy (CE)

Collision Cell Entrance Potential (CEP)

Collision Cell Exit Potential (CXP)

Compound dependent optimization is performed per manufacturer's recommendation (i.e., at method development only, then determined parameters are used). Re-optimization may be performed if needed to improve or restore method performance (for example, after significant maintenance is performed, following a significant failure or event such as moving the instrument, or after the instrument is retuned or recalibrated).

Source Dependent Parameters:

Temperature

Ion Spray Voltage

Gasses

Probe position

Source dependent parameters are more susceptible to change because they are dependent on mobile phase composition and flow. Hence, these parameters are updated when mobile phase flow or composition changes.

8.3.3 Daily Check

Overall system performance is monitored daily through the injection of a perchlorate 'Shooter', which is a known concentration of perchlorate in mobile phase. The Shooter monitors target compound response from the detector, and is injected prior to any analysis. This daily check is evaluated in terms of reasonable peak retention time, shape and response. If the Shooter does not yield reasonable characteristics, problems with the system are looked for and corrected. If the Shooter characteristics are reasonable, analysis proceeds.

8.4 GENERAL SAMPLE PREPARATION

8.4.1 Every standard, sample and quality control (QC) sample must have an equivalent amount of IS added, and each sample must have similar amount of ACN/HOAc solution added in order to improve chromatography and ensure consistent peak shape in samples.

8.4.2 Standards and controls used for calibration and analytical QC such as ICAL standards, ICV, CCV, ICB, CCB are prepared as follows without filtration:

Pipette one mL of standard or control into an autosampler vial, add 10uL of WIS, 200uL of ACN/HOAc, cap tightly. Prefiltered field samples may also be prepared in this manner.

8.4.3 Soil samples, unfiltered water samples and batch preparation QC such as method blanks (MB) and Laboratory Control Sample (LCS) must be prepared with the internal standard added prior to filtering and water extraction from soils.

Samples are spiked with an equivalent amount of WIS as was added for the analytical standards above (8.4.2). For example, if 3mL of a water sample are filtered, then 30uL of WIS is added.

After samples are extracted and/or filtered, 1mL of filtrate is added to the autosampler vial with 200uL of ACN/HOAc solution added.

8.5 INITIAL CALIBRATION

Initial calibration standards are prepared with a minimum of six concentrations (see Section 6.7.2). The range of concentrations of the initial calibration is intended to define the working range of the analytical system. One of the concentrations must be at or below the analyte reporting limit (RL). In addition, a 'Shooter' (high concentration of analyte in MP), may be prepared to show system suitability, and a reagent blank may be injected without IS added in order to show that no interference or residual Perchlorate is present in the reagents used.

8.5.1 Inject 100µL of each calibration standard solution (with internal standard and organic compound mix added) into the HPLC and acquire data. Generate the calibration curve using the internal standard (isotope dilution) method.

8.5.2 A first order regression fit of six or more calibration points that is not forced through zero (e.g., least squares method) is constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit" with perfect fit being a value of 1.0. Also note that an r-value of 0.995 is equal to an r squared value of 0.99.

8.5.3 Non-linear (quadratic) regression curve fitting may be employed, with a minimum of 6 points, following the guidelines in SW-846 Method 8000. A quadratic regression may not be used to compensate for detector saturation.

8.5.4 The type of curve fit applied should be chosen to best represent the data. Strong linearity is expected for this method. If other response is observed, check for system problems. If regression criteria cannot be met, a new initial calibration (ICAL) must be performed.

8.6 INITIAL CALIBRATION VERIFICATION (ICV)

A second source (ICV) standard is analyzed immediately after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV must be within the quantitative range of the method. The acceptance criteria for the ICV are identical to those of CCV (see Section 8.8). If the acceptance criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

8.7 PREPARATION OF SAMPLE ALIQUOT

8.7.1 Water samples are prepared by measuring a representative volume of sample into a test tube. Sample amounts depend on sample prep and cartridge clean up and may be scaled up or down as necessary. The following example is based on a 3mL sample preparation:

- Add internal standard (30µL of 50µg/L WIS).
- Mix well and then filter with (0.45 or 0.2µm PTFE membrane or equivalent).
- Transfer 1.0mL to an autosampler vial and add 200uL of the acetonitrile/acetic acid solution.

8.7.2 Solid samples are prepared by first weighing a representative 1g solid sample aliquot into a labeled 50mL centrifuge tube. MB or LCS samples are prepared with 1g of Ottawa sand. The solid sample preparation may be scaled up (i.e., 2.0g to 20mL reagent water) if additional extract volume is needed for column and/or cartridge cleanups. The following steps are based on a 1.0g sample preparation:

- Add internal standard (100µL of 50µg/L IS spiking solution).
- Add 10.0mL reagent water (resultant IS concentration is 0.5µg/L).
- Vortex the mixture, followed by sonication for a minimum of 10 minutes, followed by additional shaking and vortex mixing.
- Visually adequate separation of solids must be achieved prior to filtering the sample. Use a centrifuge to spin the samples if appropriate (i.e., centrifuge at approximately 3200rpm for 15-25 minutes).
- Filter the supernatant extract solution using a plastic syringe fitted with a 0.45 or 0.2µm PTFE membrane filter. Dispense the filtrate into an autosampler vial for analysis.
- Cleanups may be performed per SW6850 (C_{18} cartridges for removal of organic interference) and/or EPA 331.0 (Ag, H^+, Ba^{2+} cartridges) if useful for achieving performance goals.
- Transfer 1.0mL to an autosampler vial and add 200uL of the acetonitrile/acetic acid solution.

NOTE: If sample dilution is required due to high analyte concentration or high interference, the sample may have IS added after the dilution if the dilution exceeds a factor of 10. If the dilution factor is less than 10, the sample may be

reanalyzed with the original IS.

8.7.3 Quality control samples are prepared with each extraction batch of ≤20 samples:

- Method Blank - Reagent water added (water matrix) or Ottawa sand added (solid matrices), all reagents and steps are equivalent to field sample.
- LCS - Reagent water or clean (Ottawa sand) matrix spiked at a midpoint level, prepared as is field sample.
- MS - Field sample fortified with perchlorate spike.
- Duplicate - Dup a field sample or MS

8.8 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration. Acquire a CCV at the start of each analytical sequence, after each ten injections, and at the end of each sequence. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when % D is $\leq$15% at midlevel, and $\leq$50% at low level (also called LODV). If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Reanalyze the CCV. If the CCV still fails, the instrument must be recalibrated and all samples injected since the last compliant CCV must be reanalyzed.

8.9 RT AND ISOTOPE RATIO (^{35}CL/^{37}CL) CONFIRMATION

- RT will vary due to matrix effects.
- Peak is identified by coelution of the analyte with the IS. Perchlorate identity is confirmed by evaluating the 35Cl/37Cl isotope ratio.
- Perform evaluation of the 35Cl/37Cl isotope ratio for every sample, batch QC sample and standard.
- The theoretical ratio for daughter ions m/z 83/85 is approximately 3.05.
- 83/85 peak area ratio acceptance limit - should be within $\pm$30% of the mid range calibration standard or average of all of the CCV runs of the

analytical batch if calibration was performed previously. If ratio limits are not met, inject a new aliquot of sample. If interference is suspected, dilute the sample with HPLC water if sensitivity is adequate, otherwise use cartridge cleanup. If ratio is not improved, flag sample data as suspect. Note that other criteria and corrective actions may apply, consult the applicable client LIMS program specification.

- Internal Standard Response Verification: The IS area counts must be monitored throughout the run. IS area counts must be within ±50% of the average of the IS area counts of the calibration standards if calibration is performed on the same day as analysis, otherwise use the IS area counts for the first CCV of the analytical batch. If sample IS area counts do not meet the criterion, reanalyze a fresh aliquot of the sample. If the IS counts are still outside of the criterion, check the most recent CCV IS area counts. If the most recent CCV IS area counts meet the criterion, then the sample results should be considered suspect. If the most recent CCV IS area counts do not meet the criterion, corrective action must be taken to resolve the problem. Evaluate and correct as directed in the applicable LIMS program specification.

8.10 SAMPLE ANALYSIS (IDENTIFICATION, CALCULATIONS, REPORTING)
Aqueous sample extracts (with isotopically labeled perchlorate standard) are mixed with acetonitrile-acetic acid and injected for HPLC/ESI/MS/MS determination of perchlorate:

8.10.1 Confirmation is achieved via observation of coelution between perchlorate analyte ions (m/z 83 and 85) and isotopically labeled perchlorate internal standard ion (m/z 89). Relative retention time (RRT) is calculated by dividing the analyte RT by the IS RT. Acceptance limit is 1±0.02.

8.10.2 Linear regression is typically employed, quantitation of sample concentration is based on the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m}$$

where:

x = concentration of the analyte (ppb; µg/L or µg kg)

y = analyte instrument response (area units)

b = calculated intercept (area units)

m = calculated slope of the line (area/conc. in ppb; µg/L or µg/kg)

V_t = total volume of concentrated extract (L)

DF = Dilution Factor (if applicable); if no dilution, then DF = 1

NOTE: The calibration fit may be weighted (i.e., 1/x weighting) as described in SW8000.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike sample (MS) and either field sample duplicate (DUP) or matrix spike duplicate (MSD). All batch QC samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

There are three types of blanks used in this analysis: Reagent Blanks (RB), Initial and Continuing Calibration Blanks (ICB/CCB), and Method Blanks (MB).

Reagent blanks are prepared with HPLC water, ACN/HOAc solution with NO WIS added.

Calibration Blanks are prepared with HPLC water, WIS and ACN/HOAc solution, but no filtration is performed.

Method Blanks (MBs) are aliquots of matrix (i.e., water or solid) that have been prepared and analyzed in the same manner as the associated field samples. HPLC or other analyte free water is used for water samples. Ottawa sand should be used in association with solid samples. MBs are analyzed to demonstrate that interferences from the analytical system, media, glassware, and reagents are under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. An LCS is similar to a matrix spike analysis (below) in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample, a field sample or matrix spike sample is performed in duplicate. The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$\text{RPD} = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

The matrix spike is analyzed to measure matrix effects on analyte recovery. To accomplish this, a measured amount of field sample is spiked with a known amount of analyte and % Recovery is calculated as above for the LCS. See QC Table for evaluation criteria. A minimum of one MS per day and at least one per batch of 20 is required.

$$\%R = \frac{\text{(MS Sample result-Sample result)}}{\text{Spike added}} \times 100$$

9.6 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

10.1 This SOP meets the requirements of EPA SW6850.

10.2 DoD Perchlorate Handbook Rev. 1 Change 1: See Program Specification and LIMS Nickname for the detailed conformance requirements of this reference.

10.3 EPA Method 331.0: See Program Specification and LIMS Nickname for the detailed conformance requirements of this reference.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals, or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Mobile phase waste is collected and disposed of in accord with SOPs 003 and SOP 015.

11.2.2 All radioactive samples and sample preparations shall be disposed as per SOP 015.

11.2.3 All non-radioactive hazardous waste will be disposed of as per SOP 003.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

DOCUMENT REVISION HISTORY

12/31/08: Updated SOP Header to reflect ALS. Added paragraph to SUMMARY referencing program specification concepts. Minor text edits throughout. Added ICSS and ICSL reagents as Sections 6.8 and 6.9, respectively. Calibration and Tuning Section 8.3 was expanded. The last three bullets of Section 8.9 were edited. QC Table was updated (RT, Isotope Area Ratio, IRCS); also included program specification caveat in Table header. Added DoD program specification as Appendix A.

Analytical Method: EPA SW6850	**Parameter:** Perchlorate		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Note: The QC requirements depicted in this Table represent the laboratory's standard requirements and those of EPA SW6850. Consult applicable client program specification for QC requirements that supercede these criteria.			
Method Reporting Limit (MRL)	Demonstrated with every initial calibration	MRL ≥ lowest calibration standard	Correct system problem if calibration including MRL fails.
Limit of Quantitation (LOQ)	Demonstrated with every initial calibration	Documented in the specific matrix of concern, at or below the applicable regulatory limit Demonstrated with low calibration standard. Must be within 50% of true value	Apply J-flag to all results between the LOD and LOQ
Method Detection Limit (MDL), (LOD)	Upon implementation of method; annually and when major method changes are made; quarterly MDL checks suffice provided no significant method changes are made	MDL study must be performed in the matrix of interest using a standard at 1-10x MDL MDL must be validated through the analysis of a low-level matrix spike at approximately 2x MDL, must have SN ≥3 and isotope ratio of ± 30% of the ICAL mean	Run MDL verification at higher level and set MDL higher or re-perform MDL study. A valid MDL must be completed prior to analyzing samples.
Initial Calibration (ICAL); minimum six-point	At method set up and as needed (i.e., when daily calibration verification does not meet criteria) and after major maintenance	Minimum of 6 calibration standards (+ blank) to establish linearity, r≥0.995 (r^2 ≥0.99) The calibration is linear and shall not be forced through the origin. The concentration corresponding to the absolute value of the calibration curve's Y-intercept should be ≤ LOD. Or use mean response if the RSD for each analyte is ≤20% (including MRL)	Repeat ICAL. No samples may be analyzed and reported until calibration has been achieved and verified.
Initial Calibration Verification (ICV); second source standard at midpoint concentration	After each ICAL (conc. within cal. range)	% Difference (%D) ≤15%D relative to true value	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards. Problem must be corrected prior to analyzing and reporting samples.
Matrix Conductivity Threshold (MCT) study, performed to determine the maximum tolerable	At initial setup and when major changes occur in method operating procedures	Conduct study and determine MCT as discussed in the method.	The MCT for this analytical system using this method has been determined to be 16620uS/cm (2000mg/mL)

Analytical Method: EPA SW6850	**Parameter:** Perchlorate		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**

concentration of known ion suppressors			
Continuing Calibration Verification (CCV)	All samples must be bracketed by the analysis of a standard demonstrating detection and accurate quantitation Analysis of mid-level standard after every 10 field samples. and at end of seq. Alternate LL and mid level concentration.	±15% ML; ± 50% LL (LL = approx. RL) Note: LL CCV equiv. to LODV	Evaluate/correct instrument malfunction as needed (e.g., rinse column, lines); prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed after a failed CCV must be reanalyzed. - If a failed CCV for an autosampler analysis returns to acceptable calibration later in the sequence, samples following the acceptable CCV will be reported, and samples between the failed CCV and subsequent compliant CCV will be reanalyzed.
Relative Retention Time (RRT)	Evaluated with each acquisition	The RRT between m/z 83 and m/z 89 must be less than 1.0± 2% (0.98-1.02)	Determine cause of problem and take corrective action
Isotope Area Ratio (m/z 83/85) to confirm presence of perchlorate	Evaluated with each acquisition (for every standard, sample, and control)	83/85 peak area ratio must fall between ±30% of ratio of the mid range calibration standard or the average ratio of all CCVs of the analytical batch if calibration was performed on a previous day	If ratio limits are not met, inject a new aliquot of sample. If interference is suspected, dilute if sensitivity is adequate or use cartridge cleanup. If ratio is not improved, flag sample data and narrate. (Note: Laboratory practice; corrective action not specified in SW6850)
Internal Standard Response Verification (IS = IRCS)	Same level added to every standard sample or control.	IS area counts must be within ±50% of the average of the IS area counts of the calibration standards if calibration is on the same day as analysis, otherwise use the IS area counts for the 1st CCV of the analytical batch	If IS area counts do not meet acceptance criterion, analyze a second aliquot. If the IS counts are still outside of the criteria, check the most recent CCV IS area counts. If the most recent CCV IS area counts meet the criteria, then the sample results should be considered suspect. If the most recent CCV IS area counts do not meet the criteria, corrective action must be taken to

			resolve the problem.
ICB and CCB (Note: not required SW6850)	Immediately following the corresponding calibration verification samples	<RL, or as otherwise specified in the applicable LIMS program specification	Correct problem, demonstrate freedom from blank interferences and quantitative performance.
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	Perchlorate concentration <RL, or as otherwise specified in the applicable LIMS program specification	Reanalyze to determine if instrument contamination was the cause. If MB still non-compliant, initiate corrective action: - if a sample contains target compounds at ≥10X amount found in MB or if target compounds are not detected in the sample, then results may be reported; otherwise - if the samples are within the extraction holding time, then re-extract and reanalyze all associated samples containing target compounds at <10X amount found in MB - if the samples are beyond the extraction holding time, then complete an NCR and contact PM for sample disposition.
Laboratory Control Sample (LCS)	1 per preparation batch of ≤20 samples of like matrix, spiked at the RL.	Recovery within 80-120%, or as otherwise specified in the applicable LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may need to be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration

		whichever is more stringent	
Laboratory Dup. or MSD	≥1per prep. Batch of 20 samples spiked at RL.	RPD <15%	In parent sample apply J flag if criteria not met.
IS Recovery (IS = IRCS)	Same level added to every standard sample or control.	±50% of the average IS area counts of original ICAL	Determine cause of problem and take corrective action. If interference is suspected dilute and reanalyze. If correction is not possible Q flag and narrate.
Relative Retention Time	Evaluated with each acquisition	The RRT between m/z 83 and m/z 89must be less than 1.0±2% (0.98-1.02)	Determine cause of problem and take corrective action. If interference is suspected dilute and re-analyze. If correction is not possible Q flag and narrate.
Isotope Area Ratio (m/z 83/85)	Evaluated with each acquisition (for every standard, sample, and control)	Theoretical 3.06; must fall 2.3-3.8 (25% window)	If ratio limits are not met, inject a new aliquot of sample. If interference is suspected, dilute if sensitivity is adequate or use cartridge cleanup. If ratio is not improved, flag sample data and narrate.

Note that a valid MDL study and check per ALS-FC standard practice are required for DoD analyses.

STANDARD OPERATING PROCEDURE 449 REVISION 0

TITLE: DETERMINATION OF DISSOLVED GASES IN WATER SAMPLES USING GAS CHROMATOGRAPHY

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 4.7.09

QUALITY ASSURANCE MANAGER _____ DATE 4/7/09

LABORATORY MANAGER _____ DATE 4-8-09

HISTORY: DRAFT 3/25/08; Rev0, 3/20/09.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references – RSKSOP-175 and EPA Region I Technical Guidance for the Natural Attenuation Indicators: Methane, Ethane and Ethene, is used to determine concentration of dissolved gases (methane, ethane and ethane) in water samples.

Analyte	CAS #	Molecular Weight
CH_4	74-82-8	16
$C2H_4$	74-85-1	28
$C2H_6$	74-84-0	30

Other compounds may be analyzed if successful demonstration of capability (DOC) and method detection limit (MDL) studies are performed.

2. SUMMARY

A headspace volume is created in each water matrix blank, calibration standard, sample and quality control sample, by displacing water with helium at ambient pressure. Equilibrium is then attained by vortex mixing (or equivalent equilibration), and an aliquot from the headspace is then introduced to a gas chromatograph with flame ionization detection (GC/FID), to determine the concentration of dissolved gases in the water sample.

Every water blank, calibration standard, sample and quality control (QC) sample is treated equivalently. The temperature, pressure, headspace volume, equilibration procedure and injection volume are kept constant.

Standards are prepared by introduction of a selected volume of gas phase standard to the headspace of a laboratory reagent blank. The standard concentrations are calculated to reflect the total concentration (TC) of analyte per volume of water. After equilibration, a portion of the headspace in each standard is analyzed, and a linear or 2nd order calibration curve is generated that describes the relationship between instrument response and standard

concentration.

The TC of each dissolved gas in each water sample is then determined by analysis and comparison of the resulting instrument response to the calibration curve.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 ALSLG-FC's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede ALSLG-FC's's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Any co-eluting entity that responds via FID. Few method interferences are known because methane, ethene and ethane are very small and highly volatile molecules. Interfering compounds are likely to be much more highly retained on the analytical column and separated from these analytes. Typically, chromatographic interferences are not observed with this procedure.

4.2 Interferences are also minimized by the use of high purity reagents (helium or nitrogen, analyte-free water).

4.3 Methane, ethene and ethane are present in the atmosphere (methane more so than ethene and ethane). Precautions should be taken to ensure that interference from room air is avoided. The helium and method blanks serve to demonstrate adequate control of ambient interference. Refer to QC Table for guidance and corrective actions pertaining to method blank analyses.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH (GC) AND DETECTORS

Hewlett Packard 5890 Series II GC or equivalent equipped with a flame ionization detector (FID)

5.2 DATA ACQUISITION

Any data acquisition system capable of acquiring, storing and processing GC/FID data (e.g. Agilent EZChrome™ or equivalent) to support the qualitative and quantitative requirements of this method may be used.

5.3 GASES - use only ultra high purity (99.999%)

Helium (purge and carrier gas)

Hydrogen (FID detector gas)
Compressed Air (FID detector gas)

5.3 COLUMNS - Equivalent columns may also be used
Analytical Column: J&W GS-CARBONPLOT; 30m x 0.533mm x 3.00µm; 0-360ºC operating range

5.4 MEASURING DEVICES
Gas Tight Syringes, various µL ranges

5.5 CONSUMABLES

- GC septa
- VOA Vials, 40mL size
- Replacement caps with septa, for 40mL VOA vials

5.6 Vortex mixer

6. REAGENTS

6.1 GAS PHASE STANDARDS:

6.1.1 Air Liquide-Scott Specialty Gases™: Scotty® mix; methane, ethane, ethane at various applicable concentration such as 100ppm (mole), 1% (mole) and 30% (mole) in nitrogen, or equivalent

6.1.2 Alternate source check standard, if available, otherwise two different lots may be used to confirm accuracy (ICV). Other reference material concentrations may be used, as long as an appropriate calibration range is

accomplished.

6.2 Organic-free reagent water; carbon-filtered, boiled and purged with helium prior to use (SOP 511)

6.3 Methanol, HPLC grade

6.4 STANDARDS

6.4.1 All standards are maintained per SOP 300. Specific SOP instructions take precedence with regard to management of standards.

6.4.2 At minimum, two independent sources of target analyte are recommended. First source materials are used to create calibration, continuing calibration verification (CCV) and QC sample spike standards. Second source materials are used to create the initial calibration verification (ICV), which is used to independently verify the accuracy of the initial calibration (ICAL). Use a second certified standard lot if a suitable alternate standard supply is not available.

6.4.3 An appropriate volume of stock standard is aliquoted to create working standards. All standards are delivered using gas tight syringes or a vacuum manifold system or other accurate gas delivery technique. Standards diluted from stock should be prepared daily.

6.4.4 All stock and intermediate standards are documented in ALSLG-FC's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Samples should be acidified with hydrochloric acid (HCl) to pH < 2. Water samples are usually preserved by adding approximately four (4) drops of concentrated hydrochloric acid (HCl) to each 40mL VOA vial. The purpose of the hydrochloric acid is to prevent microbially induced bias of target compound concentration. If the water sample is unpreserved, the holding time is not defined. Sample analysis of unpreserved samples may proceed given client approval.

7.3 Aqueous samples are collected in 40mL glass VOA vials with screw tops and Teflon ^{TM}-lined septa. Aqueous samples should be headspace-free. It is recommended that a minimum of three vials should be collected for each field

sample. For a designated matrix spiked (MS) analysis, the client may need to provide as many as six vials. Note that a matrix spiked duplicate (MSD) analysis is not typically performed with this procedure.

7.4 Store samples at 4±2 ° C

7.5 Samples must be analyzed within 14 days of sample collection.

7.6 To prevent loss of volatile organic compounds, samples must not be opened until the time of analysis.

8. PROCEDURES

8.1 TYPICAL SYSTEM OPERATING CONDITIONS

Gas Chromatograph

Column Flow Rate (helium):	4.8 ± 0.5mL/min
Air Flow Rate:	per manufacturer's recommendation
Hydrogen Flow Rate:	per manufacturer's recommendation
Purge Valve:	On at 90s (off at 7 minute)
Injector Temp.	250°C
Detector Temp.	350°C
Column Temperature:	150°C
[1]Ramp:	150°C, 4min., 40°C/min., 240°C, 0.8min.
[1]Run Time:	8 min. (includes ramp)
Injection Volume:	300 µL

Expected Retention Times:
Methane 1.7 minute; Ethene 1.9 minute; Ethane 2.03 minute

[1] The run time may be shortened to 3 minutes by omitting the ramp. The shortened run is then an isothermal run. Periodic bake out or use of the temperature ramp may be important to avoid carryover effects in some sample matrices.

8.2 GC MAINTENANCE

Prior to establishing calibration curve or analyzing samples, the following suggested maintenance can be performed to aid in achieving more consistent results:

- Change the GC injection port septum regularly (after approximately each 50 injections).
- Bake out the GC at 250°C until the background signal reaches approximately 4 mV.
- Clean or change the GC liner if pieces of septa or other contamination begin to cause a rise in background signal or column bleed.

- Syringes may be purged with helium or nitrogen to control potential carryover effects.
- Additional GC bake-out may be added to routine sample runs to control moisture or late eluting interferences.

8.3 DISSOLVED GASES CONCEPTS

The purpose of this procedure is to identify and quantitate the concentration of a dissolved gas (methane, ethene or ethane) in an aqueous field sample.

8.3.1 Starting with a 40mL VOA vial (42.5 mL of volume), a 4.0mL headspace is created using helium supplied at near ambient pressure. Thus, 38.5mL of water sample remains.

At this point, any target analytes in the water, partition into the headspace until equilibrium between the two phases is reached.

The concentration of target analyte in the original sample, can be said to be equal to the mass of analyte partitioned to the headspace plus that remaining in the water, divided by the 38.5mL of water sample remaining in the vial.

8.3.2 A standard can be prepared in the same manner as the sample. 4.0mL of headspace is created in a vial of blank reagent water. A known amount of a reference gas standard is then added to the headspace (an equivalent amount of headspace is first withdrawn to maintain ambient pressure inside the vial), and the standard is allowed to equilibrate (same conditions as a field sample). The resulting concentration can be defined as the total mass of analyte added, divided by the water volume in the vial (38.5mL).

If a series of initial calibration standards (at different concentrations) is thusly prepared and analyzed, a calibration curve may be generated from the detector responses obtained.

Field samples may then be analyzed and their detector responses compared to the calibration curve for quantitation.

Since water volume, headspace volume, total VOA vial volume, equilibration conditions, pressure and temperature are all kept constant between standards and samples, one may calibrate and quantitate without the need to determine the concentration in the water phase using the Henry's law calculation approach.

Reference gas standards are supplied with the analyte concentration stated in ppm as calculated on a mole basis. It is necessary to first

calculate the weight per unit volume concentration of each analyte in each standard. This concentration is then used to calculate the total mass of analyte added to a standard or QC sample (via addition into the headspace).

8.3.3 CALCULATIONS

A. Unit Conversion of ppm (mole basis) to gram/liter for Gas Mixtures:

Example Given a 100 ppm (mole basis) gas mixture of CH_4 in nitrogen, calculate the concentration (g/L) of CH_4 in a 1 liter volume:

Key Assumptions

- Temperature of sample assumed to be at 22°C
- Pressure of sample assumed to be 840 bar (0.829 atm; typical Fort Collins atmospheric pressure) just before injection.

  At around atmospheric pressure, gases behave in close to ideal manner.

Using the Ideal Gas Law (PV = nRT) for a temperature of 295.15°K (22°C), a pressure of 0.829 atm (= 840mbar barometric pressure), and the gas constant R of 0.0821 liter-atm/mole-°K, it is determined that:

1 mole of ideal gas occupies 29.21 liters.

One liter of gas will then contain (1/29.21) moles.

Since the concentration of CH_4 is 100 ppm:

(total # moles per liter)(concentration of CH_4) = total number of moles of CH_4 in 1L

The concentration of 100 ppm (parts per million) is unit-less, and equals 100 mole-parts per 1,000,000 total moles = 0.000100 in decimal form; thus the amount of moles of CH4 in one liter of mixture is:

(1/29.21 moles/L)(0.000100) = 0.00000342 moles of CH_4 per liter

The analyte's molecular weight is used to determine the weight of analyte in the mixture:

Example For methane (molecular weight 16 gram/mole):

(16 gram/mole)(0.00000342 moles/L) = 0.0000547 g/L or 0.0547 mg/L

B. General Formula for Conversion of ppm (mole) to gram/liter for Gas Mixture (22°C, 0.829 atm):

$$\frac{\text{Gas Conc. (ppm in decimal form) x mole-weight (gram/mole)}}{\text{29.21 L / mole}} = \text{Conc. (g/L)}$$

C. Calculation of Concentration for Standards:

$$\frac{\text{Gas Conc. (ppm in decimal form) x mole-weight (g/mole) x Vol. Std. Added to Headspace (L)}}{\text{Volume at ambient P and T (L/mole) x Vol. Sample (L)}} = \text{Conc. (mg/L)}$$

Unit Conversions: mg/L (1000 µg/mg) = µg/L

NOTE: The gas volume to be added is first withdrawn from the headspace to maintain ambient pressure (equivalent headspace volume and pressure to that of the samples).

Concentration = total mass of analyte (in the entire vial)/volume of water in vial, mg/L or µg/L

MW = Molecular weight of analyte (g/mole)

T = Temperature

P = Pressure

Example Calculation Standard Concentration for methane (injection of 4µL of 1% mole/mole standard into a VOA vial with 4.0mL headspace):

$$\frac{\text{(0.0100 mole ratio; 1\% std.)(16g/mole)}(4\text{x}10^{-6}\text{L injected})(1\text{x}10^{6}\mu\text{g/g})}{\text{(29.21 L std. Vol. for 1 mole) (0.0385 L water)}} = 0.569\ \mu\text{gCH}_4\text{/L}$$

Calculation of sample results may be done directly by comparison to the standard total concentration curve.

8.4 INITIAL CALIBRATION

8.4.1 Initial calibration standards are prepared at a minimum of five concentrations. The range of concentrations of the initial calibration is intended to define the working range of the analytical system. One of the concentrations must be at or below the analyte reporting limit.

8.4.2 Certified gas standards, containing target analytes in nitrogen, are used to prepare the working standards. The calibration standards are prepared from water blanks and are handled as samples would be (equivalent headspace, pressure, temperature, equilibration).

8.4.3 Example standard levels are provided in the following Table. Standard concentrations were calculated based on a room temperature of 22 ºC and a barometric pressure of 840mbar. As the barometric pressure varies by less than 3% from 840mbar in Fort Collins, CO and room temperature is maintained at close to 22ºC in the laboratory, these conditions will be

routinely applied to calculate standard concentrations. Standard concentrations should be corrected if ambient conditions vary significantly.

TABLE 3
CALIBRATION STANDARDS

Target	Standard Preparation	Total Conc. ppm	TC ppb
CH4	4uL 1%	0.0005690	0.5690
	25uL 1%	0.0035563	3.5563
	100uL 1%	0.0142253	14.2253
	1000uL 1%	0.1422532	142.2532
	300uL of 30%	1.2802789	1280.2789
	3000uL of 30%	12.8027886	12802.7886
C2H4	4uL 1%	0.0009958	0.9958
	25uL 1%	0.0062236	6.2236
	100uL 1%	0.0248943	24.8943
	1000uL 1%	0.2489431	248.9431
	300uL of 30%	2.2404880	2240.4880
	3000uL of 30%	22.4048801	22404.8801
C2H6	4uL 1%	0.0010669	1.0669
	25uL 1%	0.0066681	6.6681
	100uL 1%	0.0266725	26.6725
	1000uL 1%	0.2667248	266.7248
	300uL of 30%	2.4005229	2400.5229
	3000uL of 30%	24.0052287	24005.2287

NOTE: Alternate equivalent dilution schemes may be used as appropriate. Five or more calibration levels are required. Sample injection size, headspace volume, water volume, pressure and temperature must be equal for all standards and samples (keep constant throughout each run).

8.4.4 Inject 300µL of each equilibrated calibration standard into the GC and acquire data.

8.4.5 Electronically integrated peak area responses are tabulated and quantitated using external standard quantitation. Calibration Factors (CFs) for each compound are calculated as follows:

$$CF = A_s/C_s$$

where:

A_s = response (area) for the analyte to be measured

C_s = concentration of the analyte to be measured (µg/L)

8.4.6 Since each CF represents the slope of the line between the response for that standard and the origin, then if the observed deviation between the

CF's is constant (i.e., ≤20% RSD), then the response is assumed to be invariant and the average (mean) CF may be used to quantitate sample concentrations. Percent Relative Standard Deviation (%RSD) is calculated as:

$$\%RSD = \frac{\text{Standard Deviation (SD)} * 100}{\text{Average (mean) RF}}$$

If an initial calibration point is not used for any reason, the analyst must clearly notate why the data point was not used for instrument calibration. "Picking and choosing" among calibration points in order to meet criteria is NOT acceptable. Generally, calibration points are only discarded due to easily demonstratable causes.

8.4.7 When %RSD over the calibration range is greater than 20%, linearity through the origin cannot be assumed. A first or second order regression fit of five or more calibration points that does not pass through zero (e.g., least squares method) may be constructed. The regression calculation will yield a coefficient of determination (r^2 value) that must be >0.99 to be used for sample quantitation. Note that the coefficient of determination (COD) is an expression of "goodness of fit", with perfect fit being a value of 1.0. If non-linear (quadratic) regression curve fitting is used, a minimum of 6 calibration points is required (SW8000C). A quadratic regression should not be used to compensate for detector saturation.

8.4.8 The mathematics used in least squares regression have a tendency to favor numbers of larger value over numbers of smaller value. The regression curves that are generated will therefore tend to fit points that are at the upper calibration levels better than those points at the lower calibration levels. To compensate for this, a "weighting" factor which reduces this tendency can be used. The analyst may weight the curve to either the inverse of the concentration (1/x) or to the inverse of the square of the concentration (1/x2). If regression criteria cannot be met, system repair or maintenance may be necessary and a new initial calibration must be performed.

The type of curve fit applied should be chosen to best represent the data.

8.5 INITIAL CALIBRATION VERIFICATION (ICV)

A second source (ICV) standard is analyzed immediately after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. The acceptance criteria for the ICV are identical to those of the CCV (described below). Refer to the QC Table for corrective action should the ICV analysis fail.

8.6 SAMPLE PREPARATION / ANALYSIS

8.6.1 The reagent gas (nitrogen or helium) used to create sample headspace must be sufficiently pure to support low level quantitation requirements. A system blank of helium is injected to demonstrate that helium and system background are low enough to support analytical goals.

8.6.2 A known volume of 10% or more of headspace must be generated using nitrogen or helium at close to ambient pressure. Ensure that the gas source flows at a low pressure (observe approximately one bubble per second if the gas delivery needle is monitored in vial with methanol).

8.6.3 Each VOA vial contains 42.5mL of volume. A 4.0mL helium headspace was created for the initial MDL study, calibrations and sample analyses, and should therefore be used unless further study is performed to support changing the headspace volume. The displaced water may be measured in a syringe or by weight.

8.6.4 Record the room temperature and barometric pressure in the sequence log. The value for barometric pressure may be taken from Colorado State University's weather observation station. These data show that a value of 840mbar may be used for Fort Collins' barometric pressure with minimal error.

8.6.5 The sample is equilibrated by vortex mixing at approximately 3000 rpm for at least 2 minutes. A 300µL aliquot of headspace is then injected into the GC.

8.6.6 Dilutions. If less than 10% of the original sample headspace was used in a sample analysis, a smaller aliquot, from the same headspace, may be used for gas-phase dilution. The injection size is kept constant. Otherwise, a new sample is prepared at an appropriate dilution. For example, if the head space is 4mL from a 40mL VOA vial and the sample injection is 300µL (7.5% of the headspace), a smaller aliquot of headspace can be used for dilution. The dilution to be performed is chosen to keep the response in the upper half of the calibration curve.

Example Vapor-Phase Dilution: 50µL to 42.5mL (42,500 µL) = 850x

8.7 QC SAMPLES

8.7.1 The following types of QC samples are prepared with each extraction batch of ≤20samples (see QC table for frequency, acceptance criteria and corrective actions):

- Method Blank (MB): No sample added; all reagents and Steps are equivalent to field sample.

- LCS (CCV)/LCSD: Reagent water with equivalent headspace to standard after addition of gas-phase standard. Note that for this procedure, the LCS is equivalent to a CCV (referenced by the method as a CCS). The LCSD is a Duplicate of the LCS.

- MS/MSD: Field sample (and field sample duplicate) fortified with midpoint analyte spike. MSD not required unless specified in the Program Specification or Nickname.

- Duplicate: a field sample duplicate (Dup).

8.7.2 To prepare QC samples, 40mL VOA vials are filled with reagent water (SOP 511) with zero headspace.

8.7.3 Create a 4.0mL headspace by displacing water with helium or nitrogen at close to ambient pressure.

8.7.4 Vials thusly prepared can be method blanks, or can be spiked to create working standards. Note that working standards are equivalent to LCSs for this procedure.

8.7.5 Vapor phase dilutions are performed as necessary to ensure that each analyte is quantitated within the working range of the calibration.

8.8 CONTINUING CALIBRATION VERIFICATION (CCV)

The CCV is used to confirm system response throughout an analytical sequence. The concentration of the CCV is at or around the midpoint of the initial calibration. Acquire a CCV at the start of each analytical sequence, after each twenty injections (or less), and at the end of each sequence. ALSLG-FC commonly analyses 10 samples between CCVs to reduce the amount of repeat injections, should they be required. QC samples are counted as part of the number of injections, instrument blanks are not.

The percent difference (%D, drift) must be calculated for each CCV (see equation below):

$$\%D = \left[\frac{(\text{calculated concentration}) - (\text{expected concentration})}{\text{expected concentration}} \right] (100)$$

Calibration is verified when all compounds are within 20%D. Individual compounds that exceeded 20% are noted in the data package narrative. If any CCV does not meet acceptance criteria, analyses should be halted and corrective action taken. Refer to the QC Table for corrective action in the event of CCV analysis failure.

8.9 RETENTION TIME WINDOWS

For GC methods utilizing external standard quantitation, retention times are used for analyte identification. Retention Time Windows (RTWs) are established each time a new column is installed and are used to compensate for minor retention time shifts. It is important to establish valid retention RTWs. If too tight, false negatives may result. If too loose, false positives may occur. Determine RTWs by analyzing replicates (typically three injections), of a mid-level standard containing all analytes, non-consecutively, over a 72-hour period (this approach captures system variation). Calculate the standard deviation of absolute retention time for each analyte for the set of analyses used in the RTW study. Define each analytes' RTW as the mean retention time ±3σ, such that the Upper Limit = + 3σ and the Lower Limit = -3σ.

8.10 SAMPLE IDENTIFICATION, CALCULATIONS, REPORTING

8.10.1 Dual column confirmation is not required because interferences are not observed due to strong separation/greater retention of interferences on the chromatographic column.

8.10.2 The following equation is used to quantify sample concentration when CF (or mean CF) is employed:

$$\text{Concentration } (\mu g/L) = \frac{(A_x)(DF)}{(\text{mean CF})(V_s)}$$

where:

A_x	=	analyte response (area units)
DF	=	dilution factor (if applicable); if no dilution was made, DF = 1 (dimensionless)
CF or mean CF	=	standard response (area units/concentration)
Vs	=	volume of sample analyzed (L)

8.10.3 Where linear regression is employed, quantitation of sample concentration is based on the equation of the linear curve generated during initial calibration (i.e., y = mx + b), as follows:

$$x = \frac{(y - b)\,(V_t)(DF)}{m}$$

where:

x = concentration of the analyte (µg/L)

y = analyte instrument response (area units)

b = calculated intercept (area units)

m = calculated slope of the line (area/conc. in µg/L)

V_t = total volume of concentrated extract (L)

DF = Dilution Factor (if applicable);

if no dilution, then DF = 1

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

A batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS) and laboratory control sample duplicate (LCSD). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specifications for additional or alternative requirements.

9.2 BLANKS

Method Blanks (MBs) are aliquots of matrix (i.e., water) that have been prepared and analyzed in the same manner as the associated field samples. MBs are analyzed to demonstrate that the system overall is under control. Concentrations of target analytes, if any, must be less than the reporting limit (RL), or as otherwise prescribed in the LIMS program specification.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the analytical system. An LCS is similar to a matrix spike analysis in that known concentrations of target analytes are spiked into reagent matrix (as opposed to sample matrix, as with the MS) and the percent recoveries for the analytes are calculated as shown below. See QC Table for evaluation criteria.

$$\%R = \left(\frac{\text{concentration detected}}{\text{concentration spiked}} \right)(100)$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this measurement, the laboratory control sample and/or matrix spike sample is performed in duplicate (LCSD, MSD). The results of the duplicate analyses are evaluated in terms of Relative Percent Difference (RPD), which is calculated as shown below. See QC Table for evaluation criteria.

$$RPD = \left(\frac{\text{concentration sample} - \text{concentration duplicate}}{1/2\,(\text{concentration sample} + \text{concentration duplicate})} \right)(100)$$

9.5 MATRIX SPIKE

The matrix spike is analyzed to measure matrix effects on analyte recovery. To accomplish this, a measured amount of field sample is spiked with a known amount of analyte and % Recovery is calculated as above for the LCS. See the QC Table for evaluation criteria.

$$\%R = \frac{\text{(MS Sample result-Sample result)}}{\text{Spike added}} \times 100$$

9.6 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven (7) replicates for each target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

10.1 Method RSK175: Specifies that the instrument blank (helium or nitrogen) acceptance is less than the MDL. ALSLG-FC uses less than the reporting limit (RL).

10.2 EPA Region 1, Analysis of Dissolved Methane, Ethane, and Ethene in Groundwater by a Standard Gas Chromatographic Technique: Butyl rubber VOA vial septa are specified in the EPA Region 1 method. Teflon-faced silicone septa are commonly employed by ALSLG-FC for volatile analytes. Adaptation of butyl rubber septa may be validated and adapted for this assay. ALSLG-FC has tested septa supplied to clients.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 All compressed gas cylinders must be secured at all times. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.1.8 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The aqueous sample waste shall be disposed of in the aqueous lab waste stream. A satellite waste collection vessel may be obtained from the Waste Manager.

11.2.2 Solvent wastes must be disposed of in the appropriate waste containers.

11.2.3 Any methanol, hexane or other non-halogenated organic solvents that has not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Non-halogenated Waste.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs (003, 015). Please note that all labels and markings must be defaced prior to disposal.

Analytical Method: RSK175	**Parameter:** Methane, Ethene, Ethane		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	QC Check
Initial Calibration; minimum 5-point; all analytes	As needed (i.e., when the daily calibration does not meet criteria)	Calculate linear regression (not forced through origin); use for quantitation if coefficient of determination (r^2) ≥0.990 (or r = ≥0.995) or calculate quadratic regression (minimum of six points required); use for quantitation if COD ≥0.990 ≤20%D each point	Evaluate/correct instrument malfunction and reanalyze ICAL to obtain acceptable curve
Independent Calibration Verification (ICV); all analytes	After each new initial calibration	≤20%D of each compound Note: Second lot is acceptable if second source is unavailable.	Prepare another ICV and analyze. If second ICV fails, system must be recalibrated with freshly prepared standards.
Continuing Calibration Verification (CCV); analyzed at approximately midpoint concentration level of the calibration curve	Run at start of sequence if ICAL not performed; brackets each set of 10 (or max. of 20) field sample analyses	≤20%D for each analyte or as otherwise specified in applicable LIMS program specification	Evaluate/correct instrument malfunction as needed (e.g. change septum, rinse or change liner; prepare a new standard and reanalyze. - If CCV still non-compliant, recalibrate. Samples analyzed before and after a failed CCV must be reanalyzed.
Retention Time Window (RTW); based on minimum of 3 non-consecutive injections throughout at least a 72-hour period to be representative of variation	Update whenever a new column is installed or target analytes are misidentified in a standard, LCS or MS	Column and compound specific Window is ±3x the standard deviation of the 3-injection average for the respective column Note that the ICV and CCV analyses are also used to monitor RT drift	Wider windows can be used to screen for compounds; if zero, substitute window of close eluting similar compound. Experience of analyst weighs heavily in interpretation of chromatograms (refer also to RT Shift).
Retention Time Shift; RT of analytes in CCV are evaluated against the midpoint of the ICAL	Each CCV; RT of analytes evaluated against the ICAL	Column and compound specific, must support consistent identification of analytes in know samples.	Inspect chromatographic system for malfunction; correct identified malfunctions, if appropriate Evaluate data based on comparison with other standards run during sequence, consider RTs for the surrogates and spiked compounds analyzed before and after the sample in question: - adjust the RTW to correct the shift in compound location - if no peaks are found in the adjusted window, report the compound as a

Analytical Method: RSK175	**Parameter:** Methane, Ethene, Ethane		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	QC Check
			non-detect - if peaks are present, use the confirmation column to verify identification
Method Blank (MB)	1 per preparation batch of ≤20 samples of like matrix	<RL: MB should not contain any target compounds at or above the reporting limit (RL) or per other criteria as specified in the applicable LIMS program specification	If not less than acceptable limit, correct contamination and re-analyze associated samples if possible. Note: Due to the ubiquitous nature of methane, method blanks may occasionally have concentrations >RL. Such incidents are acceptable if concentrations of methane in associated samples are either ≥5x the concentration in the method blank OR <RL for methane. If the above conditions are met, then no Non-Conformance Report (NCR) needs to be generated. If the above conditions are not met, then consult the Project Manager for guidance regarding an NCR and corrective action.
Blank Spike (BS); Laboratory Control Sample (LCS); Since an LCS is physically equivalent to a CCV, a CCV may be designated as "CCS" and used as an LCS.	1 per preparation batch of ≤20 samples of like matrix	80-120% Recovery or as specified in individual nicknames; recoveries for spiked compounds must be within these limits or other limits as specified in the LIMS program specification	Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed) - if the samples are beyond the extraction holding time, then contact PM via NCR for sample disposition. Unless otherwise directed, samples will not be extracted outside of the holding time and the data will be submitted with appropriate narration
Matrix Spike (MS) Matrix Spike Duplicate (MSD) or sample Duplicate	1 per preparation batch of ≤20 samples of like matrix	70-130% Recovery or per applicable Nickname/Program Specification; recoveries for spiked compounds should be within advisory limits The relative percent difference	See Matrix Spike actions above for recoveries outside of advisory limits. If RPDs for the spiked compounds are not within advisory limits, check for documentable errors (e.g., calculations and spike preparation). Check unspiked sample results and surrogate

Analytical Method: RSK175	**Parameter:** Methane, Ethene, Ethane		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	QC Check
		(RPD) between duplicate analysis (sample/sample duplicate or MS/MSD) should be ≤ 20 (or per Nickname/Program Specification requirement)	recoveries for indications of matrix effects. Note in narrative. If significant differences between the MS and MSD exist, reanalysis of the sample and spikes may be necessary. Discuss with Department/ Project/QA Managers. Check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze to determine if instrumental conditions were the cause. - if still non-compliant and the samples are within the extraction holding time, initiate an NCR (associated samples may be reanalyzed)
Method Detection Limit (MDL) Study; run at analyte concentrations near to the minimum detection capabilities of the method	As needed, at minimum, annually	Concentrations for the MDL study shall be at a level lower than that of the reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. If criteria still not met, discuss with Department and QA Managers (RL may be adjusted, if needed).

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references – Method SW8270D - describe a procedure to determine the concentration of semivolatile organic compounds (SVOCs) in extracts prepared from all types of solid waste matrices, soils, TCLP leachates and ground water. Direct injection of a sample may be used in limited applications.

The body of this SOP specifies the procedures to be used for SW-846 Method 8270D. Any additional or contradictory requirements for EPA Method 625 are contained in Section 10.

The following analytes have been successfully determined utilizing this analytical procedure after appropriate preparation methods are utilized. Other compounds may be determined after successful demonstration of capability (i.e., method detection limit studies and other demonstration of capability, as applicable). Analytes in the Table below are listed in elution order. Analytes that are part of Paragon's typical reporting list are presented in bold text.

TABLE 1
APPLICABLE COMPOUNDS FOR SEMIVOLATILE ANALYSIS BY SW8270D

COMPOUND	CAS Number
pyridine	110-86-1
N-nitrosodimethylamine	62-75-9
aniline	62-53-3
phenol	108-95-2
bis(2-chloroethyl)ether	111-44-4
2-chlorophenol	95-57-8
1,3-dichlorobenzene	541-73-1

2. SUMMARY

Prior to using this instrumental analytical method, the samples are extracted and appropriate concentration and cleanups are performed to prepare the extract for analysis. The semivolatile compounds are introduced into the GC/MS by injecting the extract into a gas chromatograph (GC), equipped with a narrow-bore, fused-silica capillary column. The GC oven housing the column, is temperature-programmed to facilitate analyte separation. As analytes elute from the column, they are introduced into the mass spectrometer (MS) detector via a direct connection. Identification of target analytes is accomplished by comparing their mass spectra with the electron impact spectra of authentic standards. Quantitation is accomplished by comparing the response of a major quantitation ion relative to an internal standard, using a calibration curve (at minimum, 5 points for quantitation by average response factor, or 6 points for use of a quadratic fit).

Method 8270D can be used to quantify most neutral, acidic, and basic organic compounds that are soluble in methylene chloride, and capable of being eluted without

derivatization as sharp peaks from a fused-silica capillary GC column, coated with a slightly polar silicone. Such compounds include polynuclear aromatic hydrocarbons (PAHs), chlorinated hydrocarbons and pesticides, phthalate esters, organophosphate esters, nitrosamines, haloethers, aldehydes, ethers, ketones, anilines, pyridines, quinolines, and aromatic nitro compounds and phenols, including nitrophenols.

The following compounds may require special treatment when being determined by this method:

- *Benzidine* can be subject to oxidative losses during solvent concentration. Also, chromatography is poor.
- *Hexachlorocyclopentadiene* is subject to thermal decomposition in the inlet of the gas chromatograph, chemical reaction in acetone solution, and photochemical decomposition.
- *N-nitrosodimethylamine*, *pyridine* and *1,4-dioxane* are difficult to separate from the solvent front under the chromatographic conditions described in the method.
- *N-nitrosodiphenylamine* decomposes in the gas chromatographic inlet and cannot be separated from diphenylamine.
- *Pentachlorophenol*, *2,4-dinitrophenol*, *4-nitrophenol*, *4,6-dinitro-2-methylphenol*, *4-chloro-3-methylphenol*, *benzoic acid*, *2-nitroaniline*, *3-nitroaniline*, *4-chloroaniline*, and *benzyl alcohol* are subject to erratic chromatographic behavior, especially if the GC system is contaminated with high boiling material.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analyses according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Paragon Project Manager is responsible for directing a chlorine residual check to be performed just prior to analysis, as applicable.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon’s standard criteria. It is the responsibility of all personnel who work with samples or data

involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the review sheet indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to correct any errors found during the review.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences. Determine if the source of interference is in the preparation and/or cleanup of the samples, and take corrective action to eliminate the problem.

4.2 Contamination by carryover can occur whenever high-concentration and low-concentration extracts are sequentially analyzed. To reduce carryover, the sample syringe must be thoroughly rinsed with solvent between sample introductions.

Whenever an unusually concentrated sample is encountered, a solvent blank may be injected to check for carryover contamination, thus ensuring that the autosampler, injector, and also column bleed, are not contributing carryover contamination.

4.3 Phthalate esters are used in the production of plasticizers and are ubiquitous in many commercial products used in laboratories. In particular, bis(2-ethylhexyl) phthalate is the only one of this class of compounds that is typically present in all extracts analyzed using this procedure.

5. APPARATUS AND MATERIALS

5.1 GAS CHROMATOGRAPH/MASS SPECTROMETER SYSTEM
Hewlett Packard (HP) Model 6890 GC or equivalent (temperature-programmable oven, capable of splitless or split/splitless injection, constant differential flow controllers).

HP Model 5973 or equivalent MS detector (capable of scanning from 35 to 500amu every 1sec or less; using 70 volts, nominal, electron energy in the electron impact ionization mode; capable of producing a mass spectrum for decafluorotriphenylphosphine, DFTPP, which meets all of the tune criteria in Table 3 for a 0.5µL, 25ng, injection of tuning standard; and to ensure sufficient

precision of mass spectral data, the MS scan rate shall allow acquisition of at least five spectra, while a sample component elutes from the GC).

5.2 DATA ACQUISITION AND PROCESSING SYSTEM

A computer system must be interfaced to the mass spectrometer. The system must allow the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program.

The computer must have software that can search any GC/MS data file for ions of a specific mass, and that can plot such ion abundances versus time or scan number. This type of plot is defined as an Extracted Ion Current Profile (EICP). Software must also be available that allows integrating the abundances in any EICP between specified time or scan-number limits.

The most recent version of the EPA/NIST Mass Spectral Library, or similar spectral search library, should also be available. This library is used to help to identify non-target compounds generally referred to as tentatively identified compounds (TICs). Paragon's Windows NT software uses a NIST 98K library.

5.3 COLUMNS*

Capillary Column - 30m x 0.25mm ID (or 0. 32mm ID), 0.5µm film thickness; J&W Scientific DB-5.625 or equivalent.

* equivalent columns/guard columns may also be used, providing that all method QC criteria can be met

5.4 GASES- use only ultra high purity (99.999%)

Helium: carrier gas

5.5 MEASURING DEVICES

- microsyringes, gas-tight, Precision Hamilton™ or equivalent, 1µL - 1.0mL sizes (used for spiking)
- Luer-lock syringes, Becton & Dickinson or equivalent, disposable, 5mL or 25mL (used for sample introduction)
- balance, 0.01g sensitivity (used for weighing solid sample aliquots)
- volumetric flasks, Class A, with ground glass stoppers, various sizes

5.6 CONSUMEABLE SUPPLIES

- Septa, 11mm, Restek #20365 or equivalent
- fluorocarbon O-ring, 6.5mm, Restek #20372 or equivalent
- ID splitless liner, 2mm, Restek #20796 or equivalent

- gold seal, Agilent #18740-20885 or equivalent
- bottles, glass, with Teflon™-lined screw caps or crimp tops

6. REAGENTS- Only pesticide residue grade or equivalent may be used.

6.1 methylene chloride, Burdick and Jackson #299-4 or equivalent

6.2 methanol, Burdick and Jackson #230-4 or equivalent

6.3 STANDARDS

6.3.1 All standards are maintained per PAR SOP 300, refer to this SOP for expiration information. Note that any standard or reagent must be replaced sooner that its expiration, if laboratory control samples indicate a problem, or deterioration is evident.

All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer.

Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

6.3.2 Care must be taken to maintain the integrity of all standard solutions. It is recommended that all standards (typically in methylene chloride) be stored in a freezer (-10°C to -20°C) in amber vials with firmly sealed Teflon™-lined screw-caps. If permitted by the manufacturer, unopened stock standards may be stored at room temperature in flame-sealed ampules. Standards for this procedure are sonicated, and allowed to equilibrate to room temperature before opening.

6.3.3 Two independent sources of commercial target analyte stock standards are required. The stock standards are purchased as certified solutions from suitable suppliers. Typically, concentrations of stock solutions vary from 1,000-5000µg/mL.

First source materials are used to create calibration and continuing calibration verification (CCV) standards. Second source materials are used to create the initial calibration verification (ICV) solution. Laboratory control and matrix spike standards, consisting of compounds that will be representative of the compounds being investigated, may be from either source (a third source is often used for spiking).

6.3.4 Non-target analyte internal standard (IS) and surrogate (SS) stock standards are also purchased. The IS is used to quantitate analytes detected in samples. The SS is used to monitor system performance and method effectiveness for each sample matrix.

The internal standards (ISs) used for this method are: 1,4-dichlorobenzene-d_4, naphthalene-d_8, acenaphthene-d_{10}, phenanthrene-d_{10}, chrysene-d_{12} and perylene-d_{12} (see also Table 6). These internal standards are purchased in a mix with all compounds at a concentration of 2,000µg/mL and diluted to an intermediate concentration of 1,000µg/mL. Alternative internal standard stock concentrations may be used.

An appropriate aliquot of IS solution is added to an aliquot of calibration standard or extract prior to analysis so that the resulting concentration is 40ng/µL of each internal standard. In the case of sample extracts that require dilution, the extract is first diluted and then IS is added.

If selected ion monitoring (SIM) is being used to reach lower reporting limits, a less concentrated IS solution is recommended. As a general rule, use an IS concentration that will produce a response factor of approximately 1. For most SIM applications, an IS concentration of 4ng/µL will be sufficient.

The surrogate standards currently utilized are: phenol-d_5, 2-fluorophenol, 2,4,6-tribromophenol, nitrobenzene-d_5, 2-fluorobiphenyl, and p-terphenyl-d_{l4}, 2-chlorophenol-d_4, and 1,2-dichlorobenzene-d_4. A surrogate intermediate standard is prepared in methanol at a concentration of 50µg/mL for base/neutral compounds and 75µg/mL for acid compounds. Other compounds may be used as surrogates if required by the client. During preparation, 1.0mL of this standard is typically spiked into all client and QC samples

6.3.5 Intermediate standards are created by diluting the stock standards. All dilutions should be performed using syringes, and pesticide grade solvent. The intermediate standard may contain the compounds of interest singly or mixed together. After opening/initial use, transfer the remaining stock standard to a suitable vial, such as an amber vial with a Teflon™-lined screw-cap; store with minimal headspace in a freezer (-10 to -20°C). Dilute target analyte stock standards with dichloromethane. Dilute QC standards with methanol. Intermediate standards should be checked frequently for signs of degradation,

especially just prior to preparing working calibration standards from them.

6.3.6 For tuning purposes, a methylene chloride solution containing 50ng/µL of decafluorotriphenylphosphine (DFTPP) should be purchased or prepared. The standard should also contain 50ng/µL each of 4,4'-DDT, pentachlorophenol and benzidine to verify injection port inertness and GC column performance. Also, it is possible to check the degradation of these compounds in the ICV or CCV as long as co-elution with other compounds is not present.

6.3.7 Target analyte intermediate standards are further diluted in dichloromethane to create calibration (working) standards. Prepare, at minimum, five concentrations, a minimum of six concentrations is required if higher order fits (e.g., quadratic) are to be used. One of the calibration standards should be created at a level that yields concentrations less than or equal to the reporting limit (RL). The remaining concentrations should correspond to the expected range of concentrations found in real samples, but should not exceed the working range of the GC/MS system. The laboratory shall not report a quantitative result for a target analyte that was not included in the calibration standards.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 All samples must be kept chilled (4±2°C).

7.3 Aqueous samples must be collected in one-liter amber glass bottles with Teflon™-lined caps. Soil samples must be collected in glass containers with Teflon™-lined caps.

7.4 Samples are not chemically preserved, however, sodium thiosulfate may be used to dechlorinate liquid samples that contain residual chlorine. When applicable, the Project Manager will designate the need for residual chlorine check.

7.5 Aqueous samples must be extracted within 7 days of collection, soil samples must be extracted within 14 days of collection. Extracts must be analyzed within 40 days of extraction.

8. PROCEDURE

8.1 Several techniques are available for sample preparation (i.e., extraction and concentration):

MATRIX	SW-846 METHODS
Water	3520, 3510
Soil/Sediment	3540, 3550
Waste	3540, 3580

All surrogates, and matrix spikes (as applicable) must be added to samples prior to performing the extraction step. Internal standards must be added to the resultant extracts prior to performing the GC/MS instrumental analysis.

Extracts may be cleaned up using Gel Permeation Chromatography (GPC) by Method SW3640. See SOP 641 for GPC procedures. On a limited basis, contingent upon the list of compounds to be analyzed, silica gel cleanup may be performed for semivolatile compounds. See SOP 604 for further details. All compound recoveries must be verified prior to using silica gel as a clean up technique.

8.2 DIRECT INJECTION

In very limited applications, direct injection of the non-aqueous liquid sample into the GC/MS system with a μL syringe may be appropriate. The detection limit is very high (approximately 10,000μg/L), therefore, it is only permitted where concentrations in excess of 10,000μg/L are expected.

8.3 MODES OF DATA ACQUISITION

Mass spectra may be collected in one of two ways: scan mode or selected ion monitoring (SIM) mode. Each mode of type of acquisition is discussed below:

8.3.1 SCAN MODE

A selected mass range is scanned repeatedly over the course of analysis. The typical mass range for Method 8270D is 35-500amu. A scan rate of ~1scan/sec or manufacturer's specifications should be consistent throughout the analysis.

8.3.2 SIM MODE

Specified masses are monitored at specified retention times over the course of analysis. The dwell time (length of time each ion response is measured) can also be adjusted from ion to ion. Instrument conditions, however, must be consistent for all standards, samples and quality control samples.

An example of a SIM method for polyaromatic hydrocarbons (PAHs) is listed below. In this example at the retention time of 2.80 minutes, each ion in the associated group of six ions is searched for 50msec. This monitoring will continue until 9.60 minutes when the next group

of fourteen ions is searched for 50msec each. These groups include only the primary and major secondary ions of the compounds of interest. Because the mass spectrometer is looking for fewer ions (less than 15 per scan in the example below vs 465 per scan during a standard scan mode), lower reporting limits can be achieved.

Retention Time (min)	Selected Ions	Dwell Time (msec)
2.80 (start scan time)	82, 108, 127, 128, 129, 136	50
9.60	115, 141, 142, 151, 152, 153, 154, 162, 164, 165, 166, 167, 171, 172	50
12.40	94, 122, 176, 178, 179, 188, 200, 201, 202, 203	50
15.00	125, 226, 228, 229, 236, 240, 252, 253, 260, 264	50
17.60	138, 139, 276, 277, 278, 279	50

If selected ion monitoring is being used, concentration ranges that are 10 to 100 times lower than standard scan mode may be achieved. However, a large amount of mass spectral confirmation and tentatively identified compound information is lost. Because much of the mass spectral confirmation data is not present in SIM mode, retention time confirmation becomes more important. It may be necessary to use tighter RT windows.

8.4 INSTRUMENT OPERATING CONDITIONS

Whether using scan or SIM mode, instrument operating condition may be the same. Typical instrument operation conditions are shown below:

Initial temperature:	60°C, hold for 3 minutes; 2.80 (start scan time)
Temperature program:	65-100°C at 20°C/min, hold for 1 minute; then
	100-335°C at 30°C/min
Final Temperature:	335°C, hold until benzo[g,h,i]perylene has eluted
Injector temperature:	240°C
Transfer line temperature:	280°C
Source Temperature:	According to manufacturer's specifications

Injector:	Grob-type, splitless
Injection volume:	0.5-2µL
Carrier Gas:	Helium at 40cm/sec

Split injection is allowed if the sensitivity of the mass spectrometer is sufficient.

8.5 TUNING

8.5.1 Each GC/MS system must be hardware-tuned to meet the criteria in Table 3 for a 50ng injection of DFTPP. Analyses may not begin until all criteria are met. Acquisition of the mass spectrum of DFTPP must be performed as follows:

- Three scans (the peak apex scan and the scans immediately preceding and following the apex) are acquired and averaged.
- Background subtraction is required, and must be accomplished using a single scan acquired no more than 20 scans prior to the elution of DFTPP. Background subtraction should be straightforward and designed only to eliminate column bleed or instrument background ions. Do not subtract part of the DFTPP peak.
- The GC/MS tuning standard should also be used to assess GC column performance and injection port inertness. All subsequent standards, samples, MS/MSDs and blanks associated with a DFTPP analysis must use the identical mass spectrometer instrument conditions.

8.5.2 DFTPP evaluation will always be done using scan mode so that the full mass range may be evaluated. Dwell times for ions during SIM mode will differ from those during the scan mode, but all other settings should be kept the same.

8.5.3 Benzidine and pentachlorophenol should be present at their normal responses. The tailing factor of benzidine must be less than 3.0 and of pentachlorophenol must be less than 5.0. The HP software performs the tailing factor calculation. Tailing factors are typically evaluated during the analysis of DFTPP, but may be evaluated using benzidine and pentachlorophenol from the calibration standards.

8.5.4 Degradation of DDT to DDE and DDD may not exceed 20%. If degradation is excessive and/or poor chromatography is noted, the injection port may require cleaning. It may also be necessary to

remove the first 6-12in. of the capillary column. The use of a guard column between the injection port and the analytical column may help prolong analytical column performance.

8.5.5 The internal standards selected should permit most of the components of interest in a chromatogram to have retention times of 0.80-1.20 relative to one of the internal standards. Use the base peak ion from the specific internal standard as the primary ion for quantitation (see Table 2). If interferences are noted, use the next most intense ion as the quantitation ion (i.e., for 1,4-dichlorobenzene-d4, use 152m/z for quantitation).

8.6 INITIAL CALIBRATION

8.6.1 Analyze a 0.5 to 2.0µL injection of each calibration standard (containing internal standards) and tabulate the area of the primary characteristic ion against concentration for each compound. All standard and sample injections must use a consistent injection volume. The following Table is an example of the typical calibration levels associated with initial and continuing calibration standards:

Internal Standard (ng/µL on column)	**Final Concentration (ng/µL on column)**
40	120
40	100
40	80
40	60
40	40
40	20
40	10
40	5
40	1
40	50 ICV level

Each calibration standard should be carefully evaluated before inclusion in the calibration curve.

8.6.2 To confirm that a complete injection took place, the internal standard recovery results must be within the required acceptance range. The analyst must view the standard in the data analysis section of the software. The chromatography of the standard should be examined to ensure that peak shape and separation appear to be acceptable. Extra

care should be taken with the low and the high standards as these are useful to evaluate performance problems. Compounds that commonly have poor chromatographic characteristics should be checked in each standard. These compounds are:

pyridine	n-nitrosodimethylamine
aniline	phenol
bis(2-chloroethyl)ether	benzyl alcohol
bis(2-chloroisopropyl)ether	n-nitroso-di-n-propylamine
2,4-dimethylphenol	benzoic acid
2,4,5-trichlorophenol	4-nitroaniline
benzo(b) fluoranthene	benzo(k)fluoranthene

8.6.3 Isomeric compounds and compounds which exhibit similar spectra must be checked in the data analysis section of the software and on the quantitation report to ensure that the correct compound names have been assigned to each peak. The compounds that should be checked are:

aniline & bis(2-chloroethyl)ether
the dichlorobenzenes
benzyl alcohol, 2-methylphenol, 3-methylphenol & 4-methylphenol
2,4-dimethylphenol & benzoic acid
naphthalene & 4-chloroaniline
2,4,6- and 2,4,5-trichlorophenol
2-, 3- and 4-nitroaniline
2,6- and 2,4-dinitrotoluene
fluoranthene & pyrene
phenanthrene & anthracene
benzo(a)anthracene & chrysene
the phthalates
3,3'-dichlorobenzidine, benzo(b) and (k) fluoranthene, benzo(a)pyrene
indeno(1,2,3-c,d)pyrene & benzo(g,h,i)perylene

8.6.4 Calculate response factors (RFs) for each compound relative to one of the internal standards as follows:

$$RF=(A_xC_{IS})/(A_{IS}C_x)$$

where:

Ax = Area of the characteristic ion for the compound being measured
A_{IS} = Area of the characteristic ion for the specific internal standard
C_{IS} = Concentration of the specific internal standard (ng/µL)

C_x = Concentration of the compound being measured (ng/µL)

8.6.5 A system performance check must be performed to ensure that minimum average RFs are met before the calibration curve is used. For semivolatiles, the System Performance Check Compounds (SPCCs) are: N-nitroso-di-n-propylamine, hexachlorocyclopentadiene, 2,4-dinitro-phenol, and 4-nitrophenol (see Table 4). The minimum acceptable average RF for these compounds is 0.050. These SPCCs typically have very low RFs (0.1-0.2) and tend to decrease in response as the chromatographic system begins to deteriorate or the standard material begins to deteriorate. They are usually the first to show poor performance. Therefore, they must meet the minimum requirement when the system is calibrated.

8.6.6 If the minimum response factors are not met, the system must be evaluated, and corrective action must be taken before sample analysis begins. Possible problems include standard mixture degradation, injection port inlet contamination, contamination at the front end of the analytical column, and active sites in the column or chromatographic system. This check must be met before sample analysis begins.

8.6.7 Calibration Check Compounds (CCCs) are used to evaluate the linearity of the curve and the integrity of the system. Variability for these compounds indicates a system leak and/or reactive sites on the column. The percent relative standard deviation (%RSD) should be less than 15% for each compound. However, the %RSD for each individual Calibration Check Compound (CCC) (see Table 5) must be less than 30%.

$$\%RSD = \frac{SD}{\overline{RF}} x100$$

where:

RSD = relative standard deviation

$\overline{RF}$ = Mean of all initial RFs for a compound. (Minimum, 5-point curve).

SD = standard deviation of average RFs for a compound.

$$SD = \sqrt{\sum_{i=1}^{N} \frac{(RF_i - \overline{RF})^2}{N-1}}$$

where:

RFi = RF for each of the calibration levels (minimum, 5-point cal)

N = Number of RF values (i.e., 5)

If the %RSD of any CCC is 30% or greater, then the chromatographic system is too reactive for analysis to begin. Clean or replace the injector liner and/or capillary column, then repeat the calibration procedure beginning with Section 8.4.

8.6.8 The relative retention times (RRT) of each compound are evaluated as defined in Section 8.8.

8.7 LINEARITY

If the %RSD of any compound is 15% or less, then the relative response factor is assumed to be constant over the calibration range, and the average relative response factor may be used for quantitation.

If the %RSD of any compound is greater than 15%, a calibration curve of area ratio (A/A_{is}) versus concentration ratio (C/C_{is}), using first or second order regression fit of the five or more calibration points may be constructed. The type of curve fit applied should be chosen to best represent the data. The use of calibration curves is a recommended alternative to average response factor calibration and a useful diagnostic of standard preparation accuracy and absorption activity in the chromatographic system. The coefficient of determination (COD, r^2 value) of the linear or higher order regression used to define the calibration curve, is an expression of "goodness of fit", and must be $\geq$0.99. Quadratic regressions may be used with a minimum of 6 calibration points, and must yield a COD (r^2 value) of $\geq$0.99.

Consult SW-846 Method 8000 for specific requirements pertaining to each calibration technique. Quadratic or higher order calibrations are not to be employed solely to extend the calibration range for compounds that show saturated or nearly saturated response at higher concentrations.

8.8 INITIAL CALIBRATION VERIFICATION (ICV)

An ICV must be analyzed each time a new initial calibration is performed. The ICV consists of a standard at or near the mid-point concentration of the initial calibration. The standard is prepared from a source independent from that used for the initial calibration standards.

The measured concentration of analytes in the ICV must be within 25% of the expected value for each analyte. Up to four analytes may be accepted as sporadic marginal results with percent differences of up to 50%. The ICV should be analyzed at a concentration level different from that of the CCV to ensure that the curve is valid over much of the range of the initial calibration.

8.9 ROUTINE MAINTENANCE

8.9.1 Bake out column. Extra blanks may be necessary to achieve an adequate baseline if carryover is observed. Replace the injection port

liner, pre-column, cut contaminated section from column, or replace column as necessary to alleviate sample effects limiting performance of the front of the system.

Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming. If a column is oxidized, replacement may be necessary.

8.9.2 INJECTION PORT MAINTENANCE

- Cool injection port to room temperature.
- Disconnect column and plug with old septa.
- Open top of injection port and remove liner for cleaning.
- Remove inlet seal and clean with Q-tip and $MeCl_2$.
- Rinse inlet with $MeCl_2$, scrub with micro grit, rinse again with $MeCl_2$ to remove all traces of micro grit.
- Install cleaned or new injection port seal.
- Install cleaned or new injection port liner.
- Replace septa and insert O-ring as needed.
- Seal injection port and turn injection temperature on.
- When injection temperature is reached tighten seal and turn carrier gas on for about 30 seconds. Clip about 2 or 3 inches of column and re-install.
- Turn oven to the maximum temperature of the run and bake for 5 to 10 minutes.

8.10 DAILY GC/MS CALIBRATION

8.10.1 Prior to analysis of samples, the GC/MS tuning standard must be analyzed. A 50ng injection of DFTPP must result in a mass spectrum for DFTPP that meets the criteria given in Table 3. Also, benzidine and pentachlorophenol should be present at their normal responses. The tailing factor of benzidine must be less than 3.0 and the tailing factor of pentachlorophenol must be less than 5.0. The degradation of 4,4'-DDT must be ≤20%. These criteria must be demonstrated during each 12-hour shift.

8.10.2 CONTINUING CALIBRATION VERIFICATION (CCV)
A calibration standard(s) at mid-concentration containing all semivolatile analytes, including all required surrogates, must be analyzed every 12 hours prior to sample analysis. Compare the instrument response factor from this calibration check with the SPCC, CCC and %D criteria discussed below.

8.10.3 System Performance Check Compounds (SPCCs): A system performance check must be made during every 12-hour shift. For each SPCC compound in the daily calibration, a minimum response factor of 0.050 must be obtained. This is the same check that is applied during the initial calibration. If the minimum response factors are not met, the system must be evaluated, and corrective action must be taken before sample analysis begins. Some possible problems are standard mixture degradation, injection port inlet contamination, contamination at the front end of the analytical column, and active sites in the column or chromatographic system. This criterion must be achieved before analysis begins.

8.10.4 Calibration Check Compounds (CCCs): After the system performance check is met, CCCs listed in Table 5 are used to check the validity of the initial calibration. Calculate the percent difference using:

$$\% \text{ Difference} = \frac{\overline{RFC}_I - RFC_c}{\overline{RFC}_I} x100$$

where:

$\overline{RFC}_I$ = The average response of check compound in the initial calibration.
RFC_c = RF for CCC in continuing calibration.

If a least squares regression is used, the CCC must be evaluated using a percent drift calculation. Calculate the percent drift using:

$$\%\text{Drift} = \frac{\text{CC - TC}}{\text{TC}} \times 100$$

where:

CC = Calculated concentration
TC = Theoretical concentration

If the percent difference or drift for each CCC is less than or equal to 20%, the initial calibration is assumed to be valid. If the criterion is not met (>20% difference) for any one CCC, corrective action must be taken. Problems similar to those listed under SPCCs could affect this criterion. If no source of the problem can be determined after

corrective action has been taken, a new five-point calibration must be generated. This criterion must be met before sample analysis begins.

The measured concentration of analytes other than CCCs in the CCV must be checked and all should be within 20% of the expected value for each analyte. Up to four analytes (Paragon standard target list) may be accepted as sporadic marginal results with percent differences of up to 40%. See introductory comments of this SOP for a listing of typical problematic compounds. Examples of non-standard target list compounds that may be problematic include benzidine and 3,3'-dichlorobenzidine. CCV responses for non-standard target list compounds >20% may be narrated or controlled as directed in the applicable LIMS program specification.

The internal standard responses and retention times in the calibration check standard must be evaluated immediately after or during data acquisition. If the retention time for any internal standard changes by more than 30 seconds from that in the mid-point standard level of the most recent initial calibration sequence, the chromatographic system must be inspected for malfunctions and corrections must be made, as required. If the EICP area for any of the internal standards changes by a factor of two (-50% to +100%) from that in the midpoint standard level of the most recent initial calibration sequence, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

8.11 EXTRACT ANALYSIS

8.11.1 Prior to analysis, the sample extract must be brought to room temperature and spiked with internal standards. The entire extract may be spiked, or an aliquot of the extract may be removed and spiked with an appropriate aliquot of the internal standard mixture. The resulting concentration in the extract to be analyzed must be the same as the concentration of the internal standards in the calibration standards (usually 40µg/mL).

8.11.2 Inject an aliquot of the sample extract into the GC/MS system, using the same operating conditions that were used for calibration. The injection volume must be the same volume used for the calibration standards.

8.11.3 If the response for any quantitation ion exceeds the initial calibration curve range of the GC/MS system, extract dilution must be performed. A new aliquot of the extract is diluted and IS is added to achieve a concentration of 40µg/mL of each IS. The analyst should take care to

ensure that extracts are analyzed at the greatest concentration possible while avoiding damage to the instrument.

8.11.4 Extracts may be diluted for matrix interferences to a point at which the baseline rise is equal to one half the height of the nearest internal standard, or non-target compound is the same height or greater of the nearest internal standard. Further, extracts may be diluted if, in the opinion of the analyst, the color or viscosity of the extract indicates that the matrix will interfere with the instrument's future performance.

8.11.5 Perform all qualitative and quantitative measurements as described in Section 8.12 below. Return the extracts to refrigerated storage.

8.12 DATA INTERPRETATION

8.12.1 COMPOUND IDENTIFICATION

The qualitative identification of compounds determined by this method is based on retention time, and on comparison of the sample mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method or be obtained from the NIST mass spectral library. Because close co-elution of compounds commonly masks standard spectra and cannot be corrected with background subtraction, the use of NIST mass spectral library spectra, when available, is preferred. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum. Compounds should be identified as present when the criteria below are met:

- The intensities of the characteristic ions of a compound maximize in the same scan or within one scan of each other. Selection of a peak by a data system target compound search routine where the search is based on the presence of a target chromatographic peak containing ions specific for the target compound at a compound-specific retention time will be accepted as meeting this criterion. Analyst judgment is critical in interpreting spectral data and target compound assignment by the software.
- The RT of the sample component is within ±0.06 RT units of the most recent standard component. If a retention time shift is suspected due to the sample matrix, the relative retention (RRT) time should be evaluated vs. the relative retention time of the most recent standard.

RRT = compound RT / internal standard RT

- The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.)
- Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.
- Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e., a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important. Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra, and in qualitative identification of compounds.
- When analytes co-elute (i.e., only one chromatographic peak is apparent), the identification criteria can be met, but each analyte spectrum will contain extraneous ions contributed by the co-eluting compound.

For samples containing components not associated with the calibration standards, a library search may be made for the purpose of **tentative identification**. The necessity to perform this type of **tentatively identified compound (TIC) determination** will be determined by the purpose of the analyses being conducted. Computer generated library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other.

For example, the RCRA permit or waste delisting requirements may require the reporting of non-target analytes. Only after visual comparison of sample spectra with the nearest library searches will the mass spectral interpretation specialist assign a tentative identification. Guidelines for making tentative identification are:

- Relative intensities of major ions in the reference spectrum (ions >10% of the most abundant ion) should be present in the sample spectrum.

- The relative intensities of the major ions should agree within ±20%. (Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 30 and 70%.)
- Molecular ions present in the reference spectrum should be present in the sample spectrum.
- Ions present in the sample spectrum but not in the reference spectrum should be reviewed for possible background contamination or presence of coeluting compounds.
- Ions present in the reference spectrum but not in the sample spectrum should be reviewed for possible subtraction from the sample spectrum because of background contamination or coeluting peaks. Data system library reduction programs can sometimes create these discrepancies.

8.12.2 QUANTITATIVE ANALYSIS

When a compound has been identified, the quantitation of that compound will be based on the integrated abundance from the EICP of the primary characteristic ion.

If the %RSD of a compound's average response factor is 15% or less, then the concentration in the extract may be determined using the average response factor ($\overline{RF}$) from initial calibration data and the following equation:

$$C_{ex}(mg/L) = \frac{(A_x x C_{IS})}{(A_{IS} x \overline{RF})}$$

where:

Cex = The concentration of the compound in the extract
A_x = Area of the characteristic ion for the compound being measured
A_{IS} = Area of the characteristic ion for the specific internal standard
C_{IS} = Concentration of the specific internal standard (ng/μL)

Alternatively, the regression line fitted to the initial calibration may be used for determination of the extract concentration. See Method 8000, Section 7.0 for the equations describing internal standard calibration and either linear or non-linear calibrations.

Compute the concentration of the analyte in the sample using the equations below:

8.12.2.1 The concentration of the analyte in the liquid phase of the sample, is calculated using the concentration of the analyte in the extract and the volume of liquid extracted, as follows:

$$\text{Concentration in liquid}\,(\mu g / L) = \frac{(C_{ex} x V_{ex})}{V_o}$$

where:

Vex = extract volume, in mL

Vo = volume of liquid extracted, in L

8.12.2.2 The concentration of the analyte in the solid phase of the sample, is calculated using the concentration of the analyte in the extract and the weight of the solids, as follows:

$$\text{Concentration in solid}\,(\mu g / kg) = \frac{(C_{ex} x V_{ex})}{W_s}$$

where:

Vex = extract volume, in mL

Ws = sample weight, in kg (typically reported on a dry weight basis)

8.12.2.3 Where applicable, an estimate of concentration for noncalibrated components in the sample should be made. The formula given above should be used with the following modifications: The areas Ax and Ais should be from the total ion chromatograms and the RF for the compound should be assumed to be 1. The concentration obtained should be reported indicating (1) that the value is an estimate and (2) which internal standard was used to determine concentration. Use the nearest internal standard free of interferences.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

For this method, an analysis batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). For soil and waste samples where detectable amounts of organics are present, replicate samples may be appropriate in place of matrix spike samples.

All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch.

Consult LIMS program specification for additional or alternative requirements. See QC Table for additional details.

9.2 BLANK ANALYSIS

Before processing any samples, the analyst should demonstrate, through the analysis of a method blank, that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of 20 or fewer field samples is extracted or there is a change in reagents, a method blank should be processed as a safeguard against chronic laboratory contamination. An MB must be analyzed for each 12-hour BFB tune.

Target compounds may not be detected above one-half the reporting limit (RL), or as otherwise directed in the applicable LIMS program specification. Common laboratory contaminants, such as bis(2-ethylhexyl) phthalate, are allowed at levels as high as the RL. Occurrence of common laboratory contaminants should be considered a warning and must be reported in the data package case narrative. See QC Table for further information.

9.3 SURROGATES

Surrogate recovery is monitored to assess method performance of the particular matrix. Surrogates are added to all standards, blanks, samples and QC samples prior to analysis. Recoveries should be compared to laboratory-established surrogate control limits or to client specified limits as listed in the LIMS program specification. See QC Table for corrective actions.

NOTE: Because of the number of surrogates used by this method, the laboratory will allow for samples to have one acid and one base/neutral surrogate outside limits if the remaining surrogates suggest the problem is matrix related and that there were no problems with the laboratory's performance during the extraction and analysis.

9.4 INTERNAL STANDARDS

Internal standards are added to all standards, field and quality control samples analyzed. Retention times and responses are evaluated for internal standards. See QC Table for acceptance limits and corrective actions.

9.5 LABORATORY CONTROL SAMPLES

A matrix-specific laboratory control sample (LCS) is analyzed per batch of 20 field samples. It is Paragon's practice to also analyze a laboratory control sample duplicate (LCSD) per batch of 20 field samples. LCS (LCSD) samples are

analyzed to evaluate the efficiency of the method performed. See QC Table for acceptance limits and corrective actions.

9.6 MATRIX SPIKE(S)
A matrix spike (MS) and matrix spike duplicate (MSD) sample are analyzed to evaluate the effect of the matrix. Additional sample volume of client samples is needed to perform these analyses. The frequency of the MS/MSD shall be one pair per batch of 20 field samples, assuming adequate volume has been provided. See QC Table for acceptance limits and corrective actions.

9.7 METHOD DETECTION LIMIT (MDL) STUDY
The MDL study shall consist of the analysis of a minimum of seven replicate analyses for a target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at a minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

10.1 This SOP meets the requirements of SW8270D. SW8270D does not require that CCC or SPCC compounds (as defined in SW8270C), be monitored. Paragon, however, continues to monitor these compounds routinely.

10.2 Compounds may utilize primary ions other than those listed in Table 2 of this SOP and Table 1 of the Method, if co-elution problems exist. Because the elution pattern will differ from instrument to instrument, changes may be instrument specific.

10.3 EPA METHOD 625
The items contained in this Section describe differences between Method 8270D and Method 625.

10.3.1 Method 625 prescribes different surrogates than Method 8270D. It may be permissible to use the same surrogates specified in Method 8270D, but only with approval from the QA Manager and the Project Manager. See Table 8 of Method 625 for a complete list of surrogates.

10.3.2 Surrogate concentration in Method 625 is 100ug/L. Paragon typically spikes samples to have a final concentration of 75ug/L for acid surrogate compounds and 50ug/L for base/neutral surrogate compounds.

10.3.3 Method 625 lists specific chromatographic columns and conditions (i.e., use of a packed column, and scan parameters tailored to the use of a packed column) to be used in the execution of the method. Some of these materials, apparatus, and conditions have been eclipsed by technology as described in this SOP. Section 8.1.2 of Method 625

states that technological advances are recognized and allows for use provided the precision and accuracy requirements put forth by the method can be achieved.

10.3.4 Initial Calibration - Although Method 625 permits as few as three points in the initial curve, Paragon will quantify from a 5-point curve (minimum) to meet compliance requirements for 8270D. This approach is compliant with Method 625.

10.3.5 Method 625 states that if the linearity of a compound is less than 35%RSD, an average response factor may be used. Otherwise, construct a linear curve with a correlation coefficient greater than 0.995.

10.3.6 Method 625 specifies that the DFTPP tune period is 24 hours. Method 8270D specifies DFTPP be passed every 12 hours.

10.3.7 Method 625 specifies that a continuing calibration verification (CCV) must be performed every working day (every 24 hours) rather than every 12 hours. The response for any parameter must not vary from the predicted response by more than 20%.

10.3.8 Method 625 specifies that a matrix spike and laboratory control spike must be performed on every 20 samples. The sample only needs to be spiked once; a matrix spike duplicate is not required. Also, all matrix spikes and blank spikes must contain every analyte of interest and be from a standard source independent of the calibration standard.

10.3.9 Method 625 states that a set of 4 QC Check samples must be analyzed by an analyst before any samples are processed to demonstrate the ability to perform the method. The concentrations of each compound must be 100µg/L. The results must fall within the acceptance criteria specified in Table 6 of EPA Method 625.

10.3.10 Method 625 states that the matrix spikes and blank spikes must meet the acceptance criteria listed in Table 6 from Method 625. Note that not all compounds have acceptance limits in this Table. For these compounds, the recovery must be reported; however, corrective actions based on those results are not required. Paragon will follow QC limits prescribed by our clients if requested.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

12.1.2 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

12.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.5 All flammable compounds must be kept away from ignition sources.

12.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.1.7 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

12.1.8 Food and drink are prohibited in all lab areas

12.2 WASTE DISPOSAL

Refer to Paragon Analytics SOPs 003 and 015 for proper methods of waste disposal. The waste streams associated with this procedure are halogenated organic solvents, non-halogenated organic solvents, discarded extract vials and contact waste.

DOCUMENT REVISION HISTORY

4/10/06: References to LIMS Program Specifications added. Content updated to reflect SW8270D criteria (updated from 8270C). SIM discussion augmented. DOCUMENT REVISION HISTORY added.

3/1/07: Primarily minor format changes and clarifications. Section 9 QUALITY CONTROL and QC Table revamped for consistency with similar SOPs. CCC and SPCC comment was added to DEVIATIONS Section.

TABLE 2
CHARACTERISTIC IONS FOR SEMIVOLATILE COMPOUNDS (Suggested)

COMPOUND	PRIMARY ION	SECONDARY ION
pyridine	79	52
N-nitrosodimethylamine	74	42
aniline	93	66, 65
phenol	94	65, 66
bis(2-chloroethyl)ether	93	63, 95
2-chlorophenol	128	64, 130

Analytical Method: SW8270D; EPA 625	**Parameter:** Semivolatile Organic Compounds by GC/MS		**Summary of Internal Quality Control (QC) Procedures and Corrective Action**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Tuning Criteria	Every 12 hour period	DFTPP ion ratio criteria (Table 2) PCP Tailing <5 Benzidine Tailing <3 DDT degradation ≤20%	Retune. Do not proceed with analysis until tune meets criteria. Perform injection port and column maintenance. Do not proceed until tune meets criteria
Initial Calibration (ICAL)	Following major instrument maintenance; when CCCs and/or SPCCs in the daily calibration do not meet criteria	CCC: ≤30% RSD non-CCC: ≤15% RSD SPCC: ≥0.05 RF Linear regression, $r^2 \geq 0.990$ Quadratic fit, COD ≥ 0.990	For CCC and SPCC, evaluate/correct instrument malfunction as needed; reanalyze ICAL to obtain curve that meets criteria.
Initial Calibration Verification (ICV); independent source from ICAL	Following every ICAL	Measured concentrations of all compounds should be within ±25% of expected concentrations; up to 4 results may be accepted for individual analytes with values ≤50% D	Evaluate/correct instrument malfunction as needed, prepare new standard if suspect. Reanalyze ICV. If still out, perform new ICAL
Continuing Calibration Verification (CCV); at or near mid-point	Every 12-hour period following tune, if ICAL not performed	CCC: <20 %D SPCC: >0.05 RF Measured concentrations of non-CCCs should be within ±20% of expected concentrations; up to 4 results may be accepted for individual analytes with values ≤40% D	Re-analyze the daily standard. If failure repeats, evaluate/correct instrument malfunction; perform a new ICAL NOTE: Recoveries that are high and outside of the stated acceptance criteria may be acceptable in some programs if the analyte that is high was not detected in the associated samples.
Instrument Blank	Every 12-hour period After each calibration An extraction method blank may be used. The extraction method blank should be analyzed with the associated samples.	< ½ RL for all target compounds, or as otherwise specified in applicable LIMS program specification.	Reanalyze to determine if instrument contamination was the cause. If the instrument blank is still non-compliant, correct the problem before analysis of samples.
Extraction Method Blank	One per extraction batch of ≤20samples of similar matrix.	< ½ RL for all target compounds, or as otherwise specified in applicable LIMS program specification.	Re-analyze to determine if instrument contamination was the cause. If MB is still non-compliant, correct the problem and obtain a successful MB analysis before resuming analysis of samples. Samples associated with the failed MB may need to be reanalyzed. NOTE: If problem is isolated to the method blank (associated samples meet all IS and SS criteria and no target compounds are detected above limits), report and complete a non-conformance report (SOP 928).
Surrogate Spikes (SS)	Every standard, client and QC sample	See laboratory or client-specified limits; recoveries should be	If non-compliant, check calculations and spike preparation for documentable errors.

Analytical Method: SW8270D; EPA 625	**Parameter:** Semivolatile Organic Compounds by GC/MS		**Summary of Internal Quality Control (QC) Procedures and Corrective Action**
QC Check	Frequency	Acceptance Criteria	Corrective Action
		within acceptance limits. Surrogates will be considered diluted out, if the dilution of the extract is ≥ 10X.	Reanalyze sample once (re-analysis requirements may be fulfilled by existing multiple extractions, e.g., MS, MSD, REP). If still out, report results and note in narrative. Note: Because of the number of surrogates used by this method, the laboratory will allow for samples to have one acid and one base/neutral surrogate outside limits if the remaining surrogates suggest the problem is matrix related and that there were no problems with laboratory performance during the extraction and analysis. At the client's discretion, the sample may be Submitted for re-extraction.
Internal Standard (IS)	Every standard, client and QC sample	EICP area within -50% to +100% of previous daily calibration check standard.	Inspect instrument for malfunction; correct identified malfunctions, then reanalyze samples. If no instrument malfunction is identified, reanalyze. If analysis of sample extract is still out, report results and note in narrative. Re-analysis requirements may be fulfilled by existing multiple analyses (e.g., MS, MSD, REP, sample dilutions)
Matrix Spike & Matrix Spike Duplicate (MS/MSD)	One per extraction batch of ≤20samples of similar matrix.	See laboratory or client-specified limits; recoveries should be within advisory limits. RPDs for the spiked compounds should also be within advisory limits	If non-compliant, check calculations and spike preparation for errors; correct as needed. If no errors are found, and the associated LCS is within control limits, then sample matrix effects are the most likely cause. Narrate. If significant differences (>15%) exist between the MS and MSD (or between duplicates) reanalysis of the sample and spikes may be necessary.
Laboratory Control Spike & Laboratory Control Spike Duplicates (LCS/LCSD)	One per extraction batch of ≤20samples of similar matrix; typically the LCSD is analyzed only when matrix spikes are not performed	See laboratory or client-specified limits; recoveries must be within acceptance limits. When the full list of compounds is spiked, the laboratory will accept a small number of sporadic marginal exceedances, based on the probability that a certain number of compounds will exceed their control limits. Systematic or	If non-compliant, check calculations and spike preparation for documentable errors. If no errors are found, then reanalyze LCS to determine if instrumental conditions or extraction preparation was the cause. Notify the Supervisor and initiate corrective action (NCR). Re-analyze associated samples, if appropriate. Note: recoveries that are high and outside of acceptance criteria may be acceptable, when the same target

STANDARD OPERATING PROCEDURE 511 REVISION 8

TITLE: **VOLATILES REAGENT WATER PREPARATION AND BLANK ANALYSIS**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1-8-07
QUALITY ASSURANCE MANAGER _____ DATE 1/8/07
LABORATORY MANAGER _____ DATE 1-8-07

HISTORY: Rev0, 4/5/93; Rev1, PCN #96, 12/20/93; Reviewed, no revisions, 1/13/95; Rev2, 1/13/99; Rev3, 7/9/99; Rev4, 3/26/02; Rev5, 3/14/03; Rev6, 2/13/04 & 3/10/05 (updated format); Rev7, 7/24/06; Rev8, 1/5/07.

1. SCOPE AND APPLICATION

Volatiles reagent water is prepared water that is made in the GC/MS-VOAs Lab. This reagent water is then used to make working calibration standards, dilute samples, etc. It is also used to make blanks (e.g., refrigerator, trip, method reagent) that are used in volatiles analyses. The water must be purged and heated so that no contaminants or interferences are present that could compromise the quality of volatiles sample results. This type of care must be taken for volatiles analyses so that the level of common laboratory contaminants (e.g., methylene chloride, acetone, 2-butanone) is minimized. Typical analytical methods (SW8260, SW8021) allow these common laboratory contaminants to be present at levels as high as five or ten times the analyte reporting limit (RL), contingent upon the specific contaminant, while any other target compound detected, must be at a concentration less than the analyte RL.

Note that other acceptance criteria, such as <RL common contaminants, <½ RL all other targets (DOD LIMS program specification), may apply.

2. SUMMARY

A volume of water to be prepared is collected in a glass container, purged with nitrogen gas, and heated while purging continues. The purging also continues while the processed water is allowed to cool. The prepared water is then stored in the preparation container, tightly sealed, until aliquotted for use.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to carryout these procedures as discussed in this SOP and to complete all documentation required for review.

3.2 Any personnel who note anomalies or out-of-control events associated with these procedures, or the analysis of the resultant blanks, must document the problem and take corrective action.

4. APPARATUS AND MATERIALS

4.1 hot plate

4.2 glass container, 4L or similar size, an Erlenmeyer flask is typically used

4.3 Millipore, or equivalent, benchtop water purification system. Capable of producing ultra-high purity (i.e., ASTM Type I or better) water.

5. REAGENTS

5.1 ASTM Type I Water. Although the water obtained from Paragon's laboratory deionized (DI) water system meets ASTM Type I criteria, further finished water obtained by running laboratory DI water through the benchtop Millipore purification system, is used as the source water for preparing volatiles reagent water.

5.2 Nitrogen gas, ultra pure

6. PROCEDURE

6.1 REAGENT WATER PREPARATION

6.1.1 A volume of Millipore water to be prepared is collected. Typically a 4L Erlenmeyer flask is used.

6.1.2 The container is placed on a hot plate, and the contents are purged at a moderate rate with nitrogen gas.

6.1.3 While purging continues, the container is then heated until the water boils, after which the heat is turned off.

6.1.4 The purging continues, as the prepared water cools, for at least 4-6 hours.

6.1.5 The prepared water is stored, tightly sealed, in the preparation container, until aliquotted for use.

6.2 BLANK ANALYSES

6.2.1 Refer to SOP 512 for the analysis and evaluation of refrigerator blanks. Refer to the appropriate determinative SOP (e.g., SOP 424, 525) for the analysis and evaluation of trip or method reagent blanks.

6.2.2 Per the above SOPs, the blank analysis data are documented in the instrument daily raw data files.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

Personal protective equipment (PPE) shall consist of safety glasses, a lab coat, and gloves, and must be worn at all times.

7.2 WASTE DISPOSAL

Unused prepared water may be discarded down the laboratory's drain.

HISTORY: Rev0, 12/20/93; Rev1, PCN #321, 1/13/95; Rev2, 12/29/96; Rev3, 1/11/99; Rev4, 7/9/99; Rev5, 1/10/00; Rev6, 3/26/02; Rev7, 3/14/03; Rev8, 2/13/04 and 3/10/05 (updated format); Rev9, 7/24/06; Rev10, 1/5/07.

1. SCOPE AND APPLICATION

Refrigerator blanks (storage blanks) for all refrigerators that house volatile samples, including temporary storage provided by the Sample Control walk-in cooler RU #20, are analyzed weekly per the applicable analysis method, to establish that the refrigeration units used for volatiles sample storage are contaminant-free. Documentation of refrigerator blank results is maintained for traceability purposes.

2. SUMMARY

A suite of six (6) 40mL VOA vials for each volatile sample storage unit are prepared as refrigerator storage blanks prior to the beginning of each month. The storage blank vial preparation and placement must occur 1-2 weeks prior to the beginning of each month, so that the vials are in contact with the refrigerator's environment long enough to pick up any contaminants that may be present. Reagent water (prepared per SOP 511) is used as the source water for these blanks. The blanks are stored in the appropriate storage areas, with one vial analyzed weekly (i.e., every 7 days±1 day), per the applicable Method (SW8260, SW8021). Results from the volatiles storage blank analyses are evaluated promptly to determine if contamination has occurred that may affect volatiles sample integrity.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to carryout the procedures as discussed in this SOP and to complete all documentation required for review.

3.2 Any personnel who note anomalies or out-of-control events associated with the analysis of these samples must document the problem and take corrective action.

4. APPARATUS AND MATERIALS

4.1 VOA vials, 40mL, septum-seal, certified 'clean'

NOTE: Bottle lot numbers and manufacturer's lot analysis information are

retained on file by the Sample Control Department.

4.2 granulated activated carbon, laboratory grade

5. REAGENTS

Reagent water, prepared per SOP 511

6. PROCEDURE

6.1 STORAGE BLANK PREPARATION

6.1.1 Fill six (6) 40mL VOA vials per each volatile sample storage unit with freshly prepared reagent water (SOP 511). Cap each vial and invert to ensure that it is headspace free. **Note that six vials are prepared to ensure that one vial is available for each week of the month, plus an extra vial(s) to assist in confirmation and corrective action if needed.** Document preparation on Form 342.

6.1.2 Date and initial each vial. Also label each vial as a refrigerator blank with a Departmental/location designation (e.g., "SC" for Sample Control, etc.). Place all six vials in the appropriate sample storage refrigerator. **Note that the storage blank vial preparation and placement must occur 1-2 weeks prior to the beginning of each month, so that the vials are in contact with the refrigerator's environment long enough to pick up any contaminants that may be present.**

6.2 ANALYSIS

6.2.1 One storage blank is to be analyzed weekly (i.e., every 7 days±1 day), for every refrigerator that houses volatiles samples. The storage blanks are analyzed per the applicable Method (SW8260, SW8021), and must be analyzed within the 12-hour tune for GC/MS Volatiles, and within a closing Continuing Calibration Verification (CCV) for GC Fuels. Archive the refrigerator blank analysis data along with the instrument daily raw data files.

6.2.2 Results from the storage blank analysis are to be evaluated promptly. **Target compounds -- including common laboratory contaminants (e.g., methylene chloride, acetone, 2-butanone) -- detected at or above the reporting limit (RL) are considered to be a warning of potential contamination problems and require corrective action.** If contamination at levels at or above the RL is identified, analyze another storage blank vial (i.e., one of the "extra" vials prepared) to confirm the results.

NOTE: Other acceptance criteria, such as <RL common contaminants, <½ RL all other targets (e.g., DOD LIMS program specification), may apply.

or per other applicable criteria

6.2.3 If contamination at levels at or above the RL is confirmed, proceed with corrective actions. **A Nonconformance Report (NCR), Form 313, must be processed immediately per procedures outlined in**

SOP 928.

6.3 CORRECTIVE ACTIONS

6.3.1 Corrective action shall include locating and resolving the source of contamination (e.g., leaking VOA vial, highly contaminated samples). The source can be isolated by placing it, in its original container, inside another, larger, sealed container, into which a small amount of GAC (granulated activated carbon) is placed.

6.3.2 Prepare four or more additional storage blanks per Section 6.1 of this SOP, and place them in the affected storage unit. Analyze one of the blanks daily until the contamination is less than the RL. **or per other applicable criteria**

6.3.3 Repeat Steps 6.3.1 and 6.3.2 as necessary until the contamination problem is resolved.

6.3.4 Data generated from samples stored in a refrigeration unit where refrigerator blank contamination has been confirmed shall be considered suspect and shall be documented as nonconforming data. In the event of confirmed contamination, an NCR form shall be completed and included with the data report to document and communicate the potential cross-contamination of all samples stored in the refrigerator at the time of contamination.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

Personal protective equipment (PPE) shall consist of safety glasses, a lab coat, and gloves, and must be worn at all times.

7.2 WASTE DISPOSAL

Aqueous purge and trap waste shall be disposed of in the aqueous laboratory waste stream. A satellite waste collection vessel may be obtained from the Waste Compliance Officer.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- SW-846 methods 5030C, 5035A and 8260B -- are used to determine volatile organic compounds in a variety of matrices. This SOP is applicable to nearly all types of samples, regardless of water content, including: groundwater, aqueous sludges, caustic or acid liquors, waste solvents, oily wastes, mousses, tars, fibrous wastes, polymeric emulsions, filter cakes, spent carbons or catalysts, soils, and sediments. The following compounds are presently being analyzed using this SOP. Other compounds can be analyzed after successful demonstration of capability (DOC) and method detection limits study (MDL). Analytes in the Table below are listed in typical elution order. Analytes that are part of Paragon's standard reporting list are depicted in bold.

n/a	Not applicable; not designated in method.

This SOP describes purge & trap GC/MS procedures that can be used to identify and quantify most organic compounds that have boiling points below 200°C and that are insoluble or slightly soluble in water. However, for the more soluble compounds, quantification limits are approximately five to ten times higher because of poor purging efficiency. Ketones, alcohols and aldehydes are typical of classes of compounds that may have elevated reporting limits due to their high degree of water solubility.

Note that the body of this SOP specifies the procedures to be used for Method SW8260B. Any additional or contradictory requirements for EPA Method 624 are addressed in Section 10.

2. SUMMARY

Volatile compounds are introduced into the gas chromatograph (GC) by purge & trap. Purged sample components are trapped in a tube containing suitable sorbents in accord with Methods SW5030C or 5035A. When purging is complete, the sorbent tube is heated rapidly and back-flushed with helium to desorb trapped sample components. The analytes are desorbed directly onto a narrow-bore capillary column for analysis. The column is temperature programmed to separate the analytes, which are then detected with a mass spectrometer (MS) interfaced to the gas chromatograph.

As analytes elute from the capillary column, they are introduced into the mass spectrometer via a direct connection. Identification of target analytes is accomplished by comparing their mass spectra with the electron impact spectra of authentic standards. Quantitation is accomplished by comparing the response of a major (quantification) ion relative to an internal standard with the response factor or calibration equation generated

from a multi-point calibration curve using average response factors or regression equations.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Analyst to perform the analyses according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Paragon Project Manager is responsible for directing a chlorine residual check to be performed just prior to analysis as applicable.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the review sheet indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to correct any errors found during the review.

3.6 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Major contaminant sources are volatile materials in the laboratory and impurities in the inert purging gas and in the sorbent trap. The use of non-polytetrafluoroethylene (PTFE) thread sealants, plastic tubing, or flow controllers with rubber components should be avoided since such materials out-gas organic compounds which will be concentrated in the trap during the purge operation. Analyses of reagent blanks provide information about the presence of contaminants. When potential interfering peaks are noted in blanks and the above sources are suspected, the analyst should change the purge gas source and

regenerate the molecular sieve purge gas filter and/or sorbent trap. Many trace impurities in the purge (carrier) gas are removed by passing the He through a heated catalyst bed that is capable of removing hydrocarbons and oxygen.

4.2 Interfering contamination may occur when a sample containing low concentrations of volatile organic compounds is analyzed immediately after a sample containing high concentrations of volatile organic compounds. The preventive technique is rinsing the purge needle or apparatus and sample syringes with three portions of organic-free reagent water between samples. Sample tubes are only reused if washed and baked before the next use. After analysis of a sample containing high concentrations of volatile organic compounds, one or more reagent blanks should be analyzed to check for cross-contamination. For samples containing large amounts of water-soluble materials, suspended solids, high boiling compounds or high concentrations of compounds being determined, it may be necessary to wash the purge needle or apparatus with methanol and then rinse it thoroughly with organic-free reagent water. In extreme situations, the entire sample pathway of the purge & trap may require dismantling and cleaning or replacement.

4.2.1 The relatively low purging efficiency of many analytes from a large volume sample (e.g., 10mL, 25mL) often results in significant concentrations remaining in the sample purge tube after analysis. Archon autosamplers use the same purge vessel repetitively for water analysis, but rinse the purge vessel with He and water between samples

4.2.2 If carryover contamination is suspected, (this is likely when a sample containing high concentration levels of volatile compounds is followed by a sample containing low levels of the same volatile compounds), all samples that may have been affected must be re-analyzed. Sample analysis may continue if a cleanup blank or sample following the high concentration sample is free (below the reporting limit) from compounds present over the calibration range in the high level sample. Analyst experience should be used to determine which compounds tend to carryover and at what levels.

4.2.3 Annotations made to instrument run logs should indicate if a sample contains possible carryover contamination. If the subsequent rerun of the sample confirms the presence and level of the volatile compounds, either analysis may be used. If, however, the rerun shows that the presence of the compounds was carryover contamination, only the rerun should be used. The original analysis should be considered non-usable data for the analytes that may have carried over.

4.3 Special precautions must be taken to analyze for methylene chloride. The analytical and sample storage area should be isolated from all atmospheric

sources of methylene chloride, or random background levels will result. Because methylene chloride will permeate through PTFE tubing, all gas chromatography carrier gas lines and purge gas plumbing should be constructed from stainless steel or copper tubing. Laboratory clothing worn by the analyst should be clean because clothing previously exposed to methylene chloride fumes during liquid/liquid extraction procedures can contribute to sample contamination.

4.4 Samples can be contaminated by diffusion of volatile organics (particularly methylene chloride and fluorocarbons) through the septum seal into the sample during shipment and storage. A trip blank prepared from organic-free reagent water and carried through the sampling and handling protocol serves as a check on such contamination. To check for cross-contamination during sample storage, the laboratory periodically analyzes sample storage refrigerator blanks (SOP 512).

5. APPARATUS AND MATERIALS

5.1 PURGE & TRAP AUTOSAMPLER DEVICE
Autosampler - OI 4552/Archon, Varian Archon, or equivalent
Sample concentrator - Tekmar LSC 2000, Tekmar LSC 3000 or OI 4560 Liquid Sample Concentrator equipped with VO-Carb 3000 (or OI #10) adsorbent trap, or equivalents

5.2 GAS CHROMATOGRAPH (GC), DETECTOR AND MASS SPECTRAL LIBRARY
Hewlett Packard (HP) Model 5890A or 6890 GC capable of splitless or split/splitless injection or direct interface to a purge & trap apparatus. Equipped with variable constant differential flow controllers (so that the column flow rate will remain constant throughout desorption) and a temperature-programmable oven or equivalents. Also equipped with a HP5971, 5972 or 5973 mass spectrometer detector, capable of scanning from 35 to 300amu every 2sec or less, using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer must be capable of producing a mass spectrum for p-bromofluorobenzene (BFB) which meets all of the criteria in Table 1 (shown subsequently) when 50ng or less of the GC/MS tune standard is introduced through the GC. To ensure sufficient precision of mass spectral data, the desirable MS scan rate allows acquisition of at least five spectra while a sample component elutes from the GC. The NBS/EPA/NIST mass spectral library (library may vary with instrument) is also used to identify non-target compounds generally known as tentatively identified compounds (TICs).

GC/MS interface to the mass spectrometer: Direct coupling by inserting the column into the mass spectrometer is generally used for 0.18 to 0.32mm-ID columns. Any enrichment device or transfer line can be used if all of the performance specifications described in this SOP (including tuning) can be achieved.

5.3 DATA ACQUISITION AND PROCESSING SYSTEM

A computer system that facilitates continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program. The computer must have software that allows searching any GC/MS data file for ions of a specified mass, and plotting such ion abundances versus time or scan number. This type of plot is defined as an extracted ion current profile (EICP). Software must also be available that allows integrating the abundances in any EICP between specified time or scan-number limits.

5.4 COLUMNS - Equivalent columns/guard columns may also be used

Column 1 - 60m x 0.25mm ID capillary column with RTX-624 stationary phase (Restek), 1.4µm film thickness, or equivalent

Column 2 - 60m x 0.25mm ID capillary column with RTX-VMS (Restek), 1.4µm film thickness, or equivalent

5.5 GASES- **only high purity or higher grade gases may be used!**

Helium: purge & trap and carrier gas

5.6 MEASURING DEVICES

microsyringes - 5, 10, 25, 50, 100, 250, 500, and 1,000µL

syringes - 5, 10, or 30mL, glass

syringe valve, two-way with Luer ends (three each), if applicable to the purging device

laboratory balance, 0.01g sensitivity (used for weighing solid samples)

5.7 CONSUMABLE SUPPLIES

- Compact Vespel/Graphite Ferrule, Restek #20264 or equivalent
- Graphite Ferrules, various sizes
- glass scintillation vials, 20mL and 40mL, with Teflon™/-lined/low-level siloxane screw-caps, or, glass culture tubes with Teflon™-lined screw-caps
- vials, 2mL, with Teflon™-lined screw-caps
- Pasteur pipettes, 5 ¾" and 5mL, disposable
- volumetric pipettes, 10mL, Class A, disposable
- volumetric flasks, Class A - 5mL, 50mL, and 100mL, with ground-glass stoppers
- spatula, stainless steel
- pH paper, acidic narrow range and wide range
- PTFE-coated magnetic stir bars, for use in soils purged with the Archon autosamplers (SW5035, SW5035A)
- Mininert™ or CERTAN™ vials or equivalent

6. REAGENTS - At minimum, reagent grade chemicals shall be used in all tests.

6.1 Organic-free reagent water (SOP 511)

6.2 Methanol (CH_3OH), purge & trap quality or equivalent, demonstrated to be free of analytes. Store apart from other solvents. J.T. Baker #907702 or equivalent

6.3 Pre-conditioned Ottawa sand (for use as clean matrix for method blank (MB) and laboratory control sample (LCS) analyses associated with solid matrix sample analyses): Pre-condition by drying in an oven set at 105°C or greater overnight. EMD #SX0075-3 or equivalent

6.4 STANDARDS

NOTE: Great care must be taken to maintain the integrity of all standard solutions. It is recommended that all standards in methanol be stored at –10°C to –20°C in Mininert™ or CERTAN™ vials with Teflon™-lined screw-caps. Stock standards that are not accessed as part of routine operations may be stored in 2mL glass vials with Teflon™-lined caps (i.e. Mininert™ vials are not required for rarely utilized stock standards).

6.4.1 All standards are maintained per PAR SOP 300. Two independent sources of commercial target analyte stock standards, in methanol, are required. The stock standards are purchased as certified solutions from suitable vendors. Typically, concentrations of stock solutions vary from 1,000-10,000µg/mL.

6.4.2 Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules, if recommended by the manufacturer. Standards for this procedure must be equilibrated to ˉ10-ˉ20°C (stored in freezer) before opening and protect from light. After opening/initial use, transfer remaining stock standard to a suitable vial (Mininert™ or CERTAN™ vial with a Teflon™-lined screw-cap) with minimal headspace, and store in a freezer (ˉ10-ˉ20°C). All opened stock standards must be replaced after 3 months from date opened, or sooner, if comparisons with laboratory control samples indicate a problem.

6.4.3 ***Gas stock solutions expire one week*** after the ampule has been opened and transferred to a Teflon™-lined screw cap vial or equivalent. ***Other calibration stock solutions expire three months*** after the ampule has been opened and transferred to a Mininert™ or CERTAN™ screw cap vial or equivalent. ***See SOP 300 for additional information on standards expiration.***

6.4.4 First source materials are used to create calibration and continuing calibration verification (CCV) standards. Second source materials are

used to create the initial calibration verification (ICV) solution. Laboratory control and matrix spike standards may be from either source (the second source is most commonly used for spiking).

Non-target analyte internal standard (IS) and surrogate (SS) stock standards are also purchased. The IS is used to quantitate analytes detected in samples. The SS is used to monitor system performance and method effectiveness with each sample matrix. The internal standards (ISs) used for this method are: fluorobenzene, chlorobenzene-d_5, and 1,4-dichlorobenzene-d_4. Other compounds may be used as internal standards as long as they have retention times similar to the compounds being detected. Prepare IS stock and intermediate standards in methanol using the procedures described above. It is recommended that the intermediate standard be prepared at a concentration of 50µg/mL of each internal standard compound. Typically, addition of 5µL of this standard to 5.0mL (or 5g) of sample, calibration standard, or quality control (QC) sample would be the equivalent of 50µg/L (50µg/kg). The surrogates currently utilized are: toluene-d_8, 4-bromofluoro-benzene, 1,2-dichloroethane-d_4, and dibromofluoromethane. Other compounds may be used as surrogates, depending upon the analysis requirements. A stock surrogate standard in methanol, typically at a concentration of 2,000µg/mL, should be purchased as a certified solution and stored as described above. An intermediate surrogate standard spiking solution should be prepared from the stock at a concentration of 50-250µg/mL in methanol. Each standard, sample or QC sample undergoing analysis must be spiked with the surrogate spiking solution prior to analysis. Typically, 5µL of solution containing surrogate standards and internal standards (IS), is added to every 5mL sample. Surrogates are spiked independently of ISs during preparation of initial calibration standards. Section 9 of this SOP gives definitions and uses of surrogates and QC (i.e., LCS/LCSD, MS/MSD) samples.

Prepare intermediate QC spike standards, in methanol, from volatile organic compounds that will be representative of the compounds being investigated. At a minimum, the matrix spike will include 1,1-dichloroethene, trichloroethene, chlorobenzene, toluene, and benzene, typically at a concentration of 50µg/mL for each analyte.

6.4.5 An appropriate volume of target analyte stock standard is diluted, with methanol, to a specific volume to create intermediate standards. The intermediate standard may contain the compounds of interest singly or mixed together. Intermediate standards must be stored with minimal headspace and should be checked frequently for signs of degradation, especially just prior to preparing working calibration standards from

them. Store standards in an appropriate vial with minimal headspace; the standards may be retained as prescribed in SOP 300. All dilutions should be performed using syringes, and purge & trap grade MeOH.

6.4.6 4-bromofluorobenzene (BFB) tune standard: A standard solution containing 50ng/µL of BFB in methanol is prepared.

NOTE: If using a system with automated introduction of standards, such as the O-I Archon autosampler, an equipment validation study must be performed to determine the actual volume of standard delivered. The concentration of standard may be adjusted accordingly for the actual volume delivered at the 1µL setting. For example: (1.135µL actual delivery)(441µg/mL IS/SS spiking solution)/5mL = 100µg/L.

6.4.7 Target analyte calibration (working) standards: Calibration standards at a minimum of five concentrations should be prepared from the intermediate standards. Prepare these solutions in organic-free reagent water. One of the concentrations should be at a concentration less than or equal to the reporting limit. The remaining concentrations should correspond to the expected range of concentrations found in real samples but should not exceed the working range of the GC/MS system. The laboratory shall not report a quantitative result for a target analyte that was not included in the calibration standard(s). **Aqueous calibration (working) standards are not stable and must be prepared on the day of loading on the autosampler.**

To prepare a target analyte calibration standard for purge & trap, add an appropriate volume of an intermediate standard solution to an aliquot of organic-free reagent water in a volumetric flask. Use a microsyringe and rapidly inject the alcoholic standard into the expanded area of the filled volumetric flask. Remove the needle as quickly as possible after injection. Mix by inverting the capped flask three times only. Transfer 5.0mL (10mL or 25mL if lower detection limits are required) of each standard to a gas-tight syringe along with 5µL of internal standard (for 5mL samples). Archon autosamplers add the internal standard and surrogates when programmed to do so. Then transfer the contents to a purging device or syringe. Perform purge & trap or direct injection as outlined in Methods SW5030C or SW5035A. It is also acceptable to add the appropriate amount of standard directly to a gas-tight syringe containing 5.0mL (10mL or 25mL) of organic-free reagent water.

6.4.8 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials and of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Samples from chlorinated water sources should be dechlorinated with sodium thiosulfate ($Na_2S_2O_3$) in the field at the time of collection. These samples should then be acidified with hydrochloric acid (HCl) following dechlorination. Based upon project knowledge provided by the client, where applicable, Paragon's Project Manager may instruct the volatiles analysts to test for chlorine residual just prior to preparation for analysis. A chlorine residual test kit, obtainable from the Sample Receiving Department, is used to check for chlorine residual. Notify the Project Manager immediately if residual chlorine is present.

7.3 Volatile organic analysis of water and soil samples extracted by Methods SW5030C or SW5035A must be performed within 14 days of collection unless otherwise specified by the client. Water samples are usually preserved by adding approximately four (4) drops of concentrated hydrochloric acid (HCl) to each 40mL VOA vial. The purpose of the hydrochloric acid is to prevent microbial degradation of target compounds. If the water sample is unpreserved, the holding time may be shortened to seven (7) days from the date of collection. Volatile organic analysis of soil samples received in EnCore™ samplers to be extracted by Method SW5035A shall be frozen upon receipt and analyzed within 14 days of collection. Other types of collection and preservation techniques may be required by Method SW5035A and should be evaluated according to the specific needs of the client. Other means of preservation for samples to be prepared for analysis by Method SW5035A include freezing soil in a 40mL vial after addition of water and a stir bar, as well as addition of sodium bisulfate solution ($NaHSO_4$) and a stir bar. Method SW5035A also allows preservation with methanol for solid samples with expected higher concentrations of target analytes. Preservation of samples for subsequent analysis via Methods SW5035A/8260B may be required within 48hrs after time of collection.

7.4 Just prior to preparation for analysis, obtain a small aliquot of each aqueous sample to be analyzed and using pH paper, measure the pH of each sample; record the result next to the sample's identity on the previously prepared daily sequence log. If the pH of a preserved sample is >2, immediately notify the appropriate Project Manager and discuss the pH excursion in the data package

case narrative. Aqueous samples that are intentionally not preserved at the time of collection do not require Project Management notification.

7.5 Samples to be prepared by Method SW5030C must be collected in glass containers with minimal headspace and stored at 4±2°C. Samples to be prepared by Method SW5035A should be collected in EnCore™ sampling devices and stored at <-7°C, but no less than -20°C. Other types of collection and preservation techniques may be required by Method SW5035A and should be evaluated according to the specific needs of the client.

7.6 To prevent loss of volatile organic compounds, samples must not be opened until the time of analysis.

8. PROCEDURE

Three alternate methods are provided for sample introduction. All internal standards, surrogates, and matrix spikes (when applicable) must be added to samples before purging commences:

- Purge & trap per Method SW5030C (aqueous samples)
- Purge & trap per Method SW5030C (for dilution of solid or waste liquid samples via methanol extraction described in SW5035A)
- Purge & trap per Method SW5035A for solid samples collected in a manner consistent with the method or modification thereof (for samples submitted as samples that must be transferred by laboratory personnel to a purge vessel from containers submitted by the client)

8.1 TYPICAL PURGE & TRAP DEVICE SETTINGS

Instrument conditions may be varied as needed, however, the instrument conditions employed during initial calibration (ICAL) must be used for all subsequent sample analyses that are quantitated using the initial calibration. If operating conditions are altered, a new calibration must be prepared.

<u>Purge & trap settings for OI 4560A purge & trap device:</u>
purge time = 7-11 minutes
desorb temperature = 190°C
desorb time = at least 1.0 minute
trap bake = at least 4 minutes at 210°C
(or according to manufacturer's recommendation for all parameters above)

<u>Purge & trap settings for Tekmar LSC 2000 or 3000 purge & trap device:</u>
purge time = 7-11 minutes
desorb temperature = 250°C
desorb time = at least 1.0 minute
trap bake = at least 4 minutes at 260°C
(or according to manufacturer's recommendation for all parameters above)

8.2 TYPICAL GAS CHROMATOGRAPH SETTINGS

initial temperature = 60°C
initial time = 0.1 minute
temperature ramp A = 10°C/minute
temperature ramp B = 25°C/minute
final temperature A = 105°C
final temperature B = 220°C
final hold time A = 0 minutes
final hold time B = until all compounds elute
P&T transfer line temperature = 120°C
GC/MS transfer line temperature = 280°C
injection temperature = 150°C
electron energy = 70eV (nominal)
mass range = 35-300amu
scan time = 0.6-2 seconds per scan

8.3 AUTOSAMPLER CLEANING

After use, each purge tube is removed from the autosampler, washed and regenerated per SOP 334. Additionally, each purge needle is flushed with organic-free DI water (note that the purge tube is rinsed in place, as part of the system program, if using the OI Archon autosampler), then the exterior is wiped with a KimWipe™ and MeOH.

8.4 CHROMATOGRAPHIC MAINTENANCE

8.4.1 Bake out the trap and column. Extra blanks may be necessary to achieve an adequate baseline if carryover is observed. Replace trap if performance problems are demonstrated and cannot be alleviated by routine maintenance.

8.4.2 If trap and front end are not clean and functioning properly, clip a loop from the column or replace as necessary.

8.4.3 Columns will be damaged permanently and irreversibly by contact with oxygen at elevated temperatures. Oxygen may enter the column during a septum change, when oxygen traps are exhausted, through neoprene diaphragms of regulators, and through leaks in the gas manifold. Oxidized columns will exhibit baselines that rise rapidly during temperature programming. If a column is oxidized, replacement may be necessary.

8.5 INITIAL CALIBRATION (ICAL)

Instrument conditions may be varied as needed; however, the instrument conditions employed during initial calibration must be used for all subsequent sample analyses that are quantitated using that initial calibration. If operating conditions are altered, a new calibration must be prepared.

8.5.1 Each GC/MS system must be hardware-tuned to meet Method criteria (see Table 1 below) for a 5-to-50ng injection or purging of 4-bromofluorobenzene (BFB). A BFB tune is performed prior to analysis to demonstrate the ability of the system to separate ions and assign proper ratios to fragments. Analyses must not begin until these criteria are met. Typically, 1µL of a 50ng/µL BFB tune solution is analyzed by direct injection.

TABLE 1

BFB MASS INTENSITY SPECIFICATIONS (4-BROMOFLUOROBENZENE)*

MASS	INTENSITY REQUIRED (relative abundance)
50	15 to 40% of mass 95
75	30 to 60% of mass 95
95	base peak, 100% relative abundance
96	5 to 9% of mass 95
173	less than 2% of mass 174
174	greater than 50% of mass 95
175	5 to 9% of mass 174
176	greater than 95% but less than 101% of mass 174
177	5 to 9% of mass 176

* Alternate tuning criteria may be used (e.g., CLP, EPA Method 524.2, or manufacturers' instructions), provided that method performance is not adversely affected.

8.5.2 Set up the purge & trap system as outlined in Method SW5030C, or Method SW5035A if closed system purge & trap analysis is to be utilized. A set of at least five calibration standards containing all of the target analytes and surrogates is needed. The calibration must contain a standard at or below the reporting limit for each compound, the other calibration standards should contain analytes at concentrations that define the range of the method, but do not exceed the linear range of the instrument. Due to the varying reporting limit requirements of the laboratory's clientele and the varying instrument response of the target compounds, seven levels are typically analyzed. Below is a list of typical calibration levels used during ICAL. Project requirements and instrument performance may require modifications to the levels listed.

Final Concentration (µg/L of 5mL and 5g purges)	Internal Standard (µg/L of 10mL purges)	Final Concentration (µg/L of 10mL purges)
100	25	50
75	25	35
50	25	20
20	25	10
10	25	2
5	25	1
2	25	0.5
50 CCV level	25	20 CCV level
20 ICV level	25	10 ICV level

8.5.3 Calibration must be accomplished using the sample introduction technique that will be used for sample analysis. The purging efficiency for 5mL of water is greater than that for 10mL or 25mL. Therefore, develop the standard curve using the volume of sample to be analyzed. Prepare working calibration standards as described in Section 6.

8.5.4 Tabulate the area response of the characteristic ions (see Table 2 at end of SOP) against concentration for each compound and each internal standard. Calculate response factors (RF) for each compound relative to one of the internal standards. The internal standard selected for the calculation of the RF for a compound should be the internal standard that has a retention time closest to the compound being measured. The RF is calculated as follows:

$$RF = (A_x C_{IS})/(A_{IS}C_x)$$

where:

A_x = Area of the characteristic ion for the compound being measured.

A_{IS} = Area of the characteristic ion for the specific internal standard.

C_{IS} = Concentration of the specific internal standard.

C_x = Concentration of the compound being measured.

The average RF must be calculated and recorded for each compound using at least five RF values calculated for each compound from the initial calibration curve. System performance criteria must be met before this calibration curve can be used. Five compounds (the System Performance Check Compounds, or SPCCs) are checked for a minimum average relative response factor (RRF). These compounds are chloromethane; 1,1-dichloroethane; bromoform; 1,1,2,2-tetrachloroethane; and chlorobenzene.

The minimum RRFs for volatile SPCCs are as follows:

Chloromethane	0.1
1,1-Dichloroethane	0.1
Bromoform	0.1
Chlorobenzene	0.3
1,1,2,2-Tetrachloroethane	0.3

The SPCCs are used to check compound instability and to check for degradation caused by contaminated lines or active sites in the system. Examples of these occurrences are:

Chloromethane - This compound is the most likely compound to be lost if the purge flow is too fast.

Bromoform - This compound is one of the compounds most likely to be purged very poorly if the purge flow is too slow. Cold spots and/or active sites in the transfer lines may adversely affect response. Response of the quantification ion (m/z 173) is directly affected by tuning BFB at ions m/z 174/176. Increasing the m/z 175/176 ratio relative to m/z 95 may improve bromoform response.

Tetrachloroethane and 1,1-dichloroethane - These compounds are degraded by contaminated transfer lines in purge & trap systems and/or active sites in trapping materials.

8.5.5 Using the RFs from the initial calibration, calculate and record the percent relative standard deviation (%RSD) for all compounds. The percent RSD is calculated as follows:

$$\%RSD = \frac{SD}{\overline{RF_X}} x100\%$$

where:

RSD = Relative standard deviation

RF_x = Mean of 5 initial RFs for a compound

SD = Standard deviation of the initial RFs for a compound

$$SD = \sqrt{\sum_{i=1}^{n} \frac{(RF_i - \overline{RF})^2}{n-1}}$$

where:

RF_i = RF for each of the 5 calibration levels

n = number of RF values (i.e., 5)

8.5.6 In general, the %RSD for GC/MS systems should be less than 15% for each compound. However, the %RSD for each individual Calibration Check Compound (CCC) must be equal to or less than 30%. The CCCs are:

1,1-dichloroethene
chloroform
1,2-dichloropropane
toluene
ethylbenzene
vinyl chloride

If the %RSD is >30% for any CCC, the initial calibration is not acceptable and can not be used for sample analysis. Corrective action is required to eliminate the source of the problem (i.e., system leak and/or column active sites) and a new ICAL must be performed and meet the CCC criteria before sample analysis can continue. Client calibration requirements may also be prescribed in the LIMS program specification.

8.5.7 LINEARITY

If the %RSD of any compound is <15%, then the compound's response is assumed to be constant over the calibration range, and the average relative response factor may be used for quantification.

If the %RSD of any compound is >15%, a calibration curve of area ratio (A/A_{is}) versus concentration ratio (C/C_{is}), using first or second order regression fit of the five or more calibration points, may be constructed.

The type of curve fit applied should be chosen to best represent the data.

The use of calibration curves is a recommended alternative to average response factor calibration and is a useful diagnostic of standard preparation accuracy and absorption activity in the chromatographic system. The coefficient of determination (COD, r^2 value) of the linear

or higher order regression used to define the calibration curve, is an expression of "goodness of fit", and must be ≥0.99. Quadratic regressions may be used with a minimum of 6 calibration points, and must yield a COD (r^2 value) of ≥0.99. A quadratic regression should not be used to compensate for detector saturation.

8.5.8 Calibration curves are verified each 12-hour shift by purging a continuing calibration verification standard (CCV). Recalibration is required only if calibration and on-going performance criteria cannot be met.

8.6 INITIAL CALIBRATION VERIFICATION (ICV)

A second source ICV standard is analyzed after the ICAL to independently verify the accuracy of the calibration. The concentration of the ICV should be different from that of the CCV and varied over time. If the control criteria are not met, the ICV shall be remade and analyzed to verify true concentration. If the ICV still fails, a new initial calibration must be generated.

It is recommended that the difference between the measured and expected concentrations be less than 25%. Due to the large number of analytes determined simultaneously using this procedure, it is considered likely that there may be sporadic failures of the <25% criteria. Consequently, it is permitted for the difference between expected and measured concentrations for 3 compounds out of 70 to be as high as 50% difference between measured and expected.

The second source check can also serve as the laboratory control sample (LCS) for samples analyzed in the same 12h shift as the ICAL. The LCS criteria may be different than the ICV criteria described above.

8.7 CONTINUING CALIBRATION VERIFICATION (CCV)

Performed at the beginning of each 12-hour sequence when initial calibration is not performed.

8.7.1 Prior to the analysis of samples, inject or purge 5 to 50ng of the 4-bromofluorobenzene standard following Method SW5030C or Method SW5035A. The resultant mass spectra for the BFB must meet all of the criteria given in Table 1 (shown previously) before sample analysis begins. These criteria must be met at the start of each 12-hour shift.

8.7.2 The ICAL curve for each compound of interest must be checked and verified once every 12 hours during analysis with the introduction technique used for samples. This is accomplished by analyzing a calibration standard that is at or near the midpoint concentration for the working range of the GC/MS. The SPCC compounds are checked, then the CCC compounds are checked. Then the %Ds for all target compounds are evaluated against the initial calibration.

8.7.3 SYSTEM PERFORMANCE CHECK COMPOUNDS (SPCCs)
A system performance check must be made each 12 hours. This is the same check that is applied during the initial calibration except that the daily response factor is evaluated against the criteria given previously. The SPCC criteria must be met before analysis can continue. If the minimum RRFs are not met, the system must be evaluated and corrective action must be taken before sample analysis begins. Some possible problems are: standard mixture degradation, injection port inlet contamination, contamination at the front end of the analytical column, and active sites in the column or chromatographic system.

8.7.4 CALIBRATION CHECK COMPOUNDS (CCCs)
After the system performance check is met, the CCCs are used to check the validity of the ICAL. Calculate the percent difference using the following equation:

$$\% \text{ Difference} = (RF - RF_1)/RF \times 100$$

where:

RF_1 = Calibration Check Compound standard response factor
RF = Average response factor (system performance check)

If the %D for each CCC is $\leq$20%, the initial calibration is assumed to be valid. If the criterion is not met (>20% difference) for any one CCC, corrective action must be taken. Problems similar to those discussed under SPCCs could affect this criterion. If the source of the problem cannot be determined after corrective action has been taken, a new multi-point calibration must be generated. The CCC criterion MUST be met before quantitative sample analysis begins. If the CCCs are not required analytes for all of the samples analyzed on one 12-hour shift, then all required analytes must meet the 20%D criterion.

The difference (for average RF) or drift (for regressions) for each target analyte is also evaluated against the ICAL. If a higher order equation is being utilized, the compound should be evaluated using the % drift calculation shown below:

$$\% \text{ drift} = [(\text{calc. conc.} - \text{theoretical conc.})/\text{theoretical conc.}](100\%)$$

The %D (drift or difference depending on calibration process) is evaluated for all target analytes and should be ≤20% for each target analyte, or data may need to be qualified depending on client or program specifications.

8.7.5 RETENTION TIME REPRODUCIBILITY

The internal standard responses and retention times in the check calibration standard must be evaluated immediately after or during data acquisition. If the retention time for any internal standard changes by more than 30 seconds from that in the midpoint standard level of the most recent initial calibration, the chromatographic system must be inspected for malfunctions and corrections must be made as required. If the EICP area for any of the internal standards changes by a factor of two (-50% to +100%) from that in the midpoint standard level of the most recent initial calibration, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. Samples should not be analyzed and reported if the criteria described above are not met.

8.8 SAMPLE ANALYSIS

BFB tuning criteria and calibration verification criteria (discussed above) must be met before analyzing samples. All samples and working standard solutions must be allowed to warm to ambient temperature before analysis. Set up the purge & trap system as outlined in Method SW5030C, or Method SW5035A if closed system purge & trap introduction will be used.

8.8.1 PURGE TEMPERATURE

8.8.1.1 For soil analysis, the ICAL, all CCVs, and all field and QC samples shall be heated to 40°C during the purge.

8.8.1.2 For aqueous analysis, a heated purge is not required. The same purge conditions used for soil analysis may be used for aqueous analysis, however, if the ICAL, all CCVs, and all field and QC samples are heated to 40°C during the purge.

It is recommended that purge volumes of 10 to 25mL should not use a heated purge due to the amount of water vapor that may be introduced into the purge & trap system. The ICAL, all CCVs, and all field and QC samples should be left at ambient temperature during the purge.

8.8.2 AQUEOUS ANALYSIS

8.8.2.1 The process of taking an aliquot destroys the validity of aqueous samples for future analysis; therefore, if there is only one VOA vial, the analyst should prepare a second aliquot for analysis concurrently to protect against possible loss of sample integrity, or transfer the remaining sample to a 20mL VOA vial (without headspace) and refrigerate. This second sample is maintained only until such time when the

analyst has determined that the first sample has been analyzed properly.

8.8.2.2 Remove the plunger from a 5mL leur-lock syringe. If lower detection limits are required, use a 10-to-25mL leur-lock syringe. Open the sample or standard bottle, which has been allowed to come to ambient temperature, and carefully pour the sample into the syringe barrel to just short of overflowing. Replace the syringe plunger, compress the sample and vent any residual air, while adjusting the sample volume to 5.0mL (10mL or 25mL).

8.8.2.3 Manually add 5µL (or appropriate volume) of the intermediate surrogate and internal standards to each sample (if not using an autosampler such as Archon, that adds the surrogates and/or ISs as part of the process). The surrogate and internal standards may be mixed and added as a single spiking solution. The addition of 5µL of the surrogate and internal standard spiking solution to 5mL of sample is equivalent to a concentration of 50µg/L of each standard.

8.8.2.4 For matrix spike analysis, add 2µL (or appropriate volume) of the intermediate matrix spike solution to the 5mL of sample to be purged. Disregarding any dilutions, this is equivalent to a concentration of 20µg/L of each matrix spike standard.

8.8.2.5 The sample is placed in a purge tube on the autosampler. Proceed with purge & trap analysis by Method SW5030C. If the initial analysis of a sample or a dilution of the sample has a concentration of analytes that exceeds the calibrated range of the instrument, the sample must be reanalyzed at a higher dilution.

Secondary ion quantification is allowed only when there are sample interferences with the primary ion.

When a sample is analyzed that has saturated ions from a high concentration compound, this analysis must be followed by an organic-free reagent water blank analysis. If the blank analysis is not free of interferences, the system must be decontaminated. Sample analysis may not resume until the blank analysis is demonstrated to be free of interferences (refer to Section 4 for further details).

8.8.2.6 It should be noted that most aqueous analyses (10mL and 25mL) that are performed with the use of the OI 4552/Archon or Varian Archon autosamplers undergo a different aliquotting procedure. All working standards and some sample dilutions are prepared in a 50mL volumetric flask, spiked accordingly, then are transferred to a 40mL VOA vial (without headspace). The vial is placed in the autosampler tray, where internal standards and surrogates are added automatically (if needed) and purge & trap analysis is then performed.

8.8.2.7 The following procedure is appropriate for diluting aqueous purgeable samples. Sample dilution is based on analyte concentration, non-target compound concentration, or the presence of surfactants (foaming samples). All steps must be performed without delay until the diluted sample is in a gas-tight syringe. If usable data has not been generated for a less diluted analysis, the dilution should keep the response of the major constituents (previously saturated peaks) in the upper portion of the linear range to generate the lowest reporting limits possible.

- Dilutions may be made in volumetric flasks (10 to 100mL) or gas-tight syringes (5mL or 30mL). Select the volumetric flask or syringe that will allow for the necessary dilution. Intermediate dilutions may be necessary for extremely large dilutions.

- Calculate the approximate volume of organic-free reagent water to be added to the volumetric flask selected and add slightly less than this quantity of organic-free reagent water to the flask.

- Inject the proper aliquot of sample from the syringe into the flask. Dilute the sample to the mark with organic-free reagent water. Cap the flask and invert three times. Repeat above procedure for additional dilutions.

- Fill a 5mL (or 30mL) syringe with the diluted sample. An alternative method is to inject the proper aliquot of sample directly into the 5mL or 30mL syringe filled with organic-free reagent water.

- Add 5µL (or appropriate volume) of the intermediate surrogate and internal standards to each sample. The surrogates and internal standards may be mixed and added as a single spiking solution. The addition of 5µL of the surrogates and internal standard spiking solution to 5mL of sample is equivalent to a concentration of 50µg/L of each standard.

8.8.2.8 The following procedure can be used to composite aqueous samples prior to GC/MS analysis:

- Add 5mL or equal larger amounts of each sample (up to 5 samples are allowed) to a 25mL glass syringe. Special precautions must be made to maintain zero headspace in the syringe.

- The samples must be cooled at 4+2°C during this step to minimize volatilization losses.

- Mix well and draw out a 5mL aliquot for analysis.

- Follow sample introduction, purging, and desorption steps described in Method SW5030C.

- If less than five samples are used for compositing, a proportionately smaller syringe may be used unless a 25mL sample is to be purged.

- Add 5µL (or appropriate volume) of the intermediate surrogates and internal standards to each sample. The surrogates and internal standards may be mixed and added as a single spiking solution. The addition of 5µL of the surrogates and internal standard spiking solution to 5mL of sample is equivalent to a concentration of 50µg/L of each standard.

8.8.3 SOIL SAMPLE ANALYSIS BY METHOD SW5035Amod

8.8.3.1 Homogenize the sample well, taking care to minimize the loss of volatile constituents.

8.8.3.2 Weigh 5g of soil into an appropriate purge vessel; place the sample on the autosampler. For method blanks and LCSs, 5g of Ottawa sand should be added to the purge vessel.

8.8.3.3 Add 5mL of organic-free water to the sample. In the case of LCS or MS samples, the associated spike is added with this aliquot.

8.8.3.4 The Archon autosampler adds a total of 5mL of water to each sample. The Archon autosampler also adds an appropriate amount of the intermediate surrogates and internal standard solution to the reagent water, which is then added to the sample. For matrix spike analysis, add the appropriate volume (e.g., 2µL) of the matrix spike solution with the reagent water.

8.8.3.5 The following procedure is appropriate for diluting soil purgeable samples. Soil sample dilution is based on analyte concentration or unknown compound concentration. If usable data has not been generated for a less diluted analysis, the dilution should keep the response of the major constituents (previously saturated peaks) in the upper portion of the linear range to generate the lowest reporting limits.

- Soil dilutions are made by weighing an aliquot of less than 5g of sample into the purge tube. To ensure a representative sample aliquot, no less than 0.5g of soil should be purged. For reporting purposes, a nominal amount of 5g will be considered the purge amount, and amounts less than this will be treated as dilutions. If a dilution greater than can be obtained by 0.5g of soil is required, a medium level extraction must be performed (see Section 8.8.4 below).

8.8.4 MEDIUM LEVEL SOIL SAMPLES (METHANOL-EXTRACTION)
Methanolic extraction /analysis is used for high concentration solid samples requiring dilutions greater than that which can be soundly achieved using smaller sample volume, or for samples that are difficult to homogenize.

8.8.4.1 Homogenize the sample as well as possible, taking care to minimize the loss of volatile constituents.

8.8.4.2 Weigh approximately 5g (record actual weight to 0.01g) of sample into a labeled, tared 20mL VOA vial. Clean the outer lip of the vial with a Kimwipes™ before obtaining the final weight. In some instances, such as low density soils or odd matrices, an aliquot of less than 5g may be necessary.

8.8.4.3 Add 5mL of methanol, cap and shake vigorously for 2 minutes. Allow solid and methanol to separate for at least 10 minutes. Note that alternate soil weights and methanol volumes may be used depending upon the level of sample dilution required. Enough methanol must be added to the vial to completely cover the soil aliquot.

8.8.4.4 Calculate the volume of the methanol extract that when brought to a final volume of 5mL in water, will bring the dilution concentration into the upper portion of the instrument calibration (factor in any dilution that may have been made by the initial extraction of the sample with methanol). To protect the system from trap or column overload, a maximum of 100µL of extract may be used. The dilution is prepared in the syringe used to transfer the sample to the purge vessel. Proceed with the analysis as discussed for aqueous samples above (Section 8.8.2).

8.8.4.5 A medium level blank should be prepared in the same manner using 5.0g of Ottawa sand and 5mL of methanol. 100µL of this methanol extract injected into 5mL of water is to be analyzed before the sample extract, to ensure no methanol contamination.

8.8.5 SOIL SAMPLE ANALYSIS BY METHOD 5035A

8.8.5.1 Transfer the contents of an EnCore™ soil sampler to a 40mL VOA vial containing a magnetic stir bar.

8.8.5.2 Use 5g of Ottawa sand in a 40mL VOA vial as the matrix basis for method blanks (MBs)and LCSs.

8.8.5.3 Add 5mL of organic-free water to the vial.

8.8.5.4 For matrix spikes, add 2µL (or appropriate amount) of intermediate spiking solution.

8.8.5.5 Samples may be submitted by clients in 40mL vials which already contain water, preservative ($NaHSO_4$) and stir bar or water and stir bar only. Samples submitted in vials are analyzed in the vials without opening the vial.

8.8.5.6 Place vial on the autosampler.

8.8.5.7 The Archon is used to add internal standards and surrogates solution and 5mL of organic-free water to the purge vessel bringing the final liquid purge volume to 10mL.

8.8.5.8 Place the VOA vial in the Archon autosampler which will automatically inject 1µL of surrogates and internal standards (if appropriate) prior to purging. Note: The 1µL volume is approximated; as instructed by the instrument manufacturer, the internal loop used to deliver the standard is calibrated for each autosampler to determine the absolute volume being delivered. The autosampler will stir and heat the contents of the VOA vial during the purge process.

8.8.5.9 Soil dilutions are made by weighing an aliquot of less than 5g from the Encore™ into the VOA vial. To ensure a representative sample aliquot, no less than 0.5g of soil should be purged. For reporting purposes, a nominal amount of 5g will be considered the purge amount, and amounts less than this will be treated as dilutions. If a dilution greater than can be obtained by 0.5g of soil is required, a medium level extraction must be preformed by extracting the contents of the EnCore™ as described in Section 8.8.4 above.

8.9 DATA INTERPRETATION

8.9.1 QUALITATIVE ANALYSIS

8.9.1.1 The qualitative identification of compounds determined by this method is based on retention time, and on comparison of the sample mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of the method. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity, if less than three such ions occur in the reference spectrum. Compounds should be identified as present when the criteria below are met:

- The intensities of the characteristic ions of a compound maximize in the same scan or within one scan of each other. Selection of a peak by a data system target compound search routine where the search is based on the presence of a target chromatographic peak containing ions specific for the target compound at a compound-specific retention time will be accepted as meeting this criterion.

- The relative retention time (RRT) of the sample component is within ±0.06 RRT units of the RRT of

the standard component. (RRT = RT of the analyte/ RT of the internal standard).

- The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.

- Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.

- Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e., a broadened peak with shoulders or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

- Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra and in qualitative identification of compounds. When analytes co-elute (i.e., only one total ion current chromatographic peak is apparent), the identification criteria can be met, but each analyte spectrum will contain extraneous ions contributed by the co-eluting compound. Analyst experience and judgment is important when evaluating co-eluting compounds.

8.9.1.2 For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification will be determined by the type of analyses being conducted. Guidelines for making tentative identification are:

- Relative intensities of major ions in the reference spectrum (ions >10% of the most abundant ion) should be present in the sample spectrum.

- The relative intensities of the major ions should agree within ±20%. Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 30 and 70%.

- Molecular ions present in the reference spectrum should be present in the sample spectrum.

- Ions present in the sample spectrum but not in the reference spectrum should be reviewed for possible background contamination or presence of co-eluting compounds.

- Ions present in the reference spectrum but not in the sample spectrum should be reviewed for possible subtraction from the sample spectrum because of background contamination or co-eluting peaks. Data system library reduction programs can sometimes create these discrepancies.

- Computer generated library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other. Only after visual comparison of sample with the nearest library searches will the analyst assign a tentative identification.

8.9.2 QUANTITATIVE ANALYSIS

8.9.2.1 When a compound has been identified, the quantification of that compound will be based on the integrated abundance from the EICP of the primary characteristic ion. Quantification will take place using the internal standard technique. The IS used shall be the one nearest the retention time of that of a given analyte.

8.9.2.2 When the detector response is linear and passes through the origin, calculate the concentration of each identified analyte in the sample as follows:

WATER:

$$Concentration(\mu g / L) = \frac{(A_x)(I_s)}{(A_{IS})(\overline{RF})(V_o)}$$

where:

A_x = Area of characteristic ion for compound being measured

I_s = Amount of internal standard injected (ng)

A_{IS} = Area of characteristic ion for the internal standard

$\overline{RF}$ = Mean relative response factor for compound being measured

V_o = Volume of water purged (mL), taking into consideration any dilutions made

SEDIMENT/SOIL SLUDGE (on a dry-weight basis) & WASTE (normally on a wet-weight basis):

$$Concentration(\mu g / kg) = \frac{(A_x)(I_s)V_t)}{(A_{is})(\overline{RF})(V_i)(W_s)(D)}$$

where:

A_x, I_s, A_{is}, $\overline{RF}$ = Same as for water.

V_t = Volume of total extract (µL) (Use 10,000µL or a factor of this when dilutions are made)

Vi = Volume of extract added (µL) for purging

WS = Weight of sample extracted or purged (g)

D = % dry weight of sample/100, or 1 for a wet-weight basis

8.9.2.3 Where requested by the client, an estimate of concentration for non-calibrated components in the sample may be made. The formulae given above should be used with the following modifications: The areas A_x and A_{IS} should be from the total ion chromatograms, and the RF for the compound should be assumed to be 1. The concentration obtained should be reported indicating (1) that the value is an estimate and (2) which internal standard was used to determine concentration. The chromatographic data system calculates the concentration and reports which IS was used in the calculation. Use the nearest IS free of interferences. Upon request, Paragon will report the top 10 non-calibrated

components (Tentatively Identified Compounds, TICs) with total ion areas > 10% of the total ion area of the nearest internal standard. Identification of TICs with less than 10% relative abundance is difficult at best, and generally should not be attempted. Some clients may request the reporting of more compounds or compounds with lower areas relative to the closest IS. Consult LIMS program specification for further direction.

8.9.2.4 Alternatively, the regression line fitted to the initial calibration may be used for determination of analyte concentration.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

For this method, an analysis batch is defined as a group of 20 or fewer field samples that is associated with one unique set of batch QC samples. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS), and duplicate (field sample, LCS or MS). All quality control samples must be carried through all stages of the sample preparation and measurement steps. In addition, batch QC samples should be analyzed on the same instrument as the samples in the batch. Consult LIMS program specification for additional or alternative requirements.

9.2 BLANK ANALYSIS

A method (reagent) blank (MB) must be analyzed for each 12-hour BFB tune and per batch of 20 or fewer field samples of similar matrix. Target compounds may not be detected above one-half the reporting limit (RL). Common laboratory contaminants (e.g., acetone, 2-butanone, methylene chloride) are allowed at levels as high as the RL. Occurrence of these common laboratory contaminants should be considered a warning and must be reported in the data package case narrative. See QC Table for further details.

9.3 SURROGATES

Surrogate recovery is monitored to assess method performance of the particular matrix. Surrogates are added to all standards, blanks, samples and QC samples prior to analysis. See QC Table for acceptance limits and corrective actions.

9.4 INTERNAL STANDARDS

Internal standards are added to all standards, field and quality control samples analyzed. Retention times and responses are evaluated for internal standards. See QC Table for acceptance limits and corrective actions.

9.5 LABORATORY CONTROL SAMPLES

A matrix-specific laboratory control sample (LCS) is analyzed per batch of 20 field samples. It is Paragon's practice to also analyze a laboratory control sample

duplicate (LCSD) per batch of 20 field samples. LCS (LCSD) samples are analyzed to evaluate the efficiency of the method performed. See QC Table for acceptance limits and corrective actions.

9.6 MATRIX SPIKE(S)
A matrix spike (MS) and matrix spike duplicate (MSD) sample are analyzed to evaluate the effect of the matrix. Additional sample volume of client samples is needed to perform these analyses. The frequency of the MS/MSD shall be one pair per batch of 20 field samples, assuming adequate volume has been provided. See QC Table for acceptance limits and corrective actions.

9.7 METHOD DETECTION LIMIT (MDL) STUDY
The MDL study shall consist of the analysis of a minimum of seven replicate analyses for a target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at a minimum, annually, following the guidance of SOP 329.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW8260B. Alternate quantitation ions may be used to limit or eliminate common interferences caused by co-elution of standards or matrix contributions.

EPA METHOD 624 REQUIREMENTS
Suggested surrogates and internal standards are listed in EPA 624, Table 3. Paragon uses the same surrogates and internal standards for both Methods SW8260B and EPA 624 as follows: ISs - fluorobenzene, chlorobenzene-d_5, 1,4-dichlorobenzene-d_4; SSs - toluene-d_8, 4-bromofluorobenzene, 1,2-dichloroethane-d_4 and dibromofluoromethane. Two of each of the SSs and ISs listed above are included in EPA 624, Table 3.

Method EPA 624 states that the concentration of the surrogate spike used should be 30µg/L; Paragon typically uses a 50µg/L concentration surrogate spike.

EPA 624 states specific adsorbent trap and purge & trap conditions, and chromatographic columns and conditions, as well as mass spectrometer conditions to be used in the execution of the method (i.e., specific purge time, use of a packed column, and scanning conditions tailored for packed column use). Some of these materials, apparatus, and conditions have been eclipsed by technology as described in this SOP. Note that Section 8.1.2 of Method EPA 624 provides for the use of technological advances so long as the precision and accuracy requirements put forth by the Method can be achieved.

Method EPA 624 requires at least three points in the ICAL; Paragon quantitates from a 5-to-7-point curve to meet compliance requirements for Method SW8260B. This approach also meets compliance requirements for EPA 624, as more than three points are used to calibrate.

Method EPA 624 states that if the %RSD of the average response factor is less than 35%, then an average response factor may be used. Otherwise, construct a linear curve with a correlation coefficient greater than 0.995. Paragon follows the calibration criteria discussed previously in the SOP.

EPA 624 specifies that the BFB tune period is 24 hours. Paragon follows the procedure as discussed in SW8260B, which specifies that BFB criteria must be passed every 12 hours.

Method 624 states that a continuing calibration verification (CCV) must be performed every working day (i.e., every 24 hours). Paragon observes a criterion that a CCV must be performed every 12 hours. Method 624 also requires that the results of the CCV must meet the requirements set forth in Table 5 of the Method, and that any compounds without limits in this Table must have their recovery reported, but corrective actions are not required.

EPA 624 states that a matrix spike (MS) and laboratory control spike (LCS) must be performed per every 20 samples. The native sample only needs to be spiked once; a matrix spike duplicate (MSD) sample is not required. EPA 624 also states that the matrix spikes and laboratory control (blank) spikes must meet the acceptance criteria listed in Table 5 of the Method (note that not all compounds have acceptance limits in this Table; for these compounds, the recovery must be reported, however, corrective actions based on those results are not required). Furthermore, EPA 624 discusses matching each compound's spike amount with the amount of the compound in the samples chosen for spiking, and also matching the spike amount to the appropriate regulatory level for each compound. Because samples from several sites are usually batched together, it is Paragon's practice to use only one spiking level is for each compound.

Method EPA 624 states that a set of 4 QC Check samples must be analyzed by an analyst before any samples are processed to demonstrate the ability to perform the method. The concentrations of each compound must be 20µg/L, and the results must fall within the acceptance criteria specified in Table 5 of the method. Paragon does observe Demonstration of Capability (DOC) requirements, but at the spike levels presented in the SOP and requiring that the results must meet the laboratory's LCS criteria established for the procedure (based on SW-846 guidance).

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

12.1.2 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

12.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.5 All flammable compounds must be kept away from ignition sources.

12.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.1.7 All compressed gas cylinders must be secured at all times a regulator is in place. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

12.1.8 Food and drink are prohibited in all lab areas

12.2 WASTE DISPOSAL

12.2.1 The aqueous phase of the purge & trap waste shall be disposed of in the aqueous lab waste stream. A satellite waste collection vessel may be obtained from the Waste Manager.

12.2.2 The solid phase of the purge & trap waste shall be disposed of in the contaminated soils and solids waste stream. A satellite waste collection vessel may be obtained from the Waste Manager.

12.2.3 Solvent wastes must be disposed of in the appropriate waste containers.

12.2.4 Any rinse waters used for rinsing syringes or other devices prior to sample contact may be disposed of as Aqueous Lab Waste.

12.2.5 Any methanol, hexane or other non-halogenated organic solvents that has not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Non-halogenated Waste.

12.2.6 All empty solvent bottles are disposed of according to the appropriate SOPs (003, 015). Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

2/8/07: Reference to instrument printout used as run log included in HEADER. SECTION 3 LIMS program specification language strengthened. Reorganized STANDARDS and ANALYSIS Sections, updated format, method quantitation ions defined as guidelines. Revamped QC Section and Table. Expanded SAFETY, HAZARDS & WASTE DISPOSAL Section. Added DOCUMENT REVISION HISTORY Section.

TABLE 2

CHARACTERISTIC MASSES (M/Z) FOR PURGEABLE ORGANIC COMPOUNDS

TARGET ANALYTE	PRIMARY CHARACTERISTIC ION(S)	SECONDARY CHARACTERISTIC ION(S)
dichlorodifluoromethane	85	87
chloromethane	50	52
vinyl chloride	62	64
bromomethane	96	94
chloroethane	64	66
trichlorofluoromethane	101	151, 153
acrolein	56	55, 58
1,1-dichloroethene	96	53, 61
1,1,2-trichloro-1,2,2-trifluoroethane	101	103, 151, 153
acetone	58	43
iodomethane	142	127, 141
carbon disulfide	76	78
methylene chloride	84	86, 49
trans-1,2-dichloroethene	96	61, 98
methyl tertiary butyl ether	73	57
acrylonitrile	53	52, 51
1,1-dichloroethane	63	65, 83
vinyl acetate	43	86
cis-1,2-dichloroethene	96	61, 98
2-butanone	43	72
bromochloromethane	128	49, 130
chloroform	83	85
1,1,1-trichloroethane	97	99, 61
2,2-dichloropropane	77	97
carbon tetrachloride	117	119
1,1-dichloropropene	75	110, 77
1,2-dichloroethane	62	98
benzene	78	52, 77
trichloroethene	95	97, 130, 132
1,2-dichloropropane	63	112
dibromomethane	93	95, 174
bromodichloromethane	83	85, 127
2-chloroethyl vinyl ether	63	65, 106
cis-1,3-dichloropropene	75	77, 39
4-methyl-2-pentanone	43	58, 85, 100
toluene	91	92
trans-1,3-dichloropropene	75	77, 39

TABLE 2

CHARACTERISTIC MASSES (M/Z) FOR PURGEABLE ORGANIC COMPOUNDS

TARGET ANALYTE	PRIMARY CHARACTERISTIC ION(S)	SECONDARY CHARACTERISTIC ION(S)
1,1,2-trichloroethane	83	85, 97

dibromofluorobenzene (SUR)	113	
chlorobenzene-d_5 (IS)	82	117
1,4-dichlorobenzene-d_4 (IS)	152	115,150
1,4-difluorobenzene (IS)	114	
fluorobenzene (IS)	96	70

Analytical Method: 8260B, EPA 624	**Parameter:** Volatile Organic Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
Tuning Criteria	Every 12 hour period	BFB abundance criteria (Table 1) must be met	Re-tune. Do not proceed with analysis until tune meets criteria.
Initial Calibration (ICAL)	When CCCs and/or SPCCs in the daily calibration do not meet criteria or following major instrument maintenance	CCC: ≤30% RSD; SPCC RFs ≥0.10: chloromethane, 1,1-DCA, bromoform SPCC RFs ≥0.30: chlorobenzene, 1,1,2,2-tetrachloroethane Ave RF may be used if: non-CCC s are ≤15% RSD r^2 for regression (or quadratic) curve fit must be ≥0.99; a quadratic curve may be used if 6 or more data points are used	For CCCs and SPCCs, evaluate/correct instrument malfunction (if any), reanalyze ICAL
Initial Calibration Verification (ICV): different source than that of ICAL standards	Following every ICAL	Measured concentrations of all analytes should be within 25% of expected concentrations. Sporadic failures of up to 50% allowed for up to three analytes IS retention times <30 seconds drift from mid-point in most recent ICAL IS areas –50 to +100% of corresponding internal standard area in the mid-point of the most recent ICAL	Re-analyze ICV. If still out, evaluate/correct instrument malfunction as needed; perform a new ICAL
Continuing Calibration Verification (CCV); at or near mid-point	Every 12-hour period following tune, if ICAL not performed. Required for quantitating all samples analyzed during the 12 hour sequence	CCC: ±20 %D SPCC: same requirements ICAL Measured concentrations of all non-CCC analytes should be within 20% of expected concentrations. Sporadic failures of up to 50% allowed for up to three analytes IS retention times <30 seconds drift from mid-point in most recent ICAL IS areas –50 to +100% of corresponding internal standard areas in the mid-point of the most recent ICAL	Re-analyze the daily standard. If failure repeats, evaluate/correct instrument malfunction; perform a new ICAL NOTE: Recoveries that are high and outside of the stated acceptance criteria may be acceptable in some programs if the analyte that is high was not detected in the associated samples.

Analytical Method: 8260B, EPA 624	**Parameter:** Volatile Organic Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
Method Blank (MB)	Every 12-hour period; after each calibration/check and 1 per batch of 20 samples of like matrix	< ½ RL for all target compounds, except common laboratory contaminants (e.g., acetone, 2-butanone, methylene chloride), which are allowable to the RL	Re-analyze to determine if instrument contamination was the cause. If MB is still non-compliant, correct the problem and obtain a successful MB analysis before resuming analysis of samples. NOTE: Reporting of samples associated with MBs that yield contaminants may permitted by some program specifications or at the client's discretion. Example: Toluene in MB at RL but not detected in any sample above the MDL. In this case, document occurrence and resolution using a Nonconformance Report (NCR), SOP 928.
Surrogates (SS)	Every standard, client sample and QC sample	See laboratory or other applicable limits; recoveries should be within these limits	If non-compliant, check calculations and spike preparation for errors; correct as needed. If no errors are found, sample may be reanalyzed once (note that reanalysis may be fulfilled by existing multiple analyses - e.g., duplicate, spike duplicate, dilution). If still non-compliant, report results and narrate. NOTE: Per program specifications, surrogate recovery that is high and outside of acceptance criteria, with no associated target compounds detected, may not require reanalysis.
Internal Standard (IS)	Every standard, client sample and QC sample	Average area within -50% to +100% window of corresponding daily calibration verification standard area RT shift <30 seconds compared to daily standard (STD50); relative retention time (RRT) of sample must be ± 0.06 RRT units of standard	Inspect instrument for malfunction, correct. Sample may be reanalyzed (note that reanalysis may be fulfilled by existing multiple analyses - e.g., duplicate, spike duplicate, dilution). If out-of-limit areas are explained by the sample matrix (e.g., high hydrocarbon content contributes to IS areas), reanalysis is not required. Narrate.
Matrix Spike (MS)	1 per batch of 20 samples of like matrix	See laboratory or other applicable limits; recoveries for the spiked compounds should be within these advisory limits	If non-compliant, check calculations and spike preparation for errors; correct as needed. If no errors are found, and the associated LCS is within control limits, then sample matrix effects are the most likely cause. Narrate.
Matrix Spike Duplicate (MSD) or Duplicate	1 per batch of 20 samples of like matrix	See laboratory or other applicable limits; recoveries for the spiked compounds should be within these advisory limits	If non-compliant, check calculations for errors. If significant differences exist between the duplicate results, consult with Department Manager (reanalysis of the sample and spikes may be

Analytical Method: 8260B, EPA 624	**Parameter:** Volatile Organic Compounds		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria *	Corrective Action
* NOTE: Superceding criteria specified by the client and prescribed in the LIMS program specification may apply.			
		RPDs for the spiked compounds should also be within advisory limits	necessary, or sample inhomogeniety may be the likely cause).
Laboratory Control Sample (LCS) or Duplicate	1 per batch of 20 samples of like matrix; typically the LCSD is analyzed when matrix spikes are not performed	See laboratory or other applicable limits; recoveries for the spiked compounds should be within these limits NOTE: When the full list of compounds is spiked, the laboratory will accept a small number of sporadic marginal exceedances, based on the probability that a certain number of compounds will exceed their control limits. Exceedances must be sporadic and marginal, systematic or gross failures shall not be accepted.	If non-compliant, check calculations and spike preparation for documentable errors; correct as needed. If no errors are found, then re-analyze to determine if instrumental conditions was the cause. Notify the Supervisor and initiate corrective action (NCR). Re-analyze associated samples, if appropriate. Note that recoveries that are high and outside of acceptance criteria may be acceptable, when the same target compound is not detected in any sample in the batch. Narrate.
Method Detection Limit (MDL) Study	At minimum, annually	Value must be < reporting limit	Determine the reason for failure and fix problem with system; repeat study for those analytes that did not meet criteria. Consult with Quality Assurance Manager - reporting limit may be adjusted if needed.

ALS LABORATORY GROUP - FORT COLLINS
STANDARD OPERATING PROCEDURE 603 REVISION 11

TITLE: **EXTRACTION OF HYDROCARBONS FROM SOIL AND WATER SAMPLES**

FORMS: **602** (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2.12.09

QUALITY ASSURANCE MANAGER _____ DATE 2/12/09

LABORATORY MANAGER _____ for KDC DATE 2/12/09

HISTORY: Rev0, 1/7/92; Rev1, 2/12/93; Rev2, PCN #74, 1/6/94; Rev3, 2/17/95; Rev4, 6/10/96; Rev5, 10/15/01; Rev6, 3/1/02; Rev7, 3/19/03; Rev8, 5/28/04; Rev9, 2/27/06; Rev10, 11/20/07; Rev11, 2/12/09.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes ALSLG-FC's in-house procedures used to extract Diesel Range Organics (DRO) and other extractable organic matter, from aqueous and solid matrices. Environmental samples prepared by this procedure may be subsequently analyzed via SW-846 Method 8015 or other State-specific procedure. Per SW-846 Method 3580A, high concentration organic liquid samples may be diluted (i.e., not extracted) then analyzed.

NOTE: Where DRO preparation and analysis are specified via California-LUFT (Cal Luft) procedures, this SOP is not relevant. For water samples extracted per Cal Luft field manual procedures, refer to SOP 626, Separatory Funnel Extraction. Soil samples for Cal Luft are extracted per the procedure in the field manual.

2. SUMMARY

Environmental and laboratory quality control (QC) samples are extracted with hexane. A methanol-water solution is used as a wetting agent to assist in the extraction of solid matrix samples. Solid samples are prepared by tumbling using a TCLP-type rotary tumbler, followed by centrifuging. Aqueous samples are prepared by manual shaking, followed by settling. Sodium sulfate is dissolved in all aqueous samples to help salt-out target compounds. The hexane layer, which rises to the top of each prepared sample, is drawn off and placed in a labeled extract vial. The extracts are delivered to the Fuels Group and stored in the designated refrigerator.

3. RESPONSIBILITIES

3.1 It is the responsibility of the individual performing this procedure to prepare the samples according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing

these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 ALSLG-FC's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede ALSLG-FC's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors, and documentation of measures taken to correct these errors.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the preparation or analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences upon analysis. Only scrupulously cleaned glassware and reagent grade (or better) chemicals and pesticide grade (or better) solvents may be used. These materials and the analytical system must be demonstrated to be free from interferences by the preparation and analysis of method blanks.

5. APPARATUS AND MATERIALS

5.1 sample vials with screw-tops, 40mL or other suitable size, glass, disposable

5.2 volumetric flasks, 100-200mL, glass, dedicated for petroleum hydrocarbon (DRO) preparation and kilned

5.3 solvent dispensers, pump-style or equivalent

5.4 laboratory balance capable of weighing to 0.01g, and verified per SOP 305

5.5 syringes, plastic, 60mL, disposable

5.6 syringes, glass, 1.0mL or equivalent

5.7 Pasteur pipets, glass, disposable

5.8 centrifuge

5.9 rotary tumbler, TCLP-type or equivalent

5.10 metal spatulas, kilned

6. SOLVENTS AND REAGENTS - Only reagent grade (or better) chemicals and pesticide residue grade (or better) solvents shall be used.

6.1 organic-free deionized (DI) water, obtainable from the laboratory's DI water system

6.2 hexane (C_6H_{14})

6.3 methanol (CH_3OH)

6.4 acetone (CH_3COCH_3)

6.5 sodium sulfate (Na_2SO_4), kilned

6.6 Ottawa sand, or equivalent, kilned

6.7 methanol:water solution (80/20 $^{v}/_{v}$): Prepare by mixing 4 parts methanol with 1 part DI water.

6.8 surrogate and spiking solutions: Prepared by the Fuels Group. See SOPs 406 and 300 for preparation, handling, storage and documentation details. These solutions are prepared in acetone.

NOTE: Allow all surrogate and spiking solutions to come to room temperature before use.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 All samples should be collected using an appropriate sampling plan.

7.2 Samples should be collected in glass containers with Teflon-lined lids.

7.3 Unpreserved water samples must be extracted within 7 days of collection. Usually, a 7-day holding time is observed for aqueous samples preserved with hydrochloric acid (HCl). However, some State programs may allow a 14-day to extraction holding time.

7.4 Solid matrix samples must be extracted within 14 days of collection (sooner if client specifications dictate).

8. PROCEDURES

NOTE: All abnormal conditions or odors **must** be noted on the benchsheet (Form 602). Examples of notable items include: extremely wet or rocky samples, large amounts of solids in water samples, presence of free product, hydrocarbon odor, and formation of emulsions during extraction. **Consult**

the Department Manager regarding difficult, unusual matrices.

8.1 EXTRACTION OF SOLID SAMPLES

8.1.1 Decant and discard any water layer. Mix sample thoroughly, especially composited samples. Discard any foreign objects (e.g., sticks, leaves, rocks) or any portion of the sample that appears to *not* be representative of the sample. The sample must be well-mixed to ensure that a representative sub-sample is obtained.

8.1.2 For each environmental sample, weigh approximately 20g of representative sample into a labeled 40mL glass vial with a screw-top cap. Record the weight on the benchsheet (Form 602). If sufficient sample volume was provided, choose one sample (per batch of twenty or fewer client samples) and measure a total volume of three aliquots, subdividing this volume into three labeled 40mL glass vials to serve as the sample and MS/MSD pair. This technique will help to ensure sample homogeneity.

8.1.3 For each batch of twenty (or fewer) client samples processed, prepare one solid matrix method blank (MB), and a solid matrix laboratory control sample (LCS). Note that ALSLF-FC typically also prepares a laboratory control sample duplicate (LCSD) per batch. For each of these QC samples, measure approximately 20g of kilned Ottawa sand into a 40mL glass vial with a screw-top cap. Label the vials as the MB, LCS, and LCSD.

8.1.4 Add the appropriate amount of surrogate solution (typically 1.0mL) to each prepared vial of environmental and QC sample.

NOTE: Use acetone as the solvent rinse for the syringe.

8.1.5 Add the appropriate amount of petroleum hydrocarbon (DRO) spiking solution (typically 1.0mL) to each of the LCS, LCSD, MS and MSD samples.

8.1.6 Add 20mL methanol:water solution to each environmental and QC sample.

8.1.7 Add 5.0mL of hexane to each environmental and QC sample.

8.1.8 Tightly cap each prepared sample vial and pack (with cushioning) into large plastic containers for rotary tumbling. Tumble for about 45 minutes.

8.1.9 Remove the sample vials from the tumbler and centrifuge for 4-10 minutes to separate the phases. To ensure vial integrity, the centrifuge speed must not exceed 1400 RPM – centrifuging at higher speeds risks

breakage.

If the phases do not separate, then centrifuge in subsequent 4-10 minute intervals until separation does occur, or use other mechanical or physical techniques to break the emulsion. Adding sodium sulfate to the top of the emulsion and subsequently centrifuging the sample will frequently break the emulsion as the sodium sulfate is "pulled through" it. Other approaches include freezing the emulsion or filtering through glass wool or sodium sulfate. Consult with Department Supervisor.

8.1.10 For each sample, use a clean disposable glass pipet to carefully transfer most of the top hexane layer into an appropriately labeled extract vial. Avoid transferring any solid material. **Total recovery of the hexane layer is not required because the concentration of target and surrogate compounds is assumed to be consistent throughout the hexane layer.** Cap the extract vial tightly.

8.1.11 Observing internal chain-of-custody procedures (SOP 318), deliver the extractable petroleum hydrocarbon extracts to the Fuels Group for storage and analysis.

8.2 EXTRACTION OF AQUEOUS SAMPLES

8.2.1 Kilned, dedicated volumetric flasks are used for extraction of aqueous petroleum hydrocarbon (DRO) samples. Note that because a plastic syringe is used for quantitative measurement of the sample aliquot, these flasks are *not* used in a volumetric capacity.

Assemble a sufficient number of flasks and cover the bottom of each with a layer of kilned sodium sulfate (Na_2SO_4). Label each flask with the appropriate sample number.

8.2.2 Mixing each aqueous sample prior to taking an aliquot is necessary in order to ensure that the aliquot is representative. For each client sample, use a clean 60mL plastic syringe to deliver 160mL of representative sample into the flask designated for that sample. If sufficient sample volume is present, choose one sample (per batch of twenty or fewer client samples) and measure two additional aliquots of sample (one each) into two labeled flasks to serve as the MS/MSD pair.

8.2.3 For each batch of twenty (or fewer) client samples processed, prepare one aqueous matrix method blank (MB) and an aqueous matrix laboratory control sample (LCS). Note that ALSLG-FC typically also prepares a laboratory control sample duplicate (LCSD) per batch. Use a (single) clean 60mL plastic syringe to measure a total volume of 160mL DI water into each volumetric flasks labeled as the MB, LCS and LCSD.

8.2.4 Add the appropriate amount (typically 0.8mL) of surrogate solution to each prepared flask of environmental or QC sample.

NOTE: Use acetone as the solvent rinse for the syringe.

8.2.5 Add the appropriate amount (typically 0.8mL) of petroleum hydrocarbon (DRO) spiking solution to each of the LCS, LCSD, MS and MSD samples.

8.2.6 Add 4.0mL of hexane to each environmental and QC sample.

8.2.7 Tightly cap each prepared sample flask and manually shake each one for two minutes. Allow the contents to settle. If an emulsion forms, transfer the sample to a suitable labeled vial and centrifuge. Addition of more sodium sulfate may help to break the emulsion.

8.2.8 If necessary, add enough DI water to bring the hexane layer to an accessible position in the neck of each flask.

8.2.9 For each sample, use a clean disposable glass pipet to carefully transfer most of the hexane layer from the neck of the flask into an appropriately labeled extract vial. Avoid transferring any of the aqueous layer. **Total recovery of the hexane layer is not required because the concentration of target analyte is assumed to be consistent throughout the hexane layer**.

8.2.10 Cap each extract vial tightly. Observing internal chain-of-custody procedures (SOP 318), deliver the petroleum hydrocarbon extracts to the Fuels Group for storage and analysis.

9. QUALITY CONTROL

9.1 DEFINITION OF BATCH

For this method, a preparation batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the MB, LCS, MS and laboratory duplicate (an LCSD or MSD, r both, can serve as the laboratory duplicate). All QC samples must be carried through all stages of the sample preparation and measurement steps.

9.2 METHOD BLANK

MBs are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the solid matrix method blank consists of 20g of kilned Ottawa sand, and the aqueous method blank consists of 160mL organic-free DI water. See QC Table of SOP 406 for acceptance limits.

9.3 LABORATORY CONTROL SAMPLE

The LCS is analyzed to measure the accuracy of the method in a controlled matrix. A known amount of analyte is prepared and analyzed. For this method, 20g of kilned Ottawa sand (solid matrix) and 160mL organic-free DI water (aqueous matrix) are used for the LCS. See QC Table of SOP 406 for acceptance limits.

9.4 MATRIX SPIKE SAMPLE

The MS sample is analyzed to assess the effect of matrix interferences upon the sample analysis. A known amount of analyte is spiked into a replicate aliquot of a selected sample and analyzed. See QC Table of SOP 406 for acceptance limits.

9.5 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. The LCS, MS, or both may be analyzed in duplicate to serve this purpose. Precision is expressed as Relative Percent Difference (RPD). RPD calculations are discussed in SOP 406. See QC Table of SOP 406 for acceptance limits.

10. DEVIATIONS FROM THE METHOD

The extraction procedures documented in the SOP have been developed in-house and are not based on a particular published method. There are, therefore, no deviations from a promulgated method.

11. HEALTH, SAFETY, AND WASTE DISPOSAL

11.1 HEALTH AND SAFETY

11.1.1 Read the appropriate MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). **As hexane has a TLV ≤ 50ppm, the preparation steps in this procedure which require addition of hexane must be carried out in an adequately ventilated fume hood.**

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name; NFPA Health, Flammability and Reactivity ratings; and date.

11.2 WASTE DISPOSAL

11.2.1 Hexane may be disposed of in the Acetonitrile/Non-halogenated Waste

stream.

11.2.2 Aqueous sample waste shall be disposed of in one of the Aqueous Lab Waste streams (radioactive or non-radioactive, as appropriate).

11.2.3 Solid sample waste shall be air-dried and disposed of in one of the Contaminated Soils and Solids waste streams (radioactive or non-radioactive, as appropriate).

11.2.4 Extract vials and associated extracts are disposed of by the analytical group into the appropriate extract and vial waste container.

11.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

DOCUMENT REVISION HISTORY

11/20/07: Updated LIMS program specification language Section 3.3. Revised Section 6.7 Surrogate and Spiking Solutions (removed detail and referenced SOPs 406 and 300 instead). Minor clarifications made to Section 8. Removed acceptance limits from Section 9 and referenced QC Table of SOP 406 instead. Added DOCUMENT REVISION HISTORY and Form.

2/12/09: Updated laboratory references to ALSLG-FC. Changed Title, and made DRO references more generic to accommodate alternate use of State-specific protocols. Listed acetone in reagents, and identified use of acetone for syringe rinse. Amended hexane volumes added in Section 8. Added Appendix A – FL-PRO.

APPENDIX A

HYDROCARBON EXTRACTION VIA THE FL-PRO METHOD

1. SCOPE AND APPLICATION

The procedural particulars given in this Appendix supercede the guidance given in the main body of SOP 603. The procedures depicted in this Appendix are applicable to the preparation of aqueous and solid matrix samples to be subsequently analyzed by the Florida Residual Petroleum Organic Method (FL-PRO).

2. SUMMARY

The FL-PRO Method is designed to measure concentrations of extractable petroleum hydrocarbons in water and soil in the alkane range of C_8-C_{40}. The method is based on solvent extraction, followed by GC-FID analysis. Other organic compounds, including chlorinated hydrocarbons, phenols, and phthalate esters, are measurable by this procedure, thus the resultant EPH results include these compounds.

A volume of sample is spiked with two surrogates then extracted using Methylene Chloride. The extract is concentrated, then treated with silica gel. The silica gel cleanup is a mandatory part of the procedure, designed to remove potential interferences from animal and vegetable oil, and grease and biogenic terpenes.

3. RESPONSIBILITIES
INTERFERENCES
APPARATUS AND MATERIALS
SOLVENTS AND REAGENTS

Refer to SOP 603 main text.

4. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

Certain sampling considerations apply, refer to Method for more details.
Water samples must be acidified to pH<2 with HCl or H_2SO_4.
All samples must be stored at 4±2°C until extraction.
Extraction must be performed within 7 days of collection for aqueous samples, and within 14 days of collection for solid samples.
All analyses must be performed within 40 days of extraction.

5. STANDARDS

Both surrogate and spike standard is specific to this test:

5.1 Surrogate standard contains o-terphenyl at 100ug/mL, and nonatriacontane at 600ug/mL (in acetone). Note: These concentrations are 2X those specified in the Method (Section 7.4.1), which says to add 2mL of surrogate solution. ALSLG-FC will add 1mL, therefore the doubling in concentration.

5.2 Spike contains even-numbered straight-chain alkanes from C_8 to C_{40}. The water spiking solution should be 5000ug/mL Total PHS, and the soil spike should be 3000ug/mL Total PHS (Petroleum Hydrocarbon Standard). 1mL of spike will give the required concentrations in the sample.(Method Section 7.4.3, 7.4.4).

6. PROCEDURES

6.1 EXTRACTION OF SOLID SAMPLES
10g of sample is extracted by Soxhlet (SOP 625) for 18-24 hours. (Method Section 9.1.5).

6.2 EXTRACTION OF AQUEOUS SAMPLES
1L of sample is extracted with dichloromethane by CLLE (SOP 617) for 18-24 hours. (Method Section 9.1.3).

6.3 EXTRACT CONCENTRATION
Dry and concentrate the samples using KD apparatus (SOP 607) to a final volume of 2.0mL. N-Evap (SOP637) may also be used to achieve final volume of 2.0mL. If the extract is highly colored or a precipitate forms during concentration, the final volume should be higher (5-10mL)(Method Section 9.1.2.10 thru 10.1.2.16)

6.4 SILICA GEL CLEANUP
Silica gel cleanup is mandatory for this procedure. Add 0.3g of loose silica gel to the extract and shake the mixture for 5 minutes, or pass the extract through a silica gel solid-phase extraction cartridge that has been conditioned with 5mL of dichloromethane. (Method Section 9.1.6.1)

6.5 Observing internal chain-of-custody procedures (SOP 318), deliver the petroleum hydrocarbon extracts to the Fuels Group for storage and analysis.

7. QUALITY CONTROL

See SOP 603 main text.

8. DEVIATIONS FROM THE METHOD

No technical deviations.

9. HEALTH, SAFETY, AND WASTE DISPOSAL

See SOP 603 main text.

STANDARD OPERATING PROCEDURE 604 REVISION 8

TITLE: SILICA GEL CLEANUP -- METHOD SW3630C

FORMS: 605, 609 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-14-07

QUALITY ASSURANCE MANAGER _____ DATE 11/13/07

LABORATORY MANAGER _____ DATE 11-14-07

HISTORY: Rev0, 12/12/91; Rev1, PCN #75, 1/6/94; Rev2, PCN #361, 2/17/95; Rev3, 7/15/99; Rev4, 11/18/99; Rev5, 4/9/02; Rev6, 2/13/04; Rev7, 2/27/06; Rev8, 11/12/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes procedures for the cleanup of polar interferences from extracts. This procedure is adapted from SW-846 Method 3630C. This procedure is primarily used to clean up extracts intended for analysis of Polynuclear Aromatic Hydrocarbons (PAHs).

2. SUMMARY

The extract from a sample is brought to a known volume and exchanged into the appropriate solvent (see SOPs 607 and 637). The extract is eluted through a column (or cartridge) of silica gel to remove interfering contaminants. The volume of the processed extract is then reduced using Kuderna Danish apparatus, after which the extract is exchanged into appropriate solvent and/or blown down to volume. The extract is then submitted for analysis. For extract volumes of 2mL or more, only an aliquot of the extract is cleaned up, with the remainder of the extract being reserved in the event of problems occurring during the cleanup stage.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all benchsheets or other documentation required for review.

3.2 These procedures are performed in the laboratory by personnel who have demonstrated the ability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the processing of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Method SW3630B states that phthalate esters have been detected in extracts processed with solid phase extraction cartridges. Phthalate esters are not typically analyzed as part of the process described here. However, phthalate esters may interfere with subsequent analysis by UV or other detectors. A method blank shall be prepared and analyzed with each sample set to monitor this potential interference.

5. APPARATUS AND MATERIALS

5.1 buret or chromatography column with Teflon™ stopcock, 250mm length, 10mm ID, or as suitable

5.2 Erlenmeyer flasks, various sizes

5.3 beakers, various sizes

5.4 graduated cylinders, 25 and 50mL

5.5 Pasteur pipettes, glass

5.6 buret clamps or wooden funnel racks

5.7 ring stands

5.8 wooden spatula handle or equivalent (for tapping column)

5.9 top loading balance, 0.01g sensitivity

5.10 glass wool

5.11 syringes, 5mL or as needed

5.12 vacuum manifold - VacElute Manifold SPS-24 (Analytichem International) or equivalent, consisting of glass vacuum basin, collection rack, and funnel, collection vials, replaceable stainless steel delivery tips, built-in vacuum bleed valve and gauge. The system is connected to a vacuum pump or water aspirator through a vacuum trap made from a 500mL sidearm flask fitted with a one-hole stopper and glass tubing.

6. REAGENTS - Only reagent grade or better chemicals shall be used.

6.1 silica gel cartridges, commercially prepared, Burdick and Jackson #7058G, 1g or equivalent

6.2 silica gel, 100/200 mesh, EM #SX01436-1 or equivalent
Activate in a foil-covered glass beaker at approximately 130°C for about 16hrs prior to use. Store in approximate 130°C oven when not in use.

6.3 sodium sulfate (Na_2SO_4), anhydrous, ACS granular. Purify by heating at approximately 400°C (kiln) for 2-6 hours.

6.4 SOLVENTS – **use only pesticide or HPLC grade.**

hexane	C_6H_{14}
acetone	CH_3COCH_3
methanol	CH_3OH
methylene chloride	CH_2Cl_2

7. COLUMN PROCEDURE

7.1 Collect apparatus and reagents for silica gel cleanup prior to beginning the solvent exchange (methylene chloride to hexane) process.

7.2 The solvent exchange process is described in SOP 607. Follow solvent exchange procedure, and adjust the extract volume to 2.0mL for silica gel cleanup. Decreased or increased final volume may be necessary for some extracts.

7.3 **This process must be performed in a fume hood. The dry silica gel is very fine-grained and can become airborne if not handled carefully. If inhaled, the fine particles pose a health risk.** Set up the chromatography columns as follows:

7.3.1 Plug the column with glass wool and rinse column thoroughly with methylene chloride. Leave column full and receiver 1/4 full with methylene chloride.

7.3.2 Tare a 150mL beaker on a top loading balance. Add approximately 10g of silica gel to the tared beaker. When the gel has settled in the beaker, check the weight. Add (or remove) gel to reach 10g.

7.3.3 A slurry of silica gel and methylene chloride can be made in the beaker to assist transfer to the column. Slowly pour the 10g of slurry from the beaker into the chromatography column. Rinse the beaker and column with enough methylene chloride to wash any remaining silica gel slurry into the column.

7.3.4 Place a beaker below the column. Open the stopcock on the column. Using a wooden spatula, gently tap the column to settle the silica gel slurry and remove all air. Rinse the reservoir to help settle the gel. Collect the eluting methylene chloride in a waste beaker.

7.3.5 After the silica gel slurry has settled completely, add a layer of sodium sulfate (1-2 cm thick) to the top of the column. Continue eluting the methylene chloride until the meniscus is just above the sodium sulfate layer.

7.3.6 GENERAL COMMENTS ON COLUMN LOADING AND ELUTING

- It is acceptable to stop the column flow at any time.
- It is not advisable to load and elute more than 5 samples at one time.
- If at any point during elution, the column virtually or actually stops dripping, poke the Na_2SO_4 at the top of the column with a long tipped pipette.
- All elution rates should be approximately 2 mL/min or less.
- Do not let the silica gel go dry after the rinse described in Step 7.4 below, until all eluent is collected at the end (i.e., Step 7.10).

7.4 Elute each column with 40mL hexane. Collect the eluent in a waste beaker and discard. Stop the elution when the meniscus of the hexane is just above the sodium sulfate layer.

7.5 Add the extract to the column. When the meniscus of sample is just above the sodium sulfate layer, rinse the concentrator tube with 2mL of hexane and add the rinsate to the column. Continue elution, collecting the eluent in a waste beaker.

7.6 Just prior to exposure of sodium sulfate, add 25mL hexane and continue elution.

7.7 Just prior to exposure of sodium sulfate, close stopcock to stop flow.

7.8 Position a 50mL Erlenmeyer flask beneath the column. Add 25mL of 90/10 hexane/methylene chloride and elute at a rate up to 2mL/min.

7.9 When the meniscus reaches the sodium sulfate, add 35mL of 60/40 (3:2) hexane/methylene chloride, and restart elution at a rate of up to 2mL/min.

7.10 When the column has stopped dripping, the collected fraction of the extract is concentrated to final volume as well as changed over to the final solvent per SOPs 607 and 637.

7.11 Complete benchsheets and observe proper internal chain-of-custody procedures (SOP 318) to deliver the extracts to the appropriate analytical area.

8. CARTRIDGE PROCEDURE

8.1 Place cartridge on the manifold. Condition the cartridge by eluting 5mL of methylene chloride at less than 2mL/min. flow rate into a waste tube. **Do not pull air through the cartridge after the conditioning has started, until Step 8.3 (elution) is complete.** The 2nd conditioning step is to elute 5mL hexane at less than a 2mL/min flow rate. **Do not let the silica gel in the cartridge go dry.**

8.2 Replace waste tube with a clean collection tube. Load entire extract (assuming 1 or 2mL volume) onto cartridge after exchange to hexane (described in Step 7.2). Just before the top of the cartridge goes dry, go to Step 8.3 below to elute targets.

8.3 To elute targets, add 4-5mL of 10/90 methylene chloride/hexane. When only a few millimeters of this eluting solvent remains above the gel, add 4-5mL more of 10/90 methylene chloride/hexane. When the 2nd portion of elution solvent has passed through the cartridge, the collection tube contains the cleaned up extract.

8.4 Bring the cleaned up extract to a final volume and appropriate solvent per SOPs 607 and 637.

8.5 Complete benchsheets and observe proper internal chain-of-custody procedures (SOP 318) to deliver the extracts to the appropriate analytical area.

8.6 Note that the cartridge procedure has less capacity to clean up interferences than the column procedure described in Section 7, because the cartridges contain less adsorbent material (1g versus 10g).

9. QUALITY ASSURANCE

The quality control (QC) samples associated with the sample extracts that are cleaned up using this procedure *must also* be processed through this cleanup method.

10. DEVIATIONS FROM THE METHOD

10.1 The extract is exchanged into hexane instead of cyclohexane prior to loading onto column or cartridge.

10.2 Hexane is used instead of pentane wherever referenced in SW3630. Pentane boils at very close to room temperature at Paragon's elevation.

11. SAFETY, HAZARDS AND WASTE

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 The silica gel and/or cartridges are disposed of in the Contaminated Soils and Solids waste.

11.2.2 Any hexane, acetonitrile, or other nonhalogenated organic solvents may be disposed of in the acetonitrile/Nonhalogenated waste.

11.2.3 Any methylene chloride waste may be disposed of in the halogenated solvent waste.

11.2.4 Empty solvent bottles are to be properly disposed. Please note that all labels and markings must be defaced prior to disposal.

LABORATORY MANAGER _____ DATE 11-12-07

HISTORY: Rev0, 2/13/92; Rev1, PCN #100, 1/20/94; Rev2, PCN #371, 2/17/94; Rev3, 2/18/99; Rev4, 10/25/99; Rev5, 4/6/02; Rev6, 12/5/02; Rev7, 3/6/04; Rev8, 2/27/06; Rev9, 11/12/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the drying of extracts followed by concentration using a Kuderna-Danish (K-D) apparatus and a steam bath or water bath. This procedure can also be used to exchange the extract from one solvent to another (e.g., methylene chloride to hexane).

2. SUMMARY

Extraction of samples is described in SOP 617 (Method SW3520C), SOP 625 (Method SW3540C), SOP 626 (Method SW3510C), and SOP 664 (Method SW8151A). These processes extract the water-insoluble and slightly water-soluble organic compounds from aqueous and solid samples in preparation for analysis by various determinative chromatographic procedures.

This SOP addresses the drying and concentration of extracts using a Kuderna-Danish apparatus over a steam or water bath. The extracts are dried by passing them through a column of anhydrous sodium sulfate as they are loaded into the K-D apparatus. Concentration is accomplished by using the K-D apparatus to reflux the solvent at a temperature high enough to cause excess solvent to evaporate, while collecting the organic compounds of interest in the concentrator tube attached to the bottom of the apparatus.

Final concentration of the extract using the nitrogen blowdown technique is described in SOP 637. An alternative solvent exchange procedure is also discussed in SOP 637.

3. RESPONSIBILITIES

3.1. It is the responsibility of the analyst to perform the procedure according to this SOP and to complete all benchsheets or other documentation required for review.

3.2. Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training

review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3. Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4. The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of the measures taken to correct the errors.

3.5. All personnel who work with samples involving this method have a responsibility to note any anomalies or out-of-control events associated with the processing of the samples. Any anomalies or discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1. Solvents, reagents, glassware and other hardware used in this procedure may yield artifacts and/or interferences to sample analysis. Refer to SOP 334 for guidance on glassware cleaning.

4.2. Phthalate esters are present in many types of products commonly found in the laboratory. In particular, samples and sample extracts must not be allowed to come into contact with plastics and latex products, as phthalates are easily extracted from these materials. Phthalate contamination may result if such contact occurs.

5. APPARATUS AND MATERIALS

5.1. Kuderna-Danish (K-D) apparatus consisting of the following:

concentrator tube, graduated, 10mL or other appropriate size

evaporation flask, attached to concentrator tube with a clip, 500mL or other appropriate size

macro Snyder column, 3-ball

5.2. funnels, steel or borosilicate glass

5.3. glass wool, solvent-rinsed

5.4. boiling chips, Teflon™ or silicon carbide, solvent-rinsed, approximately 10/40 mesh

5.5. Pasteur pipets, borosilicate glass, disposable

5.6. steam bath, Organomation S-Evap Model 120 or equivalent

5.7. steam generator, Chromalox Model CM13-9 or equivalent

5.8. glass syringes, 1mL or as appropriate

5.9. vials, glass, with PTFE-lined caps of appropriate size

6. REAGENTS - Only reagent grade or better chemicals shall be used.

6.1. Sodium sulfate (Na_2SO_4), granular. Purified at approximately 400 °C (kilned) for 2-4 hours in a shallow tray. The sodium sulfate and scoop are kept in a closed container to prevent contamination.

NOTE: Take care to check specific tests being performed. Some extraction processes require use of acidified sodium sulfate to avoid loss of target analytes. Examples are Methods SW8151A, EPA 615 or EPA 515.1.

6.2. SOLVENTS - **All solvents must be pesticide residue grade or equivalent**

methylene chloride (CH_2Cl_2)

hexane (C_6H_{14})

acetonitrile (CH_3CN)

methanol (CH_3OH)

7. PROCEDURE

7.1 Assemble a Kuderna-Danish concentrator by attaching a 10mL concentrator tube to a 500mL evaporative flask with a clip. Drop one or two prepared boiling chips into the concentrator tube. Boiling chips are necessary to keep the solvent from "bumping".

7.2 Prepare a drying column for each extract by placing a plug of prepared glass wool in the neck of a funnel. Pour a layer of prepared sodium sulfate on top of the glass wool so that the funnel is approximately ½ full.

7.3 Rinse the sodium sulfate drying column thoroughly with methylene chloride (or the appropriate extraction solvent, if other) and discard this rinse. Three rinses with 20-30mL of solvent are typical of this process.

7.4 Prior to pouring the sample through the drying column, look for the presence of water in the round bottom flask containing the extract. If it appears that there is water in the extract, add more sodium sulfate to the funnel and swirl prior to pouring the extract through the column.

7.5 Place a rinsed drying column into the upper opening of the K-D setup and slowly pour the extract through the sodium sulfate. After all of the extract is poured through the drying column, rinse the round bottom flask or other glassware containing the extract three times with 5-10mL methylene chloride (or other appropriate extraction solvent), and pour these rinses through the drying column. The three rinses are to ensure quantitative transfer of the extract to the Kuderna-Danish apparatus. Rinse the funnel with additional methylene chloride (or other appropriate solvent) and pass the rinse through the drying column.

NOTE: During this process, monitor the condition of the sodium sulfate to determine that the bed of sodium sulfate is not solidifying and exceeding its drying capacity. If the sodium sulfate bed can be stirred and is still free flowing, effective moisture removal from the extracts is occurring. If the sodium sulfate bed has begun to "cake", do not add more extract. Prepare another drying column as described above, re-dry the contents of the K-D flask, and continue drying the extracts.

7.6 Remove the funnel, pour the sodium sulfate contents onto a piece of foil located in a fume hood, and allow to dry.

7.7 Wet a 3-ball Snyder column with 1-2mL methylene chloride (or other appropriate solvent) poured through the top of the column. Repeat the rinse. Attach the 3-ball Snyder column to the K-D apparatus.

7.8 Place the K-D apparatus on the S-Evap so that the concentrator tube is completely in the S-Evap and the entire rounded lower surface is bathed with hot vapor from the steam generator.

7.9 Adjust the steam per manufacturer settings so that the proper rate of distillation is achieved. At the proper rate of distillation, the balls in the column will actively chatter, but the chambers will not flood.

7.10 When the apparent volume of the extract reaches 4-5mL, and if no solvent changeover is needed, remove the K-D apparatus from the S-Evap and allow it to drain and cool for at least 10 minutes with the 3-ball Snyder column in place.

NOTE: If extract volume cannot be reduced to an apparent volume of 4-5mL in a reasonable amount of time, the K-D procedure should be stopped as little or no solvent is likely remaining in the K-D apparatus. Target compounds may be lost if continued heating takes place and no solvent is left in the apparatus. A final volume of 10mL or greater is likely to be necessary if this occurs. Record on the benchsheet why the extract could not be further concentrated. Consult with the Extractions Group Leader or the Department Manager if other questions arise.

7.11 If solvent exchange is required at this point, dispense 20-50mL of the exchange solvent (5-10 times the volume of the extract in the concentrator tube is required for a successful exchange) through the Snyder column while the concentrator remains on the bath. Again concentrate the extract, raising the temperature of the S-Evap, if necessary, to maintain proper distillation. Exchange solvents that are typically used are listed in **Table 1**. Remove the K-D apparatus from the S-EVAP and allow to drain and cool for 10 minutes with the Snyder column in place.

7.12 After cooling, wipe any water remaining around the lower joint using an absorbent towel or Kim-Wipe™. Remove the Snyder column and rinse the flask and its lower joints into the concentrator tube with 1-2mL of methylene chloride or other appropriate solvent to ensure quantitative transfer of the material from the flask to the concentrator tube. Remove the plastic clip and detach the concentrator tube.

7.13 If a desired final volume below 5-10mL is needed, proceed using the nitrogen blowdown procedure (SOP 637). Nitrogen blowdown is generally not needed for methods where final extract volume is 10mL, (e.g., Methods SW8081 and SW8082). For these methods, the extract is brought to final volume during the quantitative transfer to a glass vial, which is then capped with a PTFE-lined screw cap. The extracts are then delivered to the appropriate analytical group for refrigerated storage. Internal chain of custody procedures (SOP 318) must be observed.

8. QUALITY ASSURANCE

8.1 All sample extracts and associated quality control sample extracts must be processed in the same manner using this procedure.

8.2 Re-extraction of the sample may be warranted if any of the following should occur:

The extract is concentrated to dryness.

The extract is found to contain both water and the extraction solvent after concentrating due to a loose connection between the concentrator tube and the K-D flask.

The extract is concentrated too rapidly (excessively high temperature). This may cause target analyte loss.

More than 1% of the extract is spilled while pouring through sodium sulfate.

8.3 If re-extraction is not possible due to extenuating circumstances (i.e., no sample remaining, past holding time), the extract should be kept and the benchsheet noted accordingly. Notify the Department Manager and the Project Manager so that the client can be apprised of the situation immediately, and initiate a Non-Conformance Report (NCR) per SOP 928 immediately.

9. DEVIATIONS FROM THE METHOD

This SOP meets the requirements of SW-846 Chapter 4 methods. There are no known deviations from the methods referenced in this procedure (SW3510C, SW3520C, SW3540C, SW8151A).

10. SAFETY, HAZARDS AND WASTE DISPOSAL

10.1 SAFETY AND HAZARDS

10.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

10.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

10.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). **Since methylene chloride, hexane and acetonitrile have TLVs ≤ 50ppm; the work described in this procedure must be carried out within an adequately ventilated fume hood.**

10.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

10.1.5 High-pressure steam presents severe burn hazards to humans. If it comes into contact with human tissue, the steam will rapidly cool and condense and in the process will deposit 550 calories of heat per gram of steam into the tissue. This can result in a very severe burn. **Use extreme care around sources of steam to prevent a steam burn.**

10.2 WASTE DISPOSAL

10.2.1 Hexane, acetone, or other nonhalogenated organic solvents may be disposed of in the Acetonitrile/Nonhalogenated Waste.

10.2.2 Dichloromethane (methylene chloride) is disposed of in the Halogenated Organic Waste satellite collection vessel.

10.2.3 Disposal of sample wastes are discussed in the appropriate extraction SOP.

10.2.4 The analytical groups responsible for analysis of the extracts shall dispose of the extracts and extract vials via the appropriate waste streams.

10.2.5 All empty solvent bottles shall be disposed of appropriately. Note that all labels and markings on solvent bottles must be defaced prior to disposal.

10.2.6 Dried sodium sulfate and glass wool are disposed of in the contaminated

soils and solids satellite area bucket.

1. **Water inlet valve**
2. **Steam blowout valve**
3. **Steam valve**
4. **Boiler switch knob**
5. **Steam pressure gauge**

Steam Generator Start up

1. Check to see if steam blowout valve[2] is closed. (perpendicular to pipe) If not close it.
2. Open water inlet valve[1]. (parallel to pipe)
3. Turn boiler switch knob[4] on to 250. If boiler switch light does not come on re-check in five minutes. Light should be on. If light is not coming on contact supervisor.
4. After approximately 30 minutes Steam pressure gauge[5] should read between 20-60 psi. If not, wait until desired pressure is reached.
5. Open steam valve[3]. (parallel to pipe)

Steam Generator Shutdown

Caution: Pipes and Generator will be hot!

1. Turn boiler switch knob[4] to OFF
2. Close water inlet valve[1]. (perpendicular to pipe)
3. Close steam valve[3]. (perpendicular to pipe)
4. SLOWLY* open steam blowout valve[2]. (parallel to pipe)

**Caution: Do not open blowout valve fully until a majority of the steam is released. The tubing carrying the steam outside may come out of the wall.*

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3-4-08

QUALITY ASSURANCE MANAGER Deb Schad DATE 3/4/08

LABORATORY MANAGER _____ DATE 3-4-08

HISTORY: Rev0, 4/8/92; Rev1, 7/18/92; Rev2, 3/1/93; Rev3, PCN #101, 1/21/94; Rev4, 9/18/94; Rev5, 3/15/96; Rev6, 3/1/99; Rev7, 10/25/99; Rev8, 10/25/01; Rev9, 3/6/03; Rev10, 5/12/04; Rev11, 3/9/06; Rev12, 3/4/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW-846 Method 1311 -- are designed to determine the mobility of volatile organic compounds (VOCs) present in liquids, soils, and wastes (including multiphasic samples). Application of these procedures to matrices other than those specified will be handled individually to simulate the leaching procedure as best as possible.

2. SUMMARY OF METHOD

For liquid wastes (i.e., those containing less than 0.5% dry solid material) the waste, following filtration through a 0.6 to 0.8µm glass fiber filter, is defined as the ZHE extract (leachate).

For wastes containing greater than or equal to 0.5% solids, the particle size of the waste solid phase is reduced when necessary. The liquid, if any, is separated from the solid phase in order to determine the percent solids in the sample. The solid phase is then extracted with an amount of extraction fluid equal to twenty (20) times the weight of the solid phase. For volatiles analysis only Fluid #1 is used. A special extractor vessel for volatile compounds is used in this procedure. Following extraction, the liquid extract (leachate) is separated from the solid phase by filtration through a 0.6 to 0.8µm filter.

If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is typically added back to the solid phase prior to addition of Fluid #1 and leaching. If incompatible, the initial liquid phase is analyzed separately from the leachate and the results are mathematically combined to yield a volume-weighted average concentration.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the logbooks, analytical review sheets or case narratives indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work and documentation of the measures taken to remedy any errors found in the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Major contaminant sources are volatile materials in the laboratory. Analyses of reagent blanks provide information about the presence of these contaminants. The ZHE vessels are thoroughly cleaned between uses. The vessel number used for each sample or blank is recorded in the logbook. The same vessel is not to be used repeatedly for the blank - all vessels must be used for the blank on a rotating basis.

5. APPARATUS AND MATERIALS

5.1 **Zero-Headspace Extraction vessel (ZHE),** ADAM 3745 ZHE or equivalent. These devices are used when the mobility of VOCs are of concern. The ZHE allows for liquid-solid separation (within the device), extraction, and final extract filtration without opening the vessel. Thus, headspace and potential loss of volatiles from this closed system is effectively precluded. The ZHE have an

internal volume of 500-600mL and are equipped to accommodate a 90-100mm diameter filter. The devices utilize Viton™ o-rings to form a seal. These o-rings should be inspected before each use and may need to be replaced if they show signs of wear or damage.

For the ZHE vessel to be acceptable for use, the piston within the ZHE should be mobile with approximately 15psi or less (it is helpful to first moisten the piston o-rings slightly with extraction fluid). If it takes more pressure to move the piston, the o-rings in the device should be replaced. If replacing the o-rings does not solve the problem, the ZHE is unacceptable for TCLP analyses and the manufacturer should be contacted for re-machining.

Each ZHE device contains a built-in pressure gauge. The gauge should be frequently monitored to ensure that the ZHE is free of leaks throughout the extraction process. If the gauge indicates that the ZHE is not holding pressure correctly, or if the device shows other signs of a leak, pressurize the device to 50psi, allow it to stand unattended for 1 hour, and recheck the pressure. The ZHE can also be submerged in water after pressurization to check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace o-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted. If new ZHE are purchased, they must successfully pass this pressurization test prior to being used for sample analysis.

The ZHE vessel is used for filtration of the final ZHE extract. The ZHE vessel must be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50psi). When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE vessel.

5.2 **Pressure filtration device**, Associated Design and Manufacturing Model 3750-LHWF or equivalent. A.K.A. “lunar lander”.

5.3 pH meter, accurate to $\pm$0.05 pH units @ 25°C.
Meter must be calibrated prior to use (see Form 825).

5.4 **Fiber filter**, borosilicate glass, free of binder materials, 0.6 to 0.8µm particle size. *Pre-filters must not be used.* Glass fiber filters are fragile and should be handled with care. Use Gelman #66256, 90mm or equivalent, and/or Whatman #6890-2507, 25mm or equivalent.

5.5 VOA vials, 20mL or 40mL, septum seal, certified ‘clean’.

5.6 laboratory balance, accurate to ±0.01g.

5.7 centrifuge, Fisher Scientific Marathon 10k or equivalent.

5.8 drying oven, capable of maintaining 100±20°C.

5.9 apparatus for pressurizing ZHE's: Ultra high-purity Nitrogen tank, regulator (set to around 60psi), hose, and adapter for attachment to ZHE and pressure filtration device ("lunar lander").

5.10 rotary tumbler with 30±2rpm capability, Associated Design and Manufacturing Model 3740 or equivalent.

5.11 **ZHE Extract Collection Devices**, used to collect the initial liquid phase and the final extract of the waste. Plastic gas-tight syringes (50-60mL with Luer-Lok® fitting) or TEDLAR® bags may be used. Following collection, the extract is filtered during transfer to a 'VOA' vial (20 or 40mL volume) to meet the method requirements for storage in minimal headspace conditions until time of analysis. The devices listed are recommended for use under the following conditions:

5.11.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1% of total waste), a syringe should be used to collect and combine the initial liquid and solid extract.

5.11.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1% of total waste), the syringe or the TEDLAR® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

5.11.3 If the waste contains no initial liquid phase (is 100% solid) or has no significant solid phase (is 100% liquid), either the TEDLAR® bag or the syringe may be used. If the syringe is used, discard the first 5mL of liquid expressed from the device. The remaining aliquots are used for analysis.

6. REAGENTS - Only reagent grade or better chemicals shall be used.

6.1 **reagent water**: defined as water in which an interferent is not observed at or above the method's detection limit of the analyte(s) of interest.

6.2 **glacial acetic acid (HOAc)**

6.3 **sodium hydroxide (NaOH), 12M**: Add 480g NaOH to 1000mL reagent water; mix thoroughly.

6.4 **Extraction Fluid #1**: Add several liters reagent water to a 22L container. Add 125mL HOAc and 140mL 12M NaOH. Bring final volume to 22L with reagent water. Mix thoroughly. pH must be 4.93±0.05.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 All samples should be collected using an appropriate sampling plan.

7.2 There may be requirements on the minimal size of the field sample, depending upon the physical state of the waste and the analytes of concern. An aliquot is needed for the preliminary evaluations of percent solids and particle size. Another aliquot may be needed to actually conduct the nonvolatile extraction. An additional aliquot is needed for the volatile organics extraction. Quality control (QC) samples may require additional aliquots. Further, it is wise to collect additional sample in case something goes wrong with the initial attempt to conduct the test.

7.3 Preservatives shall not be added to samples before extraction.

7.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

7.5 Because the samples are to be analyzed for volatiles, care shall be taken to minimize their loss; samples shall be collected and stored accordingly. Samples should be collected in glass jars with Teflon®-lined lids and stored at 4±2°C. (although EnCore® samplers may also be used for sample collection, their limited sampling capacity makes them less desireable for this procedure). Samples should only be opened immediately prior to extraction.

7.6 TCLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Maximum hold times are:

Sample Holding Times [days]

	Time from field collection to TCLP leaching	Time from ZHE-TCLP leaching to determinative analysis
Volatiles	14 days	14 days

8. PROCEDURES

8.1 PRELIMINARY EVALUATION

Preliminary evaluation includes: (1) determination of percent solids; (2) determination of whether or not the waste contains insignificant solids and is, therefore, its own extract after filtration; and (3) determination of whether or not the solid portion of the waste requires particle size reduction (if required, procedure is described in SOP 609).

NOTE: Even if only the volatile TCLP extraction is being done, it is often useful to perform the (initial) phase separation in order to determine the optimum sample aliquot with which to charge the ZHE. The experienced prep analyst may, however, choose to forego this procedure, as percent solids determination is also conducted as part of the procedure in determining the amount of extraction fluid to add (Steps 8.2.3 through 8.2.5).

Select samples and record on benchsheet. Perform preliminary TCLP evaluations on a minimum 100g aliquot of waste (if there is insufficient sample or it is impractical to use 100g, notate on benchsheet).

8.1.1 DETERMINATION OF PERCENT SOLIDS
PHASE SEPARATION

8.1.1.1 **Percent solids** is defined as that fraction of a waste sample (as a percentage of the total sample), from which no liquid may be forced out by an applied pressure, as described below. Visual inspection may be sufficient for this determination.

If the sample will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids), then proceed to Section 8.1.3 - Particle Size Reduction Determination.

8.1.1.2 **Phase Separation**. If the sample is liquid or multiphasic, liquid/solid separation is required to make a preliminary determination of percent solids. This involves the filtration device described in Section 5.2, and performance of the procedures outlined below:

8.1.1.2.1 Pre-weigh the filter, spatula, and beaker that will receive the filtrate. Record the weights in the appropriate boxes on the TCLP % solid benchsheet (Form 608). Foil dishes may be used to collect solids from sample with very low solids content and the foil dish weight must be recorded before solids are placed on the foil.

8.1.1.2.2 Assemble the filtration device and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

8.1.1.2.3 Weigh out a subsample of the waste (100g minimum) and record the weight. If sufficient sample is not available, record such on benchsheet.

8.1.1.2.4 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

8.1.1.2.5 Quantitatively transfer the waste sample to the filtration device (liquid and solid phases). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4±2°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm to room temperature before filtering.

8.1.1.2.6 After transferring the waste sample to the filtration device, place the spatula in the beaker, weigh, and record the initial sample weight on the TCLP % solids benchsheet.

8.1.1.2.7 Gradually apply gentle pressure of 1-10psi, until air or pressurizing gas moves through the filter. If air or filtered liquid does not move through the filter at this range of pressures and if no additional liquid has passed through the filter in a 2-minute interval, slowly increase the pressure in 10psi increments to a maximum pressure of 50psi. **Note that instantaneous application of high pressure can rupture the glass fiber filter and may cause premature plugging.**

When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50psi (i.e., filtration does not result in any additional filtrate within a 2 minute period), stop the filtration.

8.1.1.2.8 The material in the filter holder is defined as the solid phase of the sample, and the filtrate is defined as the liquid phase.

Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration as outlined above, this material may not filter. If this is the case, the material within the filtration device is defined as a solid as is carried though the TCLP extraction. **Do not replace the original filter with a fresh filter under any circumstances.** Use only one filter.

8.1.1.3 Determine the weight of the liquid phase by subtracting the weight of the empty beaker (8.1.1.2.1) from the total weight of the filtrate-filled beaker syringe; record weight on TCLP % solids benchsheet (Form 608).

Determine the weight of the solid phase (8.1.1.2.8) of the waste sample by subtracting the weight of the liquid phase (above) from the weight of the total waste sample (8.1.1.2.3); record weight on TCLP % solids benchsheet.

8.1.1.4 Calculate the percent solids as shown below:

$$\text{Percent Solids} = \frac{\text{Weight of solid (8.1.1.3)}}{\text{Total weight of waste (8.1.1.2.3)}} \times 100$$

8.1.2 DETERMINATION OF INSIGNIFICANT SOLIDS

If the percent solids as determined above (8.1.1.4) is equal to or greater than (≥) 0.5%, then proceed either to Section 8.1.3 (particle size reduction determination) or continue as outlined below (8.1.2.1), if it is noticed that a small amount of the filtrate is entrained in wetting of the filter.

If the percent solids determined (8.1.1.4) is less than (<) 0.5%, then proceed to Section 8.2 (ZHE procedure), with a fresh portion of the waste.

8.1.2.1 Remove the solid phase and filter from the filtration apparatus.

8.1.2.2 Dry the filter and solid phase at 100±20°C until two successive weighings yield the same value (±1%). Record the final weight on the benchsheet (Form 608).

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. If it is suspected that the material is flammable, drying in the hood overnight is recommended. When the filter paper is dry, re-weigh and calculate the % solids with the new value. This Step is performed when it is suspected that the weight from the moisture in the filter paper has caused the % solids value to rise above 0.5%. Perform this Step only in borderline cases.

8.1.2.3 Calculate the percent dry solids as follows:

$$\text{Percent Dry Solids} = \frac{\text{Wt dry sample + filter - Tared wt of filter}}{\text{Initial weight of sample (8.1.1.2.3)}} \times 100$$

8.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Section 8.2.

8.1.3 PARTICLE SIZE REDUCTION DETERMINATION

8.1.3.1 Using the solid portion of the sample, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1cm^2, or is smaller than 1cm in its narrowest dimension (i.e., is capable of passing through a 9.5mm [0.375 inch] standard sieve). If the particle size is larger than described above, prepare the solid portion of the sample for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above.

8.1.3.2 Note that the surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet the criteria, sample-specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

8.1.3.3 Safety concerns such as dust control may preclude the grinding of samples for particle size reduction. These safety concerns must *always* be addressed before

attempting to grind any sample. Generally due to health and safety concerns, grinding to reduce particle size is not practiced in the extractions area. Samples requiring particle size reduction have been sent to an appropriate facility before an extraction was performed.

8.1.3.4 Particle size reduction prior to leaching for volatile organics may lead to loss of target compounds, compromising the analytical results.

8.1.3.5 If a particle size reduction of the solid portion of the waste is required, continue as follows:

8.1.3.5.1 Prepare the waste for extraction by crushing, cutting or grinding the solid portion of the waste to a suitable surface area or particle size.

8.1.3.5.2 *Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4±2°C prior to particle size reduction.*

8.1.3.5.3 *The means used to effect particle size reduction must not generate heat in and of itself.*

8.1.3.5.4 *Work carefully and quickly, as exposure of the waste to the atmosphere should be avoided to the extent possible.*

8.1.3.5.5 **Note that sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth and similar) waste materials. Actual measurement of surface area is not recommended.**

8.1.3.5.6 When the surface area or particle size has been appropriately altered, proceed to Section 8.2.3 - Filtration.

8.2 ZHE PROCEDURE

Use the ZHE vessel to obtain TCLP extract for analysis of VOCs only. Leachates resulting from the use of the ZHE shall not be used to evaluate the mobility of

nonvolatile analytes (e.g., metals, pesticides, semivolatiles). The ZHE vessel has an internal capacity of 500-600mL, and can thus accommodate a maximum of approximately 25 grams of solid (defined as that fraction of a sample from which no additional liquid may be forced out by an applied pressure of 50psi), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

8.2.1 EQUIPMENT SET-UP

8.2.1.1 Charge the ZHE vessel with sample only once and do not open the device until the final extract (of the solid) has been collected. Repeated filling of the ZHE vessel to obtain 25 grams of solid is not permitted.

8.2.1.2 **Do not allow the waste, the initial liquid phase, or the extract to be exposed to the atmosphere for any more time than is absolutely necessary. Manipulation of the sample to be leached should be done when cold (4±2°C) to minimize loss of volatiles. Leaching fluids are added at room temperature. After filtration, leachates should be cooled to 4±2°C by placing the 'VOA' vial into a suitable refrigeration unit as soon as practical.**

8.2.1.3 Pre-weigh the (evacuated) filtrate collection container (5.11) and set aside. If using a Tedlar™ bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis.

8.2.1.4 Place the ZHE piston within the body of the ZHE (it is helpful to first moisten the piston o-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move after the ZHE is charged with sample (based upon sample size requirements as discussed previously). Secure the gas inlet/outlet (bottom) flange (with the valve open) onto the ZHE body per the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set the liquid inlet/outlet flange (top flange) aside.

8.2.2 ALIQUOT DETERMINATIONS

8.2.2.1 If the sample is 100% solid (8.1.1.1), weigh out a subsample (25g maximum – care should be taken to choose a sample weight that will yield sufficient leachate to support the

analysis) of the waste, record weight (Form 608), and proceed to Step 8.2.3 - Filtration.

8.2.2.2 If the waste contains <0.5% dry solids (8.1.2.3), the liquid portion of waste, after filtration, is defined as the ZHE extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required (weigh out a 100-500g subsample, record weight). Proceed to Step 8.2.3 - Filtration.

8.2.2.3 If the waste contains ≥0.5% dry solids, use the percent solids information obtained in Step 8.1.1.4 to determine the optimum sample size to charge into the ZHE vessel as follows:

$$\text{Wt of waste to charge ZHE} = \frac{10}{\text{percent solids (8.1.1.4)}} \times 100$$

Weigh out the appropriate size of waste subsample as determined and record the weight on the ZHE benchsheet (Form 608).

8.2.3 FILTRATION

8.2.3.1 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge wastes prior to filtration.

8.2.3.2 Quickly and quantitatively transfer the entire sample (liquid and solid phases) of the waste aliquot as prepared above to the ZHE vessel.

NOTE: If waste material (>1% of original subsample weight) has obviously adhered to the container used to transfer the sample to the ZHE vessel, determine the weight of this residue and subtract it from the sample weight (8.1.1.2.3) to determine the actual weight of the waste subsample that will be filtered. Record on benchsheet.

8.2.3.3 Secure the filter and support screens onto the top flange of the device and secure the top flange to the ZHE vessel body in accordance with the manufacturer's instructions. Tighten all ZHE fittings, and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the extract collection device to the top plate.

8.2.3.4 Attach the gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10psi (or more if necessary) to force all headspace *slowly* out of the ZHE vessel.

At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4±2°C reduces the amount of expressed liquid beyond what would be expressed at room temperature, then allow the sample to warm to room temperature before filtering.

If the waste is 100% solid (8.1.1.1), slowly increase the pressure to a maximum of 50psi to force most of the headspace out of the device, then proceed to Section 8.2.6 - Extraction (Tumbling).

8.2.3.5 Attach the evacuated pre-weighed 60mL plastic Luer-Lok® syringe to the liquid inlet/outlet valve of the ZHE and open the valve. Begin applying gentle pressure of 1-10psi to force the liquid phase of the sample into the filtrate collection container. **Note that instantaneous application of high pressure can rupture the glass fiber filter and may cause premature plugging.**

If no additional liquid has passed through the filter in a 2-minute interval, slowly increase the pressure in 10psi increments (and waiting a 2-minute interval with no additional liquid passing) to a maximum of 50psi.

When liquid flow has ceased such that continued pressure filtration at 50psi does not result in any additional filtrate within a 2-minute period, stop the filtration.

8.2.3.6 Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container; record weight on ZHE benchsheet. Using the information recorded on the benchsheet, calculate the amount of solid waste left inside the ZHE.

8.2.4 PHASE DISCUSSION

The material in the ZHE is defined as the solid phase of the waste and the filtrate is defined as the liquid phase. Some wastes, such as oily wastes and some paint wastes, will obviously contain some material

that appears to be a liquid. Even after applying pressure filtration, this material may not filter. If this is the case, the material within the filtration device is defined as a solid, and is carried through the TCLP extraction as a solid.

If the original waste contained <0.5% dry solids (8.1.2.3), this filtrate is defined as the TCLP extract and is analyzed directly. Proceed to Section 8.2.7 - Preparation for Volatile Analysis.

The liquid phase may now be either analyzed immediately (8.2.7), stored at 4±2°C under minimal headspace conditions until time of analysis, or recombined (if miscible) with the sample prior to tumbling.

8.2.5 Determine the weight of Extraction Fluid # 1 to add to the ZHE vessel as follows (**Extraction Fluid # 1 is used in all cases)**:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (8.1.1.4)} \times \text{weight of waste filtered (i.e., the solid waste left inside the ZHE, 8.2.3.6)}}{100}$$

Record on benchsheet (Form 608).

8.2.6 EXTRACTION (TUMBLING)

8.2.6.1 Fill a clean beaker of appropriate volume with Extraction Fluid #1, then fill a clean 60mL gas-tight Luer-Lok® syringe from the beaker. Vent residual air from the syringe so that it only contains the measured amount of fluid.

With the ZHE vessel in the vertical position, attach the syringe to the liquid inlet/outlet valve. Release gas pressure on the ZHE piston (open the gas inlet/outlet valve), open the liquid inlet/outlet valve, and depress the syringe plunger to transfer extraction fluid into the ZHE vessel. Close the liquid inlet/outlet valve and remove the syringe.

Continue to add extraction fluid to the ZHE in this manner until the appropriate amount (8.2.5) has been introduced into the device.

8.2.6.2 After the extraction fluid has been added, immediately close both the liquid inlet/outlet valve and the gas inlet/outlet valve.

8.2.6.3 Reposition the ZHE vessel in the vertical position with the liquid inlet/outlet valve on top. Pressurize to 5-10psi and slowly open the liquid inlet/outlet valve to bleed out any headspace that may have been introduced due to the addition of extraction fluid. *This bleeding should be done quickly - stop at the first appearance of liquid from the valve.* Re-pressurize to 5-10psi and check all ZHE fittings to ensure that they are closed.

8.2.6.4 Place the ZHE in the rotary extractor apparatus and rotate at 30±2 rpm for 18±2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23±2°C during agitation. SOP 663 describes the procedures for monitoring tumbler revolutions and room temperature.

8.2.6.5 Following the 18±2 hour agitation period, check the pressure gauge on the ZHE vessel to see that pressure has been maintained. If the pressure has not been maintained, the device has leaked. Check the ZHE vessel for leaking as specified in Section 5.1, and correct the problem. Perform the extraction again with a new aliquot of waste sample.

8.2.6.6 If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases.

8.2.6.6.1 If the waste contained an initial liquid phase that has been stored, the leachate may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) that holds the initial liquid phase. *A separate filtrate collection container must be used if combining would create multiple phases, or if there is not enough volume left within the filtrate collection container.*

8.2.6.6.2 After attaching the filtrate collection container (TEDLAR® bag or clean syringe) slowly open the liquid inlet/outlet valve (top flange) to collect the filtered leachate. Note that an in-line glass fiber filter may be used to filter the material within the ZHE vessel if it is suspected that the internal glass fiber filter has ruptured. *All extract shall be filtered and collected if the*

TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase that was NOT recombined with solids prior to tumbling.

8.2.6.6.3 If the original waste contained no initial liquid phase, the filtered liquid material obtained from Section 8.2.3 is defined as the TCLP extract. If the waste contained an initial liquid phase, the filtered liquid material obtained from Section 8.2.3 and the initial liquid phase (8.1.1.2) are collectively defined as the TCLP extract.

8.2.7 PREPARATION FOR VOLATILE ANALYSIS
Following collection of the TCLP extract, immediately prepare the extract for analysis (by transferring to a septum-sealed "VOA" vial) and store with minimal (preferably zero) headspace at 4±2°C until analyzed.

Analyze the TCLP extract according to the appropriate determinative method. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a volume-weighted average as shown below:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = volume of the first phases (L)

C_1 = concentration of target analyte in the first phase (mg/L)

V_2 = volume of the second phase (L)

C_2 = concentration of target analyte in the second phase (mg/L)

9. QUALITY CONTROL

9.1 A minimum of one method blank (MB) using the same extraction fluid as used for the samples (extraction fluid #1), must be analyzed for every 20 extractions that have been conducted in an extraction vessel. No more than 20 field samples may be included in a batch.

9.2 Matrix spike and laboratory control samples are prepared at the time of analysis by the volatiles analysis group.

10. DEVIATIONS FROM THE METHOD

This SOP meets the requirements of SW-846 Method 1311. There are no known deviations from this method.

It should be noted that, when only the volatile TCLP extraction is being done (i.e., no semivolatile or metals), the initial percent solids determination (using the "lunar lander") may be skipped, as the percent solids can be determined after the sample is loaded into the ZHE (Steps 8.2.3.4 through 8.2.3.6). Experience of the prep analyst weighs heavily here, as (in the case of a very wet sample matrix), too small of an aliquot into the ZHE may not yield an adequate volume of leachate for analysis.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses and a lab coat when working with chemical materials (e.g., standards, solvents, reagents, or samples).

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Glacial acetic acid has a TLV of 10ppm.

11.2 SAFETY AND HAZARDS

11.2.1 Unused sample leachate may be disposed of in the Aqueous Laboratory Waste.

11.2.2 Unused sample leachate solids may be disposed of in the Contaminated Soils and Solids Waste.

11.2.3 Waste from processing radioactive samples shall be disposed of in the appropriate radioactive waste stream.

11.2.4 All empty solvent bottles shall be disposed of according to the appropriate SOPs. All labels and markings must be defaced prior to disposal.

TEMPERATURE LOGBOOK

ORGANIC EXTRACTIONS - TCLP ROOM

Acceptable Range 23 ± 2 °C

A current temperature reading must be recorded at the onset of TCLP tumbling, and the min/max memory must be reset. DO NOT initiate tumbling if temperature is not within acceptable limits. The current temperature and min/max information must be recorded at the completion of tumbling. Both the Department and QA Managers must be notified in a timely manner if an excursion occurs.

HISTORY: New, Rev0, 2/26/92; Rev1; 7/18/92; Rev2, 3/11/93; Rev3, PCN #102, 1/21/94; Rev4, PCN# 274, 9/22/94; Rev5; 2/27/96; Rev6, 2/12/99; Rev7, 3/14/00; Rev8, 3/14/02; Rev9, 4/3/03; Rev10, 4/16/04; Rev11, 3/9/06; Rev12, 3/4/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW-846 Method 1311 -- are designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes. This procedure is performed to analyze the soluble metals and non-volatile organic compounds that could leach from a sample if it were in a landfill site. Application of these procedures to matrices other than those specified will be handled individually to simulate the leaching procedure as best as possible.

Procedures for ZHE TCLP extractions are described in SOP 608.

2. SUMMARY

For liquid wastes (i.e., <0.5% solids), the sample is filtered through a 0.7µm glass fiber filter, and the filtrate is defined as the TCLP leachate.

For samples containing ≥0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis. If necessary, the particle size of the solid phase is reduced. The solids are then leached with an amount of extraction fluid equal to twenty (20) times the weight of the solid phase. The extraction fluid employed is a function of the alkalinity of the solid phase of the waste. Following the TCLP extraction, the leachate is separated from the solids by filtration through a 0.7µm filter.

If a liquid phase was present in the sample and set aside as described above, then this liquid is combined with the leachate from the solid phase, if the two are miscible, before metals or semivolatile organic preparation for analysis. If the liquid and the leachate are not miscible, the liquid and the leachate are analyzed separately, and the results are mathematically combined to yield a volume-weighted average concentration.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct the errors that were found.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by processing and analyzing method blanks.

5. APPARATUS AND MATERIALS

Extraction vessels and filtration devices shall be made of inert materials that will not leach or absorb waste components. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high-density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) are to be used only when evaluating the mobility of metals.

5.1 rotary tumbler with 30±2rpm capability, Associated Design and Manufacturing

Model 3740 or equivalent

5.2 pH meter, accurate to ±0.05 pH units @ 25°C
Meter must be calibrated prior to use (see Form 825).

5.3 pressure filtration device, Associated Design and Manufacturing Model 3750-LHWF or equivalent. A.K.A. "lunar lander"

5.4 fiber filters, borosilicate glass, Gelman™ #66256, 0.7µm nominal or equivalent

NOTE: The glass fiber shall contain no binder materials and shall have an effective particle size of 0.6 to 0.8µm. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1.0M HNO_3, followed by three consecutive rinses with deionized water (a minimum of 1000mL per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

5.5 bottle extraction vessel, 2L or slightly larger. Borosilicate glass, 2200mL Kontes™ #332100-021 or equivalent. If PVC coated for safety, do not place in kiln. HDPE plastic, 2000mL Eagle Picher #EP150-02WM or equivalent

Paragon typically uses disposable HPDE extraction bottles for metals and semivolatile organics. The use of HDPE extraction bottles has been demonstrated to generate leachates that are free of contaminants for the analyses being conducted.

5.6 balance, accurate to within ±0.01g

5.7 beakers or Erlenmeyer flasks, glass 500mL (or 4.5oz plastic cups)

5.8 watch glass, appropriate diameter to cover beaker or Erlenmeyer flask (or cap for plastic cup)

5.9 carboys for containerizing extraction fluids

5.10 stirring hot plate, with magnetic stir bar

5.11 graduated cylinders, sized as appropriate

5.12 centrifuge

5.13 drying oven, capable of maintaining 100±20°C

6. REAGENTS - Only reagent grade or better chemicals shall be used.

6.1 water, of sufficient purity that target analytes or interferences are not observed at levels of interest for the analytes of interest. For semivolatile organics and metals

analysis, laboratory deionized (DI) ASTM Type II water meets the definition of reagent water. Prior to being used for this procedure, this water is filtered through a Millipore Synergy 185® filtration system for further purification.

6.2 glacial acetic acid (CH_3COOH), suitable for use in metals analysis

6.3 sodium hydroxide solution (NaOH), 12N

6.4 **Extraction fluid 1:** Add 21L of reagent water to a HDPE carboy. Add 126mL glacial acetic acid and 140mL 12N NaOH. Bring final volume to 22L with reagent water. Mix thoroughly (pH must be 4.93 ±0.05). Volumes of acetic acid and NaOH may be adjusted to prepare larger or smaller volumes of Extraction fluid 1.

6.5 **Extraction fluid 2:** Add 21L of reagent water to a HDPE carboy. Add 108mL glacial acetic acid. Bring final volume to 22L with reagent water. Mix thoroughly (pH must be 2.88±0.05). Volume of acetic acid may be adjusted to prepare larger or smaller volumes of Extraction fluid 2.

6.6 1N hydrochloric acid solution (HCl): In a 100mL volumetric flask with approximately 50mL reagent water, add 8.3mL concentrated HCl, bring to volume with reagent water, and mix thoroughly.

6.7 1N nitric acid solution (HNO_3):): In a 100mL volumetric flask with approximately 50mL reagent water, add 6.3mL concentrated HNO_3, bring to volume with reagent water, and mix thoroughly.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 All samples should be collected using an appropriate sampling plan.

7.2 The TCLP may place requirements on the minimal size of the field sample, depending upon the physical state of the waste and the analytes of concern. An aliquot is needed for determination of which extraction fluid is to be used during this leaching procedure. Another aliquot is required to actually conduct the leaching procedure. If volatile organics are of concern, another aliquot is required. Quality control samples may require additional aliquots. Further, it is always wise to collect additional sample in case something goes wrong with the initial attempt to conduct the test.

7.3 Chemical preservatives are not added to solid samples. Some liquid samples may contain residual chlorine and the free chlorine should be deactivated with sodium thiosulfate or another dechlorinating reagent while in the field. Preservatives shall <u>not</u> be added to samples before extraction.

7.4 Samples should be collected in Teflon-lined septum capped bottles and stored at

4±2°C. Samples may be refrigerated unless refrigeration results in irreversible physical change of the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

7.5 TCLP leachate should be prepared for analysis and analyzed as soon as possible following extraction. Leachates or portions of leachates for metallic analyte determinations must be acidified with nitric acid to a pH<2, unless precipitation occurs. Refrigeration is generally the only preservation technique applied to the leachates intended for semivolatile organic analysis. Maximum hold times are:

SAMPLE HOLDING TIMES (DAYS)

Leachate Analysis	From Field Collection to TCLP Leaching	From TCLP Leaching to Preparation for Analysis	From Preparation to Analysis
Semivolatile organics (including Pesticides, Herbicides)	14	7	40
Mercury (Hg)	28	NA	28
Metals (except Hg)	180	NA	180

NA=Not Applicable

8. PROCEDURE

8.1 PRELIMINARY EVALUATION

Preliminary evaluation includes: (1) determination of the percent solids (8.1.1); (2) determination of whether the sample contains insignificant solids and is, therefore, its own leachate after filtration (8.1.2); (3) determination of whether the solid portion of the sample requires particle size reduction (8.1.3); and (4) determination of which extraction fluid is to be used for the nonvolatile TCLP extraction of the waste (8.1.4).

Select samples to be analyzed and record on benchsheet (Form 623). Perform preliminary TCLP evaluations on a minimum 100g aliquot of sample, assuming adequate volume of sample has been provided (notate on benchsheet if otherwise); this aliquot may not actually undergo TCLP extraction.

8.1.1 DETERMINATION OF PERCENT SOLIDS
PHASE SEPARATION

8.1.1.1 Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample), from which no liquid may be forced out by an applied pressure, as described below. Visual inspection may be sufficient for this determination.

If the sample will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids), then proceed to Section 8.1.3 - Particle Size Reduction Determination.

8.1.1.2 **Phase Separation**. If the sample is liquid or multiphasic, liquid/solid separation is required to make a preliminary determination of percent solids. This involves the filtration device described in Section 5.2, and performance of the procedures outlined below:

8.1.1.2.1 Pre-weigh the filter and foil that will receive the solids, the beaker and spatula. Acid wash the filter if evaluating the mobility of metals (5.4). Record the weights in the appropriate boxes on the TCLP % solids benchsheet (Form 623).

8.1.1.2.2 Assemble the filtration device and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

8.1.1.2.3 Weigh out a subsample of the waste (100g minimum) and record the weight. If sufficient sample is not available, record such on benchsheet.

8.1.1.2.4 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered, followed by filtration of the solid portion of the waste through the same filtration system.

8.1.1.2.5 Quantitatively transfer the waste sample to the filtration device (liquid and solid phases).

8.1.1.2.6 After transferring the waste sample to the filtration device, place the spatula in the beaker and record the combined weight of both. Then continue with the calculations prompted on the benchsheet.

8.1.1.2.7 Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4±2°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm to room temperature before filtering.

8.1.1.2.8 Gradually apply vacuum or gentle pressure of 1-10psi, until air or pressurizing gas moves through the filter. If gas or air does not move through the filter at this range of pressures and if no additional liquid has passed through the filter in a 2-minute interval, slowly increase the pressure in 10psi increments to a maximum pressure of 50psi. **Note that instantaneous application of high pressure can rupture the glass fiber filter and may cause premature plugging.**

8.1.1.2.9 If after each incremental increase of 10psi, the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in a 2-minute interval, proceed to the next 10psi increment.

8.1.1.2.10 When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50psi (i.e., filtration does not result in any additional filtrate within a 2-minute period), stop the filtration.

8.1.1.2.11 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. However, even after applying vacuum or pressure filtration as outlined previously, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. **Do not replace the original filter with a fresh filter under any circumstances; use only one filter.**

8.1.1.2.12 Determine the weight of the liquid phase by subtracting the weight of the filtrate container, from the total weight of the filtrate-filled container; record on benchsheet.

8.1.1.2.13 Determine the weight of the solid phase by subtracting the weight of the liquid phase (8.1.1.2.12) from the weight of the total waste sample; record on benchsheet.

8.1.1.3 Calculate the percent solids as follows:

$$\%\ \text{solids} = 100 * \frac{\text{weight of solids (8.1.1.2.13)}}{\text{total weight of waste (from benchsheet)}}$$

8.1.2 DETERMINATION OF INSIGNIFICANT SOLIDS

If the percent solids as determined above (8.1.1.3) is equal to or greater than (≥) 0.5%, then proceed either to Section 8.1.3 (particle size reduction determination) or continue as outlined below (8.1.2.1), if it is noticed that a small amount of the filtrate is entrained in the wet filter.

If the percent solids determined (8.1.1.3) is less than (<) 0.5%, then proceed to Section 8.2 (Aliquots for Leaching).

8.1.2.1 Remove the solid phase and filter from the filtration apparatus.

8.1.2.2 Dry the filter and solid phase at 100±20°C until two successive weighings yield the same value (±1%). Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. If it is suspected that the material is flammable, drying in the hood overnight is recommended. When the filter paper is dry, re-weigh and calculate the % solids with the new value. This Step is performed when it is suspected that the weight from the moisture in the filter paper has caused the % solids value to rise above 0.5%. Perform this Step only in borderline cases.

8.1.2.3 Calculate the percent dry solids as follows:

$$\%\,\text{dry solids} = 100 * \frac{(\text{dry waste} + \text{filter}) - (\text{initial weight of filter})}{\text{initial weight of waste}} \quad (8.1.1.2.6)$$

8.1.2.4 If the percent dry solid is < 0.5%, then proceed to Section 8.2 if the nonvolatile TCLP is to be performed.

If the percent dry solid is ≥0.5%, and if the nonvolatile TCLP is to be performed, return to the beginning of this Section and, with a fresh portion of waste, determine whether particle size reduction is necessary (Section 8.1.3). **The portion of sample that has been dried is not to be used in the leaching procedure.**

8.1.3 PARTICLE SIZE REDUCTION DETERMINATION

8.1.3.1 Using the solid portion of the sample, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1cm^2, or is smaller than 1cm in its narrowest dimension (i.e., is capable of passing through a 9.5mm [0.375 inch] standard sieve). If the particle size is larger than described above, prepare the solid portion of the sample for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above.

8.1.3.2 Note that the surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet the criteria, sample-specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

8.1.3.3 Safety concerns such as dust control may preclude the grinding of samples for particle size reduction. These safety concerns must always be addressed before attempting to grind any sample. Generally due to health and safety concerns, grinding to reduce particle size is not practiced in the extractions area. Samples requiring particle size reduction have been sent to an appropriate facility before an extraction was performed.

8.1.3.4 If a particle size reduction of the solid portion of the waste is required, continue as follows:

8.1.3.4.1 Prepare the waste for extraction by crushing, cutting or grinding the solid portion of the waste to a suitable surface area or particle size.

8.1.3.4.2 *Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4±2°C prior to particle size reduction.*

8.1.3.4.3 *The means used to effect particle size reduction must not generate heat in and of itself.*

8.1.3.4.4 *Work carefully and quickly, as exposure of the waste to the atmosphere should be avoided to the extent possible.*

8.1.3.4.5 Note that sieving of the waste is not normally required. If sieving is necessary, a Teflon-coated sieve should be used to avoid contamination of the sample. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth and similar) waste materials. Actual measurement of surface area is not recommended.

If the waste as received passes a 9.5mm sieve, quantitatively transfer the solid material into an extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to 8.4 - Tumbling.

8.1.3.4.6 When the surface area or particle size has been appropriately altered, quantitatively transfer the solid material into the extractor bottle. Include the filter used to separate the initial liquid from the solid phase. Then proceed to 8.3 - Filtration.

8.1.4 EXTRACTION FLUID DETERMINATION
If the solid content of the waste is ≥0.5%, then determine the appropriate fluid for the nonvolatiles extraction as follows:

8.1.4.1 Weigh out a small subsample of the solid phase of the waste, reduce the solid (if necessary), to a particle size of

approximately 1mm in diameter or less (i.e., it should pass through a 1mm sieve), and transfer 5.0g of the solid phase to a 250mL beaker or 4.5oz cup.

8.1.4.2 Add 96.5g of reagent water to the beaker, cover with a watch glass, and stir vigorously for 5 minutes using a magnetic stirrer. Measure and record the pH. If the pH is <5.0, use Extraction fluid 1; proceed to Section 8.2.

8.1.4.3 If the pH is ≥5.0, add 3.5mL 1N HCl, slurry briefly, cover with a watch glass, heat to 50°C, and hold at 50°C for a minimum of 10 minutes (up to 30 minutes).

8.1.4.4 Let the solution cool to room temperature and record the pH. If the pH is <5.0, use Extraction fluid 1. If the pH is ≥5.0, use Extraction fluid #2. Record which fluid was used for each sample on the benchsheet (Form 623).

8.2 DETERMINATION OF ALIQUOTS FOR LEACHING

8.2.1 Label a 2000mL container with work order number, sample number, and fluid number (for metals, rinse the container with 0.1N HNO_3, followed by a rinse with deionized water). For each reagent blank, label a container with the date of tumbling, reagent blank number and fluid number.

8.2.2 Determine the number of analyses to be performed upon each sample: Herbicides, organochlorine pesticides, and semivolatiles analysis each require 100mL of tumbled fluid. Metals analysis requires 50mL of tumbled fluid. Each analysis also requires one (1) matrix spike sample/fluid/day tumbled, so these amounts may be doubled to ensure sufficient amount of fluid for all analysis and matrix spike.

Each analysis also requires a reagent blank/fluid/day tumbled, which consists of the appropriate fluid placed in an appropriate TCLP container (no solid added) and tumbled with the samples. The reagent blank should also be put on the benchsheet and carried through the tumbling/filtering/ extracting (analysis) process.

The amount of fluid added to the sample is equal to 20 times the weight of the solid (e.g., 20g of sample requires 400mL of fluid).

8.2.3 If the aliquot of the sample used for the preliminary evaluation was determined to be 100% solid (8.1.1.1), then that aliquot can be used for the nonvolatile extraction (assuming that aliquot is sufficient to generate enough leachate to support the requested analyses).

Do not use leach solid that was dried in the oven.

8.2.4 The amount of solid necessary is dependent upon whether a sufficient amount of leachate will be produced to support the required analyses. If an adequate amount of solid remains, proceed with the nonvolatile TCLP extraction (Section 8.4).

A minimum sample size of 100g (solid and liquid phases) is recommended. In some cases, a larger sample size may be appropriate, depending on the solids content (8.1.1.3) of the waste sample, whether the initial liquid phase of the waste will be miscible with the aqueous leachate of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough TCLP solids should be generated for extraction such that the volume of leachate will be sufficient to support all of the analyses required.

If the amount of leachate generated by a single TCLP extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed, and the leachates from each combined and aliquoted for analysis.

8.2.5 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solid), weigh out a subsample of the waste (100g minimum) and proceed to Section 8.3 - Filtration.

8.2.6 If the sample is liquid or multiphasic, liquid/solid separation is required as outlined in Section 8.1.1.2.

8.2.7 Weigh out an aliquot of the sample (100g minimum) and record the weight. If the waste contains <0.5% dry solids (Section 8.1.2.3), the liquid portion of the waste, after filtration, is defined as the TCLP leachate. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required.

8.2.8 For wastes containing $\geq$0.5% solids, use the percent solids information obtained in Section 8.1.1.3 to determine the optimum sample size (100g minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the TCLP leachate.

8.2.9 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the sample is centrifuged, the liquid should be decanted and filtered, followed by filtration of the solid portion of the waste through the same filtration system.

8.3 FILTRATION

8.3.1 Pre-weigh the container that will receive the filtrate; record weight.

8.3.2 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Section 5.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions if rinsed adequately prior to use (even when metals are not of concern).

8.3.3 Quantitatively transfer the waste sample (liquid and solid phases) to the filter holder. Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4±2°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm to room temperature in the device before filtering.

NOTE: If waste material (>1% of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the total sample weight to determine the weight of the waste sample that will be filtered.

8.3.4 Gradually apply vacuum or gentle pressure of 1-10psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10psi, and if no additional liquid has passed through the filter in any 2-minute interval, slowly increase the pressure in 10psi increments to a maximum of 50psi. **Note: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.**

8.3.5 When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50psi (i.e., filtration does not result in any additional filtrate within a 2-minute period), stop the filtration.

8.3.6 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, this material may not filter. If this is the case, the material

within the filtration device is defined as a solid and is carried through the extraction as a solid. **Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.**

8.3.7 Weigh the filtrate; record weight.

8.3.8 If the sample contains <0.5% dry solids, proceed to Section 8.5 - Preparation for Analysis.

If the sample contained no initial liquid phase, the filtrate is defined as the TCLP leachate; proceed to Section 8.5 - Preparation for Analysis.

8.3.9 EXTRACTION FLUID ALIQUOT DETERMINATION
Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (8.1.1.3)} \times \text{weight of waste filtered (8.3.3)}}{100}$$

8.4 EXTRACTION (TUMBLING)

8.4.1 Slowly add the calculated amount of appropriate extraction fluid to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal).

8.4.2 Secure the extractor bottle in the rotary tumbler, and rotate at 30±2 rpm for 18±2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23±2°C during the extraction period. SOP 663 describes the procedures for monitoring tumbler revolutions and room temperature.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of wastes (e.g., limed or calcium carbonate containing waste may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically vented (e.g., after 15 minutes, 30 minutes, and 1 hour), into a hood.

8.4.3 Following the 18±2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter.

8.4.4 For final filtration of the TCLP leachate, the glass fiber filter may be changed, if necessary, to facilitate filtration.

Filter(s) shall be acid-washed (see Section 5.4) if evaluating the mobility of metals.

8.4.5 Following collection of the TCLP leachate, the pH of the leachate should be recorded. Immediately aliquot and preserve the leachate for analysis.

8.4.6 The liquid phase may now be either analyzed (8.5) or stored at 4±2°C until time of analysis. If miscible, the initial liquid phase may be combined with the TCLP leachate. If the initial liquid phase of the waste is not or may not be compatible with the filtrate, do not combine these liquids. Although they are collectively defined as the TCLP leachate, they are to be analyzed separately, and their analysis results combined mathematically (8.5.2).

8.5 PREPARATION FOR ANALYSIS

8.5.1 Metals leachates must be acidified with nitric acid to pH<2. If precipitation is observed upon addition of nitric acid to a small aliquot of the leachate, then the remaining portion of the leachate for metals analyses shall not be acidified, and the leachate shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4±2°C) until analyzed.

8.5.2 The TCLP leachate shall be prepared and analyzed according to appropriate analytical methods. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to ±0.5%), conduct the appropriate preparations and analyses, and combine the results mathematically, by using a volume-weighted average as shown below:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = volume of the first phase (L)

C_1 = concentration of the analyte of concern in the first phase (mg/L)

V_2 = volume of the second phase (L)

C_2 = concentration of the analyte of concern on the second phase (mg/L)

9. QUALITY CONTROL

9.1 A minimum of one blank (using the same extraction fluid as used for the samples) must be analyzed for every 20 extractions that have been conducted in an extraction vessel. No more than 20 field samples may be included in a batch.

9.2 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.). A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

9.2.1 Matrix spikes are to be added after filtration of the TCLP leachate and before preservation. Matrix spikes should not be added prior to TCLP extraction of the sample.

9.2.2 In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentration, but may not be not less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of TCLP leachate as that which was analyzed for the unspiked sample.

9.2.3 Matrix spike recoveries are calculated by the following formula:

$$\%R\ (\%\ \text{Recovery}) = 100\ (Xs - Xu)/K$$

where:

Xs = measured value for the spike sample
Xu = measured value for the unspiked samples
K = known value of the spike in the sample

10. DEVIATIONS FROM THE METHOD

There are no known deviations from the SW-846 Method 1311 with the following exception: Paragon allows for the use of HDPE bottles for metals and semivolatile organics leaching, if approved by the client (see LIMS program specifications), and if this type of container can be shown to meet the criteria discussed in Section 5.5 (i.e., inert and does not adsorb or release target analytes).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses and a lab coat when working with chemical

materials (e.g., standards, solvents, reagents, or samples).

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.2 WASTE DISPOSAL

11.2.1 Unused sample leachate may be disposed of in the Aqueous Laboratory Waste profile.

11.2.2 Unused sample leachate solids may be disposed of in the Contaminated Soils and Solids and Solids Waste.

11.2.3 Radioactive sample disposal - the extracted solid sample residues and solid sample/Na_2SO_4 residue shall be disposed of in the Radioactive Soils and Solids container. Mixed waste solids shall be disposed of in the appropriate mixed waste container.

11.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

TEMPERATURE LOGBOOK

ORGANIC EXTRACTIONS - TCLP ROOM

Acceptable Range 23 ± 2 °C

A current temperature reading must be recorded at the onset of TCLP tumbling, and the min/max memory must be reset. DO NOT initiate tumbling if temperature is not within acceptable limits. The current temperature and min/max information must be recorded at the completion of tumbling. Both the Department and QA Managers must be notified in a timely manner if an excursion occurs.

TECHNICAL MANAGER _____ DATE 3-7-08

QUALITY ASSURANCE MANAGER _____ DATE 3/6/08

LABORATORY MANAGER _____ DATE 3-7-08

HISTORY: Rev0, 2/22/92; Rev1, 7/20/92; Rev2, PCN #118; 1/26/94; Rev3, PCN #378, 2/17/95; Rev4, 4/12/96; Rev5, 4/10/97, Rev6, 2/9/99; Rev7, 2/13/02; Rev8, 3/1/02; Rev9, 12/5/02; Rev10, 2/20/04; Rev11, 1/28/05; Rev12, 9/1/06; Rev13, 3/4/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- Method SW3520C -- describe a procedure for isolating organic compounds from aqueous samples. This procedure is applicable to the isolation of water-insoluble and slightly soluble organics in preparation for a variety of determinative chromatographic procedures. This procedure is intended for use of extraction solvents with a density greater than that of the sample. Methylene chloride is typically used, as its density is greater than that of water.

2. SUMMARY

A measured volume of sample (usually one liter) is placed into a continuous liquid-liquid extractor, adjusted to a specific pH if necessary, and extracted with methylene chloride for 18-24 hours. The extract is dried, concentrated, and, if necessary, solvent exchanged according to the analysis required. Paragon SOPs 607 and 637 describe the solvent concentration and solvent exchange procedures utilized after this extraction procedure.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the

technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Interference from phthalate esters can be minimized by using plastic-free solvent containers and scrupulously cleaned glassware (SOP 334) that has been kiln-baked or solvent-rinsed prior to use. Use of low phthalate gloves, such as nitrile, may also be important. These practices are important both in the field and in the laboratory.

4.2 Soap residue on glassware may cause degradation of certain analytes. Specifically, aldrin, heptachlor, and most organophosphorous pesticides may degrade in the presence of soap residue. Glassware shall be kiln-baked or solvent-rinsed prior to use.

4.3 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks.

4.4 Interferences co-extracted from the samples will vary considerably from source to source. If analysis of an extracted sample is hindered due to interferences, further cleanup of the sample extract may be necessary. Refer to SW-846 Method 3600C for guidance on cleanup procedures.

5. APPARATUS AND MATERIALS

5.1 continuous liquid-liquid extractors (CLEs)

5.2 condenser columns with circulating cooling water

5.3 heating mantles, rheostat controlled

5.4 round flat-bottom flasks, 500mL

5.5 PTFE boiling chips, Chemware™ D1069103 or equivalent, pre-rinsed with methylene chloride

5.6 pH indicator paper, wide (0-14) and narrow range (0-2.5 and 11-13)

5.7 syringes, 1mL or as needed

5.8 graduated cylinders, 1L and 2L

5.9 powder funnels

6. REAGENTS

NOTE: Only reagent grade or better chemicals may be used; solvents must be pesticide residue grade or equivalent. With the exception of the sodium hydroxide solution, all reagents must be stored in glass to prevent the leaching of contaminants from plastic containers.

6.1 Organic-free reagent water; laboratory deionized (DI) water is suitable for use.

6.2 Sodium hydroxide solution (NaOH). Used for pH adjustments. Made in-house from NaOH pellets (EMD or JT Baker #3722-07 or equivalent), as follows: In a large Pyrex™ beaker with magnetic stirrer, prepare a 12M solution by *slowly* adding 480g NaOH pellets per liter of reagent water. A cold-water bath is typically used to keep the solution cool while mixing, as the addition of NaOH pellets generates heat when added to the water. Store in a HDPE container, a glass container will slowly dissolve at high pH. Or, if an amber glass bottle is used, mark the bottle to be replaced in less than or equal to one year of service.

6.3 Sulfuric acid (H_2SO_4), concentrated. Used for pH adjustments. EMD #SX1247-2 or equivalent.

6.4 Methylene chloride (CH_2Cl_2, $MeCl_2$), Burdick & Jackson #299-4 or equivalent.

7. SAMPLE COLLECTION, PRESERVATION AND HOLD TIMES

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples intended to be analyzed for semivolatile organics, organochlorine pesticides, polychlorinated biphenyls, or herbicides are collected in 1L amber glass bottles, possessing a Teflon™-lined lid. Aqueous samples are not typically preserved. However, this SOP may also be used to process aqueous samples that have been preserved with acid (some State fuels programs) or dechlorinated with sodium thiosulfate ($Na_2S_2O_3$).

7.3 All samples are stored at 4±2°C.

7.4 The samples must be extracted within 7 days of collection.

8. PROCEDURE

8.1 Fill an appropriate number of round flat-bottom flasks and CLE extractors each with approximately 200mL of methylene chloride. Add several boiling chips to each round bottom flask.

8.2 Typically the entire contents of a sample bottle are extracted by this procedure, so any lack of homogeneity is likely due to the field sampling process. If high concentrations are anticipated, a smaller volume may be used and then diluted with organic-free reagent water to 1 liter. When only a portion of sample from a bottle is extracted, care must be taken to thoroughly mix the sample before taking the aliquot for analysis.

NOTE: The guidance of SW-846 suggests rinsing the sample bottle with 60mL of methylene chloride, however it is Paragon's practice to decant the sample volume for aqueous analysis. Paragon does not rinse the sample bottle to better avoid the introduction of solids as a component of the aqueous phase analysis, and also when high concentrations are anticipated or known and only a portion of the sample volume will be extracted.

8.3 If the entire contents of the sample bottle are to be extracted, mark the level of sample on the outside of the bottle. Transfer the sample directly from the sample bottle to the CLE. A powder funnel may be used to pour the sample into the CLE. Refill the bottle with tap water up to the sample level previously marked. Measure and record the volume of sample that was in the bottle using an appropriate size graduated cylinder. Alternatively, use an appropriate size graduated cylinder to measure 1 liter (nominal) of sample and transfer it quantitatively to the CLE.

8.4 If sufficient sample volume has been provided, prepare one matrix spike/matrix spike duplicate (MS/MSD) set per batch of 20 or fewer environmental samples.

8.5 Use two separate aliquots of DI water to serve as the batch method blank (MB) and laboratory control sample (LCS).

8.6 Check the initial pH of the samples with wide range pH paper and record on the laboratory benchsheet. If necessary, adjust the pH using sulfuric acid solution or 12N sodium hydroxide to the pH indicated for the specific determinative method that will be used. Record the adjusted pH on the laboratory benchsheet. See Table 1 for required pH values.

NOTE: For most preparations, the pH is checked/adjusted *before* adding any spikes. However, when preparing for semivolatiles analysis, the pH is checked/adjusted *after* the required spikes are added.

8.7 Add the appropriate volume of spike (usually 1.0mL) to the MS/MSD samples. Add the appropriate volume of spike (usually 1.0mL) to the LCS sample. Spike

all client and laboratory QC samples with an appropriate amount of surrogate (usually 1.0mL).

8.8 Add sufficient reagent water to the CLE to ensure proper operation, and extract for 18-24 hours. *Be sure the water for the condensers is circulating before switching on the heating mantles.* Record start and stop times of methylene chloride cycling on the benchsheet.

8.9 After the extraction period, allow the extractor to cool for at least one half hour, then detach the boiling flask. If extraction at a secondary pH is not required, the extract is dried and concentrated using procedures from SOP 607 (Kuderna Danish procedure) and SOP 637 (nitrogen blowdown procedure). See Table 1 for pH information.

8.10 If extraction at a secondary pH is required, attach a clean round bottom flask containing 200mL of methylene chloride to the CLE. Carefully, while stirring, adjust the pH of the aqueous phase to the second pH indicated in Table 1. Extract for 18-24 hours, allow to cool, and detach the boiling flask. *Note that if performing Method SW8270, the acid/neutral and base extracts may be combined prior to concentration.*

9. QUALITY CONTROL

Re-extraction of the sample may be warranted if any of the following should occur:

- If the cooling water in the condenser column is left off and solvent volume is lost through the condenser or the flat bottom flask boils to dryness.
- If an emulsion forms that blocks the flow of solvent through the dump tube, the entire contents of the CLE should be transferred to a separatory funnel, the emulsion broken, and the contents quantitatively transferred to a clean CLE.
- Contamination of extracts or samples.
- Cross-contamination resulting from transferring the sample/extract to or from the wrong funnel or flask indicated for that sample or extract.

If re-extraction is not possible due to extenuating circumstances (e.g., no sample remaining, past holding time) the extract should be kept and the benchsheet noted accordingly. The Project Manager and Department Manager should be notified. In all cases, whether or not re-extraction is possible, a "NonConformance" (NCR) form must be initiated and processed (see SOP 928).

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW3520C. There are no known deviations from the method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples).

11.1.3 Any chemicals with a Threshold Limit Value of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Methylene chloride has a TLV ≤50ppm.

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Expired standards are returned to the analytical group that prepared them to be disposed of in a proper waste stream.

11.2.2 Methylene chloride is disposed in the halogenated organic waste satellite collection vessel.

11.2.3 Extracted non-radioactive water is disposed of in the CLE aqueous waste stream.

11.2.4 Extracted radioactive water is disposed of in the radioactive CLE aqueous waste stream.

11.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. All labels and markings must be defaced prior to disposal.

Timer Operation

1) **CLLE only** - check that the plugs connected to the power strip correspond to the heating mantles you wish to use.

   Soxhlet only - unplug the Variac(s) power cord(s) from the 3-outlet heavy-duty extension cord. Variac cords are marked with either the Variac # or "aqua" colored tape, or both. **MAKE SURE** the Variac(s) you are using correspond to the six-position set-up you want to run. Then, plug the Variac cord(s) into either (or both) of the 2 outlets on the digital timer. Each Variac is labeled as to which digital timer it should be plugged into. Check that the timer # on the Variac matches the timer # you are plugging it into. After plugging the Variac(s) into the timer, turn the Variac(s) on, using either the toggle or circular switch, depending on the model. Flip the appropriate toggle switches on the soxhlet heating mantle bank, to activate the position(s) you want to run.

2) Check that the **day-of-week**, **time**, and **AM/PM** on the timer are correct (press "CLOCK" on the timer). If any of the date/time display is incorrect, reset the clock as described in **Appendix A**.

3) Program the timer as follows:

   a: Press "PROG" button on the timer once. The left-hand side of the timer display should look like this:

   
   b: Press "DAY" button until the day of the week you want the timer to start (i.e., begin extraction) is indicated at the top of the display screen.

   c: Press "HOUR" button until the hour you want the timer to start is displayed. **MAKE SURE** that the hour selected is correct, with respect to AM/ PM, as timer does not display or run on "military" time.

   d: Press "MIN" button until the minute you want the timer to start is displayed. Holding down the "MIN" button will cause it to scroll.

   e: Once date/time to turn **ON** is established, press "PROG" again. The left-hand side of the timer display should now look like this:

   
   f: **Repeat steps b-d** to program what time you want the timer stop (i.e., stop extraction). When complete, press "CLOCK" to return to the current date/time display.

   g: Check/confirm program **ON** date and time, by pressing "PROG" once. Check/ confirm program **OFF** date and time, by pressing "PROG" again. Press "CLOCK" to go back to the current date and time display.

   h: Lastly, press the "MODE" button until "**AUTO**" is displayed to the left on the date/ time display. **MAKE ABSOLUTELY SURE** that timer is set to "AUTO" mode, and not "OFF," "ON," or "RDM;" as these other modes will either cause timer to not turn on, turn on immediately, or turn on at a semi-random time.

4) The timer is now ready to run your program!

Important Notes:

- While the timer(s) will accept up to 7 different event programs, it is **not advised** that you use this feature. Rather, reprogram the timer under Event 1 (indicated by the little number "1" in the Program display) each time you want to program start / stop dates and times.
- When you are done using timer (i.e., your extraction is complete and you are finished using the timer to run samples) **it is important that you unplug the Variac cord** from the timer and plug it back into the 3-outlet heavy-duty extension cord; **as well as turning off the Variac power switch**. If you leave the Variac(s) plugged into the timer, the set program will run again in 1 week (if timer is on AUTO mode), regardless of whether CLLEs/Soxhlets are actually set up. This is a potential fire hazard, as the heating mantles get hot enough to scorch paper. Also, **press "MODE" on timer until "OFF" is displayed to the left of the date/ time display**. This turns the set program off, preventing the timer from re-running the program in seven days.
- The timer's clock runs on one "AA" battery. The battery in each timer should be replaced approximately every June and December to ensure performance of the timers. To replace, use a small Phillips-head screwdriver to remove the battery cover on the back of the timer, and install a fresh battery in the correct orientation.

APPENDIX A
SETTING CLOCK

1) Press "CLOCK" to view the currently programmed date and time. If it is not correct… while holding down "CLOCK":
   a: Press "DAY" until correct day-of-week is displayed.
   b: Press "HOUR" until correct hour is displayed, **remember to set correct hour by AM/ PM.**
   c: Press "MIN" until correct minute is displayed.
2) Release "CLOCK" button. The display should now give the correct date and time. As an example, if it is three-o-clock in the afternoon on Wednesday, the display should read:

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 622 REVISION 6

TITLE: WASTE DILUTION EXTRACTION -- METHOD SW3580A

FORMS: NONE

APPROVED BY:
TECHNICAL MANAGER _____ DATE 27 Feb 06
QUALITY ASSURANCE MANAGER _____ DATE 2/27/06
LABORATORY MANAGER _____ DATE 2-27-06

HISTORY: Rev0, 7/17/92; Rev1, PCN #383, 2/17/95; Rev2, 7/15/99; Rev3, 3/01/02; Rev4, 3/14/03; Rev5, 4/27/04; Rev6, 2/27/06. re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the extraction of waste samples by SW-846 Method SW3580A and pertains to oil samples or other methylene chloride or hexane miscible organic liquids that are to be analyzed for a variety of organic compounds, generally utilizing SW-846 methods.

2. OVERVIEW

Approximately 1g of sample is diluted with hexane, methylene chloride or other appropriate solvent to 10mL in a Class A volumetric flask. Cleanup procedures are generally recommended and vary depending on the analytical method to be employed. Appropriate cleanups include methods SW3620 (SOP 648), SW3665 (SOP 651), SW3630 (SOP 604), and SW3640 (SOP 641).

3. RESPONSIBILITIES

3.1 Analysts must demonstrate the capability to generate acceptable It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct those errors.

3.4 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the processing of the samples on the bench sheet. Any discrepancies must be noted and corrective action taken and documented.

4. APPARATUS AND MATERIALS

4.1 volumetric flasks, Class A, 10mL or as appropriate

4.2 vials, screw-top with Teflon liner, 40mL or as appropriate

4.3 analytical balance (±0.0001g sensitivity)

4.4 Pasteur pipettes, disposable

4.5 pipette bulb

5. REAGENTS – Only pesticide residue grade or equivalent may be used.

5.1 hexane (C_6H_{14}), pesticide residue grade or equivalent

5.2 methylene chloride (CH_2Cl_2), pesticide residue grade or equivalent

5.3 surrogate and matrix spike standard solutions

6. PROCEDURES

6.1 To ensure homogenous sub-sampling, even single-phase liquids generally require homogenization by stirring or mixing prior to taking an aliquot. If liquids are multiphasic, the phases may need to be separated prior to taking an aliquot. Multiphasic liquids often have an aqueous phase and an organic phase. This procedure is not suitable for preparing aqueous phases. If two or more organic phases are present then all of the organic phases may be prepared by this procedure.

Measure and record the proportion of each phase prior to taking an aliquot. Weigh out approximately 1g of sample into a 10mL volumetric flask. Record the weight (to ±0.0001g) in the appropriate logbook. Lesser volumes of sample can be weighed out if prior knowledge indicates this is appropriate. Repeat for the matrix spike/matrix spike duplicate (MS/MSD) pair, as applicable.

6.2 Prepare a method blank (MB) in a volumetric flask using an aliquot of solvent (typically 9mL). Likewise, prepare aliquots for the laboratory control sample (LCS, typically 8mL) and the laboratory control sample duplicate (LCSD), if

applicable. Typical solvents for this procedure are hexane for SW8081 or SW8082, and methylene chloride for SW8270.

6.3 Add the appropriate volume of surrogate to all field and quality control (QC) samples (typically 1mL).

6.4 For the LCS and LCSD, and the MS/MSD, spike with the proper volume of matrix spike standard solution (typically 1mL).

6.5 Dilute samples and QC to full volume (10mL) with the appropriate solvent for the analytical method.

NOTE: It is important to bring the samples to final volume ***exactly***. The bottom of the solution's meniscus should rest exactly on the top of the line etched on the volumetric flask.

6.6 Stopper all volumetric flasks and shake until well mixed (approximately two minutes).

6.7 The extracts are now ready for appropriate cleanups. If no cleanups are required, the extracts may be delivered to the appropriate analytical group (observe SOP 318 internal chain of custody procedures). Extracts should be transferred to appropriate vials before delivery to the analytical group.

7. SAFETY, HAZARDS AND WASTE

7.1 SAFETY AND HAZARDS

7.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

7.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

7.1.3 Any chemicals with a Threshold Limit Value (TLV) ≤50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). **Methylene chloride and hexane have a TLV = 50ppm and use of these solvents must be performed in an adequately ventilated fume hood.**

7.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name; NFPA Health, Flammability, and Reactivity ratings; and date.

7.2 WASTE DISPOSAL

7.2.1 Any hexane, acetone, or other nonhalogenated organic solvents may be disposed of in the Acetonitrile/Nonhalogenated Waste.

7.2.2 Methylene chloride should be disposed of in the Halogenated Waste stream.

7.2.3 The extract vials and the associated extracts are disposed of by the analytical group receiving them in the appropriate waste stream.

7.2.4 All empty solvent bottles are disposed of according to the appropriate procedures. Please note that all labels and markings must be defaced prior to disposal.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 625 REVISION 11

TITLE: **SOXHLET EXTRACTION - METHOD SW3540C**

FORMS: **605, 606, 609, 616** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3-7-08

QUALITY ASSURANCE MANAGER _____ DATE 3/6/08

LABORATORY MANAGER _____ DATE 3-7-08

HISTORY: Rev0, 2\19\92; Rev1, PCN #133, 2/11/94; Rev2, PCN #438, 4/18/95; Rev3, 5/20/96; Rev4, 2/16/99; Rev5, 3/1/02; Rev6, 5/1/02; Rev7, 12/2/02; Rev8, 3/6/04; Rev9 11/22/04; Rev10, 7/5/06; Rev11, 3/4/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references - SW846 Method 3540C, describe a procedure for extracting non-volatile and semivolatile organic compounds from solids such as soils, sludges, and wastes. The Soxhlet extraction process ensures intimate contact of the sample matrix with the extraction solvent. This method is applicable to the isolation and concentration of water-insoluble and slightly water soluble organics in preparation for various determinative chromatographic procedures.

2. SUMMARY OF METHOD

A weighed sample is chemically dried by mixing with anhydrous sodium sulfate, then placed in an extraction thimble. The thimble is then loaded into the Soxhlet apparatus and spiked appropriately. The sample is extracted for 16-24 hours. The extract is then dried, concentrated, and as necessary, exchanged into a solvent compatible with the clean up or determinative method that follows. Paragon SOPs 607 and 637 describe the solvent concentration and solvent exchange procedures utilized after this extraction procedure.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the

technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

3.5 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

4. INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks.

4.2 Interferences co-extracted from the samples will vary considerably from source to source. If analysis of an extracted sample is hindered due to interferences, further clean up of the sample extract may be necessary. Refer to SW-846 Method 3600C for guidance on clean up procedures.

4.3 Interference from phthalate esters can be minimized by using plastic-free solvent containers and scrupulously cleaned glassware (SOP 334) that has been kiln-baked or solvent-rinsed prior to use. Use of low phthalate gloves, such as nitrile, may also be important. These practices are important both in the field and in the laboratory.

4.4 Soap residue on glassware may cause degradation of certain analytes. Specifically, aldrin, heptachlor, and most organophosphorous pesticides may degrade in the presence of soap residue. All glassware should be hand-rinsed thoroughly with hot water after washing with soap. Soxhlet glassware is also kilned after washing (SOP 334).

5. APPARATUS AND MATERIALS

5.1 Soxhlet extractors

5.2 condenser columns with circulating cooling water

5.3 round flat-bottom flasks, 500mL

5.4 heating mantles, rheostat controlled

5.5 Teflon™ boiling stones, or glass boiling chips, or equivalent

5.6 syringes, 1.0mL or as needed

5.7 glass or paper thimble or glass wool (used when sample aliquot will not fit into thimble)

5.8 laboratory balance, capable of weighing to 0.01g, and verified per SOP 305

5.9 beakers, 400mL

5.10 spatula, metal or wooden

6. REAGENTS

6.1 Ottawa sand, EMD, Cat. SX0075-3 or equivalent.

6.2 Sodium sulfate (Na_2SO_4), anhydrous, granular, ACS grade. EMD, Cat. SX0760E-5, or equivalent. *Purify by heating at approximately 450°C for two to six hours or by pre-cleaning with methylene chloride.*

6.3 Methylene chloride (CH_2Cl_2), Burdick & Jackson, Cat. 299-4, or other extraction solvents as appropriate, pesticide residue grade or equivalent

NOTE: Paragon has historically used methylene chloride only for Method SW3540C preparations. This follows the guidance of SW-846, which allows for the use of alternative extraction solvents. Documentation of performance is contained in REPORT: DCM_Acetone (J:\Audits and Corrective Actions\Findings and Corrective Actions\Topical Corrective Actions\DCM_Acetone).

Note that information regarding spike solutions (i.e., surrogate, laboratory control sample, matrix spike) is contained in the associated determinative SOP.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Soil samples intended to be analyzed for semivolatile organics, organochlorine pesticides, polychlorinated biphenyls or herbicides are collected in a wide-mouth glass jar with Teflon™-lined lid. Soil samples are not chemically preserved.

7.3 Soil samples must be extracted within 14 days of collection.

7.4 All samples and extracts are stored at 4±2°C.

8. PROCEDURE

8.1 SAMPLE HANDLING

8.1.1 Decant and discard any water layer. Take care to discard any foreign objects (e.g., sticks, leaves, rocks) or any portion of the sample that appears to ***not*** be representative of the sample. Mix sample thoroughly

to ensure that a representative sample is obtained, especially composited samples. *Note that samples that consist of multiple phases must be prepared by the phase separation method in Chapter Two of SW-846. This SOP addresses solids only.*

8.1.2 Safety concerns such as dust control may preclude the grinding of samples for particle size reduction. These safety concerns must always be addressed before attempting to grind any sample. Generally, grinding to reduce particle size is not practiced in the extractions area. Samples requiring size reduction have been sent to an appropriate facility before an extraction was performed.

8.1.3 Gummy, fibrous, or oily materials not amenable to grinding should be cut, shredded, or otherwise broken up to allow mixing and maximum exposure of the sample surfaces for extraction. *Consult the Department Manager regarding difficult, unusual matrices.* The addition of anhydrous sodium sulfate to the sample (in a 1:1 ratio) may make the mixture amenable to grinding.

8.2 Place approximately 300mL of extraction solvent into a 500mL round bottom flask containing several clean boiling stones. Attach the flask to the Soxhlet extractor, and label the round bottom flask appropriately.

8.3 Weigh 30g (nominal) of sample and record the weight to the nearest ±0.01g on the benchsheet.

8.4 Blend the sample aliquot with approximately 30-60g of anhydrous sodium sulfate and place the mixture in an extraction thimble. Load the thimble in a way that allows it to drain freely for the duration of the extraction period. Carefully place the thimble into a Soxhlet setup. If sufficient sample is available, prepare one field sample per batch in triplicate (extra sample aliquots to serve as the matrix spike and matrix spike duplicate, MS/MSD). Some clients may require the preparation of an unspiked sample duplicate (DUP).

8.5 For each batch of 20 or fewer samples, prepare two aliquots of Ottawa sand as described above, one to serve as the method blank (MB) and one to be spiked as the laboratory control sample (LCS). Note that three aliquots of Ottawa sand may need to be prepared if an LCSD is to be analyzed.

8.6 Add the appropriate volume (usually 1.0mL) of surrogate standards to all prepared field and quality control (QC) samples. If aliquots for matrix spiking have been prepared, spike these with the appropriate volume (usually 1.0mL) of matrix spike standard. Also spike (typically 1.0mL) the aliquot(s) of Ottawa sand designated as the LCS.

8.7 Extract the samples for 16-24 hours at a rate of 4-6 cycles per hour. Record the start and stop times of methylene chloride cycling on the laboratory benchsheet.

8.8 After the extraction is complete, allow the extracts to cool. Then dry and concentrate the extracts per SOP 607 (Kuderna Danish procedure) and SOP 637 (nitrogen blowdown procedure).

9. QUALITY CONTROL

Re-extraction of the sample may be warranted if any of the following should occur:

- If the condenser column cooling water is left off and solvent volume is lost through the condenser or the round bottom flask boils to dryness.
- Phthalate contamination due to contact of extracts or sample with latex or vinyl gloves worn by technicians.
- Cross-contamination resulting from transferring the sample/extract to or from the wrong Soxhlet indicated for that sample or extract.

If re-extraction is not possible due to extenuating circumstances (e.g., no sample remaining, past holding time) the extract should be kept and the benchsheet noted accordingly. The Project Manager and Department Manager must be notified. In all cases, whether or not re-extraction is possible, an NCR (SOP 928) must be initiated and processed.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW3540C. Extraction is performed with dichloromethane. Method SW3540C calls for dichloromethane:acetone or hexane:acetone extraction. The suitability and performance of dichloromethane only is documented in REPORT: DCM_Acetone (J:\Audits and Corrective Actions\Findings and Corrective Actions\Topical Corrective Actions\DCM_Acetone).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Methylene chloride has a TLV ≤50ppm.

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Methylene chloride solutions are disposed of in the Halogenated Organic Waste satellite collection vessel.

11.2.2 The solid sample residues and solid sample/Na_2SO_4 residue shall be disposed of in the Contaminated Soils and Solids Waste. Radioactive solid sample residues and solid sample/Na_2SO_4 residue shall be disposed of in the Radioactive Soils and Solids Waste satellite collection vessel. Note that mixed waste solids/prepared sample residues must be disposed of in the appropriate Mixed Waste container.

11.2.3 Expired standards shall be returned to the analytical group that prepared them; the expired standards will then be disposed of in the proper waste stream.

11.2.4 All empty solvent bottles shall be disposed of according to the appropriate SOPs; all labels and markings must be removed or defaced prior to disposal.

Timer Operation

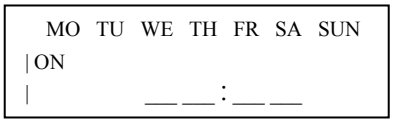
1) **CLLE only** - check that the plugs connected to the power strip correspond to the heating mantles you wish to use.

Soxhlet only - unplug the Variac(s) power cord(s) from the 3-outlet heavy-duty extension cord. Variac cords are marked with either the Variac # or "aqua" colored tape, or both. **MAKE SURE** the Variac(s) you are using correspond to the six-position set-up you want to run. Then, plug the Variac cord(s) into either (or both) of the 2 outlets on the digital timer. Each Variac is labeled as to which digital timer it should be plugged into. Check that the timer # on the Variac matches the timer # you are plugging it into. After plugging the Variac(s) into the timer, turn the Variac(s) on, using either the toggle or circular switch, depending on the model. Flip the appropriate toggle switches on the soxhlet heating mantle bank, to activate the position(s) you want to run.

2) Check that the **day-of-week**, **time**, and **AM/PM** on the timer are correct (press "CLOCK" on the timer). If any of the date/time display is incorrect, reset the clock as described in **Appendix A**.

3) Program the timer as follows:

a: Press "PROG" button on the timer once. The left-hand side of the timer display should look like this:

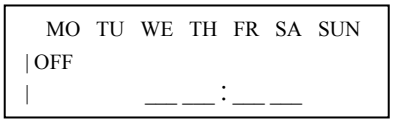


b: Press "DAY" button until the day of the week you want the timer to start (i.e., begin extraction) is indicated at the top of the display screen.

c: Press "HOUR" button until the hour you want the timer to start is displayed. **MAKE SURE** that the hour selected is correct, with respect to AM/ PM, as timer does not display or run on "military" time.

d: Press "MIN" button until the minute you want the timer to start is displayed. Holding down the "MIN" button will cause it to scroll.

e: Once date/time to turn **ON** is established, press "PROG" again. The left-hand side of the timer display should now look like this:



f: **Repeat steps b-d** to program what time you want the timer stop (i.e., stop extraction). When complete, press "CLOCK" to return to the current date/time display.

g: Check/confirm program **ON** date and time, by pressing "PROG" once. Check/ confirm program **OFF** date and time, by pressing "PROG" again. Press "CLOCK" to go back to the current date and time display.

h: Lastly, press the "MODE" button until "**AUTO**" is displayed to the left on the date/ time display. **MAKE ABSOLUTELY SURE** that timer is set to "AUTO" mode, and not "OFF," "ON," or "RDM;" as these other modes will either cause timer to not turn on, turn on immediately, or turn on at a semi-random time.

4) The timer is now ready to run your program!

Important Notes:

- While the timer(s) will accept up to 7 different event programs, it is **not advised** that you use this feature. Rather, reprogram the timer under Event 1 (indicated by the little number "1" in the Program display) each time you want to program start / stop dates and times.
- When you are done using timer (i.e., your extraction is complete and you are finished using the timer to run samples) **it is important that you unplug the Variac cord** from the timer and plug it back into the 3-outlet heavy-duty extension cord; **as well as turning off the Variac power switch**. If you leave the Variac(s) plugged into the timer, the set program will run again in 1 week (if timer is on AUTO mode), regardless of whether CLLEs/Soxhlets are actually set up. This is a potential fire hazard, as the heating mantles get hot enough to scorch paper. Also, **press "MODE" on timer until "OFF" is displayed to the left of the date/ time display**. This turns the set program off, preventing the timer from re-running the program in seven days.
- The timer's clock runs on one "AA" battery. The battery in each timer should be replaced approximately every June and December to ensure performance of the timers. To replace, use a small Phillips-head screwdriver to remove the battery cover on the back of the timer, and install a fresh battery in the correct orientation.

APPENDIX A

SETTING CLOCK

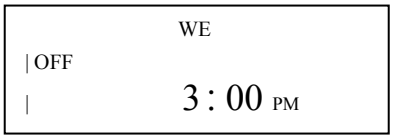
1) Press "CLOCK" to view the currently programmed date and time. If it is not correct… while holding down "CLOCK":

   a: Press "DAY" until correct day-of-week is displayed.

   b: Press "HOUR" until correct hour is displayed, **remember to set correct hour by AM/ PM.**

   c: Press "MIN" until correct minute is displayed.

2) Release "CLOCK" button. The display should now give the correct date and time. As an example, if it is three-o-clock in the afternoon on Wednesday, the display should read:



Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 626 REVISION 9

TITLE: **SEPARATORY FUNNEL LIQUID-LIQUID EXTRACTION -- METHOD SW3510C**

FORMS: **602, 605, 606, 609, 616**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9.5.06

QUALITY ASSURANCE MANAGER _____ DATE 9/5/06

LABORATORY MANAGER _____ DATE 9-5-06

HISTORY: Rev0, 2/10/92; Rev1, PCN #282, 11/10/94; Rev2, 4/12/96; Rev3, 2/12/99; Rev4, 2/13/02; Rev5, 3/01/02; Rev6, 12/03/02; Rev7, 2/23/04; Rev8, 11/22/04; Rev9, 9/1/06.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW-846 Method 3510C -- describe a procedure for isolating organic compounds from aqueous samples. This method is applicable to the isolation and concentration of water-insoluble and slightly water-soluble organics in preparation for various chromatographic procedures.

2. SUMMARY

A measured volume of sample, usually 1 liter, is serially extracted at a specified pH with methylene chloride, using a separatory funnel. The extract is dried, concentrated, and, as necessary, exchanged into a solvent compatible with the cleanup and analysis to follow. See Table 1 for specified pH values. Paragon SOPs 607 and 637 describe the solvent concentration and solvent exchange procedures utilized after this extraction procedure.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the extraction according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data and/or the associated extracts as appropriate.

3.4 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented..

4. INTERFERENCES

4.1 Interference from phthalate esters can be minimized by using plastic-free solvent containers and scrupulously cleaned glassware (SOP 334) that has been kiln-baked or solvent-rinsed prior to use. Use of low phthalate gloves, such as nitrile, may also be important. These practices are important both in the field and in the laboratory.

4.2 Soap residue on glassware may cause degradation of certain analytes. Specifically, aldrin, heptachlor, and most organophosphorous pesticides may degrade in the presence of soap residue. Glassware shall be kiln-baked or solvent-rinsed prior to use.

4.3 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks.

4.4 Interferences co-extracted from the samples will vary considerably from source to source. If analysis of an extracted sample is hindered due to interferences, further cleanup of the sample extract may be necessary. Refer to SW-846 Method 3600C for guidance on cleanup procedures.

5. APPARATUS AND MATERIALS

5.1 separatory funnels, adequate size to allow adequate mixing of sample and solvent, with Teflon™ stopcock, and Teflon™ or glass stopper

5.2 graduated cylinder, 1 or 2L

5.3 powder funnels

5.4 pH paper, wide and narrow range

5.5 solvent collection vessels -- Erlenmeyer or round flat-bottom flask of appropriate size (250-500mL)

5.6 syringes, 1mL or as needed

6. SOLVENTS AND REAGENTS

NOTE: Only reagent grade chemicals may be used. Reagents must be stored in glass to prevent the leaching of contaminants from plastic containers.

6.1 Organic-free reagent water; the laboratory deionized (DI) water is suitable.

6.2 Sodium hydroxide (NaOH). JT Baker #3722–07 or equivalent. Used for pH adjustments. In a large Pyrex™ beaker with magnetic stirrer, prepare 12M solution by slowly adding 480g NaOH pellets per liter of reagent water. A cold-water bath is typically used to keep the solution cool while mixing, as the addition of NaOH pellets generates heat when added to the water. Should be stored in an HDPE container, as a glass container might slowly dissolve at high pH.

6.3 Sulfuric acid (H_2SO_4), concentrated. Used for pH adjustments. EMD #SX1247-2 or equivalent.

6.4 Sodium sulfate (Na_2SO_4), anhydrous, granular. EMD #SX0760E-5 or equivalent. Purify by heating at 450°C for two hours or by pre-cleaning with methylene chloride.

6.5 Methylene chloride (CH_2Cl_2), Burdick & Jackson #299-4 or equivalent.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Aqueous samples intended to be analyzed for semivolatile organics, organochlorine pesticides, polychlorinated biphenyls, organophosphorous pesticides, Cal LUFT or herbicides are collected in 1L amber glass bottles equipped with a Teflon™-lined lid. Aqueous samples are not typically preserved. This SOP may, however, be used to process aqueous samples that have been preserved with acid (per some State fuels programs) or dechlorinated with sodium thiosulfate ($Na_2S_2O_3$).

7.3 All samples are stored at 4±2°C.

7.4 Samples must be extracted within 7 days of collection.

8. PROCEDURE

8.1 Carefully solvent rinse all glassware, stoppers, and stopcocks to be used in the extraction procedure with appropriate solvent. Glassware that has been kilned

and sealed need not be solvent rinsed.

8.2 Assemble the separatory funnel, being careful not to touch the center portion of the Teflon™ stopcock.

8.3 Typically the entire contents of a sample bottle are extracted, so any lack of homogeneity is likely due to the field sampling process. If high concentrations are anticipated, a smaller volume may be used and then diluted with organic-free reagent water to 1L. When only a portion of sample from a bottle is extracted, care must be taken to thoroughly mix the sample before obtaining the aliquot.

NOTE: The guidance of SW-846 suggests rinsing the sample bottle with 60mL of methylene chloride, however, it is Paragon's practice to decant the sample volume for aqueous analysis. Paragon does not rinse the sample bottle to better avoid the introduction of solids as a component of the aqueous phase analysis, and also when high concentrations are anticipated or known and when only a portion of the sample volume is extracted.

8.4 If the entire contents of the sample bottle are to be extracted, mark the level of sample on the outside of the bottle. Transfer the sample directly from the sample bottle to the separatory funnel. A dedicated powder funnel may be used to pour the sample into the separatory funnel.

Refill the bottle with tap water up to the sample level previously marked. Pour the bottle's tap water contents out into a graduated cylinder of appropriate size to determine the volume of sample that was used. Record on benchsheet.

Alternatively, use an appropriate size graduated cylinder to directly measure 1L (nominal) of sample and transfer it quantitatively to the separatory funnel.

8.5 If sufficient sample volume has been provided, one matrix spike/matrix spike duplicate (MS/MSD) set per batch of 20 or fewer environmental samples will be prepared (typically 1.0mL of spike standard is added to the designated aliquot). Use two separate aliquots of DI water to serve as the batch method blank (MB) and laboratory control sample (LCS); typically 1.0mL of spike standard is added to the designated aliquots.

Add the appropriate volume (usually 1.0mL) of surrogate to all client and QC samples. The spikes are added before pH adjustment.

8.6 Check the initial pH of the sample with wide range pH paper and record on the laboratory benchsheet. If necessary, adjust the pH using sulfuric acid solution or 12N sodium hydroxide to the pH indicated for the specific determinative method that will be used. Record the adjusted pH on the laboratory benchsheet. See Table 1 for required pH values.

8.7 Add 60-80mL of methylene chloride to the separatory funnel.

NOTE: **Methylene chloride creates excessive pressure very rapidly.** Therefore, initial venting should be performed immediately after the separatory funnel has been sealed and shaken once, and then again after shaking it twice.

Always vent funnel into the hood and away from any person to avoid methylene chloride exposure.

Vent funnel slowly or sample will be lost due to rapid reversal of vapor pressure.

8.8 Seal and shake the separatory funnel vigorously for two minutes with frequent venting to release excess pressure.

8.9 Allow the organic phase to separate from the aqueous phase completely (for at least 10 minutes).

If an emulsion layer forms, it must be broken up. The optimum technique to break the emulsion depends on the sample, and may require stirring, filtration of the emulsion through glass wool, centrifugation, or other physical methods. More details follow.

After the ***last*** shake out has been performed, the emulsion may be broken up by pouring it into a beaker and slowly adding Na_2SO_4 and stirring until the water is absorbed into the Na_2SO_4. If the emulsion cannot be broken (recovery of <80% of the methylene chloride, corrected for the water solubility of methylene chloride), then transfer the sample, solvent, and emulsion into the extraction chamber of a continuous liquid-liquid extractor (CLE) and proceed as described in SOP 617. If transferred to a CLE, a set of new QC samples will also have to be prepared.

8.10 Collect the methylene chloride (solvent phase) in a 250mL Erlenmeyer flask or other appropriate collection vessel.

8.11 Repeat the extraction two more times using 60mL of fresh solvent each time. Combine the three solvent extracts in an appropriate glass flask (i.e., 500mL flat bottom flask).

8.12 If further pH adjustment and extraction is required, adjust the pH of the aqueous phase to the desired pH (see Table 1). Serially extract three times with 60mL portions of methylene chloride as described above. Collect and combine these three extracts and label the combined extract appropriately.

8.13 If the extracts are to be analyzed by method SW8270, the acid/base-neutral extracts may be combined prior to concentration.

8.14 The extract is dried and concentrated using procedures from SOP 607 (Kuderna Danish procedure) and SOP 637 (nitrogen blowdown procedure).

9. QUALITY CONTROL

9.1 Re-extraction of the sample may be warranted if any of the following should occur:

- An emulsion layer forms that cannot be broken up using physical methods and is greater than 20 percent of the total volume.
- The Teflon™ stopcock or stopper leak solvent when shaken.
- Either solvent or sample is lost due to inadequate venting of the separatory funnel.
- Phthalate contamination due to contact of extracts or sample with latex or vinyl gloves worn by technicians.
- Cross-contamination resulting from transferring the sample or extract to or from the wrong separatory funnel or flask indicated for that sample or extract.

If re-extraction is not possible due to extenuating circumstances (e.g., no sample remaining, past holding time) the extract should be kept and a notation made on the benchsheet. Notify the Project Manager and Department Manager.

In all cases, whether or not re-extraction is possible, an NCR (see SOP 928) must be initiated.

9.2 All QC samples must be subjected to exactly the same procedures as those used on actual samples.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW3510C. Section 8.3 details Paragon's procedure for achieving representative and reproducible sample aliquots. There are no known deviations from the method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples).

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Methylene chloride has a TLV ≤ 50ppm.

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Return expired standards to the analytical group that originally prepared them for proper disposal.

11.2.2 Methylene chloride is disposed in the Halogenated Organic Waste satellite collection vessel.

11.2.3 Extracted water is disposed of in the CLE aqueous waste stream.

11.2.4 Extracted radioactive water is disposed of in the radioactive CLE aqueous waste stream.

11.2.5 All empty solvent bottles are disposed of according to the appropriate SOPs. All labels and markings must be defaced prior to disposal.

STANDARD OPERATING PROCEDURE 629 REVISION 10

TITLE: **DETERMINATION OF IGNITABILITY BY THE PENSKY-MARTENS CLOSED-CUP TESTER -- METHODS SW1010A AND ASTM93-80**

FORM: **632** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-14-07

QUALITY ASSURANCE MANAGER _____ DATE 11/12/07

LABORATORY MANAGER _____ DATE 11-14-07

HISTORY: Rev0, 2/12/92; Rev1, PCN #135, 2/11/94; Rev2, PCN #441, 4/18/95; Rev3, 3/15/96; Rev4, 1/29/98; Rev5, 10/25/99; Rev6, 3/01/02; Rev7, 3/14/03; Rev8, 5/12/04; Rev10, 2/27/06; 11/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedure used to determine ignitability (flash point). This SOP is based on EPA SW-846 Method 1010A and ASTM Method 93-80. A Pensky-Martens closed-cup tester is used to determine the flash point of various liquids (e.g., fuel oils, lube oils), including those that tend to form a surface film under test conditions. Liquids containing non-filterable, suspended solids may also be tested using this method. A modified test for analyzing soils is also included.

2. SUMMARY OF METHOD

The sample is heated at a slow, constant rate (with liquid samples undergoing continuous stirring). A small flame is directed into the sample cup at regular intervals with simultaneous interruption of stirring. The flash point is the lowest temperature, corrected to a barometric pressure of 101.3kPa (760mm Hg), at which application of the test flame ignites the vapor above the sample.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible.

The criteria defined in the Program Specification supercede PAR's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct the errors that were found during review.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Interferences that may affect flash point values are: sudden changes in ambient pressure, sample homogeneity, drafts, and operator bias.

4.2 Samples having a pH≤2 or pH≥12 should not be placed in the sample cup as corrosion of the brass may occur.

4.3 Tars and or asphalt-like material may ruin the cup. The analyst should use caution in placing these organic solids in the cup.

5. APPARATUS AND MATERIALS

5.1 Pensky-Martens closed-cup flash tester, as described in Annex A1 of ASTM Method D93-80.

5.2 verified thermometer with a range of -20 to 150°C.

5.3 ignition source such as cigarette lighter or matches

6. REAGENTS

6.1 p-xylene – 1,4-dimethylbenzene ($C_6H_4(CH_3)_2$), (at least 97% pure)

6.2 acetone (CH_3COCH_3) and/or dichloromethane (CH_2Cl_2), for cleaning cup between samples

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 All samples should be collected according to an approved sampling plan.

7.2 Samples must be collected in glass containers and stored at 4±2°C. Samples should NOT be collected in plastic bottles, since volatile compounds may diffuse though the walls of the bottle.

7.3 Preservatives shall not be added to samples.

7.4 Method SW1010A does not specify a holding time for this analysis. Paragon's policy-defined maximum holding time allowance for conducting this test is 28 days from sample collection.

8. PROCEDURES

8.1 INSTRUMENT VERIFICATION PROCEDURE

A verification of instrument performance must be done at the beginning of each analytical batch (i.e., immediately before samples are analyzed), after every 10 samples, and immediately after the last field sample is analyzed. See Section 9.3 for acceptance criteria and corrective action if instrument verification fails.

8.1.1 Thoroughly clean and dry all parts of the sample cup and its accessories before starting the verification. Wash the cup with soap and water, rinse thoroughly with water, rinse with acetone three times, and then rinse with dichloromethane three times. Place the cup in the hood to air dry. Be sure that the stirrer is in place before beginning verification.

8.1.2 When the sample cup is clean and dry, the tester must be checked to demonstrate that it is in proper working order.

8.1.3 Add p-xylene to the cup until it reaches the fill line (approximately 75mL). Place the lid on the cup, making sure the locating device is properly engaged. Temporarily turn off the fume hood so that drafts will not affect the verification or analysis. It may be necessary to cool the sample cup before proceeding if the cup begins to retain heat from previous analyses. To cool the cup, gently place the sample cup in the cooling cup on the right side of the apparatus after adding a small amount of ice. Generally, rinsing the cup with methylene chloride will cool the cup enough to start the process.

NOTE: After p-xylene has been added to the cup, do not agitate the cup excessively.

8.1.4 Insert the thermometer into the appropriate slot on top of the sample cup. When the temperature of the p-xylene has dropped below 15°C, remove the sample cup from the cooling cup, wipe off any excess water from the sample cup, and place the sample cup into the heating mantle so that the cup fits securely. Attach the stirring probe to the stirrer on top of the sample cup.

8.1.5 Connect the gas line to the tester. Turn on the gas valve and apply the ignition source to the gas port outlet located on the top front of the

sample cup. Adjust the flame to a 3.2-4.8mm diameter (the flame should be under ~13mm in length).

NOTE: Be sure that all flammable materials are removed from the immediate vicinity of the tester before igniting the lighter and that the hood is off.

8.1.6 Turn on the toggle switch labeled "ON." This switch starts the stirring motor.

8.1.7 The white dial located to the right of the toggle switch turns on the heating element. The heating element will not work if the toggle switch is off. Turn the white dial to initiate heating at a rate of approximately 2°C per minute. Usually the first mark on the white dial is sufficient.

8.1.8 Apply the test flame at intervals of less than 5°C by operating the mechanism on the cover that controls the shutter and test flame burner. Lower the flame into the vapor space of the cup, for approximately 1 second, and quickly raise it to its high position.

8.1.9 The p-xylene (or any sample) is deemed to have a flash when a large flame appears and instantaneously propagates over the surface of the sample. The temperature at which this occurs is the flash point.

NOTE: Occasionally, when a temperature just below the flashpoint is reached, the application of the test flame will cause a blue halo or an enlarged flame**; this is not a flash point and the appearance of this halo should not be mistaken for a true flash.**

8.1.10 Under normal operating conditions, the corrected flash point for p-xylene should be 27±1°C. If the flash is outside this range then check the instrument and thermometer and determine the flash point of p-xylene again. If corrected flash point is not within ±1°C of 27°C, then analysis of samples can not proceed until the instrument can be verified to be working properly.

8.1.11 Verification of instrument performance must be done after every 10 samples, and after the last field sample is analyzed. See Section 9.3 for acceptance criteria and corrective action if this QC check fails.

8.2 SAMPLE PREPARATION

Reference methods allow for samples that are known to not contain high concentrations of volatiles, or that are very viscous, to be 'warmed' until they are reasonably fluid before being tested.

Note that if the sample *is* suspected to contain a high concentration of volatile components, or is a soil/solid, this treatment is not to be performed.

Per method directives, no sample is to be heated more than is absolutely necessary, and no sample should ever be heated to a temperature that is within 17°C of the expected flash point.

Because Paragon generally does not have *a priori* knowledge of samples, this warming as described is not performed, because it cannot be conducted without compromising the sample's integrity.

8.3 PROCEDURE FOR LIQUID SAMPLES

8.3.1 Follow the cleaning procedure as outlined in Section 8.1.1.

8.3.2 Fill the sample cup, as outlined in Section 8.1.3, with an aliquot of client sample.

8.3.3 Follow the procedure outlined in Section 8.1.4, with the exception of lowering the temperature of the sample down to a maximum of 4±2°C before placing the sample cup on the apparatus' stove. Therefore, samples should be left in the refrigerator until just prior to analysis.

8.3.4 Follow the procedure outlined in Sections 8.1.5 through 8.1.11 and apply the test flame approximately every 5°C, until a flash point has been observed, or until a temperature of 96.5°C is reached.

NOTE: Occasionally the test flame will ignite the vapor in the cup to such an extent that a flame will shoot out of the cup, or the test flame will grow very large when the shutter is opened, yet the vapors inside the cup do not ignite and propagate across the surface of the liquid. *Both of these phenomena are called a vapor flash, and the temperature at which this was observed must be noted on the benchsheet*. This occurrence is not a flash point.

8.3.5 Occasionally the test flame will be extinguished as the shutter is opened, but before the test flame can be fully lowered into the cup. The temperature at which this is first observed should be noted on the benchsheet as follows: "Non-flammable vapors began extinguishing the test flame at X°C."

When this occurs, gas will continue to flow into the sample cup, and may ignite the next time the flash point is checked, thus giving a false flash point. Be aware that as soon as the test flame begins to be

extinguished, the observation of a true flash point is practically impossible from that point to the completion of the test.

8.3.6 After a flash point has been observed or the temperature has reached 96.5°C, remove the sample cup from the stove and place in the cooling cup so the cup may cool down. Adding ice to the cooling cup will facilitate this step.

8.3.7 If no flash point is observed, report **"The flash point is >96.5 °C."**

8.3.8 If a flash point is observed, it must by confirmed by repeating the determination of the flash point.

The original aliquot shall be discarded, the cup cleaned, and the test repeated with a fresh test aliquot. The 2nd determination should be within ±5°C of the first determined flash point.

When performing the confirmation analysis, apply the test flame approximately every 5°C until a temperature of 15°C below the first observed flash point is reached, and then apply the test flame at intervals of 1-2°C.

Record second observed flash point. If the flash point cannot be confirmed, write in the comments section that the observed flash point could not be confirmed.

8.4 PROCEDURE FOR SUSPENSIONS OF SOLIDS AND HIGHLY VISCOUS LIQUIDS

Bring the material to be tested and the tester to a temperature of 20±5°C. Stirring in a downward direction, raise the temperature throughout the duration of the test at a rate of not less than 1-5°C/min.. With the exception of these requirements for rates of stirring and heating, proceed as prescribed in Section 8.3.

8.5 PROCEDURE FOR SOLIDS AND SOILS

Follow the same procedure as for liquids as outlined in Section 8.3, with the following exceptions:

8.5.1 Remove the stirrer from the sample cup; **Do Not Stir Soil/Solid Samples.** If the stirrer is not removed, either the stirrer will break or the thermometer will break when the toggle switch is turned on.

8.5.2 If non-flammable vapor begins to extinguish the test flame, note in the comments section the temperature at which this was first observed. Water vapor will continue to extinguish the test flame as the temperature is increased, so increase the rate of heating to a rate of 5°C

per minute, and apply the test flame at intervals of approximately every 5°C.

8.5.3 Continue testing the sample following the procedure as outlined in section 8.3.5-8.3.7

8.5.4 If a flash point is observed, confirm the flash point by running the confirmation analysis as outlined in Section 8.3.8.

8.6 CALCULATIONS

8.6.1 Call the CSU Atmospheric Sciences weather station or locate their web site (currently http://atmos.colostatee.edu/~autowx/) and record or print the ambient barometric pressure at the Fort Collins Weather Station on the University campus at the time of the test. When the pressure differs from 101.3 kPa (760 mm Hg), correct the flash point as follows:

corrected flash point = C+0.25 (101.3-K) (1)

corrected flash point = C+0.033 (760-P) (2)

where:

C= observed flash point, degrees Celsius

P= ambient barometric pressure, mm Hg

K= ambient barometric pressure, kPa

8.6.2 The barometric pressure used in the correction calculation is the pressure for the laboratory at the time of the test. Many aneroid barometers, like the ones used at weather stations and airports, are pre-corrected to give sea level readings, which would be incorrect for this test. However, the CSU Atmospheric Sciences Fort Collins Weather Station provides an uncorrected barometric pressure, and its readings may be used for this correction.

9. QUALITY CONTROL

9.1 Method blanks, matrix spike samples, matrix spike duplicate samples, and blank spike samples are *not* required for this test.

9.2 One duplicate analysis (on a new aliquot of sample) must be performed after every 10 samples. If one of the samples analyzed in a batch has a flash point that was confirmed, then this sample may be used as the duplicate sample for that batch. If there are no samples in a batch that exhibited a flash point, then any sample in the batch may be selected for duplicate analysis. For this test, a duplicate analysis of the same test sample should have results that agree to within ±5°C of the original. In the event that this criteria is exceeded for a sample that

does exhibit a flash point, the operator should examine the results of the p-xylene calibration verifications that preceded and follow the test samples. If these calibration verifications are acceptable, then a non-homogeneous sample matrix is suspected, and this conclusion will be noted in the case narrative.

9.3 Verify the instrument performance at the start of an analytical sequence, after every 10 samples, and again after the last sample, as described in Section 8.1. The acceptance criteria for this verification check standard is that the measured corrected flash point for p-xylene must agree to within ±1°C of the known flashpoint for p-xylene. If the instrument performance cannot be verified, then the test apparatus should be thoroughly cleaned, dried, and the verification performed again. If the second attempt at verification is successful, then the samples preceding the verification can be reported. If on a second attempt the flashpoint of p-xylene is not within acceptance criteria, then the preceding samples cannot be reported. Maintenance or repairs will be necessary, and successful verification of instrument performance must be completed before samples can be analyzed and reported.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW1010A. Method 1010A directs the reader to ASTM Method D93-80 for additional information, and those requirements have been incorporated into this SOP. There are no known deviations from these referenced Methods.

11. HEALTH, SAFETY AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Acetone and dichloromethane each has a TLV≤50ppm.

11.1.4 The analyst must minimize his/her exposure to p-xylene - prolonged overexposure can adversely affect the central nervous system.

11.1.5 The analyst must remove all flammable materials from the immediate vicinity of the testing apparatus, and make other analysts aware of the use of the flame so they do not bring any flammable materials into the vicinity of the apparatus while testing is being performed.

11.1.6 The analyst must exercise and take appropriate safety precautions during the initial application of the test flame, since samples containing low flash material may give an abnormally strong flash when the test flame is applied to the sample.

11.1.7 Perform this test in a fume hood. To prevent disturbance of the flame when samples are tested, the hood should be turned off so as not to be drawing air. Turn the hood back on between analyses.

11.1.8 Any non-original containers being used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Any p-xylene, hexane, acetone, or other nonhalogenated organic solvents may be disposed of in the Acetonitrile/Nonhalogenated Waste Profile.

11.2.2 Dichloromethane (methylene chloride) solutions are disposed of in the Halogenated Organic Waste satellite collection vessel.

11.2.3 Allow sample aliquots to cool before disposing into appropriate Solid or Liquid waste profile.

11.2.4 All empty solvent, reagent, and sample containers are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

re-released without revision 3/9/09 DAS

1. SCOPE AND APPLICATION

Elemental sulfur is encountered in many sediment samples, marine algae, and some industrial wastes. The solubility of elemental sulfur in various extraction solvents is very similar to the solubility of polychlorinated biphenyls and organochlorine pesticides in the extraction solvents. Therefore, the sulfur interference follows along with the pesticides through normal extraction and cleanup techniques.

This standard operating procedure (SOP) and the referenced method, SW3660B, describe procedures to remove elemental sulfur from extracts using metallic copper. Method SW3660B also provides a procedure to minimize sulfur using tetrabutyl-ammonium sulfite reagent. Paragon currently only performs the cleanup utilizing copper.

This cleanup procedure is performed on organochlorine pesticide and PCB extracts in which sulfur is present, or when sulfur may be expected in the sample extract. Cleanup is performed prior to analysis on electron capture detectors (ECDs). Figure 1 shows a PCB extract analyzed before sulfur cleanup was performed. An Aroclor pattern can be seen, but the quantification is hindered by the presence of sulfur in the extract. Figure 2 shows the same extract analyzed after sulfur cleanup was performed. The Aroclor pattern is much easier to identify and quantify after the sulfur has been removed.

2. SUMMARY OF PROCEDURE

Sample extracts that require cleanup are mixed with copper. The mixture is shaken and the extract is then removed from the copper reagent.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review (e.g., benchsheet).

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration of capability may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder file indicates that this review for completeness, precision and accuracy has been done and found to be satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

This procedure requires that the copper powder be very reactive, as evidenced by a bright shiny appearance (see Step 7.2 for the preparation of this reagent). However, care must be taken to remove all traces of the acid used to prepare the copper, in order to avoid possible degradation of some analytes.

5. APPARATUS AND MATERIALS

5.1 micro spatulas

5.2 Pasteur pipettes, disposable

5.3 glass vials with PTFE-lined caps, assorted sizes

6. REAGENTS - only reagent grade chemicals and pesticide residue grade or equivalent solvents may be used

6.1 copper (Cu) turnings or powder, Aldrich 26609-4 or equivalent

6.2 organic-free reagent water, laboratory deionized (DI) water is suitable

6.3 nitric acid (HNO_3), dilute: add a few drops conc. nitric acid (J.T. Baker #9598-34 or equivalent) to 50mL reagent water

6.4 acetone (CH_3COCH_3), Burdick & Jackson, Cat. #010-4 or equivalent

6.5 hexane (C_6H_{14}), Burdick & Jackson, Cat. #216-4 or equivalent

6.6 nitrogen gas, high purity

7. REMOVAL OF SULFUR USING COPPER

7.1 The sample extract is exchanged to hexane and concentrated to the desired final volume by Organic Extractions personnel per SOPs 607 and 637. If yellow sulfur crystals are present, centrifuge or let the crystals settle, draw-off the extract with a Pasteur pipet and transfer to a glass vial. If no sulfur crystals are visible, transfer approximately 1mL of the extract to a vial or other suitable container.

7.2 Remove oxides from the surface of the copper particles by treating with dilute nitric acid. Rinse several times with organic-free reagent water to remove all traces of acid, rinse with acetone, and dry under a stream of nitrogen.

7.3 Add 0.1-2g of cleaned copper to each vial and cap.

7.4 Vigorously shake each vial containing copper and extract for at least 1 minute.

7.5 Allow the copper to sink to the bottom of the vial.

7.6 Separate the extract from the copper using a Pasteur pipet. Place the extract in a clean vial.

7.7 If the surfaces of copper remaining in the vial are discolored from copper sulfide (CuS) precipitation, then repeat Steps 7.2 to 7.6.

8. QUALITY CONTROL

The method blank (MB) and laboratory control sample (LCS) associated in the sample extraction batch to be cleaned, are to be carried through this cleanup procedure exactly as the samples are processed. All reagents should be checked prior to use to verify that interferences do not exist.

9. DEVIATIONS FROM METHOD

There are no known deviations from the referenced method.

10. SAFETY, HAZARDS AND WASTE DISPOSAL

10.1 SAFETY AND HAZARDS

10.1.1 Read the MSDSs before prior to using any solvents or reagents for the first time.

10.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

10.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Concentrated nitric acid and hexane have TLVs ≤50ppm.

10.2 WASTE DISPOSAL

10.2.1 Any hexane, acetone, or other nonhalogenated organic solvents may be disposed of in the Acetonitrile/Nonhalogenated Waste.

10.2.2 The extract vials and associated extracts may be disposed of intact in the Discarded Extract Vial waste.

10.2.3 All empty solvent bottles are to be disposed of appropriately. Note that all labels and markings must be defaced prior to disposal.

10.2.4 Copper solids are disposed of in the Contaminated Soils and Solids Waste.

TITLE: CONCENTRATION AND SOLVENT EXCHANGE BY THE NITROGEN BLOWDOWN TECHNIQUE

FORMS: ~~604, 609, 611, 616, 635~~ **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11/12/07

QUALITY ASSURANCE MANAGER _____ DATE 11/12/07

LABORATORY MANAGER _____ DATE 11-12-07

HISTORY: Rev0, 1/15/92; Rev1, PCN #144, 2/25/94; Rev2, PCN #445, 4/18/95; Rev3, 3/1/99; Rev4, 4/9/02; Rev5, 12/5/02; Rev6, 3/6/04; Rev7, 11/22/04; Rev8, 11/20/06; Rev9, 11/12/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the procedure for concentrating extracts to a final volume by the nitrogen blowdown (N-Evap) technique. This SOP is based on procedures described in SW-846 Methods 3510C, 3520C, 3540C and 3550B.

2. SUMMARY

An aliquot of sample is extracted with solvent per SOPs 617, 625, 626, 664 or 665. The extracts from these procedures (except SOP 665) are dried, and then concentrated in a Kuderna-Danish (K-D) apparatus (SOP 607). During the K-D procedure, the extracts are concentrated to approximately 6-10mL. If necessary, the extracts are further concentrated to a smaller final volume by the N-Evap technique described in this SOP. This final concentration is accomplished by applying a steady stream of nitrogen gas over the extract to gently evaporate solvent. Changeover to another solvent can also be performed as part of the N-Evap process.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the LIMS program specification supercede Paragon's

standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks.

4.2 Interferences co-extracted from the samples will vary considerably from source to source. If analysis of an extracted sample is hindered due to interferences, further cleanup of the sample extract may be necessary. Refer to SW-846 Method 3600C for guidance on cleanup procedures.

4.3 Soap residue on glassware may cause degradation of certain analytes. Specifically, aldrin, heptachlor, and most organophosphorous pesticides may degrade in the presence of soap residue. All glassware should be hand rinsed thoroughly with hot water after washing with soap (SOP 334).

4.4 Interference from phthalate esters can be minimized by using plastic-free solvent containers and scrupulously cleaned glassware that has been kiln-baked or solvent-rinsed prior to use (SOP 334). KD concentrator tubes are also kilned after washing.

Use of low phthalate gloves, such as nitrile, may also be important. These practices are important both in the field and in the laboratory.

5. APPARATUS AND MATERIALS

5.1 Organomation N-Evap Model 115, 40 positions or equivalent

5.2 concentrator tubes, glass, 10mL or other size as needed

5.3 Pasteur pipettes, glass, disposable

5.4 graduated pipettes, glass, disposable

5.5 glass syringes, 0.5-2mL or as appropriate

5.6 glass vials with PTFE-lined screw caps, various sizes

6. REAGENTS

6.1 SOLVENTS – **must be pesticide residue or HPLC grade**

methylene chloride (CH_2Cl_2)

hexane (C_6H_{14})

acetonitrile (CH_3CN)

6.2 Nitrogen (N_2), 99.999% purity

7. PROCEDURE

NOTE: This procedure must be performed in a fume hood. **Plastic tubing must not be used, as it may introduce contaminants.**

7.1 Place the 10mL concentrator tubes in the N-Evap rack. **Be careful to hold the retaining spring back when you place the tube in the slot, as it may spring forward and break the tube.** Place a Pasteur pipette into the Teflon™ holder that corresponds to each concentrator tube.

7.2 Close the main flow valve on the N-Evap using the small black knob to the right. Open the valve on the nitrogen tank (approximately 1/4 turn).

7.3 Open the appropriate nitrogen flow valve at the top of each pipette by slowly turning 1/2 turn counterclockwise and then slowly open the main flow valve on the N-Evap a small amount. Adjust the flow so that each concentrator tube receives a steady, gentle stream of nitrogen that creates an indentation on the top of the extract without causing splashing. To ensure effective blowdown, lower the tip of the pipette to approximately 0.5-1cm above the solvent surface. Use the individual flow valves to adjust and maintain the flow rate. **The nitrogen flow rate must be kept low enough so that only a small indentation in the solvent is observed. Flow rates that cause splashing also cause target analytes to be lost during the blowdown.**

NOTE: Because flow is controlled at the N_2 tank, by the main flow valve of the N-Evap, and by each pipette controller, flow rate varies per N-Evap station. Hence, documentation of actual gas flow received by the sample at the pipette level is not possible. To verify proper flow was used, however, the 'Y' (yes) for the 'Gas flow properly set per station?' prompt, must be circled on the benchsheet."

Amended

7.4 As the solvent volume decreases, the internal walls of the concentrator tube must be rinsed several times with solvent. **Do not evaporate the sample to dryness.** Also, lower the pipettes as necessary to maintain the 0.5-1cm distance from the tip of the pipette to the solvent surface.

7.5 If solvent exchange is required, blow the extract down to approximately 0.5mL, then add 5-6mL of exchange solvent to each concentrator tube (exchange solvents are listed in Table 1). Continue the blowdown procedure until the solvent level reaches 0.5mL again. Repeat this step at least two times. Stop the procedure if volume is 0.5mL or less (when the volume of extract is reduced below 0.5mL, target analytes may be lost).

7.6 When the apparent volume of the extract is reduced to approximately the desired final volume (0.5-10mL depending on the analysis to be performed), remove the concentrator tube, **being careful to hold the retaining spring back as it may snap on the concentrator tube and cause sample loss through breakage or spillage.**

7.7 Bring the extract to the required final volume during quantitative transfer of each sample to a labeled glass vial with a PTFE-lined screw cap. Extracts with a final volume of 2mL or less (e.g., SW8270, SW8330), are generally measured using glass gas tight syringes. Those extracts with final volumes of greater than 2mL are quantitatively transferred to vials of appropriate size. Transfer all extract and rinsate from the concentrator tube to the vial.

For extracts with final volumes of greater then 2mL, a standard vial with appropriate final solvent is created using a volumetric pipette. Fill a vial to the desired final volume with solvent and label with date on cap to avoid confusing it with sample extracts. When vialing sample extracts, place the standard vial on a level surface and top off sample extracts to the desired final volume dropwise using a fine tipped solvent bottle or pipette. Final volume is achieved when the meniscus in the extract vial is level with that in the standard vial.

Observe proper chain-of-custody procedures (SOP 318) to deliver the extracts to the appropriate analytical group for refrigerated storage.

7.8 Turn off the main N_2 valve when the N-Evap is not in use.

8. QUALITY CONTROL

Note that all field and laboratory quality control (QC) samples must be processed in the same manner. Re-extraction of the sample may be warranted if any of the following should occur:

The extract is concentrated to dryness.

The extract is spilled.

The extract is solvent exchanged into the wrong solvent.

If re-extraction is not possible due to extenuating circumstances (e.g., no volume remaining, hold time exceeded), then the extract should be kept and the occurrence noted on the benchsheet. A Non-Conformance Report (NCR, SOP 928) must be initiated, and the Department and Project Managers notified.

9. DEVIATIONS FROM THE METHOD

This SOP meets the requirements of SW-846 Chapter 4 methods. There are no known deviations from these methods (i.e., SW3510C, 3520C, 3540C and 3550B).

10. SAFETY, HAZARDS AND WASTE DISPOSAL

10.1 SAFETY AND HAZARDS

10.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

10.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

10.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Methylene chloride, hexane and acetonitrile have TLVs ≤ 50ppm.

10.1.4 Any non-original containers being used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

10.2 WASTE DISPOSAL

10.2.1 Disposal of remaining extracts and vials is the responsibility of the analytical group receiving the extracts.

10.2.2 All empty solvent, reagent, or sample containers shall be disposed of appropriately. All labels and markings must be defaced prior to disposal.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 640 REVISION 7

TITLE EXTRACTION AND GRAVIMETRIC DETERMINATION OF HEXANE EXTRACTABLE MATERIAL IN SOLIDS – METHOD SW9071B

FORMS: 603 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3/1/07

QUALITY ASSURANCE MANAGER _____ DATE 2/28/07

LABORATORY MANAGER _____ DATE 3-1-07

HISTORY: Rev0, 12/15/91; Rev1, PCN # 155, 3/7/94; Rev2, PCN #358, 2/16/95; Rev3, 1/10/00; Rev4, 8/29/02; Rev5, 2/23/04; Rev6, 2/27/06; Rev7, 3/1/07. re-released without revision 3/9/09 DAS

1.0 SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW-846 Method 9071B -- describe procedures for measuring the hexane extractable matter (HEM) in soils, sludges, sediments or other solid samples. These procedures are applicable to the determination of relatively non-volatile hydrocarbons, vegetable oils, animal fats, waxes, soaps, greases, and related matter.

Note that these procedures are **not** recommended for measurement of light hydrocarbons that volatilize at temperatures below 85°C. Under the conditions of this SOP, petroleum fuels, from gasoline through Fuel Oil Number 2, are completely or partially lost in the solvent extraction process.

Some crude oils and heavy fuel oils contain a significant percentage of residue materials that are not soluble in the solvents used in this procedure. Accordingly, recoveries of these materials will be low.

2.0 SUMMARY

A representative portion of solid is acidified with concentrated HCl and mixed with a drying agent (sodium sulfate). The sample is then extracted with hexane, using a Soxhlet apparatus. The hexane is evaporated from the sample and the dry residue (hexane extractable material, HEM) is measured gravimetrically.

3.0 RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of

Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4.0 INTERFERENCES

4.1 Organic residues on glassware, dust or other particulate matter can interfere with this procedure.

4.2 The method is strictly empirical. Meaningful results can be obtained only by strict adherence to all details of the process.

5.0 APPARATUS AND MATERIALS

5.1 analytical balance, 0.0001g sensitivity, calibration verified per SOP 305

NOTE: A 2mg weight is used in addition to the standard (SOP 305) calibration verification. This 2mg calibration verification is recorded on the benchsheet.

5.2 beaker, 500mL

5.3 autopipetor (for acidification)

5.4 spatula, wooden, disposable

5.5 boiling flask, flat bottom, 500mL

5.6 PTFE-boiling chips: pre-clean by rinsing with methylene chloride, then dry

5.7 lint-free wipes, such as KimWipes®

5.8 desiccator, containing indicating Drierite™

5.9 hot plates

5.10 soxhlet apparatus, including glass (re-useable) thimbles

5.11 steam generator and S-Evap unit or equivalents

5.12 vacuum pump, with inlet hose

6.0 SOLVENTS

6.1 n-hexane, 85% purity, 99% minimum saturated C_6 isomers, residue less than 1mg/L

6.2 acetone, ACS grade, residue less than 1mg/L

6.3 dichloromethane, pesticide grade

7.0 REAGENTS - Only reagent grade or better chemicals shall be used.

7.1 hydrochloric acid (HCl), concentrated

7.2 sodium sulfate (Na_2SO_4), anhydrous, granular: Kiln for a minimum of 4 hours; cool to room temperature before use.

7.3 Ottawa sand.

8.0 STANDARDS

8.1 All standards are maintained per PAR SOP 300. Unopened stock standards are valid until the manufacturer's expiration date, and may be stored at room temperature in flame-sealed ampules or as otherwise recommended by the manufacturer. After opening ampule, the stock solution may be stored at room temperature in a tightly capped vial, and retained for up to six months (typically, the remainder of stock is discarded, instead). Intermediate standards (e.g., OPR Spiking Solution) may also be stored in a tightly sealed container at room temperature, and retained for up to six months. Standards may be replaced sooner if laboratory quality control (QC) analyses or other factors indicate deterioration.

All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials, and also documents the concentration of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer.

8.2 corn oil reference standard, Mazola™ or equivalent: Dilute in acetone to appropriate concentration (typically 0.1g/mL).

9.0 SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

9.1 Samples should be collected according to an approved sampling plan.

9.2 Soil samples should be collected in a wide-mouth glass jar and must be kept cool (4±2°C). Chemical preservation consists of addition of 1mL concentrated HCl to 100g of sample in the field. If this cannot be accomplished, then the sample is acidified prior to extraction.

9.3 No holding time has been established for this determination; Paragon observes a 28-day holding time to extraction for this procedure.

10.0 PROCEDURE

10.1 PREPARED GLASSWARE

A sufficient number of boiling flasks must be prepared to accommodate all field and QC samples (e.g., MB, LCS/LCSD, MS/MSD) in the batch. Label, add 3-5 boiling chips, wipe and weigh each flask on the analytical balance to the nearest 0.1mg. Record the weight on the benchsheet.

NOTE: Because the flasks are cleaned (SOP 334) and dried in a kiln, they do not need to be rinsed with hexane and dried prior to use. Because of potential residues, the flasks should not be touched by bare hands (use clean gloves, tongs, etc.) Store the flasks in a desiccator until needed.

One method blank (MB) and one laboratory control sample (LCS), consisting of a 50g aliquot of acidified, prepared Ottawa sand (see below), must be prepared with each batch of twenty or fewer field samples. If the client provided sufficient sample volume, prepare one sample in the batch in triplicate; the two additional acidified, prepared sample aliquots serve as the matrix spike and matrix spike duplicate (MS/MSD). If not enough sample volume was provided, prepare the LCS in duplicate (LCSD). The spiking of the MS and LCS aliquots are discussed below.

10.2 SAMPLE PREPARATION

10.2.1 Decant and discard any standing water from samples. Mix each sample thoroughly, and discard any foreign material such as sticks, leaves and rocks, that is not representative of the sample matrix. **Some clients may want the sample analyzed as submitted; refer to lab notes/LIMS Program Specification.**

10.2.2 Weigh an appropriate volume (10-50g) of sample into a 250mL beaker. Add concentrated HCl (0.3-1.0mL, typically 0.5mL is added) if sample is not already acidified. Bubbling may occur upon the first addition of HCl, strongly alkaline samples will require additional acid; up to 2mL HCl may be added.

10.2.3 Next, add an equal weight of granular sodium sulfate. Mix the sodium sulfate with the sample matrix until the sample aliquot is completely

dry. Note that if the sample was wet or particularly alkaline, more sodium sulfate may be needed.

10.3 Transfer an aliquot of prepared sample (typically 50g) to a glass thimble. **Rinse the beaker with hexane, allowing the wash to drain into the soxhlet thimble, thus effecting a quantitative transfer.**

10.4 Spike the MS and LCS and duplicate (MSD or LCSD) with corn oil solution (typically, 1mL of 0.1g/mL solution is spiked).

10.5 Assemble the soxhlet apparatus, add approximately 300mL hexane to each soxhlet unit. Apply heat to the flat bottom flask, and allow to reflux for 18±2hrs.

10.6 Transfer the flask to the S-Evap unit and evaporate the extracts to dryness. The temperature of the S-Evap should be maintained at <85°C to ensure that the more volatile components extracted into the hexane are not lost. Use the vacuum pump with inlet hose to remove residual hexane vapors from the flasks.

10.7 Place each flask in the desiccator for several hours.

10.8 Remove each flask from the desiccator and weigh on the analytical balance; record weight on benchsheet. Return each flask to the desiccator and allow to sit for several more hours. Re-weigh. **If the flask hasn't achieved constant weight, it may still contain residual solvent or water vapors. Continue to store then weigh until constant weight is achieved.**

10.9 Calculate HEM per Section 11 below.

11.0 CALCULATIONS

11.1 Calculate the sample HEM as follows:

$$\text{HEM (mg/kg)} = \frac{\text{gain in weight of flask (mg)}}{\text{Weight of wet solids(kg) x dry weight fraction}}$$

11.2 Calculate the recovery of the LCS using the following equation:

$$\text{Recovery (\%R)} = \frac{\text{measuredconc.of HEM}}{\text{spikedconc.of HEM}} \text{ X } 100$$

11.3 Calculate the recovery of the MS/MSD samples as follows:

$$\text{Recovery (\%R)} = \frac{\text{HEM}_{\text{Found}} - \text{HEM}_{\text{Sample}}}{\text{HEM}_{\text{Target}}} \text{ X } 100$$

where:

HEM_{Found} = calculated HEM concentration in the MS or MSD

HEM_{Sample} = calculated HEM concentration in the field sample

HEM_{Target} = the target concentration of the added HEM spike

11.4 Calculate the Relative Percent Deviation (RPD) of the MS/MSD samples using the following equation:

$$RPD\ (\%) = \frac{\left|HEM_{MS} - HEM_{MSD}\right|}{\left(\frac{HEM_{MS} + HEM_{MSD}}{2}\right)} X\ 100$$

where:

HEM_{MS} = calculated HEM concentration in the MS

HEM_{MSD} = calculated HEM concentration in the MSD

12.0 QUALITY CONTROL

12.1 DEFINITION OF BATCH

A batch is defined as a group of $\leq$20 field samples of like matrix that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the MB, LCS (LCSD) and matrix spike and duplicate (MS/MSD). All QC samples must be carried through all stages of the sample preparation and measurement steps.

12.2 METHOD BLANK

Method blanks are aliquots of clean matrix (i.e., Ottawa sand) that have been prepared and analyzed in the same manner as the associated field samples. To be acceptable, concentrations of analytes of interest detected (if any) in the MB must be below the analyte reporting limit, or as otherwise specified in the LIMS program specification. If this criterion is not met, analyses should be halted and the source of the contamination found and corrected. See also attached QC Table.

12.3 LCS SAMPLE

This sample is comprised of a known concentration of target analyte contained in a clean matrix (Ottawa sand). The laboratory control sample (LCS) is analyzed to demonstrate the accuracy of the analytical test. LCS recovery is calculated as shown in Section 11. See QC Table for evaluation criteria.

12.4 MS AND DUPLICATE

Matrix spikes consist of field samples into which known concentrations of target analytes are added and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. MS recovery is calculated as shown in Section 11, see QC Table for evaluation criteria.

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this analysis, either the matrix spike analysis (MSD) or the laboratory control sample (LCSD) can be performed in duplicate. Recovery is calculated as shown in Section 11, and precision (see Section 11 for calculation), is evaluated in terms of RPD. See QC Table for acceptance limits.

Possible causes for matrix spiked failure include:

- sample heterogeneity
- a sample matrix which inhibits extraction of spiked compounds
- high levels of HEM that "swamp out" the small amount of extractable materials added with the spike.

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived, and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation will be made in the data package narrative.

12.5 A METHOD DETECTION LIMIT (MDL) STUDY shall consist of the ANALYSIS of a minimum of seven replicate analyses for a target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at a minimum, annually, following the guidance of SOP 329.

13.0 DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW9071B, with the following exceptions:

- Up to 50g of sample is extracted for 18±2 hrs, rather than the 10g sample aliquot extracted for 4hrs as suggested in the Method.
- Corn oil is used as the reference standard, in place of a hexadecane/stearic acid standard.

14.0 SAFETY, HAZARDS AND WASTE DISPOSAL

14.1 SAFETY AND HAZARDS

14.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

14.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

14.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

14.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

14.2 WASTE DISPOSAL

14.2.1 Any hexane or other nonhalogenated organic solvents that have not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste or Radioactive Lab Waste, as appropriate.

14.2.2 All empty solvent bottles shall be disposed of appropriately; note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

1. SCOPE AND APPLICATION

Gel-Permeation Chromatography (GPC) is primarily used as a cleanup procedure in the extraction of soils/sediments/tissues that contain high molecular weight organic compounds such as lipids, polymers, proteins or resins. Typical indicators of the need for GPC cleanup are thick, viscous, or opaque extracts that likely cannot be concentrated to the required final volume. Extracts for Method SW 8081, SW 8082 and SW 8270 analysis can be cleaned using this method. This standard operating procedure (SOP) pertains to all extracts suitable for GPC cleanup. Consult with supervisor for other applications including SW 8141.

2. SUMMARY

Molecules are separated in the GPC column on the basis of their size. Smaller molecules enter the pores of the column's packing material, thereby eluting later than larger molecules that flow more directly through the column as they are excluded from the gel pores. The column effluent containing the larger molecules is ("dumped") discarded into the waste container. The later-eluting solvent fractions that contain the compounds of interest are "collected" in a flask. The GPC cleaned sample is then concentrated using a Kuderna Danish apparatus (SOP 607) followed by nitrogen blowdown (SOP 637) to appropriate final volume.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency evaluation test.

3.3 The Department Supervisor or designee performs final review and sign-off of the

data. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the processing of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

A reagent blank should be analyzed for all compounds of interest prior to the use of this method. The levels of interferences should be below the reporting limits of the analytes of interest before this method is performed on actual samples.

5. APPARATUS AND MATERIALS

5.1 GPC Autoprep 1000 (O.I. Analytical.)

5.2 glass column, 25mm I.D. x 600-700mm length

5.3 syringe, 10mL with Luerlock fittings (syringe with a Teflon plunger is preferred)

5.4 PTFE filters, 0.45µm

5.5 UV detector, Milton Roy, or equivalent

5.6 recorder: Kipp and Zonen BD 40, or equivalent

5.7 aluminum foil

5.8 volumetric flask, 500mL or as needed

5.9 SX-3 Bio-Beads (O.I. Analytical)

5.10 graduated cylinders

5.11 250-500mL flasks

6. REAGENTS

6.1 methylene chloride (CH_2Cl_2) - pesticide residue grade

6.2 calibration standards - generally purchased as a concentrate and contains the following compounds at the listed concentrations and is diluted prior to use:

corn oil	250mg/mL
bis(2-ethylhexyl)phthalate	5mg/mL
methoxychlor	1mg/mL
perylene	0.2mg/mL
sulfur	0.8mg/mL

NOTE: In order to monitor the instrument elution profile, a check standard is analyzed at a minimum of once each 7 days when samples are being cleaned up. One mL of the solution above is diluted to 10mL with methylene chloride and the entire volume is used for calibration of the instrument.

NOTE: If the standard is prepared from neat compounds caution must be taken to ensure that the sulfur is dissolved in the standard. Molecular sulfur is not very soluble in methylene chloride. However, it is soluble in warm corn oil. Therefore, one approach is to weigh out the corn oil, warm it and transfer the weighed amount of sulfur into the warm corn oil. Mix it and then transfer into a volumetric flask with methylene chloride, along with the other calibration compounds. If prepared from neat standards, then store the calibration solution in an amber glass bottle with a Teflon-lined screw-cap at 4±2°C, and protect from light (refrigeration may cause the corn oil to precipitate). Before use, allow the calibration solution to stand at room temperature until the corn oil dissolves).

Ampules of calibration standard obtained from a vendor should be stored as recommended by the manufacturer. Unopened ampules of calibration standard expire per the maufacturer's date. If a stock is prepared in house the calibration standard solution expire in 6 months from date of preparation, or more frequently if necessary following the guidance from the latest revision of SOP 300.

6.3 Gases -ultra high purity
nitrogen
helium

7. PROCEDURES

7.1 OVERVIEW OF DAILY PROCEDURES

7.1.1 Re-swell the gel as described in Section 7.3, if necessary. Solvent is typically pumped continuously through the gel in the column to avoid drying and shrinking of the resin.

7.1.2 Fill solvent bottle with methylene chloride. Make sure the waste container has enough volume to catch the waste from the cleanup run to

be performed.

7.1.3 Set the flow-rate. (See Section 7.4)

7.1.4 Turn on the UV detector to warm up for a minimum of ten minutes. Turn on the recorder, and turn off the chart speed. Set variance to a span of 50mV and the chart speed to 5mm per minute.

7.1.5 Calibrate the GPC (see Section 7.5). Typical GPC settings obtained from the calibration are listed below:

	8270	8081/8082
dump time	23 min.	29 min.
collect time	26 min.	19 min.
wash time	11 min.	12 min.

These times are determined from the calibration and vary depending upon the results of the calibration standards. Set the times into the controller before loading the samples. The UV detector and chart recorder are usually turned off after the calibration. Some clients may require UV traces of each sample injected for clean up, so the detector and chart recorder would then be left on.

7.1.6 Load samples. (See Section 7.6)

7.1.7 Label 250mL flat bottom flasks (or 500mL flat bottom flasks if the sample is split) with the appropriate test, work order number, and sample number. This will be the collection vessel. Make sure that GPC is written somewhere on the collection vessel. Insert the appropriate numbered tubule into the collection vessel.

7.1.8 When all samples have been run through, the GPC will shut itself off. If traces of each sample were required, turn off the power to the UV detector and recorder, cap the pen. Close the nitrogen valve if desired, but the nitrogen is typically left on for solvent recycling. Remove collection vessels. Cap them with 24/40 stoppers or aluminum foil , and empty the waste container.

7.2 COLUMN PACKING

7.2.1 Place approximately 70g of SX-3 Bio-beads in a flask. The beads are typically purchased in 70g jars. Cover the beads with at least two inches methylene chloride. Swirl to insure the wetting of all the beads. Cover with aluminum foil, and allow the beads to swell for a minimum of 2 hours (preferably overnight in a hood).

7.2.2 The plunger assemblies of the column should be equidistant from the

column ends. Secure the upper plunger in the column by inserting and turning clockwise until snug.

7.2.3 Invert the column and clamp to a ring stand. Place the tubing into a waste beaker. Allow excess methylene chloride to drain from the column. Leave a small amount of methylene chloride in the column to minimize the formation of bubbles.

7.2.4 Swirl the bead/solvent slurry to get a homogeneous mixture. Drain the excess methylene chloride directly into the waste beaker, and then start draining the slurry into the column. Maintain contact between the flask and column wall while draining. A small glass funnel can aid this process. This will help to minimize bubble formation. Swirl occasionally to keep the slurry homogeneous. Drain enough to fill the column. Place the tubing from the column outlet into a waste beaker below the column, open the stopcock (if attached), and allow the excess solvent to drain. Raise the tube to stop the flow, and close the stopcock when the methylene chloride level is just above the top of the gel. Add additional methylene chloride to rewet the gel. Rinse any remaining beads from the inner walls of the top of the columns with methylene chloride. Attempt to slurry all beads into the column before proceeding to Step 7.2.5 below.

7.2.5 Insert lower plunger (the longer one) into the column until it touches the gel, and tighten the plunger by turning it clockwise until snug. Make the seal just tight enough so that any beads on the glass surface will be pushed forward, but loose enough so that the plunger can be pushed forward.

CAUTION: Do not tighten the seal if beads are between the seal and the glass surface because this can damage the seal and cause leakage. If this happens, immediately pull the plunger out and rinse it with methylene chloride to remove beads. Wipe the inside portion of the column with a Kimwipe to remove beads.

7.2.6 Compress the column as much as possible without applying excessive force. The following steps may not be necessary if all beads were slurried into the column in Step 7.2.4 above. If necessary, loosen the seal and gradually pull out the plunger. Rinse and wipe off the plunger. Slurry any remaining beads and transfer them into the column. Repeat this step until the plunger can be inserted and pushed in without allowing the beads to escape the seal. If the plunger cannot be inserted and pushed in without allowing beads to escape around the seal, continue compression of the beads without tightening the seal, and loosen and remove the plunger as described. Repeat this procedure

until the plunger is inserted successfully. Push the plunger until it meets the gel.

7.2.7 Connect the column input and output lines to the column and install the column on the GPC.

7.2.8 Connect the column input and output lines to the appropriate lines coming from the GPC.

7.2.9 Nitrogen must be connected to the GPC so solvent flow can take place. Start pumping solvent through the column at approximately 5mL per minute for about one hour.

7.2.10 Turn the pump off and connect column output line to the solvent line leading to the UV Detector.

7.2.11 Follow the procedure to "Re-swell" the gel for an additional 1-2 hours minimum and preferably overnight (see Section 7.3).

7.2.12 If the column still has air pockets after re-swelling the gel, turn off the pump. Loosen the lower column plunger and compress the column. Then re-tighten and start the pump to continue pumping solvent through the column. Continue with this procedure until approximately 6-10psi backpressure is achieved. Inverting the column and running solvent "backwards" can also be helpful when trying to remove air bubbles.

7.2.13 When the GPC column is not to be used for several days, turn off the pumps, and connect the column outlet line to the column inlet to prevent column drying and/or channeling. If channeling occurs, the gel must be removed from the column, reswelled, and repoured as described above. If drying occurs, methylene chloride should be pumped through the column until the observed column pressure is constant and the column appears wet. Always recalibrate after column drying has occurred to verify retention times have not changed.

7.3 RE-SWELLING THE PACKING MATERIAL.

7.3.1 If the column has been disconnected from the GPC, re-connect the column input and output lines to the appropriate lines from the GPC.

7.3.2 Press INDEX on the controller box until "CHECK SOLVENT FLOW RATE" is displayed. Start pump by pressing "run/stop" button on GPC. This is an excellent time to ensure that standards are ready and equilibrated to room temperature.

7.3.3 If the GPC was not used for a while, the methylene chloride may have

evaporated from the pump and caused the pump to lose its prime. If this occurs, the pump will not operate effectively and thus will not be able to pump methylene chloride out of the reservoir. The pump will need to be primed.

7.3.4 Continue pumping methylene chloride through the column until the column is saturated. No bubbles should be coming out of the column, and the system pressure should remain steady.

7.4 FLOW-RATE CHECK

7.4.1 After the column has been saturated, the flow rate of the solvent should be checked in order to determine if the system is functioning properly. The flow rate of the solvent should be 5.0±0.1mL/minute.

7.4.2 Obtain a stopwatch, and a 100mL graduated cylinder. The pump should still be working. Make sure that gloves are worn.

7.4.3 Disconnect the column output line from the GPC. At the instant the column output line is placed in the graduated cylinder, start the stopwatch timing for ten minutes. At the end of ten minutes take the column output line out of the graduated cylinder and reconnect to the GPC. Read the volume collected in the graduated cylinder. This volume should be between 49-51mL. If the volume is not within this range, adjust the flow rate as indicated in Section 7.4.4.

7.4.4 The flow rate can be adjusted by the controls located on the front panel of the GPC between the pump start/stop button and the pump prime button. Push the up arrow to increase the flow and push the down arrow to lower the flow.

7.4.5 After adjustment, allow the GPC to run for 30 minutes. Repeat the flow check above to confirm that the flow rate is correct.

7.5 CALIBRATION

7.5.1 The GPC must be calibrated every time the column is changed, when channeling is suspected (indicated by dramatic changes in flow rate, see Section 7.4), or every seven days, to show that the instrument is functioning properly and that the condition of the column has not changed.

7.5.2 After checking the flow rate, allow the GPC to run for 30 minutes. Turn on the UV detector and chart recorder. Warming up the UV detector for a minimum of 30 minutes helps to ensure stable absorbance readings.

7.5.3 Put 10mL calibration solution (Section 6.2) into a syringe. Filter the

solution through a 0.45µm PTFE filter into a GPC tube. Make sure the top of the GPC tube is not chipped or defective. Place the tube on a position on the GPC after rinsing the sample pickup line with methylene chloride. When screwing the GPC tube onto the loading station, make sure the tube fits snugly.

7.5.4 Press INDEX on the controller box until "DUMP TIME = 22:00?" is displayed. The number displayed will be the dump time of the previous run, so it may not be 22 minutes. Press 60:00, and then press ENTER. The display should read "DUMP TIME = 60:00".

7.5.5 Press INDEX once. The display should now read "COLLECT TIME = 28:00?". Press zero (0) four times and then press ENTER. The display should now read "COLLECT TIME = 00:00". If the question mark remains on the display, you forgot to press ENTER.

7.5.6 Press INDEX once. The display will now read "WASH TIME = 10:00?". Press zero (0) four times and then press ENTER. The display should now read "WASH TIME = 00:00".

7.5.7 Press INDEX once. The display will now read "START WITH SAMPLE NUMBER = 06?", or with whatever station number the GPC was last programmed to begin processing. Press 01 if calibration standard is at position 1, and then press ENTER.

7.5.8 Press INDEX once. The display will now read "TERMINAL SAMPLE NUMBER = 21", or with whatever station number the GPC was last programmed to end processing. Press the same number as you had for beginning processing, and then press ENTER.

7.5.9 Press INDEX twice. The display should now read "SMPLS 01-01 MODE GPC ONLY TIME=60:00 PUSH RUN?". The last number after SMPLS 01-01 above indicates which position the run will stop at. "TIME" indicates the dump time. To insure that all data is correctly entered, press INDEX and read the display. If the display is correct, continue pressing INDEX until the display reads "PUSH RUN".

7.5.10 Start the paper running on the recorder. The variance should be set at 50mV, and the chart speed should be set at 5mm per minute. For clients with special requirements, see the supervisor. Uncap the pen and zero the pen on the first thick horizontal line. When the pen reaches a vertical line, push RUN and make a mark on the chart where the pen was when started.

7.5.11 When 60 minutes has gone by, processing will be complete, and the GPC will shut itself off. This is indicated by a repetitious and loud

clicking sound that will continue for five to ten seconds. Go to the GPC and press INDEX twice until the pump can be restarted again by pushing "run/stop" on the GPC. Otherwise methylene chloride will drain out of the column, and the column conditions may change. If this occurs, the GPC must be re-calibrated.

7.5.12 Take the chart from the recorder and lay it out on a flat surface. The plot on the chart should consist of five peaks in the following elution order:

corn oil (generally two peaks)
bis(2-ethylhexyl)phthalate
methoxychlor
perylene
sulfur

For SW 8270 analysis the corn oil represents the high molecular weight compounds that will be dumped, and the phthalate/methoxychlor/perylene represent the compounds of interest. For SW 8081 analysis the corn oil and the phthalate represent the high molecular weight compounds, and the methoxychlor/perylene represent the compounds of interest.

7.5.13 Calculate the dump time: Measure the number of centimeters it took for the corn oil to go through, and multiply this value by two. This is the amount of time that it took for all the corn oil to elute through the column.

For SW 8270 analysis, calculate the dump time so that corn oil is dumped and >85% of bis(2-ethylhexyl)phthalate is recovered. Collection should stop after perylene elutes but before sulfur elutes.

For SW 8081 analysis, the dump time should be a value that allows removal of the corn oil and ≥ 85% removal of phthalate. Greater than 95% recovery of the methoxychlor is needed. Stop collection after perylene elutes but before sulfur elutes.

7.5.14 Calculate the collect time: Measure the number of centimeters it took for the phthalate/methoxychlor/perylene to elute through the column from the end of the dump time. Multiply this value by two. Continue to collect until just prior to the elution of sulfur.

7.5.15 Calculate the wash time: Add the dump time and collect time, and subtract the sum from 60 minutes. The wash time should be at least 10 minutes.

7.5.16 Enter the calculated dump time, collect time, and wash time into the GPC. and record these times on the GPC bench sheet and chromatogram. Once entered the program must be saved to the GPC memory by pushing "Program Save" and "enter". Record the system pressure on the GPC bench sheet and chromatogram.

- The UV trace must exhibit the following requirements:

  Peaks must be observed and should be symmetrical for all compounds in the calibration solution. Corn oil typically partially separates into two peaks.

  Corn oil and phthalate peaks must exhibit >85% resolution.

  Phthalate and methoxychlor peaks must exhibit >85% resolution.

  Methoxychlor and perylene peaks must exhibit >85% resolution.

  Perylene and sulfur peaks must not be saturated and must exhibit >90% baseline resolution. In addition, the retention times of the calibration compounds must be within ±5% of their retention time in the previous calibration. A copy of the UV trace of the calibration solution must be submitted with the data for the associated samples.

  If these requirements cannot be met, a new column may need to be packed. Old packing material may be cleaned by processing several 5mL volumes of butyl chloride through the system. Butyl chloride removes the discoloration and particles that may have precipitated out of the methylene chloride extracts. This may correct the problem. If column maintenance does not restore the performance of the column, the column must be repacked with new packing and recalibrated.

- Record on GPC bench sheet which column/GPC this was run on, the "dump" time, "collect" time, "wash" time, date, analysis, analyst, methylene chloride lot #, flow rate, calibration solution and expiration date, system pressure, room temperature and what samples were placed on which stations. Record on the chromatogram the date, "dump" time, "collect" time, "wash" time, what compound each peak represents and the percent resolution of each peak. A baseline needs to be drawn on the chromatogram so resolution can be calculated.

  For both SW 8270 and SW 8081, analyze a GPC reagent blank (see section 4). Pipette 10mL of clean methylene chloride into clean GPC tube, rinse the sample pickup line of Station 2 for

example and place the 10mL GPC reagent blank on Station 2. Treat this GPC reagent blank as a regular sample through the rest of the extraction process. **The position used for the GPC blank must be random.**

- Some samples may contaminate the SX-3 Bio Beads and change the retention volume of the GPC column. Therefore system calibration and analyte recovery must be checked whenever a sample causes significant discoloration of the GPC column. Even if no permanent darkening is visible, GPC calibration must be checked not less than once every seven days the GPC is in use. In many cases, the SX-3 Bio Beads may be used for several months as long as the column calibration and flow rate remains constant.

7.6 SAMPLE LOADING

It is very important to have consistent laboratory temperatures during an entire GPC run, which could be 24 hours or more. If temperatures are not consistent, retention times will shift, and the dump and collect times determined by the calibration standard no longer will be appropriate. The ideal laboratory temperature to prevent out gassing of the methylene chloride is 72°F.

7.6.1 All samples going through the GPC must be filtered using a 0.45µm PTFE filter, and must be in methylene chloride. It may be easiest to blow down the sample to approximately 2mL on the N-evap before filtering the sample into a GPC tube. Make sure the tube is labeled correctly. Very viscous samples may be separated into several aliquots to enable filtering.

7.6.2 Rinse each GPC tube three times with methylene chloride before filtering samples into the tube. Filtering is accomplished by drawing or pipetting sample into a 5 to 10mL syringe with a luerlock tip, connecting the PTFE filter via the Luer fitting and forcing the extract through the filter into a GPC tube. After filtering, additional methylene chloride is passed through the filter and into the GPC tube, then at least 3 "air purges" (pulling air into the syringe) of the filter are performed to ensure complete transfer of compounds of interest.

7.6.3 Take a clean GPC tube, pipette in 10mL of methylene chloride, and tightly seal the top of the tube with aluminum foil. Bring the volume in the GPC tubes containing the filtered samples to 10mL using the sealed tube as a guide. After bringing sample to 10mL, tightly seal the tube with aluminum foil.

NOTE: Highly viscous extracts will not be injected onto the GPC column effectively so they must be split and diluted. If after

bringing a sample to 10mL the sample is viscous and/or opaque, the sample should be split to avoid overloading the column. Split the sample by pipetting 5.0mL into another GPC tube, and bring the volume of both up to 10mL. Place both GPC tubes on stations in sequential order. Any sample extract with a viscosity greater than that of a 1:1 glycerol: water solution also should be split. Several splits may be necessary for highly viscous samples.

7.6.4 When the samples have been brought to a volume of 10mL, place the samples on the GPC with the lightest colored samples on first, and the darkest samples on last. If none of the samples are dark or viscous, the order placed on the GPC is up to the discretion of the analyst.

7.6.5 Rinse the line of the station with methylene chloride. Place the line into the GPC tube, and screw the tube on until it fits snugly. Pumping methylene chloride through the sample lines may be needed to ensure no sample carryover occurs.

7.6.6 As each GPC station is loaded, make notations in the GPC bench sheet indicating station numbers, corresponding samples loaded onto the stations numbers, whether the sample was split, how many times, and analysis if more than one analysis is being run.

7.6.7 Label a 250mL flask with the appropriate test, work order and sample number. This will be used as a collection vessel. Make sure that GPC is written somewhere on the collection vessel. Insert the appropriate numbered tube (that corresponds to the station on which the sample was placed) into the collection vessel after rinsing the tube with methylene chloride. If the sample was split between two stations, place both tubes into a 500mL flask.

7.6.8 Enter the station on which processing is to begin, and enter the station on which processing will terminate. All stations between these two stations must have samples loaded on them, because the GPC will load samples in sequential order.

7.6.9 If the client requires all chromatographs to be delivered with the results of the analysis, then a chromatograph of the samples going through GPC clean up must also be included in the final package. Follow the procedure outlined above in Section 7.5.10 if this is required. Make sure there is enough paper and the pen has enough ink. Record the date and analysis on the chart paper.

7.6.10 Check to make sure that both methylene chloride reservoirs are full. Also, check to make sure there is at least 500-1000psi of nitrogen in the

tank. When everything has been checked, press RUN.

7.6.11 Monitor sample volumes collected. Changes in sample volumes collected may indicate one or more of the following problems:

- Change in solvent flow rate, caused by channeling in the column or changes in column pressure.
- Increase in column operating pressure due to the absorption of particles or gel fines onto the analytical column gel.
- Leaks in the system or significant variances in room temperature.

7.6.12 When processing is completed, shut off the nitrogen valve, cap the pen, turn off the recorder and UV detector and if the GPC will not be used that day, connect the column outlet line to the column inlet as described in Step 7.2.12. Alternatively, put the column outlet into the larger methylene chloride reservoir to recycle solvent through column.

7.6.13 Seal the collection vessel with a ground glass or Teflon stopper, and continue processing the sample as required by the appropriate method, and according to the appropriate SOPs.

8. DEVIATIONS FROM METHOD

This SOP meets the requirements of Method SW 3640A, with the following exception: Gravimetric screening is not performed. Instead, samples are split on the basis of darkness and viscosity. There are no other known deviations to the method.

9. SAFETY HAZARDS AND WASTE DISPOSAL

9.1 SAFETY AND HAZARDS

9.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents.

9.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

9.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked within a laboratory fume hood (e.g., solvents and acids). Dichloromethane has a TLV ≤50ppm.

9.1.4 The exhaust system for the GPC room must be on at all times the GPC is being used.

9.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with

compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

9.2 WASTE DISPOSAL

9.2.1 The GPC methylene chloride waste collection vessel is drained into the Halogenated Waste when full.

9.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 642 REVISION 8

TITLE: **GRAVIMETRIC DETERMINATION OF PERCENT MOISTURE FOR SOLID MATRICES**

FORM: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8/17/07
QUALITY ASSURANCE MANAGER _____ DATE 8/16/07
LABORATORY MANAGER _____ DATE 8-20-07

HISTORY: Rev0, 2/11/92; Rev1, PCN #447, 4/18/95; Rev2, 3/11/97; Rev3, 1/10/00; Rev4, 3/1/02; Rev5, 3/17/03; Rev6, 4/16/04; Rev7, 2/27/06; Rev8, 8/16/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the process for determining percent moisture in solid materials (soil, sludge, etc.). The value obtained is then used for correcting analysis results that are reported on a dry weight basis.

2. SUMMARY

A measured aliquot of solid sample is taken from a field sample and placed in a tared drying dish. The sample is placed in a drying oven at 105±5°C. After drying to a constant weight, the dried sample is weighed and compared to the initial wet weight of the sample. From these measurements, the percent moisture of the initial sample is obtained.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to the SOP and to complete all documentation required for review. Any anomalies or out-of-control events must be noted and corrective action taken and documented.

3.2 It is the responsibility of all personnel who work with the samples or data involving this method to consult applicable LIMS program specification for client specific requirements prior to initiating handling of samples or data.

4. INTERFERENCES

Soil or other solid materials containing large pieces of rock or other debris make reproducibility of the sub-sampling process difficult. Therefore, percent moisture reproducibility and interpretation may also be affected.

5. APPARATUS AND MATERIALS

5.1 tongue depressors, wood

5.2 aluminum weighing dishes, 57mm

5.3 laboratory balance, 0.01g sensitivity, typically interfaced to computer so that Paragon LIMS can automatically capture the data

5.4 vented drying oven, capable of maintaining 105±5°C

5.5 desiccator cabinet with viable Drierite® dessicant

6. SAMPLE COLLECTION, PRESERVATION AND HANDLING

Soil samples received from the field are stored in sealed containers that prevent the loss of moisture during storage.

7. PROCEDURE

7.1 Record the balance ID in the open LIMS prep batch. Place a labeled, empty weighing dish onto a verified (SOP 305) zeroed balance. Record the mass of each dish in the 'dish weight' column in the open LIMS prep batch. Tare the balance with the empty weighing dish on the balance.

7.2 Pour off any standing water from the sample. Mix the sample thoroughly after removing rocks and sticks. Add approximately 10g of "wet" sample to the tared weighing dish. Record the mass of sample in the 'wet sample' column in the open LIMS prep batch. Care shall be taken to ensure homogeneity in the sample and its duplicate and in all other samples. Non-homogenous samples may not be representative and may yield high Relative Percent Difference (RPD) values.

7.3 Place the prepared samples in the vented drying oven, and record the oven identification number and the time the drying starts in the LIMS prep batch. Note that ovens are operated per SOP 320, temperatures are checked and recorded each business day.

7.4 Dry the samples for at least 10 but not more than 24 hours. If dried less than ten hours, it must be documented that constant weight (±0.01g) was attained. At least one hour of drying time is required between repetitive weighing of the sample to document constant weight. Drying time is defined as the elapsed time heated in the oven.

7.5 Remove the dried sample from the oven and immediately place it in the desiccator cabinet to cool for 15 to 30 minutes. Record the time the samples were removed from the oven in the LIMS prep batch.

7.6 Weigh and record the mass of the dish plus the dried sample in the appropriate column of the LIMS prep batch. Do not use the dried sample for any other analysis (with possible exception of some radiochemistry analyses).

8. CALCULATIONS

Calculations are performed in LIMS based on the following:

a. Mass of dried sample (M) = $m_3 - m_1$

b. %moisture = $(1 - M/m_2) \times 100$

where:

m_1 = mass of weighing dish
m_2 = mass of "wet" sample
m_3 = mass of weighing dish with dried sample

9. QUALITY CONTROL

9.1 METHOD BLANK

A labeled, empty weighing dish is the "blank" for each batch of ≤20 moisture samples analyzed.

9.2 DUPLICATE

One sample per 10 or less field samples from each batch of twenty or less samples is prepared in duplicate. Precision is measured as Relative Percent Difference (RPD), which is calculated in LIMS as follows:

$$RPD = \frac{(\%moisture\ sample - \%moisture\ duplicate)}{1/2(\%moisture\ sample + \%moisture\ duplicate)} * 100$$

If the samples used for duplicate analysis contain less than 10% moisture, then the RPD quality control limit is <67%. If the samples used for duplicate analysis contain > 10% moisture, then the RPD quality control limit is <30%.

9.3 Moistures below 1% are not accurately measured using this procedure. Thus, Paragon views 1% as a practical quantitation limit for this procedure.

10. DEVIATIONS FROM THE METHOD

This SOP is based on information presented in SW-846, Method 3540C, Section 7.2. There are no known deviations from the method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.2 Samples known to contain explosive or highly flammable material or samples that require explosive analyses should not be placed in the drying oven. Fibrous samples that are known to or suspected to contain asbestos should not be dried in this manner. They may be dried in a desiccator to a constant weight.

11.2 WASTE DISPOSAL

11.2.1 The dried solid sample residues and solid sample removed from the sample container but not used shall be disposed of in the Contaminated Soils and Solids Waste.

11.2.2 Radioactive solids must be placed in the Radioactive Solids waste stream.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 648 REVISION 7

TITLE: FLORISIL CLEANUP – METHOD SW3620C

FORMS: 616 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-14-07

QUALITY ASSURANCE MANAGER _____ DATE 11/14/07

LABORATORY MANAGER _____ DATE 11-14-07

HISTORY: NEW, Rev0, 5/92; Rev1, PCN #162, 3/14/94; Rev2, 11/18/99; Rev3, 4/9/02; Rev4, 3/14/03; Rev5, 4/16/04; Rev6, 3/9/06; Rev7, 11/12/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references -- SW3620C, describes the use of Florisil to clean up interferences from extracts prior to analysis for organochlorine pesticides. Florisil, a registered trade name of U.S. Silica Co., is a magnesium silicate with basic properties. At Paragon, it is used to separate analytes from interfering compounds prior to analysis by gas chromatographic methods (SW8081 or EPA 608). Method SW3620 describes cleanup of extracts for other analytical processes, which are not addressed in this SOP.

2. SUMMARY

This procedure describes Florisil cleanup of solvent extracts of environmental samples using solid phase extraction cartridges. Each cartridge is washed with solvent immediately prior to use. The extract is loaded onto the cartridge, which is then eluted with suitable solvents. A vacuum manifold is used to obtain reproducible results. The eluate is then further concentrated prior to gas chromatographic analysis. This cleanup is only effective if there are differences in polarity of target and interfering compounds. The procedure described separates polar non-target analytes from the non-polar organochlorine pesticide target compounds.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review. The Technician must demonstrate the capability to generate acceptable results utilizing these methods, this demonstration may come in the form of Supervisory/training review or the results of precision and accuracy tests performed.

3.2 It is the responsibility of all personnel who work with the samples or data involving this method to consult applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Any anomalies or out-of-control events must be noted and corrective action taken and documented.

4. INTERFERENCES

Method SW3620C states that phthalate esters have been detected in extracts processed with solid phase extraction cartridges. Phthalate esters are not analyzed as part of the process described here. However, phthalate esters may interfere with subsequent analysis by electron capture detectors. The batch method blank(s) prepared with the sample set must also be subjected to this cleanup procedure and serve to monitor this potential interference.

5. APPARATUS AND MATERIALS

5.1 Vacuum manifold, VacElute Manifold SPS-24 (Analytichem International) or equivalent, consisting of glass vacuum basin, collection rack and funnel, collection vials (test tubes, ~15mL capacity), replaceable stainless steel delivery tips, built-in vacuum bleed valve and gauge. The system is connected to a vacuum pump or water aspirator through a vacuum trap made from a 500mL sidearm flask fitted with a one-hole stopper and glass tubing.

5.2 Glass vials, appropriate sizes, with PTFE-lined caps

5.3 Volumetric pipettes, glass, disposable

6. SOLVENTS AND REAGENTS- ALL SOLVENTS SHOULD BE ACS GRADE

6.1 Florisil cartridges, 40µm particles, 60 Angstrom pores, 1g, B&J #7108G or equivalent. The cartridges consist of an appropriately-sized glass or polypropylene tube, with the 1g of Florisil held between two polyethylene or stainless steel frits with 20µm pores.

6.2 Hexane (C_6H_{14})

6.3 Acetone (CH_3COCH_3)

6.4 Hexane/Acetone (90/10, v/v), used as the eluent solution

6.5 2,4,5-trichlorophenol Florisil cartridge check solution: Prepare a solution of 2,4,5-trichlorophenol in acetone or hexane (concentration - 100ng/mL or as suitable).

6.6 Single component pesticide Florisil cartridge check solution: Use a solution containing all single component target compounds in hexane (concentration - 100ng/mL or as suitable).

6.7 Check mixture for the Florisil cartridges: Combine 0.5mL of the 2,4,5-trichlorophenol solution (Section 6.4) and 0.5mL of the pesticide check solution (Section 6.5) with 1mL of hexane. This solution is to be used whenever the cartridge check is to be performed (Section 7.3).

7. PROCEDURES

The extract has previously been concentrated to a predetermined volume following SOPs 607 and 637.

7.1 CARTRIDGE SET-UP AND CONDITIONING

7.1.1 Arrange the cartridges on the manifold in the closed-valve position and place wash collection test tubes in holders below the cartridges.

7.1.2 Turn on the vacuum and adjust to 5-10”Hg (5”Hg provides better control of the flow rates).

7.1.3 Condition the cartridges by washing with a minimum of 5mL hexane/acetone (90:10, v/v). This is accomplished by passing at least 5-10mL of the hexane/acetone solution through the cartridge. While the cartridges are being washed, adjust the vacuum applied so that the flow rate through each cartridge is approximately equal. When there is still approximately 1mm of solvent above the sorbent bed, stop the conditioning process. **Do not allow cartridges to become dry after they have been washed.**

7.1.4 After the cartridges have been conditioned, the vacuum is released, the test tubes with the washing solution are removed, and labeled 15mL test tubes are placed in the holders below the cartridges. Other collection vials may be used as appropriate. Care must be taken to ensure that the solvent line from each cartridge is placed inside the corresponding collection vial as the manifold top is replaced.

7.2 CARTRIDGE PROCEDURE FOR ORGANOCHLORINE PESTICIDES

7.2.1 Load 2.0mL of the extract (or cartridge check solution) on to the cartridge. Lesser volumes may be used as appropriate, particularly for extracts thought to contain high concentrations of interferences. Allow the extract to pass through the cartridge bed at approximately 2mL/minute. If entire extract is to be transferred, proceed to Section 7.2.2. If only a measured aliquot of extract is to be loaded on to the cartridge, proceed to Section 7.2.3.

7.2.2 After the entire extract has passed into the top frit of the cartridge, but before the cartridge becomes dry, rinse the sample vial with an additional 0.5-1mL hexane. Add the rinse to the cartridge to complete the quantitative transfer.

7.2.3 Add 3-4mL hexane/acetone (90:10, v/v) to the cartridge. Turn on the vacuum pump and adjust the pressure to 5-10”Hg. Allow the solvent to soak the sorbent bed for about 1min before drawing through the cartridge. Slowly let the eluting solvent through the cartridge (1-

2mL/min) and collect the eluate into the test tube. Repeat additions of elution solvent until approximately 9mL has been taken through the cartridge. It is not necessary to soak the sorbent bed for each addition, but **do not** allow the cartridge to dry between each addition of eluent.

7.2.4 Concentrate the extract to a final volume of 2.0mL (or the original volume of the extract aliquot taken) per SOP 637 (nitrogen blowdown), and vial the finished extracts.

7.2.5 Complete benchsheet (Form 616) and observe proper internal chain-of-custody procedures (SOP 318) to deliver the extracts to the appropriate analytical area.

7.3 CARTRIDGE CHECK PROCEDURE

7.3.1 Whenever a new lot of Florisil cartridges are received or for every 300 cartridges used of a lot, one cartridge must be tested to ensure acceptability (see Section 8.2 for acceptance criteria). The check must be performed at whichever is more frequent of the new lot or 300 cartridges used.

7.3.2 Condition the cartridge as described in Section 7.1, and then perform the cartridge cleanup starting with Section 7.2.1 using the aliquot of the performance check solution previously described (Section 6.6).

8. QUALITY CONTROL

8.1 The efficiency of each lot of Florisil cartridges must be verified using the Florisil check standard (Section 6.6). Cartridges from a given lot number may be used to process samples once a test of the performance check standard has yielded acceptable results. Up to 300 cartridges from a single lot can be used per successful lot check.

8.2 Acceptance criteria for Florisil cartridge performance check: the lot of Florisil cartridges is acceptable if all pesticides are recovered at 80-120%, the recovery of 2,4,5-trichlorophenol is less than 5%, and no peaks interfering with the target analytes are detected. The analytical group maintains records of each lot check that is performed. Documentation of each lot check may be required to be included in final data packages by some clients.

8.3 All quality control samples associated with the sample extracts that are cleaned using this procedure must also be processed through this cleanup method.

9. DEVIATIONS FROM THE METHOD

Concentrations of analytes in the lot check solution have been adjusted to be within the working range of the analytical instrument in use. Method SW3620C has acknowledged that the concentrations listed in SW3620B were in error. Acceptance criteria for

quantitative recovery of the target compounds suggested in the method is 80-110% recovery for a subset of target compounds. Paragon checks for quantitative recovery of all single component target and surrogate compounds and utilizes control limits of 80-120% recovery. No other deviations from the organochlorine pesticide cleanup portion of Method SW3620 are known.

10. SAFETY, HAZARDS AND WASTE DISPOSAL

10.1 SAFETY AND HAZARDS

10.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents.

10.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

10.1.3 Chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Hexane and acetone have TLV <50ppm.

10.1.4 Non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

10.2 WASTE DISPOSAL

10.2.1 Any hexane, acetone, or other nonhalogenated organic solvents may be disposed of in the Acetonitrile/Nonhalogenated Waste Profile.

10.2.2 Extracts and the vials associated with the extracts are be disposed of by the analytical group in the appropriate waste extract stream.

10.2.3 Empty solvent bottles are disposed of appropriately. Please note that all labels and markings must be defaced prior to disposal.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the method it references -- SW-846 3665A, describe the cleanup of sample extracts prior to analysis for polychlorinated biphenyls (PCBs) by method SW8082. This procedure is currently performed on all extracts to be subsequently analyzed by method SW8082. This procedure is not used to clean extracts for other analytical processes performed at Paragon, as it will oxidize most organic compounds to varying degrees. Method SW3665A states that the permanganate portion of the cleanup should be performed "if necessary". Paragon's experience has shown that permanganate cleanup is generally not necessary; hence it is not addressed in our procedures or this SOP.

2. SUMMARY

A sample extract from Paragon SOPs 617, 622, 625 or 626 is solvent exchanged from methylene chloride to hexane following Paragon SOPs 607 and 637 (extracts from SOP673, being extracted with hexane, do not require exchange). The extract is then vigorously mixed with concentrated sulfuric acid and subsequently centrifuged to separate the hexane extract from the sulfuric acid. This cleanup may be repeated if necessary. Batch QC elements (blanks, spikes, and replicates) must be subjected to the same cleanup as the samples associated with them.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review. The Technician must demonstrate the capability to generate acceptable results utilizing these methods, this demonstration may come in the form of Supervisory/training review or the results of precision and accuracy tests performed.

3.2 It is the responsibility of all personnel who work with the samples or data involving this method to consult applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Any anomalies or out-of-control events must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Analytical interferences may be caused by contaminants in solvents, reagents, glassware, or other sample processing hardware. All of these materials must be routinely demonstrated to be free of interferences, under the conditions of the analysis, by processing and successfully analyzing method blanks.

4.2 This technique will not remove chlorinated benzenes, chlorinated naphthalenes, and a number of chlorinated pesticides.

5. APPARATUS AND MATERIALS

5.1 glass Pasteur pipets

5.2 centrifuge, Fisher Scientific Marathon 10K or equivalent

5.3 vials, appropriate sizes, with PTFE-lined screw-top caps

6. REAGENTS - All reagents must be analytical reagent grade or better

6.1 concentrated sulfuric acid (H_2SO_4)

6.2 hexane

7. PROCEDURES

7.1 Bring the extract to a predetermined volume in hexane (typically 10mL).

7.2 Place the extract in a 40mL vial (other sized vials may also be used, as appropriate).

7.3 Add 20mL of H_2SO_4 (volume of acid should be twice that of extract, if final volume of extract varies from 10mL) to the extract. Cap tightly and shake each vial containing the extract and acid thoroughly for 1 to 2 minutes. A vortex mixer may be utilized, or the vials may be vigorously shaken by hand.

CAUTION: Avoid skin contact - sulfuric acid causes burns!

7.4 Centrifuge the mixture for 3-5 minutes at no higher than 1500rpm to separate the acid and extract layers. Alternatively, the mixture of hexane and acid can be left for 15-20 minutes to separation on its own.

7.5 Examine the hexane layer. It should not be highly colored, nor should it have a visible emulsion or cloudiness. If a clean hexane layer is achieved, proceed to Step 7.7. If the hexane layer is colored, or the emulsion persists, remove the hexane layer (and, if present, as much of the emulsion as possible) from the top of the vial and transfer the hexane to a fresh vial. The remaining acid layer can be disposed of properly at this point. Add another portion of concentrated sulfuric acid (2:1, v/v) to the hexane extract and perform Steps 7.3 and 7.4 again. Record

the number of cleanup steps in the logbook if any samples required repeated cleanups.

7.6 Normally, extracts do not require more than two acid washes, although oil samples or oily samples may require three. The method blank and laboratory control samples need only be acid washed once.

7.7 Use a disposable pipet to transfer the hexane layer into an appropriate size vial with PTFE-lined cap. Dispose of the acid layer into the concentrated acid waste.

No acid should be present in the extract to be delivered, as it can damage the analytical instrumentation used. Visually inspect for the presence of two phases after the transfer. If any acid is seen, carefully transfer the hexane phase to a fresh vial.

7.8 Re-extraction and notification of the Department Manager may be warranted if a large amount of the extract is lost during the acid cleanup (i.e. if less than 1mL is remaining). If re-extraction is not possible due to extenuating circumstances (e.g, no sample remaining, past holding time), the extract should be kept and notation made on the benchsheet.

7.9 Complete benchsheet (Form 616) and observe proper internal chain-of-custody procedures (SOP 318) to deliver the extracts to the appropriate analytical area.

8. QUALITY CONTROL

The associated quality control samples (blanks, spikes, duplicates, replicates) for sample extracts that are acid cleaned must also be processed through the same cleanup procedure. This is done in order to demonstrate that the compounds of interest are being quantitatively recovered after acid cleanup.

9. DEVIATIONS FROM THE METHOD

9.1 The referenced Method SW3665A suggests use of 1:1 sulfuric acid/water (v/v). Paragon uses concentrated sulfuric acid.

9.2 The permanganate oxidation step of the cleanup method is not utilized at this time by Paragon and is not described in this SOP.

9.3 Section 7.1.9 of Method SW3665A describes a post-cleanup "extraction" of the sulfuric acid with 1mL of clean hexane ("to ensure quantitative transfer of the PCB's"). This step is not performed at Paragon and is not described in this SOP. Historical recoveries of PCB's in LCS/D samples do not indicate significant negative bias as a result of omitting this step.

10. SAFETY, HAZARDS AND WASTE DISPOSAL

10.1 SAFETY AND HAZARDS

10.1.1 Applicable material safety data sheets (MSDSs) must be read prior to

using any solvents or reagents for the first time.

10.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

10.1.3 Chemicals with a Threshold Limit Value (TLV) of less than 50ppm must be worked with in a laboratory fume hood (e.g., solvents and acids). **As sulfuric acid TLV<50ppm and hexane TLV = 50ppm both fall in this category, the procedure must be done in a properly working fume hood.**

10.1.4 All flammable compounds must be kept away from ignition sources.

10.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, date prepared or transferred and the initials of the preparer.

10.2 WASTE DISPOSAL

10.2.1 Hexane wastes (that have contacted samples) may be disposed of in the TSCA PCB Waste.

10.2.2 The sample remainders, extract vials and associated extracts may be disposed of intact in the PCB Debris waste.

10.2.3 Aqueous corrosive waste that may contain PCBs in excess of 50ppm will be disposed of by lab packing for TSCA disposal.

10.2.4 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 658 REVISION 7

TITLE: PAINT FILTER LIQUIDS TEST – SW9095A

FORMS: 648

APPROVAL:

TECHNICAL MANAGER _____ DATE 2-27-2006

QUALITY ASSURANCE MANAGER _____ DATE 2/28/06

LABORATORY MANAGER _____ DATE 2-28-06

HISTORY: Rev0, 9/15/92; Rev1, PCN #165, 3/14/94; Rev2, PCN #457, 4/18/95; Rev3, 10/27/99; Rev4, 3/26/02; Rev5, 3/14/03; Rev6, 5/12/04; Rev7, 2/27/06. **re-released w/o revision 11/9/07 DAS**

1. SCOPE AND APPLICATION

This procedure and the Method it references, SW-846 9095A, are used to determine the presence of free liquids in a representative sample of waste. Method SW 9095A can be used to determine compliance with 40 CFR 264.314 and 265.314. Free liquids, by definition, are any material that passes through the mesh portion of the filter.

2. SUMMARY

A predetermined amount of material is placed in a paint filter. If any portion of the material passes through and drops from the filter within five minutes, the material is deemed to contain free liquids.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the logbook pages, analytical review sheets or case narrative indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct any errors that were found in the data during review.

3.4 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Filter media can separate from the filter cone upon exposure to alkaline materials. This development causes no problem if the sample is not disturbed.

4.2 Temperature can affect test results if the test is performed below the freezing point of any liquid in the sample. This procedure is performed at ambient temperature in the laboratory. Ambient temperature is generally 23±4°C in the laboratory.

5. APPARTUS AND MATERIALS

5.1 conical paint filters, mesh number 60±5% (fine meshed size) and available at local paint stores

5.2 ring stands and rings

5.3 beakers or graduated cylinders, 100mL

5.4 glass or steel funnels with wide bottom opening or fluted funnels

5.5 stop watch or timer

6. REAGENTS

None.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Samples may be contained in any glass or plastic container.

7.3 No chemical preservation is required as part of this procedure.

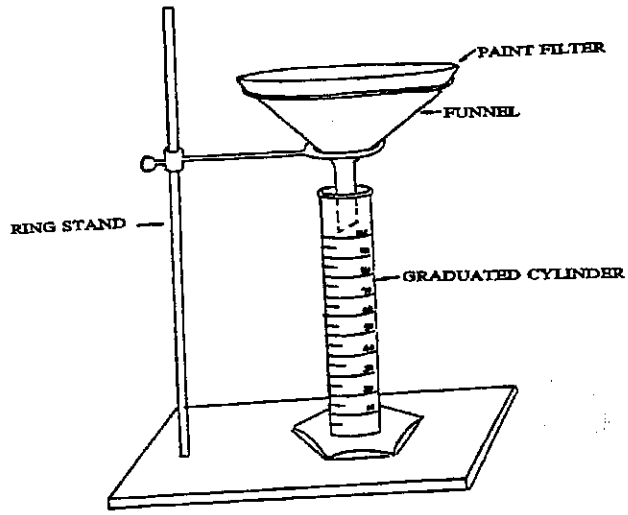
7.4 Refrigerated storage for samples submitted for this procedure is not required. However, refrigerated preservation may be required for other tests being performed on the samples.

8. PROCEDURE

8.1 Assemble the test apparatus as follows: secure a ring on a ring stand with sufficient height to allow a beaker or a graduated cylinder to be placed under it as

shown in Figure 1 below. A fluted funnel or a wide-opening funnel may be placed in the ring, and the paint filter into the glass funnel as shown in Figure 1.

Figure 1
PAINT FILTER TEST APPARATUS



8.2 A 100mL or 100g aliquot is required for this test. The aliquot must be representative of the sample. If it is not possible to obtain a sample of 100mL or 100g that is sufficiently representative of the waste, the analyst may use larger size samples in multiples of 100mL or 100g. However, when larger samples are used, analysts shall divide the sample into 100mL or 100g portions and test each portion separately.

8.3 Place sample aliquot in the filter. If the sample is of such light density that it overflows the filter, then the sides of the filter can be extended upward by taping filter paper to the inside of the filter and above the mesh. Settling the sample into the paint filter may be facilitated by lightly tapping the side of the filter as it is being filled. If the waste filled paint filter cannot sustain its weight on the ring stand, then a fluted funnel (Figure 1) or a funnel with a mouth that allows at least 1 inch of the filter mesh to protrude should be used to support the filter.

8.4 In order to ensure uniformity and standardization of the test, material such as sorbent pads or pillows that do not conform to the shape of the paint filter should be cut into small pieces and poured into the filter. The particles to be tested should be reduced to smaller than 1cm (i.e., should be capable of passing through

a 9.5mm, 0.375inch standard sieve). Sample size reduction may be accomplished by cutting the material with scissors, shears, knife, etc., so as to preserve the integrity of the sample as much as possible. *Grinding sorbent materials should be avoided as this may destroy the integrity of the sorbent and produce many "fine particles" that would not normally be present.*

8.5 For brittle materials larger than 1cm that do not conform to the filter, light crushing to reduce oversize particles is acceptable if it is not practical to cut the material. Materials such as clay, silica gel, and some polymers may fall into this category.

8.6 Allow sample to drain for 5 minutes into the beaker or graduated cylinder.

8.7 If any portion of the test material collects in the beaker or graduated cylinder in the 5 minute period, then the material is deemed to contain free liquids for purposes of 40 CFR 264.314 and 265.314. Record the volume or weight of sample that passed through the filter.

9. QUALITY CONTROL

9.1 Method blanks are not analyzed as part of this procedure.

9.2 Laboratory control samples are not analyzed as part of this procedure.

9.3 One sample should be analyzed in duplicate with each batch, if sample volume is adequate. Batches are defined as 20 or fewer field samples prepared and analyzed as a unit.

10. DEVIATION FROM THE METHOD

There are no known deviations from the referenced Method.

11. SAFETY, HAZARDS, AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.2 Particle size reduction as discussed above may produce fine particles that can be ingested. Any size reduction efforts must be performed in a manner that minimizes exposure to these fines.

11.1.3 This procedure should be conducted in an appropriately ventilated hood enclosure as the samples should be considered as potential hazards.

11.2 WASTE DISPOSAL

11.2.1 This test is nondestructive and the sample aliquots used for this procedure may be utilized in other procedures in the lab where appropriate.

11.2.2 Any non-radioactive solid sample residues should be disposed of in the Contaminated Soils and Solids waste stream.

11.2.3 Any radioactive solid sample residues shall be disposed of in the Radioactive Soils and Solids waste stream.

11.2.4 Any non-radioactive liquid sample residues should be disposed of in the Hazardous Aqueous Waste (if water) or if an organic liquid in the Oil and Grease Waste (non-PCB).

11.2.5 Any radioactive liquid sample residues should be disposed of in the Mixed Hazardous Radioactive Liquids waste stream.

11.2.6 Empty sample containers are defaced prior to disposal.

re-released without revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the monitoring of Toxic Characteristic Leaching Procedure (TCLP) tumbler revolutions per minute (RPM). This procedure also describes how Paragon monitors room temperature for all leaching procedures (SW1311, SW1312, and Cal-WET).

2. SUMMARY

Uniquely identified tumblers are loaded with samples and tumbling is initiated. At the beginning and the end of the tumbling process, the RPMs of the tumblers are measured and recorded on a benchsheet. TCLP room temperature s monitored throughout the entire leaching procedure using a min/max thermometer that is verified annually (SOP 923). The TCLP room temperature during tumbling is recorded on the benchsheet.

3. RESPONSIBILITIES

3.1 Organic Extractions personnel are responsible for monitoring and controlling the temperature of the TCLP room. To help keep temperature constant, use of outside and inside doors proximate to this area is limited. As necessary, Organic Extractions staff shall notify the Facilities Manager when thermostatic adjustment to control TCLP room temperature is necessary.

3.2 Organic Extractions personnel are responsible for ensuring that the electronic thermometer used to monitor TCLP room temperature is functioning properly (as needed, replacement batteries can be obtained from the QA Department), and that the correct thermometer is indicated in the laboratory logbook. A replacement thermometer is available from the Quality Assurance (QA) Department should malfunction occur.

3.3 The QA Department is responsible for managing thermometers (including their annual verification per SOP 923) and for providing temperature record logbooks, as needed.

3.4 It is the responsibility of the Technician to perform these tasks according to this SOP and to complete all documentation required for review. Any anomalies or out-of-control events must be noted and corrective action taken and documented.

4. APPARATUS AND MATERIALS

4.1 Tumbler, with 30±2 RPM capability, Associated Design and Manufacturing Model 3740 or equivalent

4.2 Stopwatch, VWR #62379-460 or equivalent

4.3 Electronic min/max thermometer, with external probe immersed in liquid, VWR #62379-549 or equivalent (NIST-traceable)

5. PROCEDURE

5.1 Note room temperature before tumblers are turned on. If room temperature is not 21-25°C, then do not start the tumbling. Bring room temperature to 21-25°C before tumbling samples.

5.2 Load samples onto tumbler and turn on tumbler. SOPs 608, 609, 666, 668 and 669 provide guidance on various leaching procedures.

5.3 Reset the min/max thermometer when tumbling starts.

5.4 Start the stopwatch and count the revolutions for 30 seconds, counting each time the orange dot on the moving part lines up with the orange dot on the stationary part. Record the revolutions (multiplied by 2) on the benchsheet.

The measured RPM for the units during tumbling must be 30±2. If the measured rate of revolution is out of this range, tag the tumbler "Out of Service" (SOP 317) and notify the Department Manager.

Also record on the benchsheet:

- numbers on the tumblers used (tumbler #)
- date and time the tumbling starts
- initials of the Technician taking initial readings

5.5 Just before the tumbling is complete, measure RPMs as described in Step 5.4; record on benchsheet.

Also record on the benchsheet:

- the minimum and maximum temperature of the TCLP room during the tumbling process
- date and time the tumbling stops
- initials of the Technician taking final readings

6. QUALITY ASSURANCE

6.1 If initial RPM is within specifications but final RPM measurement indicates the tumbler is out of specification, then this must be documented using a Non-Conformance Report (NCR, SOP 928).

6.2 The room temperature must be 23±2°C for Methods SW-846 1311 and 1312. Document on an NCR if temperature is outside of the acceptable range during tumbling process.

7. SAFETY AND HAZARDS

7.1 Always inspect electrical cords and switches prior to using electrical equipment.

7.2 Take care when operating moving machinery. Do not let long hair hang loose or wear ties and/or loose fitting clothing.

STANDARD OPERATING PROCEDURE 664 REVISION 8

TITLE: **EXTRACTION AND DERIVATIZATION OF SAMPLES FOR HERBICIDE ANALYSIS BY GAS CHROMATOGRAPHY -- METHODS SW8151A, EPA 615, AND EPA 515.1**

FORMS: **604 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-2007

QUALITY ASSURANCE MANAGER _____ DATE 11/20/07

LABORATORY MANAGER _____ DATE 11-21-07

HISTORY: Rev0, 12/20/93; Rev1, PCN #385, 2/17/95; Rev2, 4/16/02; Rev3, 8/5/02; Rev4, 4/3/04; Rev5, 11/22/04; Rev6, 3/9/06; Rev7, 7/24/06; Rev8, 11/20/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references - Methods SW8151A, EPA 615 and EPA 515.1, are used to prepare liquid (all) and solid (SW8151A) matrices for subsequent analysis for chlorinated acid herbicides by gas chromatography. The following compounds typically comprise Paragon's herbicide target analyte list:

Dalapon	Silvex
Dicamba	2,4,5-T
MCPP	2,4-DB
MCPA	Dinoseb
Dichloroprop	2,4-Dichlorophenylacetic acid
2, 4-D	

Other compounds are listed in Methods EPA 515.1, EPA 615, and SW8151A; these compounds may be extracted using this procedure after successful completion of method detection limit (MDL) studies and initial demonstration of capability (DOC).

2. SUMMARY OF METHOD

Herbicides are produced and applied in several chemical forms (i.e., acids, salts, esters, etc.). This procedure addresses the preparation of liquid and solid matrix environmental field samples and quality control (QC) samples for total herbicide content analysis. Samples are extracted, hydrolyzed, concentrated by Kuderna-Danish (SOP 607), and then derivatized (to methyl esters) using diazomethane. The resultant methyl-esterified extracts are then solvent exchanged into hexane by a nitrogen evaporation procedure (SOP 637) before subsequent gas chromatographic (GC) analysis (SOP 434).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform this procedure according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work and documentation of the measures taken to correct the errors that were found.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Method interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing hardware that can lead to discrete artifacts or elevated baselines in chromatograms. All materials must be routinely demonstrated to be free from interferences under the conditions of the analysis.

4.2 Organic acids, especially chlorinated acids, cause the most direct interference with the subsequent analysis. One of the common target compounds, *dinoseb*, is a nitrophenol. As a class of compounds, phenols may be extracted, derivatized, and subsequently interfere with the analysis procedure if they respond to the electron capture detector used in the analysis (SOP 434).

4.3 Sodium sulfate must be acidified before use. After the hydrolysis step in the procedure, it is very important to maintain pH of aqueous solutions below the lowest pK_a of the desired target compounds to ensure successful recovery.

4.4 Ether extracts must be free of water and methylene chloride prior to the derivatization steps or poor recoveries will be obtained.

5. APPARATUS AND MATERIALS

5.1 separatory funnels with PTFE stopcock and stopper, 250-2000mL, as appropriate

5.2 soxhlet apparatus consisting of the following:

- 500mL round flat bottom flasks
- soxhlet extractors
- fritted glass thimbles
- condensers with circulating cooling water

5.3 phosphoric acid acidified glass wool, Supelco #2-0383 or equivalent

Alternatively, glass wool may be acidified in-house using 8µ Corning #3950 glass wool or equivalent as follows:

5.3.1 Pour 150mL of ether into a 1000mL beaker. Slowly add 2.5mL conc. sulfuric acid.

5.3.2 Submerge as much glass wool as possible in the acidified ether.

5.3.3 The ether is evaporated by placing the beaker on top of the S-Evap steam bath in a fume hood. Swirl occasionally as the ether evaporates.

5.3.4 After ether is completely evaporated, place acidified glass wool in labeled container, cap and store.

5.4 beakers and Erlenmeyer flasks, various sizes as appropriate

5.5 boiling chips, PTFE, Chemware #D1069103 or equivalent or silicon carbide.
Rinse first with methylene chloride, then with diethyl ether prior to use.

5.6 Pasteur pipets, glass or plastic, disposable

5.7 glass vials, with screw tops equipped with PTFE septa, 10mL, 40mL, or as appropriate

5.8 PTFE tubing

5.9 magnetic stir bar and stir plate

5.10 powder funnels

5.11 pH paper, narrow (acidic and basic) and wide range

5.12 peroxide test strips (0-25ppm): EM Science #10011-1 or equivalent

NOTE: Always check peroxide level of ether prior to use. Apply solvent to test strip and evaluate as compared to reference scale. If the level of peroxide in the ether is ≥10ppm, then ether is NOT suitable for use! Notify Supervisor immediately.

5.13 Kuderna-Danish (K-D) apparatus consisting of the following:
- concentrator tubes, graduated, 10mL or other appropriate size
- evaporation flasks, attached to the concentrator tube with a clip, 500mL or other appropriate size
- 3-ball macro Snyder columns

5.14 top-loading balance, capable of weighing to ±0.1g, verified per SOP 305

5.15 glass syringes, 0.5-1mL or as appropriate

5.16 graduated cylinders, 20-2000mL as appropriate

6. SOLVENTS AND REAGENTS

6.1 SOLVENTS - **All solvents must be pesticide residue grade or equivalent.**

6.1.1 methanol (CH_3OH, MeOH): Burdick & Jackson #230-4 or equivalent

6.1.2 methylene chloride ($MeCl_2$, DCM), Fisher, #D154-4 or equivalent

6.1.3 n-hexane (C_6H_{14}), Fisher #H300-4 or equivalent

6.1.4 methyl tert-butyl ether ($(CH_3)3(COCH_3)$), JT Baker #9043-02 or equivalent

6.1.5 diethyl ether ($C_2H_5OC_2H_5$), Burdick & Jackson #107-4 or equivalent.

Must be peroxide-free and stabilized with BHT (not ethanol) or unpreserved

6.1.6 organic-free reagent water, Paragon's deionized (DI) water passed through a Milli-Q Plus system for additional purification

6.2 REAGENTS - **All reagents must be ACS reagent grade or better.**

6.2.1 sodium chloride (NaCl), VWR #SX0420-5 or equivalent

6.2.2 hydrochloric acid (HCl), concentrated, EMD #HX0603-75 or equivalent

6.2.3 sulfuric acid (H_2SO_4), concentrated, EMD #SX1247-2 or equivalent.

Make a 1:2 (v/v) solution by adding 1 part acid to 2 parts DI water. Used for pH adjustment.

CAUTION: Always add acid to water. Prepare in Pyrex™ glass beaker or jar. Reaction produces heat.

6.2.4 acidified anhydrous sodium sulfate (Na_2SO_4), EMD #SX0760E–5 or equivalent.

Purify by heating at about 450ºC (kiln) for 3-6 hours in a shallow tray.

Acidify as follows:

6.2.4.1 Weigh 1kg of dried sodium sulfate into a 2L flask or beaker. Slowly add 8mL of concentrated sulfuric acid to 450mL of ether in a 1000mL beaker. Pour the acidified ether into the 1kg sodium sulfate and mix thoroughly. Place mixture on top of steam bath and stir with a glass rod every few minutes to evaporate the ether.

6.2.4.2 After the sodium sulfate is dry, mix 1g of the resulting solid with 5mL of organic-free reagent water and measure the pH of the mixture. The solution pH must be below 3. Place the dried acidified sodium sulfate in a labeled clean jar, cap and store.

6.2.5 Carbitol® Also known as di(ethylene glycol) ethyl ether or (2-ethoxyethoxy) ethanol. Aldrich Chemicals #E455-0 or equivalent

6.2.6 Diazald® (N-methyl-N-nitroso-p-toluenesulfonamide), Aldrich Chemicals, #D2800-0 or equivalent

6.2.7 potassium hydroxide (KOH), VWR #VW5040-1 or equivalent.

Make 37% (w/v) solution by dissolving 37g of potassium hydroxide pellets in 100mL DI water.

6.3 GASES

nitrogen gas, 99.999% purity. Used for diazomethane generation and for concentration and solvent exchange of final extract (SOP 637).

6.4 SPIKE SOLUTIONS

Laboratory control, matrix and surrogate spike solutions are prepared by the analytical group according to SOPs 434 and 300 and provided to the extractions group for use. These spike solutions are documented in Paragon's Standards and Reagents database. Currently, 2,4-dichlorophenylacetic acid (DCAA) is used as the surrogate for this procedure.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Liquid samples are generally not chemically preserved and must be collected in amber glass containers (generally 1000mL) with Teflon™-lined lids. Samples must be maintained at 4±2°C and be extracted within 7 days of collection. Sodium thiosulfate ($Na_2S_2O_3$) may be used to remove free chlorine present in liquid samples if obtained from a processed water source. This should be accomplished by the client in the field. The Project Manager may specify the need for residual chlorine check of the sample upon receipt. Additionally,

samples for Method EPA 608 may need to have pH adjusted upon receipt.

7.3 Solid samples are collected in wide-mouth glass containers with Teflon™-lined lids. Solid samples are not chemically preserved but must be maintained at 4±2°C. Solid samples must be extracted within 14 days of collection.

8. EXTRACTION AND DERIVATIZATION PROCEDURES

8.1 WASTE DILUTION (SW3580A)

Organic liquids are prepared for analysis using Paragon SOP 622 and the following notes:

8.1.1 An appropriate volume of surrogate (and matrix spike standard, where appropriate) is added to each sample prior to dilution.

8.1.2 Diethyl ether is used as the dilution solvent.

8.1.3 Depending on the required analysis, extracts may require further preparation before delivery to the appropriate analytical group. If the sample is to be analyzed for both herbicide esters and acids, then the extract must be hydrolyzed and derivatized. Proceed to Section 8.2.3. If the analysis is for acid herbicides only, proceed to Section 8.5 for derivatization. Consult Department Manager for further direction if necessary.

8.2 SOIL SAMPLES

Soil samples are first extracted under acidic conditions. The extracts are then hydrolyzed prior to further extraction, concentration, and derivatization.

NOTE: Paragon extracts solid samples for herbicide analysis by soxhlet extraction (Paragon SOP 625) after acidifying the sample/sodium sulfate matrix. Section 7.2 of SW8151A discusses sonication and shaker extraction. As the guidance of SW-846 states, alternative preparation methods are acceptable provided the laboratory establishes performance documentation, which shows the procedure employed provides appropriate performance for the intended application. Paragon has met this requirement (refer to REPORT: Soxhlet Extraction of Herbicides in Soils, J:\Audits and Corrective Actions\ Findings and Corrective Actions\Topical Corrective Actions\Sox_Herb_SO).

8.2.1 SOIL SAMPLE PREPARATION

8.2.1.1 Decant and discard any water layer present on a sediment sample. Take care to discard any foreign objects (e.g., sticks, leaves, rocks) or any portion of the sample that appears to ***not*** be representative of the sample. Mix sample thoroughly, especially composited samples, to

ensure that a representative sample is obtained. ***Consult Department Manager regarding difficult, unusual matrices.***

8.2.1.2 Homogenize sample and place 30g into a 400mL thick-walled beaker with enough sodium sulfate to dry the sample. Adjust to pH<2 using concentrated HCl, 2mL of acid is generally adequate. If a significant reaction occurs (evidenced by rapid fizzing) upon addition of HCl to the sample, more acid may be required to adjust the pH.

8.2.1.3 Mix the sample, sodium sulfate and acid thoroughly. The mixture should be free flowing when dried sufficiently. Additional sodium sulfate may be necessary. *Be careful that the mixture will not exceed the capacity of the glass thimble.*

8.2.2 SOIL SAMPLE EXTRACTION

8.2.2.1 Quantitatively transfer the dried sample mixture to a Soxhlet thimble. Add 1.0mL of a 2.0mg/kg herbicide surrogate spiking solution to all field and QC samples. To the LCS, LCSD, MS, and MSD samples, also add 1.0mL of the herbicide spiking solution (0.25mg/kg to 250mg/kg spike component concentrations).

8.2.2.2 Per Paragon SOP 625, extract the samples with methylene chloride for 16-24 hours. Allow extract and apparatus to cool to room temperature before disassembling.

8.2.3 SOIL SAMPLE HYDROLYSIS

8.2.3.1 Quantitatively transfer the extract from the flat bottom flask into a 500mL Kuderna-Danish (K-D) flask connected to a 10mL concentrator tube. Add boiling chips and attach a rinsed/pre-wetted macro Snyder column. Evaporate the extract in a steam bath to a volume of approximately 5mL following SOP 607.

8.2.3.2 Remove the flask from the bath and allow the extract to cool to room temperature.

8.2.3.3 Add 5mL 37% KOH and 25mL organic-free water to the extract contained in the K-D concentrator. Add a few boiling chips. Reflux in a steam bath (S-Evap) or water bath at 65-70°C until the hydrolysis step is complete (usually 1-2 hours). The methylene chloride will have completely evaporated when the hydrolysis is complete.

Remove flasks and cool to room temperature (approximately 1 hour).

8.2.3.4 Transfer the aqueous hydrolysate to a 250mL separatory funnel. Check that the pH of the hydrolysate is pH≥12. Extract 3 times with 60mL methylene chloride. Each extraction consists of vigorous agitation (approximately 2 minutes for the first extraction, 1.5 minutes for the second, and 1 minute for the third) with periodic venting followed by approximately 10 minutes of settling for separation of the organic and aqueous phases.

If an emulsion interface between the layers is more than one-third the volume of the solvent layer, further mechanical techniques (stirring, filtration, centrifugation, etc.) are required to achieve suitable separation. SOP 626 provides further guidance on how to break emulsions. Drain and discard methylene chloride (the bottom layer) after each clean-up extraction. **It is particularly important to make sure that as much methylene chloride as possible is removed after the third extraction** - residual methylene chloride remaining in the sample during acidification (Section 8.2.3.5) will lead to poor target recoveries.

NOTE: These three extractions with methylene chloride serve to clean up neutral or basic non-target compounds from the sample prior to extraction of the target compounds.

8.2.3.5 After the third clean-up extraction is completed, adjust the pH of the aqueous hydrolysate to pH<2 with sulfuric acid solution. Typically, 5mL acid or less is needed.

8.2.3.6 Extract the acidified aqueous hydrolysate 3 times with diethyl ether. Add 60mL of ether for the first extraction, and 40mL for the second and third. Each extraction consists of vigorous agitation (about 2 minutes for the first extraction, 1.5 minutes for the second, and 1 minute for the third) with periodic venting followed by about 10 minutes settling for separation of the organic and aqueous phases. The ether extract layer will be at the top.

Drain the aqueous layer into an Erlenmeyer flask or beaker. Drain the ether extract into a 250mL Erlenmeyer flask or 250mL round flat bottom flask containing 10-25g of acidified sodium sulfate. Return the aqueous portion to

the separatory funnel.

8.2.3.7 After all three portions of extract have been drained into the collection flask containing acidified sodium sulfate, cap and let the extract dry for at least two hours (preferably overnight). Make sure the sodium sulfate is still loose and friable. If not, add more acidified sodium sulfate and let extract dry for at least 2 more hours.

8.2.3.8 Proceed to Section 8.4 - EXTRACT CONCENTRATION.

8.3 AQUEOUS SAMPLES

Aqueous samples are first hydrolyzed, then extracted under acidic conditions by separatory funnel.

8.3.1 AQUEOUS SAMPLE PREPARATION

8.3.1.1 Assemble 1.5-2 liter separatory funnels and add 250g NaCl to each. Mark the volume of sample on the sample bottle. Decant 1 liter (or other volume as suitable) of sample into a separatory funnel. Retain the original sample container; refill the container up to the mark with tap water and measure volume of sample to be extracted using a graduated cylinder. Place cleaned stoppers in each funnel and gently shake to dissolve salt. General guidance for separatory funnel extractions is provided in SOP 626. .

8.3.1.2 Spike all blanks, field samples and QC samples with 1.0mL of a 2.0mg/kg surrogate spiking solution. Additionally, spike LCS, LCSD, MS, and MSD QC samples with 1.0mL of the herbicide spiking solution (0.25mg/kg to 250mg/kg spike component concentrations).

8.3.2 AQUEOUS SAMPLE HYDROLYSIS

8.3.2.1 Add enough base (KOH) to each separatory funnel to raise to pH>12 (about 15mL of KOH solution is generally adequate). Place stopper in each separatory funnel and shake for 10-20 seconds. Check the pH of the solution using narrow range pH paper. If the pH is not >12, then add more base and repeat this step.

NOTE: This is a critical step. The pH must be 12 or greater or target compounds may be lost in later steps of this procedure. This high pH is also necessary for complete hydrolysis of herbicide esters in the sample.

8.3.2.2 Let hydrolyzing samples sit for 1-2 hours at room temperature.

8.3.2.3 After the 1-2 hour hydrolysis step, extract 3 times with 60mL methylene chloride. Each extraction consists of vigorous agitation (approximately 2 minutes for the first extraction, 1.5 minutes for the second, and 1 minute for the third) with periodic venting followed by approximately 10 minutes of settling for separation of the organic and aqueous phases.

If an emulsion interface between the layers is more than one-third the volume of the solvent layer, further mechanical techniques (stirring, filtration, centrifugation, etc.) are required to achieve suitable separation. SOP 626 provides further guidance on how to break emulsions.

Drain and discard methylene chloride (the bottom layer) after each clean-up extraction. **It is particularly important to make sure that as much methylene chloride as possible is removed after the third extraction -** residual methylene chloride remaining in the sample during acidification (Section 8.3.2.1) will lead to poor target recoveries.

NOTE: These three extractions with methylene chloride serve to clean up neutral or basic non-target compounds from the sample prior to extraction of the target compounds.

8.3.3 AQUEOUS SAMPLE EXTRACTION

8.3.3.1 Add 5-15mL of cold (4±2°C) sulfuric acid solution, seal the separatory funnel and shake for 10-20 seconds to mix the acid with the sample, venting several times to release pressure. Check the pH. If the pH is ≤2, then proceed to the next step. If the pH is not ≤2, then adjust by adding more acid.

8.3.3.2 Extract the acidified aqueous hydrolysate 3 times with diethyl ether. Add 80mL of ether for the first extraction, and 60mL for the second and third. Each extraction consists of vigorous agitation (about 2 minutes for the first extraction, 1.5 minutes for the second, and 1 minute for the third) with periodic venting followed by about 10 minutes settling for separation of the organic and aqueous phases. The ether extract layer will be at the top.

Drain the aqueous layer into an Erlenmeyer flask. Drain the ether extract into a 250mL Erlenmeyer flask or 250mL round flat bottom flask containing 10-25g of acidified sodium sulfate. Return the aqueous portion to the separatory funnel.

8.3.3.3 After all three portions of extract have been drained into the collection flask containing acidified sodium sulfate, allow the combined extract to remain in contact with the drying agent for at least 2 hours (overnight is preferable). **Drying is critical to allow complete derivatization of any target compounds that may be present. Any moisture remaining in the extract will lessen the effectiveness of the diazomethane reagent, which can result in poor recovery.** Test to ensure that the drying capacity of the acidified sodium sulfate has not been exceeded. This can be done by swirling the flask and observing that the sodium sulfate is loose and friable versus caked. The amount of acidified anhydrous sodium sulfate is adequate if some free-flowing crystals remain. Add more acidified sodium sulfate if caking or clumping is evident, and allow to sit for at least more 2 hours.

8.4 EXTRACT CONCENTRATION

8.4.1 Plug a funnel with acidified glass wool and a few grams of acidified sodium sulfate; rinse with a few mL of ether and discard the rinse. Pour the dried extract through the prepared funnel and collect in a 500mL K-D flask with concentrator tube attached. Use a clean glass rod to crush any caked sodium sulfate and transfer the drying agent to the funnel.

8.4.2 Rinse the drying flask and funnel with 20-30mL of diethyl ether. Pour the rinse ether through the prepared funnel and into the K-D flask.

8.4.3 Place a few boiling chips into the K-D flask and attach a three-ball (macro) Snyder column that has been rinsed/pre-wetted with ether.

8.4.4 Reduce the volume to approximately 5mL per SOP 607. Allow the ether extract and the apparatus to cool to room temperature. Proceed to Section 8.5 (derivatization) for EPA 615 or SW8151A samples.

NOTE: For EPA 515.1 samples, reduce to an apparent volume of 0.5mL; the nitrogen-blow down technique (SOP 637) may be used. This volume must be solvent exchanged (SOP 637) to MTBE. Add 5mL of MTBE to the 0.5mL and reduce to 0.5mL again. Proceed to Section 8.5 (derivatization).

8.5 DERIVATIZATION BY IN SITU GENERATION OF DIAZOMETHANE
Prepared and concentrated extracts are derivatized (to methyl esters) using diazomethane. Diazomethane can be generated via a bubbler apparatus fabricated in-house or by using a diazald kit purchased from a suitable vendor. The bubbler method is suggested for all samples and is the technique described in this procedure because it is safer to use than the diazald kit.

8.5.1 Add 200µL of methanol to each extract to be derivatized.

8.5.2 Fabricate the diazomethane bubbler apparatus as shown in Figure 1.

8.5.3 Add 5mL of diethyl ether to the first 40mL vial.

8.5.4 Add the following to the second 40mL vial and immediately place the bubbler exit tube into the concentrator tube containing the sample extract:

2mL diethyl ether
4mL carbitol
5mL 37% KOH
4.5g Diazald

8.5.5 Apply nitrogen flow (1-2mL/min) to bubble diazomethane through the extract for up to 10 minutes, or until the yellow color of diazomethane persists. When the mix of reagents is optimum, many extracts will turn yellow in 30 seconds or less.

8.5.6 When the yellow color persists in the extract, remove the PTFE-tubing from concentrator tube. Seal the concentrator tube with a Teflon™ or Neoprene™ stopper. Allow to sit at room temperature in the hood for 20 minutes.

8.5.7 Remove the stopper from the concentrator tube after the 20 minute reaction time and allow the tube to stand open until the evolution of nitrogen gas has stopped. If not already present, a boiling chip may be added to aid the decomposition of excess diazomethane.

NOTE: Solutions of diazomethane decompose rapidly in the presence of solid materials (e.g., silicic acid, sodium sulfate or boiling chips).

8.5.8 The derivatized extracts are exchanged from ether to hexane per Paragon SOP 637.

9. QUALITY CONTROL

9.1 DEFINITION OF A PREPARATION BATCH

For this method, a preparation batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike (MS) sample and laboratory duplicate. An LCSD or MSD (or both) can serve as the laboratory duplicate. All quality control samples must be carried through all stages of the sample preparation and measurement steps.

9.2 METHOD BLANK

Method blanks (MB) are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the method blank consists of 30g of kilned Ottawa sand (solid matrix) or 1000mL organic-free DI water (aqueous matrix). See QC Table of SOP 434 for acceptance limits.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method in a controlled matrix. A known amount of analyte is prepared and analyzed. For this method, 30g of kilned Ottawa sand (solid matrix) and 1000mL organic-free DI water (aqueous matrix) are used for the LCS. Results obtained are compared to results expected. See QC Table of SOP 434 for acceptance limits.

9.4 MATRIX SPIKE SAMPLE

The matrix spike (MS) sample is analyzed to assess the effect of matrix interferences upon the sample analysis. A known amount of analyte is spiked into a replicate aliquot of a selected sample and analyzed. Results obtained are compared to results expected. See QC Table of SOP 434 for acceptance limits.

9.5 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. The LCS, MS or both may be analyzed in duplicate to serve this purpose. Precision is expressed as Relative Percent Difference (RPD). RPD calculations are discussed in SOP 434.

10. DEVIATIONS FROM THE METHODS

This SOP meets the requirements of methods SW8151A, EPA 615 and EPA 515.1 except as noted:

10.1 Methods SW8151A and EPA 515.1 discuss the use of silicic acid to destroy the diazomethane present in the extract. Paragon removes excess diazomethane by streaming nitrogen on the extract during the solvent changeover and by the addition of a boiling chip.

10.2 Methods SW8151A and EPA 515.1 state that glassware used in this procedure

"must be acid-rinsed" prior to use to avoid analyte loss. Instead, Paragon kilns glassware at high temperature (approximately 450°C) prior to use. Historical data and internal studies have shown that kilning adequately addresses the problem of potential analyte loss due to residual alkaline substances.

10.3 Soxhlet extraction of solids is not referenced in method SW8151A. Paragon has shown that use of Soxhlet extraction as detailed in Paragon SOP 664 and documented in REPORT: Soxhlet Extraction of Herbicides in Soils (J:\Audits and Corrective Actions\ Findings and Corrective Actions\Topical Corrective Actions\Sox_Herb_SO) provides high performance and compliant results.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Special precautions must be taken when working with diazomethane. It is carcinogenic and can explode under certain conditions.

Carcinogenic: Avoid breathing vapors; use in well-ventilated hood.

Explosion hazard: Avoid ground surfaces (e.g., ground glass joints, glass stirrers). Do not heat above 90°C. Use of a safety screen is suggested.

11.1.2 Read the appropriate MSDS before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Methylene chloride, hexane, methyl tert-butyl ether, diethyl ether and methanol have TLV≤50ppm.

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Aqueous waste may be disposed of in the AQLW (separate radioactive and non-radioactive) waste streams.

11.2.2 Solid sample waste should be disposed of in the contaminated soils and solids waste streams (radioactive or non-radioactive, as appropriate).

11.2.3 Liquid waste left over from the diazomethane generation procedure is disposed of in the AQLW stream. Wait about an hour after the extracts are derivatized (to allow diazomethane generation to cease completely) before disposal of this waste.

11.2.4 Halogenated organic wastes may be disposed of in the Halogenated Organic Wastes satellite collection vessel.

11.2.5 Any ether, hexane or other nonhalogenated organic solvent that has not been potentially contaminated with PCBs may be disposed of in the Acetonitrile/Nonhalogenated Waste.

11.2.6 Disposal of extracts and extract vials is managed by the group responsible for the analysis.

11.2.7 All empty solvent bottles must be disposed of appropriately. Please note that all labels and markings must be removed or defaced prior to disposal.

Comments:

Timer Operation

1) **CLLE only** - check that the plugs connected to the power strip correspond to the heating mantles you wish to use.

   Soxhlet only - unplug the Variac(s) power cord(s) from the 3-outlet heavy-duty extension cord. Variac cords are marked with either the Variac # or "aqua" colored tape, or both. **MAKE SURE** the Variac(s) you are using correspond to the six-position set-up you want to run. Then, plug the Variac cord(s) into either (or both) of the 2 outlets on the digital timer. Each Variac is labeled as to which digital timer it should be plugged into. Check that the timer # on the Variac matches the timer # you are plugging it into. After plugging the Variac(s) into the timer, turn the Variac(s) on, using either the toggle or circular switch, depending on the model. Flip the appropriate toggle switches on the soxhlet heating mantle bank, to activate the position(s) you want to run.

2) Check that the **day-of-week**, **time**, and **AM/PM** on the timer are correct (press "CLOCK" on the timer). If any of the date/time display is incorrect, reset the clock as described in **Appendix A**.

3) Program the timer as follows:

   a: Press "PROG" button on the timer once. The left-hand side of the timer display should look like this:

```
   MO TU WE TH FR SA SUN
|ON
|          __ __ : __ __
```

   b: Press "DAY" button until the day of the week you want the timer to start (i.e., begin extraction) is indicated at the top of the display screen.

   c: Press "HOUR" button until the hour you want the timer to start is displayed. **MAKE SURE** that the hour selected is correct, with respect to AM/ PM, as timer does not display or run on "military" time.

   d: Press "MIN" button until the minute you want the timer to start is displayed. Holding down the "MIN" button will cause it to scroll.

   e: Once date/time to turn **ON** is established, press "PROG" again. The left-hand side of the timer display should now look like this:

```
   MO TU WE TH FR SA SUN
|OFF
|          __ __ : __ __
```

   f: **Repeat steps b-d** to program what time you want the timer stop (i.e., stop extraction). When complete, press "CLOCK" to return to the current date/time display.

   g: Check/confirm program **ON** date and time, by pressing "PROG" once. Check/ confirm program **OFF** date and time, by pressing "PROG" again. Press "CLOCK" to go back to the current date and time display.

   h: Lastly, press the "MODE" button until "**AUTO**" is displayed to the left on the date/ time display. **MAKE ABSOLUTELY SURE** that timer is set to "AUTO" mode, and not "OFF," "ON," or "RDM;" as these other modes will either cause timer to not turn on, turn on immediately, or turn on at a semi-random time.

4) The timer is now ready to run your program!

Important Notes:

- While the timer(s) will accept up to 7 different event programs, it is **not advised** that you use this feature. Rather, reprogram the timer under Event 1 (indicated by the little number "1" in the Program display) each time you want to program start / stop dates and times.
- When you are done using timer (i.e., your extraction is complete and you are finished using the timer to run samples) **it is important that you unplug the Variac cord** from the timer and plug it back into the 3-outlet heavy-duty extension cord; **as well as turning off the Variac power switch**. If you leave the Variac(s) plugged into the timer, the set program will run again in 1 week (if timer is on AUTO mode), regardless of whether CLLEs/Soxhlets are actually set up. This is a potential fire hazard, as the heating mantles get hot enough to scorch paper. Also, **press "MODE" on timer until "OFF" is displayed to the left of the date/ time display**. This turns the set program off, preventing the timer from re-running the program in seven days.
- The timer's clock runs on one "AA" battery. The battery in each timer should be replaced approximately every June and December to ensure performance of the timers. To replace, use a small Phillips-head screwdriver to remove the battery cover on the back of the timer, and install a fresh battery in the correct orientation.

APPENDIX A

SETTING CLOCK

1) Press "CLOCK" to view the currently programmed date and time. If it is not correct… while holding down "CLOCK":
   a: Press "DAY" until correct day-of-week is displayed.
   b: Press "HOUR" until correct hour is displayed, **remember to set correct hour by AM/ PM.**
   c: Press "MIN" until correct minute is displayed.
2) Release "CLOCK" button. The display should now give the correct date and time. As an example, if it is three-o-clock in the afternoon on Wednesday, the display should read:

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 665 REVISION 7

TITLE: **EXTRACTION OF EXPLOSIVES FROM WATER AND SOIL -- SW-846 METHODS 8330 AND 8332**

FORMS: **635** **(use current iteration)**

APPROVAL:

TECHNICAL MANAGER _____ DATE 11-14-07

QUALITY ASSURANCE MANAGER _____ DATE 11/2/07

LABORATORY MANAGER _____ DATE 11-14-07

HISTORY: NEW, PCN #464, 4/24/95; Rev1, 2/09/96; Rev2, 9/26/01; Rev3, 3/01/02; Rev4, 3/14/03; Rev5, 4/28/04; Rev6, 2/27/06; Rev7, 11/12/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references (SW-846 Methods 8330 and 8332) are intended for the extraction of explosive residues from water (surface or ground) and soil/sediment samples for subsequent analysis by HPLC using an ultraviolet (UV) detector.

2. SUMMARY

Aqueous samples are extracted by a salting-out procedure with acetonitrile (ACN) and sodium chloride (NaCl). The small volume of ACN that remains undissolved above the salty water is drawn off and transferred to a concentrator tube. The ACN is then concentrated to a final volume, typically 1.5mL, by nitrogen blowdown (SOP 637). As described in SOP 404 (SW-846 Method 8330) and SOP 408 (SW-846 Method 8332), extracts from aqueous samples are mixed with acidified water prior to analysis. Aqueous samples known to contain more than 10µg/L of explosives may be better analyzed by direct aqueous injection. Soil and sediment samples are extracted using ACN in a cooled ultrasonic bath. A portion of the extract is mixed with an aqueous calcium chloride ($CaCl_2$) solution to aid flocculation, then centrifuged, and finally filtered.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the logbook pages, analytical review sheets or case narrative indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct any errors that were found in the data during review.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield discrete artifacts and/or elevated chromatographic baselines, causing misinterpretation of the chromatograms. All of these materials must be demonstrated to be free from interferences.

4.2 Tetryl can decompose rapidly in acetonitrile/water solutions. The decomposition of tetryl proceeds more rapidly at temperatures above room temperature; therefore, samples and extracts should not be exposed to temperatures above room temperature. Acetonitrile extracts from aqueous samples are mixed with acidified water prior to analysis to minimize the base-catalyzed degradation of tetryl during analysis. The appropriate analytical SOPs are referenced previously.

5. APPARATUS AND MATERIALS

5.1 Volumetric flasks, appropriate sizes

Water samples are extracted in 500mL volumetric flasks because of the ease of removing the extract from the thin neck. These flasks are not used for volumetric purposes; therefore, they may be placed in the kiln for cleaning and they need not be Class A glassware. **The flasks must be permanently marked or segregated as unsuitable for volumetric use if they have been kilned or if the extraction vessels are not Class A glassware.**

5.2 magnetic laboratory stirrer, and PTFE stir bars

5.3 scintillation vials, glass, with Teflon-lined caps, 20mL

5.4 vials, glass, with screw caps, 2mL and 4mL sizes

5.5 ultrasonic bath with chiller coil and adequate circulating cooling water

5.6 concentrator tubes, 10mL

5.7 nitrogen evaporation apparatus (NEVAP)

5.8 balance, capable of accuracy to ±0.01g

5.9 graduated cylinders- appropriate sizes

5.10 syringes, 5mL, glass or plastic disposable

5.11 pipettes, 5mL

5.12 Pasteur pipettes

5.13 centrifuge

5.14 desiccating cabinet

5.15 pH test paper, acidic

6. REAGENTS – Only reagent grade or better chemicals shall be used.

6.1 acetonitrile (CH_3CN), HPLC grade

6.2 sulfuric acid (H_2SO_4), concentrated

6.3 calcium chloride ($CaCl_2$): prepare an aqueous solution of 5g/L and adjust pH to approximately 3 or slightly less with a few drops of concentrated sulfuric acid.

6.4 sodium chloride (NaCl): the NaCl may need to be pre-rinsed with acetonitrile (CH_3CN), dried and purified at approximately 450°C (kilned) for four (4) hours, if necessary.

6.5 organic-free reagent water - HPLC grade water may be purchased for this process or deionized organic free water produced in the lab may be used if proven to be suitable.

6.6 Ottawa sand

6.7 indicating Drierite®

6.8 standard solutions - these are purchased from a vendor and diluted for surrogate and matrix spiking solutions by the analytical group.

CAUTION: Do not let explosive standards evaporate to dryness, as they may present an explosion hazard.

6.8.1 Water matrix spike -- generally contains all target analytes or those required by the client. The concentration of each analyte is typically 1.5µg/mL.

6.8.2 Soil matrix spike -- typically contains all target analytes or those required by the client. The concentration of each analyte in the soil matrix spike is typically 10µg/mL.

6.8.3 Water Surrogate -- 1,4-dinitrobenzene (0.75µg/mL) is currently utilized, but other surrogates and concentrations may be used.

6.8.4 Soil Surrogate -- 1,4-dinitrobenzene (5.0µg/mL) is currently utilized, but other surrogates and concentrations may be used.

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

7.1 Samples should be collected according to an approved sampling plan.

7.2 Water samples should be collected in amber glass containers with PTFE-lined caps. Soil samples should be collected in glass containers, preferably amber glass.

7.3 Samples and sample extracts must be stored in the dark at 4±2ºC (refrigerated). From the time of collection, sample holding times are 7 days for waters and 14 days for soils.

8. PROCEDURE

8.1 PREPARATION OF WATER SAMPLES (LOW-LEVEL EXTRACTION)

8.1.1 Typically only a portion of the sample is used for this extraction, thus care must be taken to mix the sample thoroughly before the aliquot is taken. Aqueous samples with sediment present are generally not mixed prior to decanting because the particles may cause emulsions during the extraction process.

8.1.2 Add 115g of sodium chloride and a solvent-rinsed stir bar to each of the volumetric flasks. Decant 350mL of sample into the 500mL flask. Volumetric flasks provide a thin neck that aids in removal of the acetonitrile layer after mixing; these flasks are not used for quantitative measurement of volumes. Stir to dissolve salt.

8.1.3 Spike 1.0mL of water surrogate into all field and quality control (QC) samples and 1.0mL of water matrix spike solution into the MS/MSD and LCS/(LCSD) samples.

8.1.4 Stir on the magnetic laboratory stirrer, maintaining a strong vortex at all times. After the salt is completely dissolved, add 80mL of

acetonitrile and continue stirring. Reagent water may be added at any time to bring the acetonitrile layer into the neck of the flask.

8.1.5 Continue to stir for at least 10 minutes. Tap the side of the flask frequently to prevent the acetonitrile from sticking to the sides of the flask.

8.1.6 Stop the stirring and allow the phases to separate for five minutes minimum. The acetonitrile layer should be 3-5mL. If the acetonitrile layer is less than 2mL, then add a few mL of acetonitrile and stir again. If the acetonitrile layer is greater than 5mL, then add a few mL of water and repeat the stirring.

8.1.7 After the phases have separated, remove the acetonitrile extract with a minimal amount of water (typically no more than 50-100µL) using a Pasteur pipette and place in a 10mL concentrator tube or similar size glass container.

8.1.8 Add 2-3mL of acetonitrile to the flask and repeat Steps 8.1.5 through 8.1.7 **twice more**, placing the acetonitrile into the appropriate collection vial.

8.1.9 If there is water present in the combined extracts (visible as a bottom layer), use a Pasteur pipette or a syringe to carefully remove as much of the water from the concentrator tube as possible. The acetonitrile and water may separate better if drawn up into the pipette and then used to rinse the tube. Several repetitions of this step usually turn the acetonitrile milky and leave the water clear.

8.1.10 Concentrate the acetonitrile to ~1.5mL on the NEVAP per SOP 637 with the following exception - the water bath should be turned **off** and extracts should not come in contact with a heat source.

8.1.11 Adjust the final volume to 1.5mL and transfer the acetonitrile extract to a 2mL screw-cap vial. Complete the internal chain-of-custody process (SOP 318), and place the extracts in the HPLC extract refrigeration, unit for storage.

8.1.12 One method blank (MB) and laboratory control sample (LCS), consisting of aliquots of organic-free reagent water, are to be prepared per each batch of samples. One matrix spike/matrix spike duplicate (MS/MSD) is also to be prepared per each batch of samples, as sample volume permits. In some cases, a laboratory control sample duplicate (LCSD) may also be prepared, particularly if MS/MSD samples cannot be prepared.

8.1.13 Preparation of water samples for high level analysis by direct aqueous injection consists of filtering the water sample, and is performed by the HPLC analyst following the appropriate analytical SOP.

8.2 PREPARATION OF SOIL SAMPLES

8.2.1 Decant and discard any water layer on a sediment sample. Discard any foreign objects (e.g., sticks, leaves, rocks) or any portion of the sample that appears to not be representative of the sample. Mix sample thoroughly to ensure that a representative sample is obtained, especially composited samples. *Consult the Department Manager for difficult, unusual matrices.*

8.2.2 Dry an aliquot of the solid sample in air at room temperature or colder until completely dry, insuring that the samples are not exposed to direct sunlight. To speed up the drying process, place a homogenized aliquot of the sample into an appropriately labeled aluminum weighing dish. The dish and sample are then placed in the extraction hood or desiccating cabinet until dry.

Under no circumstances may soil samples for explosives analysis be placed in the oven to hasten the drying process.

8.2.3 Because soil samples are completely dried before extraction is performed, there is no need to determine percent moisture for samples undergoing this procedure. Moisture determinations of samples suspected to contain high concentrations of explosives should be discouraged to prevent accidentally placing samples containing explosives in the oven.

8.2.4 Weigh approximately 2g of air-dried soil into a 20mL vial with Teflon-lined cap. Record the weight of the sample to the nearest 0.01g in the logbook (Form 635). Smaller aliquots of sample may be used for difficult matrices such as tissues or if high concentrations of explosives are expected.

8.2.5 Select a sample from which to prepare the MS/MSD. A 6g aliquot of this sample should be homogenized prior to sub-sampling the three aliquots (i.e., unspiked native, MS, MSD).

8.2.6 Prepare a method blank and an LCS using aliquots of Ottawa sand. An LCSD may also be prepared.

8.2.7 Spike 1.0mL of soil surrogate into all client samples and quality control (QC) samples.

8.2.8 Spike 1.0mL of soil matrix spike solution into the MS, MSD, LCS, and LCSD.

8.2.9 Add 9.0mL of acetonitrile and cap each vial -- **with the following exceptions** -- to the MS, MSD, LCS, and LCSD, add 8.0mL of acetonitrile. Cap. The volume of solvent in the extraction vessel should be 10mL after spiking and solvent addition takes place.

8.2.10 Place the vials in the sonic bath. As the sonic bath operates, the temperature of the water will rise and may cause degradation of the explosive analytes. To prevent degradation, be sure the copper cooling coil is in the sonic bath and the cold water is running continuously. Extract for 18±2 hours, ensuring that the water level in the bath is at or above the solvent level in the 20mL vials. *The 18±2 hour extraction time may cause degradation of nitroglycerin as documented in Method SW8332. A shorter sonication time (2hr) may be used when analysis of this target compound alone is requested.*

8.2.11 **Note: To minimize the possibility of introducing non-target (chromatographically interfering) contaminants to the sample extracts, syringes should be pre-rinsed with acetonitrile prior to being used to aliquot extracts.** Remove a 5.0mL aliquot of prepared extract, and combine it with a 5.0mL volume of the acidified 5g/L $CaCl_2$ solution in a glass scintillation vial. Record the $CaCl_2$ volume on the benchsheet. Let the solution sit for 10-15 minutes so that flocculation can occur. Centrifuge the extract/$CaCl_2$ solution at a setting of no higher than 1500rpm for 3-10 minutes.

8.2.12 After centrifugation, filter through a 0.45µm PTFE filter into a 4mL screw cap glass vial and record the final volume as 20mL.

8.2.13 Complete the internal chain-of-custody process (SOP 318), and place the extracts in the HPLC extract refrigeration, unit for storage.

9. QUALITY CONTROL

The laboratory must extract a method blank(MB), a laboratory control sample (LCS), a matrix spike and a matrix spike duplicate (MS/MSD) for each analytical batch (up to a maximum of 20 samples/batch). Laboratory control duplicate samples may be required and may be used instead of MS/MSD if insufficient sample volume is available for an MS/MSD pair or at the request of the client. For soil and waste samples where detectable amounts of organics are present, replicate samples may be appropriate in place of matrix spike samples.

10. DEVIATIONS FROM THE METHOD

This procedure conforms to the referenced method (SW-846 8330) with the following exception -- Aqueous extracts are not back-extracted as suggested in the method. This back-extraction is performed to minimize potential interferences with HMX determination on the C18 column. The interference presumably is from nitrate ions, which absorb strongly at 254nm. Paragon has not observed this interference, and thus back-extraction is not performed.

11. SAFETY, HAZARDS, AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 **This procedure is designed for the extraction of environmental levels of explosives from soils and waters. The procedure is not intended for operations involving pure product explosives or non-environmental levels of explosives.**

11.1.2 **Samples containing explosive material may under no circumstances be heated in any fashion (e.g., boiling a solution or drying a sample in an oven). Also, all operations in the sonic bath must be performed with cooling coil in place and operational, and the cold water must be turned on.**

11.1.3 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

11.1.4 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.5 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). **Acetonitrile (TLV< 50ppm) must be used in a properly ventilated fume hood.** Flammable solvents shall be kept away from ignition sources.

11.1.6 Finely divided soils should be handled in fume hood.

11.1.7 Any non original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name; NFPA Health, Flammability, and Reactivity ratings; and date.

11.2 WASTE DISPOSAL

11.2.1 The non-radioactive solid sample residues shall be disposed of in the Contaminated Soils and Solids Waste. Radioactive sample residues are placed in Radioactive Solids Waste stream.

11.2.2 Acetonitrile solvent wastes are disposed of in the Non-Halogenated Solvent Waste stream.

11.2.3 Extracted non-radioactive waters are disposed of in the Aqueous Laboratory Waste. Radioactive aqueous sample residues are placed in Radioactive Aqueous Waste stream.

11.2.4 Extract vials and their contents are disposed of in an appropriate waste stream by the analytical group they were delivered to.

11.2.5 All empty solvent or reagent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

11.2.6 Radioactive sample disposal - the extracted solid sample residues shall be disposed of in the Radioactive Soils and Solids container. Mixed waste solids shall be disposed of in the appropriate mixed waste container.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 666 REVISION 6

TITLE: WASTE EXTRACTION TEST (Cal-WET) FOR THE ANALYSIS OF METALS AND SEMIVOLATILE ORGANIC COMPOUNDS

FORMS: 623, 825, 345 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-12-07

QUALITY ASSURANCE MANAGER _____ DATE 11/12/07

LABORATORY MANAGER _____ DATE 11-12-07

HISTORY: Rev0; PCN # 501, 6/12/95; Rev1, 11/27/96; Rev2, 10/27/99; Rev3, 4/23/02; Rev4, 2/13/04; Rev5, 2/27/06; Rev6, 11/12/07.

1. SCOPE AND APPLICATION

The Waste Extraction Test (WET) described in this Standard Operating Procedure (SOP) is used to determine the amount of extractable metals and semivolatile substances in a waste or other material. The procedure follows the guidelines found in Title 22, Division 4.5, Chapter 11, Article 5, Section 66261.126, Appendix II of the California Code of Regulations.

2. SUMMARY

The extraction procedures outlined in this SOP are the initial steps in determining the metals, semivolatile organics, and other inorganics that can be leached from a sample. Analysis of the leachate is performed after digestions and extractions of the leachate are completed in accordance with additional Paragon SOPs. The leaching solution for semivolatile organics and most metals and inorganics such as fluoride, is a citrate buffer (pH=5). Deionized water is the leaching solution for hexavalent chromium determination.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 This procedure is performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests, or the successful analysis of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the

laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the Technician/Analyst who performed the work and documentation of measures taken to correct any errors that were found in the data.

3.5 All personnel who use this procedure have a responsibility to note any anomalies or out-of-control events associated with processing the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks (see Quality Control Section).

5. APPARATUS AND MATERIALS

5.1 rotary tumbler with 30±2rpm capability, Associated Design and Manufacturing Model 3740 or equivalent

5.2 pH meter, accurate to ±0.05 pH units @ 25°C
Meter must be calibrated prior to use (see Form 825)

5.3 magnetic stir plate, and PTFE stir bars

5.4 polyethylene (metals) and/or glass (semivolatile organics) containers with lids, wide mouth, 1000-2500 mL. **Rinse containers with 1:1 nitric acid followed by several rinses with deionized water before use.**

5.5 polyethylene bottles, 4oz

5.6 glass bottles, amber, 1L

5.7 0.45µm filters

5.8 pressure filtration device, Associated Design and Manufacturing Model 3750-LHWF or equivalent. A.K.A. "lunar lander"

5.9 centrifuge tubes, glass and polyethylene

6. REAGENTS - Only reagent grade or better chemicals shall be used.

6.1 interferent-free laboratory deionized (DI) water

6.2 citric acid monohydrate

6.3 sodium citrate dihydrate

6.4 sodium hydroxide (NaOH), 4N

6.5 **sodium citrate buffer, 0.2M , pH = 5.0±0.1**: For each 500mL needed, add 29.4g sodium citrate dihydrate to DI water, mix thoroughly and bring to 500mL final volume. Adjust fluid pH by adding 4N NaOH drop-wise until the pH reaches 5.0±0.1. Alternatively, for each 500mL needed, add 21g citric acid monohydrate to water, mix thoroughly and bring to 500mL final volume. Add 4N NaOH dropwise until the pH reached stabilizes between 5.0±0.1.

6.6 nitric acid (HNO_3), concentrated

6.7 **nitric acid solution, 1:1 (v:v):** Prepare by slowly adding 500mL of concentrated acid to 500mL of reagent water in a Pyrex™ beaker or flask while stirring. Do not add water to concentrated acid.

6.8 N_2 (99.999% purity)

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Soils to be leached for semivolatile organic compounds should be leached within 14 days of sampling. Soils to be leached for metals should be leached within 6 months of sampling.

7.2 Chemical preservation is not generally utilized for solids samples. Refrigeration to 4±2°C may be needed for some samples submitted for this procedure. Room temperature storage may be adequate for samples to be leached and analyzed for metals only.

7.3 Portions of WET leachates for subsequent organic or fluoride analysis are not chemically preserved. Extraction or analysis must start within 24hrs of collection unless the leachate is frozen as a means of preservation. Portions of WET leachates for metals analysis are chemically preserved with nitric acid as described in Section 8.10.

8. SAMPLE COLLECTION, PRESERVATION AND HANDLING

8.1 Categorize samples to be leached as follows:

Type i = a solid

Type ii = a liquid-solid mixture with more than (≥) 0.5% filterable solids

Type iii = a non-filterable sludge, slurry, or oily, tarry resinous material

8.2 Inspect samples to ensure they will pass through a No.10 (2mm) sieve, keeping in mind that rocks, glass, etc, that are extraneous, are irrelevant as hazardous

constituents to the waste, and shall be removed and discarded. Samples that will not pass through a No.10 standard sieve will need to be milled or crushed. Due to safety concerns, such as dust control, this milling is not generally done at Paragon (see 11.1.7).

8.3 The filterable liquid portion of a ***type ii*** sample is considered part of the leachate. The volume of liquids obtained after pressure filtration using a 0.45µm filter shall be recorded on the benchsheet. The filterable liquids shall be retained. The solids retained on the 0.45µm filter are leached in the same manner as ***type i*** and ***iii.*** After leaching, the retained filtered liquids are combined with the filtered leachate to create the final leachate.

8.4 Label each 1000mL wide mouth container with a sample number. **Rinse containers before use with 1:1 nitric acid followed by several rinses with deionized water.** Use polyethylene containers for metals only extractions; use glass containers when both metals and semivolatiles are to be extracted and analyzed (unless other containers are approved by the client - consult the applicable LIMS program specification). Consult with Supervisor for sample's scheduled tests and final extract volumes needed.

8.5 Prepare the leaching fluid (0.2M sodium citrate for semivolatile organics and metals, deionized water for hexavalent chromium). The ratio of leaching fluid to sample should be maintained at 10 mL/g. If 50g of sample are not available for leaching, adjust leaching fluid volume to maintain this ratio. **Flush extraction fluid with N_2 gas for 15 minutes to remove O_2 immediately prior to adding extraction fluid to samples.**

8.6 Add the appropriate volume of leaching fluid (as discussed above) to the weighed samples. Rapidly seal the container and tumble per Step 8.7 below.

8.7 Place samples on a rotating tumbler for 48±2 hours. **Record the time tumbling was initiated on the benchsheet. Record the room temperature per Paragon SOP 663.** The room temperature must be maintained between 20° and 40°C during the tumbling. Tumbler revolutions per minute are not specified in the Cal-Wet procedure, but Paragon follows the guidelines of 30±2 rpm from SW-846 Method 1311. Actual rpms are measured and recorded on the benchsheet per SOP 663.

8.8 Reactions in the tumbling vessel may cause a pressure buildup in the vessel. The extraction bottles may need to be vented frequently when tumbling is initiated. Vent every 15 minutes or as necessary, until pressure buildup stops.

8.9 Stop tumbler and remove samples from tumbler after 48±2 hours, and allow solids to settle. Record time tumbling was halted on benchsheet. Record the

minimum and the maximum temperature during the 48±2hr tumbling on the benchsheet.

8.10 The leachate must be filtered before analysis for metals or organics (0.45µm). For many samples, it may be necessary or advisable to centrifuge or pre-filter using a larger pore size filter, before final filtration at 0.45µm. Acidify a portion of the filtrate with HNO3 acid (5% v/v) if metals analysis is required. For example, 50mL of filtered leachate is acidified with 2.5mL of concentrated HNO_3.

8.11 Store the WET leachates for metals analysis in labeled 4oz plastic bottles. The WET leachates for organics or fluoride analysis need to be preserved by freezing (**Caution**: glass bottles are used to store leachates for semivolatile organic analysis; polyethylene bottles are used to store leachates for fluoride analysis), or extracted in preparation for analysis within 24 hours of filtration.

9. QUALITY CONTROL

One method blank (MB) consisting of an aliquot of laboratory DI water will be processed with each batch of samples, containing up to twenty (20) samples per batch.

10. DEVIATIONS FROM THE METHOD

This procedure meets the requirements of the California Title 22 WET procedure with the exception of particle size reduction. Because of safety concerns, particle size reduction is not performed at Paragon (see Section 11.1.7).

11. SAFETY, HAZARDS AND WASTE

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs before prior to preparing standards or using any solvents or reagents for the first time.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals, or within a laboratory area.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.5 Any venting operations that are carried out on the sample container during the initial phase of the tumbling must be performed in a fume hood.

11.1.6 All compressed gas cylinders must be secured at all times. The cylinder cap must be installed immediately after removing the regulator and before removing the tie down strap or chain from the cylinder. The cylinder shall be secured to a gas cart for transport.

11.1.7 Safety concerns such as dust control may preclude the grinding of samples for particle size reduction. These safety concerns must *always* be addressed before attempting to grind any sample. Generally, due to health and safety concerns, grinding to reduce particle size is not practiced in the extractions area. Samples requiring particle size reduction have been sent to an appropriate facility before an extraction was performed.

11.2 WASTE DISPOSAL

11.2.1 Corrosive only wastes such as the citric acid buffer used in this procedure are disposed of by discharging into the Paragon wastewater treatment facility. These materials that are corrosive only (e.g., no hazardous components or characteristics other than corrosivity) may be neutralized in the water treatment facility.

11.2.2 The aqueous samples or supernatant of solid samples shall be disposed of in the Aqueous Laboratory Waste stream.

11.2.3 The non-radioactive soil/solid samples and sediments of solid samples shall be disposed of in the Contaminated Soils and Solids .

11.2.4 Radioactive sample disposal - the extracted solid sample residues residue shall be disposed of in the Radioactive Soils and Solids container. Mixed waste solids shall be disposed of in the appropriate mixed waste container.

11.2.5 All empty solvent bottles or sample containers must be disposed of appropriately. Please note that all labels and markings must be defaced prior to disposal.

TEMPERATURE LOGBOOK

ORGANIC EXTRACTIONS - TCLP ROOM

Acceptable Range 23 ± 2 °C

A current temperature reading must be recorded at the onset of TCLP tumbling, and the min/max memory must be reset. DO NOT initiate tumbling if temperature is not within acceptable limits. The current temperature and min/max information must be recorded at the completion of tumbling. Both the Department and QA Managers must be notified in a timely manner if an excursion occurs.

STANDARD OPERATING PROCEDURE 668 REVISION 4

TITLE: **SYNTHETIC PRECIPITATION LEACHING PROCEDURE (SPLP) FOR THE ANALYSIS OF METALS AND SEMIVOLATILE ORGANICS -- METHOD SW1312**

FORMS: **623, 646, 825, 345 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3-4-08

QUALITY ASSURANCE MANAGER _____ DATE 3/4/08

LABORATORY MANAGER _____ DATE 3-4-08

HISTORY: Rev0, 10/28/99; Rev1, 8/23/02; Rev2, 3/6/04; Rev3, 3/9/06; Rev4, 3/4/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW-846 Method 1312 -- are designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes. Application of these procedures to matrices other than those specified will be handled individually to simulate the leaching procedure as best as possible.

Procedures for ZHE SPLP extractions are described in SOP 669.

2. SUMMARY

For liquid wastes (i.e., <0.5% solids), the sample is filtered through a 0.7µm glass fiber filter, and the filtrate is defined as the SPLP leachate.

For samples containing ≥0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis. If necessary, the particle size of the solid phase is reduced. The solids are then leached with an amount of extraction fluid (the extraction fluid employed is a function of the region of the country where the sample site is located, and of the type of matrix and analyses required), equal to twenty (20) times the weight of the solid phase. Following the SPLP extraction, the leachate is separated from the solids by filtration through a 0.7µm filter.

If a liquid phase was present in the sample and set aside as described above, then this liquid is combined with the leachate from the solid phase, if the two are miscible, before metals or semivolatile organic preparation for analysis. If the liquid and the leachate are not miscible, the liquid and the leachate are analyzed separately, and the results are mathematically combined to yield a volume-weighted average concentration.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the bench sheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct the errors that were found.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by processing and analyzing method blanks.

5. APPARATUS AND MATERIALS

Extraction vessels and filtration devices shall be made of inert materials that will not leach or absorb waste components. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high-density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) are to be used only when evaluating the mobility of metals.

5.1 rotary tumbler with 30±2rpm capability, Associated Design and Manufacturing Model 3740 or equivalent

5.2 pH meter, accurate to ±0.05 pH units @ 25°C
Meter must be calibrated prior to use (see Form 825).

5.3 pressure filtration device, Associated Design and Manufacturing Model 3750-LHWF or equivalent. A.K.A. "lunar lander".

5.4 fiber filters, borosilicate glass, Gelman™ #66256, 0.7µm nominal or equivalent

NOTE: The glass fiber shall contain no binder materials and shall have an effective particle size of 0.6 to 0.8µm. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1.0M HNO_3, followed by three consecutive rinses with deionized water (a minimum of 1000mL per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

5.5 bottle extraction vessel, 2L or slightly larger. Borosilicate glass, 2200mL Kontes™ #332100-021 or equivalent. If PVC coated for safety, do not place in kiln. HDPE plastic, 2000mL Eagle Picher #EP150-02WM or equivalent

Paragon typically uses disposable HPDE extraction bottles for metals and semivolatile organics. The use of HDPE extraction bottles has been demonstrated to generate leachates that are free of contaminants for the analyses being conducted.

5.6 balance, accurate to within ±0.01g

5.7 beakers or Erlenmeyer flasks, glass 500mL (or 4.5oz plastic cups)

5.8 watch glass, appropriate diameter to cover beaker or Erlenmeyer flask (or cap for plastic cup)

5.9 carboys for containerizing extraction fluids

5.10 stirring hot plate, with magnetic stir bar

5.11 graduated cylinders, sized as appropriate

5.12 centrifuge

5.13 drying oven, capable of maintaining 100±20°C

6. REAGENTS - Only reagent grade or better chemicals shall be used.

6.1 water, of sufficient purity that target analytes or interferences are not observed at levels of interest for the analytes of interest. For semivolatile organics and metals analysis, laboratory deionized (DI) ASTM Type II water meets the definition of reagent water. Prior to being used for this procedure, this water is filtered through a Millipore Synergy 185® filtration system for further purification.

6.2 sulfuric acid (H_2SO_4), used in combination with nitric acid to adjust pH of leaching solution.

6.3 nitric acid (HNO_3), used in combination with sulfuric acid to adjust pH of leaching solution, as well as to prepare 1N HNO_3 for rinsing metals from containers and filters.

6.4 sulfuric acid/nitric acid (60/40% w/w). Carefully mix 60g of concentrated sulfuric acid with 40g of concentrated nitric acid. If preferred, a more dilute acid mixture may be prepared and used to more easily adjust pH of the extraction fluids.

6.5 **SPLP Extraction fluid 1**: Make by adding the 60/40 weight percent mixture of sulfuric and nitric acids (or a suitable dilution) to water until the pH is 4.20 ±0.05. *This fluid is used to determine the leachability of soil from a site that is east of the Mississippi River, and the leachability of wastes and wastewaters.*

6.6 **SPLP Extraction fluid 2**: Make by adding the 60/40 weight percent mixture of sulfuric acid and nitric acids (or a suitable dilution) to water until the pH is 5.00 ±0.05. *This fluid is used to determine the leachability of soil from a site that is west of the Mississippi River.*

6.7 **SPLP Extraction fluid 3**: This fluid is laboratory deionized water and is used to determine cyanide leachability.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 All samples should be collected using an appropriate sampling plan. Since samples that are predominantly liquid may not have enough solids to obtain 100g by filtration, several hundred grams of sample may be necessary to properly conduct this procedure.

7.2 Chemical preservatives are not added to solid samples. Some liquid samples may contain residual chlorine and the free chlorine should be deactivated with sodium thiosulfate or another dechlorinating reagent while in the field. Preservatives shall <u>not</u> be added to samples before extraction.

7.3 Samples should be collected in Teflon-lined septum capped bottles and stored at

4±2°C. Samples may be refrigerated unless refrigeration results in irreversible physical change of the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

7.4 SPLP leachate should be prepared for analysis and analyzed as soon as possible following extraction. Leachates or portions of leachates for metallic analyte determinations must be acidified with nitric acid to a pH<2, unless precipitation occurs. Refrigeration is generally the only preservation technique applied to the leachates intended for semivolatile organic analysis. Maximum hold times are:

MAXIMUM HOLD TIMES (DAYS)

Leachate Analysis	From Field Collection to SPLP Leaching	From SPLP Leaching to Preparation for Analysis	From Preparation to Analysis
Semivolatile organics (including Pesticides, Herbicides)	14	7	40
Mercury (Hg)	28	NA	28
Metals (except Hg)	180	NA	180

NA=Not Applicable

8. PROCEDURES

8.1 PRELIMINARY EVALUATION

Preliminary evaluation includes: (1) determination of the percent solids (8.1.1); (2) determination of whether the sample contains insignificant solids and is, therefore, its own leachate after filtration (8.1.2); (3) determination of whether the solid portion of the sample requires particle size reduction (8.1.3) and (4) determination of which extraction fluid is to be used for the nonvolatile SPLP extraction of the waste (8.1.4).

Select samples to be analyzed and record on benchsheet. Perform preliminary SPLP evaluations on a minimum 100g aliquot of sample, assuming adequate volume of sample has been provided (notate on benchsheet if otherwise); this aliquot may not actually undergo SPLP extraction.

8.1.1 DETERMINATION OF PERCENT SOLIDS
PHASE SEPARATION

8.1.1.1 Percent solid is defined as that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out under applied pressure, as described below. Visual inspection may be sufficient for this determination.

If the sample will obviously yield no liquid when subjected to pressure filtration (i.e., it is 100% solids), then proceed to Section 8.1.3 - Particle Size Reduction Determination.

8.1.1.2 **Phase Separation**. If the sample is liquid or multiphasic, liquid/solid separation is required to make a preliminary determination of percent solids. Phase separation involves the filtration device discussed in Section 5.3, and is accomplished per the procedure outlined below:

8.1.1.2.1 Weigh the filter paper for each sample and record this weight on the benchsheet (Form 623). Weigh the collection flask for each sample and record this weight on the benchsheet. Acid wash the filter if evaluating the mobility of metals (5.4).

Place the filter on the support screen. Assemble the filtration device.

8.1.1.2.2 Transfer an aliquot of the waste (100g minimum) into a beaker. Record the combined weight of the sample, beaker and spatula on the benchsheet.

8.1.1.2.3 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If centrifugation is used, then the liquid should be decanted and filtered, followed by filtration of the solid portion of the waste through the same filtration system.

8.1.1.2.4 Quantitatively transfer the waste sample to the filtration device (liquid and solid phases).

8.1.1.2.5 After transferring the sample to the filtration device, place the spatula in the beaker and record the combined weight of both. Then continue with the calculations prompted on the benchsheet.

8.1.1.2.6 Spread the waste sample evenly over the

surface of the filter. If filtration of the waste at 4±2°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm to room temperature before filtering.

8.1.1.2.7 Gradually apply vacuum or gentle pressure of 1-10psi, until air or pressurizing gas moves through the filter. If gas or air does not move through the filter at this range of pressures and if no additional liquid has passed through the filter in a 2-minute interval, slowly increase the pressure in 10psi increments to a maximum pressure of 50psi. **Note that instantaneous application of high pressure can rupture the glass fiber filter and may cause premature plugging.**

If after each incremental increase of 10psi, the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in a 2-minute interval, proceed to the next 10psi increment.

When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50psi (i.e., filtration does not result in any additional filtrate within a 2-minute period), stop the filtration.

8.1.1.2.8 The material in the filter holder is defined as the solid phase of the sample, and the filtrate is defined as the liquid phase.

Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. However, even after applying vacuum or pressure filtration as outlined previously, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. **Do not replace the original filter with a fresh filter under any circumstances; use only one filter.**

8.1.1.2.9 Determine the weight of the liquid phase by subtracting the weight of the filtrate container (8.1.1.1) from the total weight of the filtrate-filled container; record on benchsheet.

8.1.1.2.10 Determine the weight of the solid phase of the waste sample by subtracting the weight of the liquid phase (8.1.1.9) from the weight of the total waste sample; record on benchsheet.

8.1.1.3 Calculate the percent solids as follows:

$$\%\ \text{solids} = 100 * \frac{\text{weight of solids (8.1.1.10)}}{\text{total weight of waste (from benchsheet)}}$$

8.1.2 DETERMINATION OF INSIGNIFICANT SOLIDS

If the percent solids as determined above (8.1.1.3)is equal to or greater than (≥) 0.5%, then proceed either to Section 8.1.3 (particle size reduction determination) or continue as outlined below (8.1.2.1), if it is noticed that a small amount of the filtrate is entrained in the wet filter.

If the percent solids determined (8.1.1.3) is less than (<) 0.5%, then proceed to Section 8.2 (Aliquots for Leaching).

8.1.2.1 Remove the solid phase and filter from the filtration apparatus.

8.1.2.2 Dry the filter and solid phase at 100±20°C until two successive weighings yield the same value (±1%). Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. If it is suspected that the material is flammable, drying in the hood overnight is recommended. When the filter paper is dry, re-weigh and calculate the % solids with the new value. This Step is performed when it is suspected that the weight from the moisture in the filter paper has caused the % solids value to rise above 0.5%. Perform this Step only in borderline cases.

8.1.2.3 Calculate the percent dry solids as follows:

$$\%\,\text{dry solids} = 100 * \frac{(\text{dry waste} + \text{filter}) - (\text{initial weight of filter})}{\text{initial weight of waste (8.1.1.6 or 8.1.1.8)}}$$

8.1.2.4 If the percent dry solid is < 0.5%, then proceed to Section 8.2 if the nonvolatile SPLP is to be performed.

If the percent dry solid is ≥0.5%, and if the nonvolatile TCLP is to be performed, return to the beginning of this Section and, with a fresh portion of waste, determine whether particle size reduction is necessary (Section 8.1.3). **The portion of sample that has been dried is not to be used in the leaching procedure.**

8.1.3 PARTICLE SIZE REDUCTION DETERMINATION

8.1.3.1 Using the solid portion of the sample, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1cm^2, or is smaller than 1cm in its narrowest dimension (i.e., is capable of passing through a 9.5mm [0.375 inch] standard sieve). If the particle size is larger than described above, prepare the solid portion of the sample for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above.

8.1.3.2 Note that the surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet the criteria, sample-specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

8.1.3.3 Safety concerns such as dust control may preclude the grinding of samples for particle size reduction. These safety concerns must always be addressed before attempting to grind any sample. Generally due to health and safety concerns, grinding to reduce particle size is not practiced in the extractions area. Samples requiring particle size reduction have been sent to an appropriate facility before an extraction was performed.

8.1.3.4 If a particle size reduction of the solid portion of the waste is required, continue as follows:

8.1.3.4.1 Prepare the waste for extraction by crushing, cutting or grinding the solid portion of the waste to a suitable surface area or particle size.

8.1.3.4.2 *Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4±2°C prior to particle size reduction.*

8.1.3.4.3 *The means used to effect particle size reduction must not generate heat in and of itself.*

8.1.3.4.4 *Work carefully and quickly, as exposure of the waste to the atmosphere should be avoided to the extent possible.*

8.1.3.4.5 Note that sieving of the waste is not normally required. If sieving is necessary, a Teflon-coated sieve should be used to avoid contamination of the sample. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth and similar) waste materials. Actual measurement of surface area is not recommended.

If the waste as received passes a 9.5mm sieve, quantitatively transfer the solid material into an extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to 8.4 - Tumbling.

8.1.3.4.6 When the surface area or particle size has been appropriately altered, quantitatively transfer the solid material into the extractor bottle. Include the filter used to separate the initial liquid from the solid phase. Then proceed to 8.3 - Filtration..

8.1.4 EXTRACTION FLUID DETERMINATION

If the solid content of the waste is ≥0.5%, then determine the appropriate fluid for the nonvolatiles extraction as follows:

8.1.4.1 For soils, if the sample is from a site that is east of the Mississippi River, Extraction fluid #1 should be used. If the sample is from a site that is west of the Mississippi River, Extraction fluid #2 should be used.

8.1.4.2 For wastes and wastewater, Extraction fluid #1 should be used.

8.1.4.3 For cyanide-containing wastes and/or soils, Extraction fluid #3 (reagent water) must be used, because leaching of cyanide-containing samples under acidic conditions may result in the formation of hydrogen cyanide gas.

8.2 DETERMINATION OF ALIQUOTS FOR LEACHING

8.2.1 Label a 2000mL container with work order number, sample number, and fluid number (for metals, rinse the container with 0.1N HNO_3, followed by a rinse with deionized water). For each reagent blank, label a container with the date of tumbling, reagent blank number and fluid number.

8.2.2 Determine the number of analyses to be performed upon each sample: Herbicides, organochlorine pesticides, and semivolatiles analysis each require 100mL of tumbled fluid. Metals analysis requires 50mL of tumbled fluid. Each analysis also requires one (1) matrix spike sample/fluid/day tumbled, so these amounts may be doubled to ensure sufficient amount of fluid for all analyses and matrix spike quality control samples.

Each analysis also requires a reagent blank/fluid/day tumbled, which consists of the appropriate fluid placed in a container (no solid added) and tumbled with the samples. The reagent blank should also be put on the benchsheet and carried through the tumbling/filtering/extracting (and analysis) process.

The amount of fluid added to the sample is equal to 20 times the weight of the solid (e.g., 20g of sample requires 400mL of fluid).

8.2.3 If the aliquot of the sample used for the preliminary evaluation was determined to be 100% solid (8.1.1.1), then that aliquot can be used for the nonvolatile extraction (assuming that aliquot is sufficient to generate enough leachate to support the requested analyses).

Do not use leach solid that was dried in the oven.

8.2.4 The amount of solid necessary is dependent upon whether a sufficient

amount of leachate will be produced to support the required analyses. If an adequate amount of solid remains, proceed with the nonvolatile SPLP extraction (Section 8.4).

A minimum sample size of 100g (solid and liquid phases) is recommended. In some cases, a larger sample size may be appropriate, depending on the solids content (8.1.1.3) of the waste sample, whether the initial liquid phase of the waste will be miscible with the aqueous leachate of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough SPLP solids should be generated for extraction such that the volume of leachate will be sufficient to support all of the analyses required.

If the amount of leachate generated by a single SPLP extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed, and the leachates from each combined and aliquoted for analysis

8.2.5 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solid), weigh out a subsample of the waste (100g minimum) and proceed to Section 8.3 – Filtration.

8.2.6 If the sample is liquid or multiphasic, liquid/solid separation is required as outlined in Section 8.1.1.2..

8.2.7 Weigh out an aliquot of the sample (100g minimum) and record the weight. If the waste contains <0.5% dry solids (Section 8.1.2.3), the liquid portion of the waste, after filtration, is defined as the TCLP leachate. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required.

8.2.8 For wastes containing $\geq$0.5% solids, use the percent solids information obtained in Section 8.1.1.3 to determine the optimum sample size (100g minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the TCLP leachate.

8.2.9 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the sample is centrifuged, the liquid should be decanted and filtered, followed by filtration of the solid portion of the waste through the same filtration system.

8.3 FILTRATION

8.3.1 Pre-weigh the container that will receive the filtrate; record weight.

8.3.2 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Section 5.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions even when metals are not of concern.

8.3.3 Quantitatively transfer the sample (liquid and solid phases) to the filter holder. Spread the sample evenly over the surface of the filter. If filtration of the waste at 4±2°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm to room temperature in the device before filtering.

NOTE: If waste material (>1% of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Step 8.3.6, to determine the weight of the waste sample that will be filtered.

8.3.4 Gradually apply vacuum or gentle pressure of 1-10psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10psi, and if no additional liquid has passed through the filter in any 2-minute interval, slowly increase the pressure in 10psi increments to a maximum of 50psi. **Note Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.**

8.3.5 When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50psi (i.e., filtration does not result in any additional filtrate within a 2-minute period), stop the filtration.

8.3.6 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

NOTE: Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in the Section 8.2, this material may not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the extraction as a solid. **Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.**

8.3.7 Weigh the filtrate; record weight.

8.3.8 If the sample contains <0.5% dry solids, proceed to Section 8.5 - Preparation for Analysis.

If the sample contained no initial liquid phase, the filtrate is defined as the SPLP leachate; proceed to Section 8.5 - Preparation for Analysis.

8.3.9 EXTRACTION FLUID ALIQUOT DETERMINATION
Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (8.1.1.3)} \times \text{weight of waste filtered (8.3.3)}}{100}$$

8.4 EXTRACTION (TUMBLING)

8.4.1 Slowly add the calculated amount of appropriate extraction fluid to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal).

8.4.2 Secure the extractor bottle in the rotary tumbler, and rotate at 30±2 rpm for 18±2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23±2°C during the extraction period. SOP 663 describes the procedures for monitoring tumbler revolutions and room temperature.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of wastes (e.g., limed or calcium carbonate containing waste may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically vented (e.g., after 15 minutes, 30 minutes, and 1 hour), into a hood.

8.4.3 Following the 18±2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter.

8.4.4 For final filtration of the SPLP leachate, the glass fiber filter may be changed, if necessary, to facilitate filtration.

Filter(s) shall be acid-washed (see Section 5.4) if evaluating the mobility of metals.

8.4.5 Following collection of the SPLP leachate, the pH of the leachate should be recorded. Immediately aliquot and preserve the leachate for analysis.

8.4.6 The liquid phase may now be either analyzed (8.5) or stored at 4±2°C until time of analysis. If miscible, the initial liquid phase may be combined with the SPLP leachate. If the initial liquid phase of the waste is not or may not be compatible with the filtrate, do not combine these liquids. Although they are collectively defined as the SPLP leachate, they are to be analyzed separately, and their analysis results combined mathematically (8.5.2).

8.5 PREPARATION FOR ANALYSIS

8.4.1 Metals aliquots must be acidified with nitric acid to pH<2. If precipitation is observed upon addition of nitric acid to a small aliquot of the leachate, then the remaining portion of the leachate for metals analyses shall not be acidified, and the leachate shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4±2°C) until analyzed.

8.4.2 The SPLP leachate shall be prepared and analyzed according to appropriate analytical methods. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to ±0.5%), conduct the appropriate analyses, and combine the results mathematically by using a volume-weighted average as shown below:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = volume of the first phase (L)

C_1 = concentration of the analyte of concern in the first phase (mg/L)

V_2 = volume of the second phase (L)

C_2 = concentration of the analyte of concern on the second phase (mg/L)

9. QUALITY CONTROL

9.1 A minimum of one blank (using the same extraction fluid as used for the samples) must be analyzed for every 20 extractions that have been conducted in an extraction vessel. No more than 20 field samples may be included in a batch.

9.2 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.). A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

9.2.1 Matrix spikes are to be added after filtration of the TCLP leachate and before preservation. Matrix spikes should not be added prior to TCLP extraction of the sample.

9.2.2 In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentration, but may not be not less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of TCLP leachate as that which was analyzed for the unspiked sample.

9.2.3 Matrix spike recoveries are calculated by the following formula:

$$\%R\ (\%\ Recovery) = 100\ (Xs - Xu)/K$$

where:

Xs = measured value for the spike sample
Xu = measured value for the unspiked samples
K = known value of the spike in the sample

10. DEVIATIONS FROM THE METHOD

There are no known deviations from the SW-846 Method 1312 with the following exception: Paragon allows for the use of HDPE bottles for metals and semivolatile organics leaching, if approved by the client (see LIMS program specifications), and if this type of container can be shown to meet the criteria discussed in Section 5.5 (i.e., inert and does not adsorb or release target analytes).

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses and a lab coat when working with chemical materials (e.g., standards, solvents, reagents, or samples).

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.2 WASTE DISPOSAL

11.2.1 Unused sample leachate may be disposed of in the Aqueous Laboratory Waste.

11.2.2 Unused non-radioactive sample solids may be disposed of in the Contaminated Soils and Solids Waste.

11.2.3 Unused radioactive sample solids may be disposed of in the appropriate Radioactive Waste stream (consult with Waste Compliance Officer).

11.2.4 All empty solvent bottles shall be disposed of appropriately. Note that all labels and markings must be defaced prior to disposal.

TEMPERATURE LOGBOOK

ORGANIC EXTRACTIONS - TCLP ROOM

Acceptable Range 23 ± 2 °C

A current temperature reading must be recorded at the onset of TCLP tumbling, and the min/max memory must be reset. DO NOT initiate tumbling if temperature is not within acceptable limits. The current temperature and min/max information must be recorded at the completion of tumbling. Both the Department and QA Managers must be notified in a timely manner if an excursion occurs.

STANDARD OPERATING PROCEDURE 669 REVISION 4

TITLE: **SYNTHETIC PRECIPITATION LEACHING PROCEDURE (SPLP) OF SAMPLES FOR THE ANALYSIS OF VOLATILE ORGANIC COMPOUNDS (VOCs) BY ZERO HEADSPACE EXTRACTION (ZHE) -- METHOD SW1312**

FORMS: **608, 825, 345 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3.4.08

QUALITY ASSURANCE MANAGER _____ DATE 3/4/08

LABORATORY MANAGER _____ DATE 3-4-08

HISTORY: Rev0, 10/28/99; Rev1, 9/19/02, Rev2, 2/13/04; Rev3, 3/9/06; Rev4, 3/4/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW-846 Method 1312 -- are designed to determine the mobility of volatile organic compounds (VOCs) present in liquids, soils, and wastes (including multiphasic samples). Application of these procedures to matrices other than those specified will be handled individually to simulate the leaching procedure as best as possible.

2. SUMMARY OF PROCEDURE

For liquid samples (i.e., those containing less than 0.5% dry solid material), the sample, following filtration through a 0.6 to 0.8µm glass fiber filter, is defined as the SPLP extract (leachate).

For samples containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis. The particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid (reagent water) equal to twenty (20) times the weight of the solid phase. A special extractor vessel for volatile compounds is used in this procedure. Following extraction, the liquid extract (leachate) is separated from the solid phase by filtration through a 0.6 to 0.8µm filter.

If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is typically added back to the solid phase prior to addition of reagent water and leaching. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the logbooks, analytical review sheets or case narratives indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work and documentation of the measures taken to remedy any errors found in the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Possible contaminant sources are volatile solvents used in the laboratory. Analyses of reagent blanks provide information about the presence of these contaminants. The ZHE vessels are thoroughly cleaned between uses. The vessel number used for each sample or blank is recorded in the logbook. The same vessel is not to be used repeatedly for the blank - all vessels must be used for the blank on a rotating basis.

5. APPARATUS AND MATERIALS

5.1 **Zero-Headspace Extraction vessel (ZHE)**: ADAM 3745 ZHE or equivalent. These devices are used when the mobility of VOCs are of concern. The ZHE allows for liquid-solid separation (within the device), extraction, and final extract filtration without opening the vessel. Thus, headspace and potential loss of volatiles from this closed system is effectively precluded. The ZHE have an internal volume of 500-600mL and are equipped to accommodate a 90-100mm diameter filter. The devices utilize Viton™ o-rings to form a seal. These o-rings should be inspected before each use and may need to be replaced if they show signs of wear or damage.

For the ZHE vessel to be acceptable for use, the piston within the ZHE should be mobile with approximately 15psi or less (it is helpful to first moisten the piston o-rings slightly with extraction fluid). If it takes more pressure to move the piston, the o-rings in the device should be replaced. If replacing the o-rings does not solve the problem, the ZHE is unacceptable for SPLP analyses and the manufacturer should be contacted for re-machining.

Each ZHE device contains a built-in pressure gauge. The gauge should be frequently monitored to ensure that the ZHE is free of leaks throughout the extraction process. If the gauge indicates that the ZHE is not holding pressure correctly, or if the device shows other signs of a leak, pressurize the device to 50psi, allow it to stand unattended for 1 hour, and recheck the pressure. The ZHE can also be submerged in water after pressurization to check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace o-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted. If new ZHE are purchased, they must successfully pass this pressurization test prior to being used for sample analysis.

The ZHE vessel is used for filtration of the final ZHE extract. The ZHE vessel must be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50psi). When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE vessel.

5.2 **Pressure filtration device**, Associated Design and Manufacturing Model 3750-LHWF or equivalent. A.K.A. “lunar lander”.

5.3 pH meter, accurate to +0.05pH units @ 25 °C
Meter must be calibrated prior to use (see Form 825).

5.4 **Fiber filter**, borosilicate glass, free of binder materials, 0.6 to 0.8µm particle size. *Pre-filters must not be used.* Glass fiber filters are fragile and should be handled with care. Use Gelman #66256, 90mm or equivalent, and/or Whatman #6890-2507, 25mm or equivalent.

5.5 VOA vials, 20mL or 40mL, septum seal, certified ‘clean’.

5.6 laboratory balance, accurate to ±0.01g

5.7 centrifuge

5.8 drying oven, capable of maintaining 100±20°C

5.9 apparatus for pressurizing ZHE's: Ultra high-purity Nitrogen tank, regulator (set to around 60psi), hose, and adapter for attachment to ZHE and pressure filtration device ("lunar lander").

5.10 rotary tumbler with 30±2rpm capability, Associated Design and Manufacturing Model 3740 or equivalent

5.11 **ZHE Extract Collection Devices**, used to collect the initial liquid phase and the final extract of the waste. Plastic gas-tight syringes (50-60mL with Luer-Lok® fitting) or TEDLAR® bags may be used. Following collection, the extract is filtered during transfer to a 'VOA' vial (20 or 40mL volume) to meet the method requirements for storage in minimal headspace conditions until time of analysis. The devices listed are recommended for use under the following conditions:

5.11.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1% of total waste), a syringe should be used to collect and combine the initial liquid and solid extract.

5.11.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1% of total waste), the syringe or the Tedlar® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

5.11.3 If the waste contains no initial liquid phase (is 100% solid) or has no significant solid phase (is 100% liquid), either the Tedlar® bag or the syringe may be used. If the syringe is used, discard the first 5mL of liquid expressed from the device. The remaining aliquots are used for analysis.

6. REAGENTS

reagent water: defined as water in which an interferent is not observed at or above the method's detection limit of the analyte(s) of interest. Paragon's laboratory deionized water is suitable for use. This DI (reagent) water is used as the ZHE extraction fluid.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples should be collected using an appropriate sampling plan.

7.2 There may be requirements on the minimal size of the field sample, depending upon the physical state of the waste and the analytes of concern. An aliquot is needed for the preliminary evaluations of percent solids and particle size. Another aliquot may be needed to actually conduct the nonvolatile extraction. An additional aliquot is needed for the volatile organics extraction. Quality control (QC) samples may require additional aliquots. Further, it is wise to collect

additional sample in case something goes wrong with the initial attempt to conduct the test.

7.3 Preservatives shall not be added to samples before extraction.

7.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

7.5 Because the samples are to be analyzed for volatiles, care shall be taken to minimize their loss; samples shall be collected and stored accordingly. Samples should be collected in glass jars with Teflon®-lined lids and stored at 4±2°C. (although EnCore® samplers may also be used for sample collection, their limited sampling capacity makes them less desireable for this procedure). Samples should only be opened immediately prior to extraction.

7.6 SPLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for volatile organic analyses shall be exposed to the atmosphere for as short a time as possible to minimize losses.

7.7 SPLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Maximum hold times are:

Sample Holding Times [days]

	Time from field collection to SPLP leaching	Time from ZHE-SPLP leaching to determinative analysis
Volatiles	14 days	14 days

8. PROCEDURE

8.1 PRELIMINARY EVALUATION

Preliminary evaluation includes: (1) determination of percent solids; (2) determination of whether or not the waste contains insignificant solids and is, therefore, its own extract after filtration; and (3) determination of whether or not the solid portion of the waste requires particle size reduction (if required, procedure is described in SOP 609).

NOTE: Even if only the volatile SPLP extraction is being done, it is often useful to perform the (initial) phase separation in order to determine the optimum sample aliquot with which to charge the ZHE. The experienced prep analyst may, however, choose to forego this procedure, as percent solids determination is also conducted as part of the procedure in determining the amount of extraction fluid to add (Steps 8.2.3 through 8.2.5).

Select samples and record on benchsheet (Form 608). Perform preliminary SPLP evaluations on a minimum 100g aliquot of waste (if there is insufficient sample or it is impractical to use 100g, notate on benchsheet).

8.1.1 DETERMINATION OF PERCENT SOLIDS
PHASE SEPARATION

8.1.1.1 Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample), from which no liquid may be forced out by an applied pressure, as described below. Visual inspection may be sufficient for this determination.

If the sample will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids), then proceed to Section 8.1.3 - Particle Size Reduction Determination.

8.1.1.2 **Phase Separation**. If the sample is liquid or multiphasic, liquid/solid separation is required to make a preliminary determination of percent solids. This involves the filtration device described in Section 5.2, and performance of the procedures outlined below:

8.1.1.2.1 Pre-weigh the filter, spatula, and beaker that will receive the filtrate. Record the weights in the appropriate boxes on the TCLP % solid benchsheet (Form 608). Foil dishes may be used to collect solids from sample with very low solids content and the foil dish weight must be recorded before solids are placed on the foil.

8.1.1.2.2 Assemble the filtration device and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

8.1.1.2.3 Weigh out a subsample of the waste (100g minimum) and record the weight. If sufficient sample is not available, record such on benchsheet.

8.1.1.2.4 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered

followed by filtration of the solid portion of the waste through the same filtration system.

8.1.1.2.5 Quantitatively transfer the waste sample to the filtration device (liquid and solid phases). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4±2°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm to room temperature before filtering.

8.1.1.2.6 After transferring the waste sample to the filtration device, place the spatula in the beaker, weigh, and record the initial sample weight on the TCLP % solids benchsheet.

8.1.1.2.7 Gradually apply gentle pressure of 1-10psi, until air or pressurizing gas moves through the filter. If gas or air does not move through the filter at this range of pressures and if no additional liquid has passed through the filter in a 2-minute interval, slowly increase the pressure in 10psi increments to a maximum pressure of 50psi. **Note that instantaneous application of high pressure can rupture the glass fiber filter and may cause premature plugging.**

When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50psi (i.e., filtration does not result in any additional filtrate within a 2 minute period), stop the filtration.

8.1.1.2.8 The material in the filter holder is defined as the solid phase of the sample, and the filtrate is defined as the liquid phase.

Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration as outlined above, this material may not filter. If this is the case, the material within the filtration

device is defined as a solid as is carried though the SPLP extraction. **Do not replace the original filter with a fresh filter under any circumstances.** Use only one filter.

8.1.1.3 Determine the weight of the liquid phase by subtracting the weight of the empty beaker (8.1.1.2.1) from the total weight of the filtrate-filled beaker syringe; record weight on TCLP % solids benchsheet (Form 608).

Determine the weight of the solid phase (8.1.1.2.8) of the waste sample by subtracting the weight of the liquid phase (above) from the weight of the total waste sample (8.1.1.2.3); record weight on TCLP % solids benchsheet.

8.1.1.4 Calculate the percent solids as shown below:

$$\text{Percent Solids} = \frac{\text{Weight of solid (8.1.1.3)}}{\text{Total weight of waste (8.1.1.2.3)}} \times 100$$

8.1.2 DETERMINATION OF INSIGNIFICANT SOLIDS

If the percent solids as determined above (8.1.1.4) is equal to or greater than (≥) 0.5%, then proceed either to Section 8.1.3 (particle size reduction determination) or continue as outlined below (8.1.2.1), if it is noticed that a small amount of the filtrate is entrained in wetting of the filter.

If the percent solids determined (8.1.1.4) is less than (<) 0.5%, then proceed to Section 8.2 (ZHE procedure), with a fresh portion of the waste.

8.1.2.1 Remove the solid phase and filter from the filtration apparatus.

8.1.2.2 Dry the filter and solid phase at 100±20°C until two successive weighings yield the same value (±1%). Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. If it is suspected that the material is flammable, drying in the hood overnight is recommended. When the filter paper is dry, re-weigh and calculate the % solids with the new value. This Step is performed when it is suspected that the weight from the moisture in the filter paper has

caused the % solids value to rise above 0.5%. Perform this Step only in borderline cases.

8.1.2.3 Calculate the percent dry solids as follows:

$$\text{Percent Dry Solids} = \frac{\text{Wt dry sample + filter - Tared wt of filter}}{\text{Initial weight of sample (8.1.1.2.3)}} \times 100$$

8.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Section 8.2.

8.1.3 PARTICLE SIZE REDUCTION DETERMINATION

8.1.3.1 Using the solid portion of the sample, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than $3.1cm^2$, or is smaller than 1cm in its narrowest dimension (i.e., is capable of passing through a 9.5mm [0.375 inch] standard sieve). If the particle size is larger than described above, prepare the solid portion of the sample for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above.

8.1.3.2 Note that the surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet the criteria, sample-specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

8.1.3.3 Safety concerns such as dust control may preclude the grinding of samples for particle size reduction. These safety concerns must *always* be addressed before attempting to grind any sample. Generally due to health and safety concerns, grinding to reduce particle size is not practiced in the extractions area. Samples requiring particle size reduction have been sent to an appropriate facility before an extraction was performed.

8.1.3.4 Particle size reduction prior to leaching for volatile organics may lead to loss of target compounds, compromising the analytical results.

8.1.3.5 If a particle size reduction of the solid portion of the waste is required, continue as follows:

8.1.3.5.1 Prepare the waste for extraction by crushing, cutting or grinding the solid portion of the waste to a suitable surface area or particle size.

8.1.3.5.2 *Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4±2°C prior to particle size reduction.*

8.1.3.5.3 *The means used to effect particle size reduction must not generate heat in and of itself.*

8.1.3.5.4 *Work carefully and quickly, as exposure of the waste to the atmosphere should be avoided to the extent possible.*

8.1.3.5.5 **Note that sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth and similar) waste materials. Actual measurement of surface area is not recommended.**

8.1.3.5.6 When the surface area or particle size has been appropriately altered, proceed to Section 8.2.3 - Filtration.

8.2 ZHE PROCEDURE

Use the ZHE vessel to obtain SPLP leachate for analysis of VOCs only. Leachates resulting from the use of the ZHE shall not be used to evaluate the mobility of nonvolatile analytes (e.g., metals, pesticides, semivolatiles). The ZHE vessel has an internal capacity of 500-600mL, and can thus accommodate a maximum of approximately 25 grams of solid (defined as that fraction of a sample from which no additional liquid may be forced out by an applied pressure of 50psi), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

8.2.1 EQUIPMENT SET-UP

8.2.1.1 Charge the ZHE with sample only once and do not open the device until the final leachate (of the solid) has been collected. Repeated filling of the ZHE to obtain 25 grams of solid is not permitted.

8.2.1.2 **Do not allow the sample, the initial liquid phase, or the leachate to be exposed to the atmosphere for any more time than is absolutely necessary. Manipulation of the sample to be leached should be done when cold (4±2°C) to minimize loss of volatiles. Leaching fluids are added at room temperature. After filtration, leachates should be cooled to 4±2°C by placing the 'VOA' vial into a suitable refrigeration unit as soon as practical.**

8.2.1.3 Pre-weigh the (evacuated) filtrate collection container (5.11) and set aside. If using a Tedlar™ bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis.

8.2.1.4 Place the ZHE piston within the body of the ZHE (it is helpful to first moisten the piston o-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move after the ZHE is charged with sample (based upon sample size requirements as discussed previously). Secure the gas inlet/outlet (bottom) flange (with the valve open) onto the ZHE body per the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set the liquid inlet/outlet flange (top flange) aside.

8.2.2 ALIQUOT DETERMINATIONS

8.2.2.1 If the sample is 100% solid (8.1.1.1), weigh out a subsample (25g maximum – care should be taken to choose a sample weight that will yield sufficient leachate to support the analysis) of the waste, record weight, and proceed to Step 8.2.3 - Filtration.

8.2.2.2 If the waste contains <0.5% dry solids (8.1.2.3), the liquid portion of waste, after filtration, is defined as the ZHE extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required (weigh out a 100-500g subsample, record weight). Proceed to Step 8.2.3 - Filtration.

8.2.2.3 If the waste contains ≥0.5% dry solids, use the percent solids information obtained in Step 8.1.1.4 to determine the optimum sample size to charge into the ZHE vessel as follows:

$$\text{Wt of waste to charge ZHE} = \frac{10}{\text{percent solids (8.1.1.4)}} \times 100$$

Weigh out the appropriate size of waste subsample as determined and record the weight on the ZHE benchsheet (Form 608).

8.2.3 FILTRATION

8.2.3.1 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge wastes prior to filtration.

8.2.3.2 Quickly and quantitatively transfer the entire sample (liquid and solid phases) of the waste aliquot to the ZHE vessel.

NOTE: If waste material (>1% of original subsample weight) has obviously adhered to the container used to transfer the sample to the ZHE vessel, determine the weight of this residue and subtract it from the sample weight (8.1.1.2.3) to determine the actual weight of the waste subsample that will be filtered.

8.2.3.3 Secure the filter and support screens onto the top flange of the device and secure the top flange to the ZHE body in accordance with the manufacturer's instructions. Tighten all ZHE fittings, and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the leachate collection device to the top plate.

8.2.3.4 Attach a gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10psi (or more if necessary) to force all headspace *slowly* out of the ZHE vessel.

At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4±2°C reduces the amount of expressed liquid beyond what would be expressed at room temperature, then allow the sample to warm to room temperature before filtering.

If the waste is 100% solid (8.1.1.1), slowly increase the pressure to a maximum of 50psi to force most of the

headspace out of the device, then proceed to Section 8.2.6 - Extraction (Tumbling).

8.2.3.5 Attach the evacuated pre-weighed 60mL plastic Luer-Lok® syringe to the liquid inlet/outlet valve of the ZHE and open the valve. Begin applying gentle pressure of 1-10psi to force the liquid phase of the sample into the filtrate collection container. **Note that instantaneous application of high pressure can rupture the glass fiber filter and may cause premature plugging.**

If no additional liquid has passed through the filter in a 2-minute interval, slowly increase the pressure in 10psi increments (and waiting a 2-minute interval with no additional liquid passing) to a maximum of 50psi.

When liquid flow has ceased such that continued pressure filtration at 50psi does not result in any additional filtrate within a 2-minute period, stop the filtration.

8.2.3.6 Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container; record weight on ZHE benchsheet. Using the information recorded on the benchsheet, calculate the amount of solid waste left inside the ZHE.

8.2.4 PHASE DISCUSSION

The material in the ZHE is defined as the solid phase of the sample and the filtrate is defined as the liquid phase. Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying pressure filtration, this material may not filter. If this is the case, the material within the filtration device is defined as a solid, and is carried through the SPLP extraction as a solid.

If the original waste contained <0.5% dry solids (8.1.2.3), this filtrate is defined as the SPLP leachate and is analyzed directly. Proceed to Section 8.2.7 - Preparation for Volatile Analysis.

The liquid phase may now be either analyzed immediately (8.2.7), stored at 4±2°C under minimal headspace conditions until time of analysis, or recombined (if miscible) with the sample prior to tumbling.

8.2.5 EXTRACTION FLUID ALIQUOT DETERMINATION

Determine the weight of reagent water to add to the ZHE as follows:

$$\text{Weight of reagent water} = \frac{20 \times \text{percent solids (8.1.1.4)} \times \text{weight of waste filtered (i.e., the solid waste left inside the ZHE, 8.2.3.6)}}{100}$$

8.2.6 EXTRACTION (TUMBLING)

8.2.6.1 Fill a clean beaker of appropriate volume with reagent water, then fill a clean 60mL gas-tight Luer-Lok® syringe from the beaker. Vent residual air from the syringe so that it only contains the measured amount of fluid.

With the ZHE vessel in the vertical position, attach the syringe to the liquid inlet/outlet valve. Release gas pressure on the ZHE piston (open the gas inlet/outlet valve), open the liquid inlet/outlet valve, and depress the syringe plunger to transfer extraction fluid into the ZHE vessel. Close the liquid inlet/outlet valve and remove the syringe.

Continue to add reagent water to the ZHE in this manner until the appropriate amount (8.2.5) has been introduced into the device.

8.2.6.2 After the reagent water has been added, immediately close both the liquid inlet/outlet valve and the gas inlet/outlet valve.

8.2.6.3 Reposition the ZHE vessel in the vertical position with the liquid inlet/outlet valve on top. Pressurize to 5-10psi and slowly open the liquid inlet/outlet valve to bleed out any headspace that may have been introduced due to the addition of reagent water. *This bleeding should be done quickly - stop at the first appearance of liquid from the valve.* Re-pressurize to 5-10psi and check all ZHE fittings to ensure that they are closed.

8.2.6.4 Place the ZHE in the rotary extractor apparatus and rotate at 30±2 rpm for 18±2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23±2°C during agitation. SOP 663 describes the procedures for monitoring tumbler revolutions and room temperature.

8.2.6.5 Following the 18±2 hour agitation period, check the pressure gauge on the ZHE vessel to see that pressure has

been maintained. If the pressure has not been maintained, the device has leaked. Check the ZHE vessel for leaking as specified in Section 5.1, and correct the problem. Perform the extraction again with a new aliquot of waste sample.

8.2.6.6 If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases.

8.2.6.6.1 If the waste contained an initial liquid phase that has been stored, the leachate may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) that holds the initial liquid phase. *A separate filtrate collection container must be used if combining would create multiple phases, or if there is not enough volume left within the filtrate collection container.*

8.2.6.6.2 After attaching the filtrate collection container (TEDLAR® bag or clean syringe) slowly open the liquid inlet/outlet valve (top flange) to collect the filtered leachate. Note that an in-line glass fiber filter may be used to filter the material within the ZHE vessel if it is suspected that the internal glass fiber filter has ruptured. *All extract shall be filtered and collected if the TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase that was NOT recombined with solids prior to tumbling.*

8.2.6.6.3 If the original sample contained no initial liquid phase, the filtered liquid material obtained from Section 8.2.3 is defined as the SPLP leachate. If the sample contained an initial liquid phase, the filtered liquid material obtained from Section 8.2.3 and the initial liquid phase (8.1.1.2) are collectively defined as the SPLP leachate.

8.2.7 PREPARATION FOR VOLATILE ANALYSIS
Following collection of the SPLP leachate, immediately prepare the

leachate for analysis, by transferring to a septum-sealed "VOA" vial, and store with minimal headspace at 4±2°C until analyzed.

The SPLP leachate is analyzed according to the appropriate determinative method. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phase (L)

C_1 = The concentration of the analyte of concern in the first phase (mg/L)

V_2 = The volume of the second phase (L)

C_2 = The concentration of the analyte of concern in the second phase (mg/L)

9. QUALITY CONTROL

9.1 A minimum of one method blank (MB), using the same extraction fluid (reagent water) as used for the samples, must be analyzed for every 20 extractions that have been conducted in an extraction vessel. No more than 20 field samples may be included in a batch.

9.2 Matrix spikes and laboratory control samples are prepared at the time of analysis by the volatiles analysis group.

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of SW-846 Method 1312. There are no known deviations from this method.

It should be noted that, when only the volatile TCLP extraction is being done (i.e., no semivolatile or metals), the initial percent solids determination (using the "lunar lander") may be skipped, as the percent solids can be determined after the sample is loaded into the ZHE (Steps 8.2.3.4 through 8.2.3.6). Experience of the prep analyst weighs heavily here, as (in the case of a very wet sample matrix), too small of an aliquot into the ZHE may not yield an adequate volume of leachate for analysis.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses and a lab coat when working with chemical materials (e.g., standards, solvents, reagents, or samples).

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.2 WASTE DISPOSAL

11.2.1 Unused sample liquids may be disposed of in the Aqueous Laboratory Waste.

11.2.2 Unused sample leachate solids may be disposed of in the Contaminated Soils and Solids.

11.2.3 Waste from processing radioactive samples shall be disposed of in the appropriate radioactive waste stream.

11.2.4 All empty solvent bottles shall be disposed of according to the appropriate SOPs. All labels and markings must be defaced prior to disposal.

TEMPERATURE LOGBOOK

ORGANIC EXTRACTIONS - TCLP ROOM

Acceptable Range 23 ± 2 °C

A current temperature reading must be recorded at the onset of TCLP tumbling, and the min/max memory must be reset. DO NOT initiate tumbling if temperature is not within acceptable limits. The current temperature and min/max information must be recorded at the completion of tumbling. Both the Department and QA Managers must be notified in a timely manner if an excursion occurs.

STANDARD OPERATING PROCEDURE 670 REVISION 12

TITLE: ANALYSIS OF TOTAL ORGANIC CARBON BY METHODS EPA 415.1, SW9060, AND SM5310 C

FORMS: 647 **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11-14-07

QUALITY ASSURANCE MANAGER _____ DATE 11/13/07

LABORATORY MANAGER _____ DATE 11-14-07

HISTORY: **SOP 803:** Rev0, PCN #182, 3/1/94; Rev1, 4/11/96; Rev2, 3/13/97; Rev3, 6/15/99; Rev4, 3/3/00; Rev5, 2/11/02; Rev6, 4/3/02. **SOP 670:** Rev7, 8/13/02; Rev8, 3/14/03; Rev9, 5/26/04; Rev10, 8/23/04; Rev11, 2/27/06; Rev12, 11/12/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- EPA 415.1, SW9060 and SM5310 C -- describe procedures for the analysis of Total Organic Carbon (TOC) in water. These procedures are applicable to the measurement of organic carbon contained in drinking, surface, ground, and saline waters, as well as domestic and industrial wastes. Exclusions are noted under Inferferences (Section 4).

This procedure is applicable only to homogenous samples that can be injected into the instrument reproducibly by the autosampler.

The forms of carbon that can be measured by this procedure include the following:

- soluble, nonvolatile organic carbon (e.g., natural sugars)
- soluble, non-purgeable volatile organic carbon (e.g., mercaptans, alkanes, low molecular weight alcohols)
- insoluble, partially volatile carbon (e.g., low molecular weight oils)
- insoluble, particulate carbonaceous materials (e.g., cellulose fibers)
- soluble or insoluble carbonaceous materials adsorbed or entrapped on insoluble inorganic suspended matter (e.g., oily matter adsorbed on silt particles).

Because of purging, most volatile organic solvents may be lost.

2. SUMMARY

TOC concentration in water is measured by the use of an automated TOC analyzer. The sample is acidified (if not preserved prior to receipt) and sparged with nitrogen (N_2) gas to remove inorganic carbon. Organic carbon is then oxidized to carbon dioxide (CO_2) by persulfate ($S_2O_8^{-2}$) in the presence of ultraviolet (UV) light. The resultant CO_2 is sparged from the sample and carried in a stream of N_2 gas to a non-dispersive infrared detector

(NDIR). TOC concentration in the sample is calculated as a function of CO_2 peak area by use of a linear equation generated from a previously analyzed multipoint initial calibration. Sample aliquots, reagents and waste are transferred through the system by means of the autosampler apparatus.

Dissolved Organic Carbon (DOC) can also be measured by this procedure. Although Paragon prefers that samples be filtered prior to receipt at the laboratory, this filtering can be done after receipt.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating logbooks, analytical review sheets and/or the case narrative indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work of the errors and documentation of measures taken to correct these errors.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Any inorganic carbon (e.g., dissolved CO_2, HCO_3^-, and CO_3^{-2}) present in the sample at the oxidation step will contribute to the CO_2 reaching the detector and consequently give a high bias to the measured TOC concentration. Inorganic

carbon must either be removed from the sample prior to the oxidation step, or be accounted for in the final calculation. When the Phoenix 8000 instrument is operating in the TOC mode, the sample is routinely acidified and sparged to remove inorganic carbon prior to oxidation of organic carbon. Note that volatile organic compounds may be lost when inorganic carbon is sparged from the sample.

4.2 A study published by the instrument vendor (Tekmar-Dohrmann) indicates that sulfuric acid (H_2SO_4) could form SO_3 gas in the UV reaction cell. Because SO_3 has similar absorption in the infrared region as CO_2, the SO_3 can cause a positive interference in the NDIR detector of the instrument. Therefore, it is recommended that phosphoric acid (H_3PO_4) be used instead of H_2SO_4 where acid preservation is designated for aqueous TOC samples.

Acidification to pH$\leq$2 at time of collection is desirable for unstable samples, however, it should be noted that acid preservation invalidates any inorganic carbon determination on the samples.

4.3 Chloride (Cl^-) ions can react with persulfate in the reaction cell to form Cl_2 (gas). If the Cl^- concentration in a sample is high (≥ 1000mg/L) this reaction can compete with the oxidation of organic C for persulfate. This reaction can lead to excessive peak tailing of the signal from the NDIR detector. At very high Cl^- concentrations (common to brines, seawater, and some chemical wastewaters) the effect can be severe and low TOC recovery can result because some of the organic matter will not be oxidized in the established analysis time. Therefore, hydrochloric acid (HCl) should not be used as a preservative for water samples designated for TOC analysis. As noted previously, the instrument manufacturer recommends the use of phosphoric acid as a preservative for aqueous samples.

4.4 Because solid particles can plug or damage the 8-port valve in the instrument, it may be necessary to filter samples that contain particulates or to allow the solids to settle out prior to analysis.

5. APPARATUS AND MATERIALS

5.1 Phoenix 8000 TOC analyzer (Tekmar-Dohrmann), or equivalent

5.2 pH paper, narrow-range, acidic

5.3 vials, glass, 40mL VOA-type

5.4 syringe filters, Life Sciences IC Acrodisc®, 25mm, 0.45um Supor® (PES) membrane, or equivalent, for filtering samples prior to DOC analysis (Section 12)

6. REAGENTS - Only reagent grade or better chemicals shall be used

6.1 nitrogen (N_2), 99.999% purity, used as carrier and purge gas

6.2 reagent water, (HPLC grade or Milli-Q ASTM Type II)

6.3 phosphoric acid, H_3PO_4, concentrated, reagent grade

6.4 acid reagent for IC sparging: Add 100mL conc. H_3PO_4, to 500mL of reagent water.

6.5 potassium hydrogen phthalate (KHP), used to create the in-house first-source TOC stock solution.

6.6 copper (Cu) granules

6.7 tin (Sn) granules

6.8 sodium persulfate reagent: transfer 100g of sodium persulfate ($Na_2S_2O_8$) to a large beaker. To the beaker add 850mL of reagent water and 36mL of conc. H_3PO_4. Place a magnetic stir bar into the beaker and stir on a magnetic stir plate until all of the solid particles are dissolved. (expiration date = 1 year).

6.9 STANDARDS

6.9.1 TOC stock solution, 1000mg/L TOC, first source: Prepared in-house by adding 2.13g of KHP ($C_8H_5KO_4$) to a 1L Class A volumetric flask half-filled with reagent water. Place a magnetic stir bar into the flask and stir on a magnetic stir plate until all of the solid particles are dissolved. Carefully add 1.0mL of phosphoric acid to acidify the solution to pH $\leq$2, let cool to room temperature. Bring to near full volume with reagent water and verify solution pH as $\leq$2. Bring to full volume with reagent water. **Refrigerate.** The expiration date of this solution is 1 year or less as described in SOP 300. Discard the solution if a precipitate forms or degradation is suspected.

6.9.2 Initial calibration standards: Prepared at a minimum of 5 levels to bracket the linear range of the detector. Prepared by diluting aliquots of the 1000mg/L TOC stock solution with reagent water. Calibration standards with concentrations of 10mg/L or greater can be stored for 1 year or as described in SOP 300. Standards with concentrations of less than 10mg/L are made daily upon use.

6.9.3 "Demand" TOC reference standard, second source: This is a stock standard solution obtained from a commercial vendor that is used to prepare the ICV/LCS standard. Alternately, the standard can be prepared in-house from sources independent of the calibration solutions, per the directions contained in the referenced method. The expiration date of this standard is the manufacturer's expiration date or 1 year from preparation ($\geq$10mg/L), whichever is shorter.

6.9.4 ICV/LCS (Initial Calibration Verification and Laboratory Control Sample): An aliquot of the "Demand" TOC reference stock standard is diluted with reagent water according to instructions provided by the vendor. The reference concentration of the prepared standard is

provided by the vendor and may vary from lot number to lot number. The concentration of the ICV is typically different from the CCV and between 20-40mg/L.

6.9.5 CCV (Continuing Calibration Verification) standard: An aliquot of the TOC stock solution is diluted with reagent water to a concentration at or below the mid-point of the calibration range. The concentration of the CCV is typically 30mg/L for a calibration range of 0.5-60mg/L. This standard expires in the shorter of 6 months or the expiration date of the standard it was prepared from.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples should be collected according to an approved sampling plan.

7.2 Sampling and storage of samples in amber glass bottles is preferable. Plastic containers, such as conventional polyethylene and cubitainers, are permissible if it is established that the containers do not contribute contaminating organics to the sample or adsorb organics from the sample.

7.3 Methods EPA 415.1 and SW9060 provide for chemical preservation of samples using either hydrochloric (HCl) or sulfuric (H_2SO_4) acid. Method SM5310 C provides for chemical preservation of samples using either sulfuric or phosphoric acid (H_3PO_4). As discussed in Section 4.2, a technical note released by the instrument manufacturer (Tekmar-Dohrmann) recommends use of phosphoric acid to avoid possible instrumental interferences. Although Paragon can accept and process samples preserved with any of the three acids, it is Paragon's preference and practice to provide for phosphoric acid preservation to pH$\leq$2.

7.4 The referenced methods do not prescribe a maximum holding time allowance. Because of the possibility of oxidation or bacterial decomposition of some components of aqueous samples, the time between collection of samples and analysis should be minimized. Paragon's policy is to analyze samples within 28 days of collection.

7.5 Samples should be kept cool (4±2°C) and protected from sunlight and atmospheric oxygen.

8. PROCEDURE

8.1 INSTRUMENT SET UP

Prior to analyis, check to see each of the following are adequate for the amount of samples to be analyzed:

8.1.1 N_2 carrier gas, 500^+psi from cylinder.

8.1.2 Ample supplies of persulfate reagent, sparging acid, and reagent water.

8.1.3 Halogen scrubber, ample life.

8.1.4 Carrier gas flow rate (200cc/min, ±10%).

8.1.5 Gas/liquid separator water level filled to waste outlet.

8.1.6 Mist trap is empty, drain if necessary.

8.1.7 Thumbscrews of 8-port valve are hand tightened.

8.2 INITIAL CALIBRATION

8.2.1 Prepare calibration standards as described in Section 6.9 above. Typical concentrations comprising the calibration curve are 1.0, 4.0, 10, 20 and 40ppm.

8.2.2 Analyze the calibration standards on the instrument using the instrument software (TOC Talk™).

8.2.3 After analyzing the standards, the instrument software will calculate a linear equation to fit concentration with instrument response. To be acceptable, the coefficient of variation (r^2 or "r-squared" value on the output) must be 0.99 or greater.

8.3 CALIBRATION VERIFICATION

8.3.1 ICV: After an acceptable initial calibration has been established, an initial calibration verification (ICV) check standard must be analyzed. The ICV must be prepared from a parent source that is independent from that used to prepare the calibration standards. The ICV is typically prepared at a concentration near the midpoint of the calibration range, although other concentrations should be analyzed occasionally. See Section 6.9.4 above for preparation guidance, and QC Table following for acceptance criteria and corrective measures to be taken if necessary.

Since there is no sample preparation step involved in this analysis, the ICV check standard can serve a dual role as the laboratory control sample (LCS) for a quality control (QC) batch of 20 or fewer samples.

8.3.2 CCV: A CCV check standard is run at the beginning and conclusion of each analytical sequence and after every 15 or fewer injections in the sequence. **If running samples by SW9060 protocol, this CCV should be prepared from a source other than that used to prepare the ICAL (i.e., a second source)**. Preparation of the CCV is described in Section 6.9.5. Refer to QC Table following for acceptance criteria and corrective measures to be taken if necessary.

8.4 SAMPLE ANALYSIS

8.4.1 Samples must be analyzed for TOC in QC batches of 20 or fewer samples. See Section 9 for QC requirements (type and frequency).

Confirm that pH is ≤2 for each sample prior to analysis and record the pH test result on Form 647.

8.4.2 Prior to aliquoting, all samples should be homogenized by thorough shaking or agitation of the sample bottle.

8.4.3 For samples analyzed per Method SW9060 protocol, quadruplicate analyses must be performed for all field samples. Report the average result of the four (4) analyses and the RSD (Relative Standard Deviation). The range of values may be obtained from the raw data.

8.4.4 If the TOC concentration of a sample exceeds the calibration range (i.e., exceeds the concentration of the highest calibration standard), the sample must be diluted and reanalyzed as necessary until the concentration is within range.

9. QUALITY CONTROL (QC)

See QC Table following for acceptance criteria and corrective measures to be taken if necessary.

9.1 METHOD BLANK

One method blank (MB) must be analyzed with every QC batch of 20 or fewer samples to demonstrate that potential contaminants within the analytical system are in control. The MB consists of an aliquot of reagent water.

9.2 LABORATORY CONTROL SAMPLES

One laboratory control sample (LCS) must be analyzed with every QC batch of 20 or fewer samples to demonstrate the effectiveness of the analytical system. The LCS composition is identical to that of the ICV check standard (see Section 6.9.4). Since there is no preparation step in this analysis, the ICV check standard at the beginning of an analytical sequence can serve a dual role as the LCS for a QC batch.

9.3 MATRIX SPIKES

Matrix spike (MS) samples consist of field samples into which known concentrations of target analytes have been introduced. Analysis of matrix spikes provides information on the effect of sample matrix on target analyte detection. A matrix spike duplicate (MSD) is typically run with the MS.

Sample volume permitting, one pair of matrix spike/matrix spike duplicate (MS/MSD) analyses must be performed for every 20 samples. The matrix spiked samples are prepared by spiking aliquots of a selected field sample in the preparation batch with aliquots of the 1000mg/L stock standard.

Analyte recovery for the MS and MSD is calculated as shown below:

$$\%R = \frac{(Conc._{Found} - Conc._{.Sample})}{Conc._{Target}} \quad X \quad 100$$

where:

$Conc_{Found}$ = analyte concentration found in the MS or MSD sample

$Conc_{Sample}$ = analyte concentration found in the field sample

$Conc_{Target}$ = target (anticipated) analyte concentration based on amount spiked

As a measure of precision, the relative percent difference (RPD) of the laboratory duplicate sample pair (or MS/MSD or LCS/LCSD pair) is calculated as shown below:

$$RPD\ (\%) = \frac{(Result_{MS} - Result_{MSD})}{(Result_{MS} + Result_{MSD}) / 2} \quad X \quad 100$$

9.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. The LCS, MS, or both may be analyzed in duplicate to serve this purpose. Precision is expressed as Relative Percent Difference (RPD) (see above).

SW9060 protocol requires a "spike duplicate sample for every 10 samples". If analyzing samples by SW9060 protocol, include either an LCSD or (if sufficient sample volume is provided) an MSD *for every 10 samples analyzed*. If there is insufficient sample for the MSD, then either a second LCS/D pair can be analyzed in the latter half of the prep batch, or prep batches may be limited to 10 samples. **Note that this requirement does not apply to samples being analyzed by Method 415.1.**

9.5 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall be conducted in the manner prescribed by SOP 329. The MDL study shall be performed as needed and at a minimum, annually.

10. DEVIATIONS FROM METHOD

See discussion in Sections 4.2 and 7.4 regarding acid preservation of samples. Methods 415.1 and SW9060A both describe the homogenization of samples by means of a blender. In order to protect the instrument from being clogged by particulate matter, this approach is not utilized at Paragon (see Section 8.4). This SOP contains no other known deviations from the promulgated methods.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The laboratory facilities are equipped with safety shower, eyewash station, fire extinguisher, fire blanket, and first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

11.1.5 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

11.1.6 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL
The aqueous solution left over from the Potassium Hydrogen Phthalate (KHP) standard preparations as well as all of the acidified aqueous sample waste should be disposed of in the Aqueous Laboratory Waste stream.

DOCUMENT REVISION HISTORY

11/12/07: Extensive reworking and clarification. Added DOC language Section 2, updated LIMS program specification language Section 3.3, added sample homogenization text Section 8 and spike duplicate analysis verbiage Section 9.4. Removed Section 8 language about acidifying MB with phosphoric acid (samples arrive already acidified). Removed QC acceptance criteria in body and referenced QC Table instead, added LIMS program specification limits reference as footnote to QC Table. Removed references to drinking water analyses throughout. Added reference to internal study of syringe filters and network location to REFERENCES 12.6. Added DOCUMENT REVISION HISTORY.

Analytical Method: EPA 415.1; SW9060, SM5310 C	**Parameter:** Total Organic Carbon (TOC) by Oxidation		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria **	Corrective Action
Initial Calibration, minimum 5-point	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	r^2 must be ≥ 0.99	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Initial Calibration Verification (ICV), second source check standard run near mid-point of calibration curve (Because no sample preparation steps are involved, the ICV can also serve as the LCS for the initial QC batch of samples analyzed)	Once after each initial calibration	For Method 415.1 and SW9060 analyses, the ICV result must be within ±15% of the expected concentration	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV), run at or below midpoint of calibration; CCV concentration must be different from ICV concentration	Run after every 15 or fewer sample injections and to begin and end an analytical sequence	For Method 415.1 and SW9060 analyses, the CCV result must agree within ±15% of the expected concentration	Check that calculations and preparation are correct, evaluate/ correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Laboratory Control Sample (LCS), second source standard run near mid-point of calibration curve (The ICV can also serve as the LCS for the initial QC batch of samples analyzed)	One LCS in every QC batch of 20 or fewer samples	For Method 415.1 and SW9060 analyses, the LCS result must be within ±15% of the expected concentration	Check calculations, spike preparation, and freshness of the standard used for spiking. Prepare another LCS and analyze. If LCS still fails, samples in QC batch must be reanalyzed.
Laboratory Duplicate (DUP)	For Method 415.1 and SW9060, the LCSD & MSD both can serve as a laboratory duplicate analysis	For both Method 415.1 and SW9060, the RPD between the duplicate pair should be ≤20%	For RPDs outside of QC limits, check all calculations for errors. Narrate.
Method Blank (MB)	One MB per every QC batch of 20 or fewer samples	For Method 415.1 and SW9060 analyses, the MB result must not exceed RL (usually 1mg/L TOC)	Prepare another MB and analyze. If MB still fails, samples in QC batch must be reanalyzed.
Matrix Spike and Matrix Spike Duplicate (MS/MSD)	Volume permitting, one MS/MSD pair per batch of ≤ 20 field samples	For Method 415.1 and SW9060 analyses, MS/MSD recoveries should meet advisory limits of ±20% (80-120% of the expected values)	Check for documentable errors (e.g., calculations and spike preparation). For Method 415.1 and SW9060 analyses, sample matrix effects are

Analytical Method: EPA 415.1; SW9060, SM5310 C	**Parameter:** Total Organic Carbon (TOC) by Oxidation		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria **	Corrective Action
		and RPD should be $\leq$ 20	analyses, sample matrix effects are the most likely cause if no errors are found. Document and note in case narrative.
Method Detection Limit (MDL) Study; run per guidance in SOP329	As needed and, at minimum, annually	Positive result < analyte reporting limit (usually 1.0PPM for both Method 415.1 and SW9060 analyses)	Determine the reason for failure and correct problem with system; then repeat study. If MDL study still not acceptable, discuss with Department and QA Managers, RL may be adjusted, if necessary.

**** Acceptance Limits are as stated within Table, or as otherwise specified in the applicable LIMS program specification.**

STANDARD OPERATING PROCEDURE 671 REVISION 6

TITLE: **DETERMINATION OF N-HEXANE EXTRACTABLE MATERIAL (HEM) AND SILICA GEL TREATED HEXANE EXTRACTABLE MATERIAL (SGT-HEM) BY EXTRACTION AND GRAVIMETRY FOR AQUEOUS SAMPLES -- METHODS EPA 1664A AND SW9070A**

FORMS: **603 (use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2/20/07
QUALITY ASSURANCE MANAGER _____ DATE 2/20/07
LABORATORY MANAGER _____ DATE 2-20-07

HISTORY: Was previously SOP 1115. As SOP 671, Rev2, 9/19/02; Rev3, 12/9/02; Rev4, 2/23/04; Rev5, 2/27/06; Rev6, 2/9/07.

1.0 SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- EPA 1664A and SW9070A -- are used to determine the content of n-hexane extractable material (HEM) in environmental water samples. Extractable materials that may be analyzed are relatively non-volatile hydrocarbons, vegetables oils, animal fats, waxes, soaps, greases and related materials. This method is not applicable to measurement of materials that volatilize at temperatures below approximately 85°C. The typical reporting limit is 5.0mg/L, which is equivalent to the Minimum Level (ML) required in Method 1664A. Note that SW-846 Method 9070A directs the reader to EPA Method 1664A, Publication No. EPA-821-R-98-002, for the method procedure. The suffix "A" and the method title were inadvertently omitted during the last promulgation as part of SW-846 Update IIIA.

2.0 SUMMARY

A 1L sample is acidified to pH ≤2 and serially extracted three times with n-hexane in a separatory funnel. The extract is dried over sodium sulfate. The solvent is ~~distilled~~ evaporated DAS from the extract and the HEM is desiccated and weighed. If the HEM is to be used for determination of SGT-HEM, the HEM is re-dissolved in n-hexane, then an amount of silica gel proportionate to the amount of HEM is added to remove polar materials. The solution is filtered to remove the silica gel, the solvent ~~distilled~~ evaporated DAS, and the SGT-HEM is desiccated and weighed.

3.0 RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of

Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notifying the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this procedure to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4.0 INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing equipment are possible sources of contamination. Thorough cleaning of glassware is necessary. Materials used in the analysis must be demonstrated to be free of interferences by analyzing laboratory blanks.

4.2 Fine particulates suspended in the sample, as well as the sodium sulfate used in this procedure, could cause a positive interference by passing through the filter paper. If the filter paper is inadequate for removal of the fine particulates, then use of a 0.45µm filter is recommended.

4.3 Some crude oils and heavy fuel oils contain a significant percentage of materials that are not soluble in n-hexane (e.g., asphaltenes). Accordingly, recoveries of these materials may be low.

5.0 APPARATUS AND MATERIALS

5.1 boiling flasks, 500mL

5.2 PTFE-boiling chips: pre-clean by rinsing with methylene chloride, then dry

5.3 desiccator

5.4 indicating Drierite™

5.5 lint-free wiping cloths (e.g., KimWipes™), used to keep boiling flasks free of external contamination

5.6 analytical balance, 0.0001g sensitivity, calibration verified per SOP 305

NOTE: A 2mg weight is used in addition to the standard (SOP 305) calibration verification. This 2mg calibration verification is recorded on the benchsheet.

5.7 separatory funnels, with PTFE stopcock and stopper, 1500mL

5.8 graduated cylinder, 1L

5.9 Erlenmeyer flasks, 1500mL, or as appropriate

5.10 funnels, glass, for holding filter paper

5.11 filter paper, Whatman Glass Fiber Filter, GF/F, 142mm, #1825-142 or equivalent

5.12 steam generator and S-Evap unit or equivalents

5.13 Pasteur pipets, disposable

5.14 drying oven capable of maintaining 130-150ºC, and monitored per SOP 320

5.15 vacuum pump, with inlet hose

5.16 stirring hot plate

5.17 PTFE-coated magnetic stir bars

6.0 SOLVENTS

6.1 n-hexane, 85% purity, 99% minimum saturated C_6 isomers, residue less than 1mg/L.

6.2 acetone, ACS grade, residue less than 1mg/L.

7.0 REAGENTS

7.1 organic-free reagent water: laboratory deionized (DI) water is suitable.

7.2 hydrochloric acid (HCL) or sulfuric acid (H_2SO_4), 1:1 Solution: Mix equal volumes of ACS grade concentrated HCl or H_2SO_4 into DI water.

7.3 anhydrous sodium sulfate (Na_2SO_4), ACS grade, granular: Kiln for a minimum of 4 hours; cool to room temperature before use.

7.4 silica gel, anhydrous, 75-150µm, Davisil Grade 923, Supelco #21447-7a or equivalent. Dry at 130-150ºC for a minimum of 24 hrs. This material is stored in the drying oven until use.

8.0 STANDARDS

8.1 stearic acid, 98% minimum purity.

8.2 hexadecane, 98% minimum purity.

8.3 All standards are maintained per PAR SOP 300. Unopened stock standards are valid until the manufacturer's expiration date and may be stored at room temperature in flame-sealed ampules or as otherwise recommended by the manufacturer. After opening ampules, the stock solution may be stored at room temperature in a tightly capped vial and retained for up to six months, however, the unused stock remaining after opening and initial use is typically discarded. Intermediate standards (e.g., OPR Spiking Solution) may also be stored in a tightly sealed container at room temperature and retained for up to six months. Standards may be replaced sooner if laboratory quality control (QC) analyses or other factors indicate deterioration.

Target analyte stock standards are generally purchased as certified solutions, and used to create calibration and spike standards. **Note that for this analysis, only *one* source of standard is required, a check standard from an independent (2^{nd}) source is *not* required for this procedure.**

8.4 On-going Precision and Recovery (OPR) Spiking Solution (Hexadecane/Stearic acid): The OPR Spiking Solution is used to create laboratory control samples (LCSs), and is either purchased as a 4.0mg/mL in acetone commercial standard, or prepared as follows: Place 200±2mg of stearic acid and 200±2mg of hexadecane in a 100mL volumetric flask and fill to the mark with acetone. After the hexadecane and stearic acid have dissolved, transfer the solution to a 100-150mL glass container with a Teflon-lined cap; label appropriately. Verify concentration of spiking solution by removing 10.0mL of the solution and placing it in a tared weighing pan. Evaporate to dryness in a fume hood, then weigh. The mass of the residual materials in the pan must be 40±1mg.

8.5 All stock and intermediate standards are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials, and also documents the concentration of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis are maintained by the applicable laboratory Department.

9.0 SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

9.1 Samples should be collected according to an approved sampling plan.

9.2 A minimum of 1L of representative sample collected in a clean glass bottle is needed for analysis. If selected samples are to be used for matrix spike/matrix spike duplicate analysis, then additional aliquots must be collected accordingly.

9.3 If a sample is known or suspected to contain greater than 1,000mg/L of HEM, then a smaller volume of sample may be utilized for this analysis. **Note that this**

analysis does not allow subsampling of a water sample from the collection bottle at the laboratory. If smaller sample aliquots are desired, then they must be collected in the field, then shipped to the laboratory for analysis.

9.4 The pH of the sample is adjusted to ≤2 with hydrochloric or sulfuric acid, at the time of collection. If a sample when checked for pH at the laboratory upon receipt yields a pH >2, the Paragon Project Manager (PM) is notified, and will contact the client for instructions as to whether or not sample analysis should proceed.

9.5 Samples are stored at 4±2°C until analysis. No holding time has been established for this determination; Paragon observes a 28-day holding time to extraction for this procedure.

10.0 PROCEDURE

10.1 A sufficient number of boiling flasks must be prepared to accommodate all field and QC samples (e.g., MB, LCS/LCSD, MS/MSD) in the batch. Label, add 3-5 boiling chips, wipe and weigh each flask on the analytical balance to the nearest 0.1mg. Record the weight on the benchsheet.

NOTE: Because the flasks are cleaned (SOP 334) and dried in a kiln, they do not need to be rinsed with hexane and dried prior to use. Store the flasks in a desiccator until needed.

One method blank (MB) and one OPR spike sample (LCS, see Section 8 above), must be prepared with each batch of twenty or fewer field samples. Though not required by the Methods, it is Paragon's policy to prepare and analyze a duplicate laboratory control sample (LCSD), with each batch. Use a 1000mL aliquot of DI water for the MB, LCS and LCSD sample (place each DI water aliquot into an appropriately labeled separatory funnel). If the client provided sufficient sample volume, also prepare a matrix spike/matrix spike duplicate (MS/MSD) with each batch. Acidify all QC samples to pH<2. Spike LCS/LCSD and MS/MSD samples with OPR Spiking Solution to yield a target value of 40mg HEM/sample.

10.2 EXTRACTION

10.2.1 Using a marking pen, mark the sample's water level on the side of the sample container. Carefully pour the sample into a clean 1500mL separatory funnel.

10.2.2 Add 15mL of n-hexane to the emptied sample bottle, and re-cap with the container's lid. Shake the bottle to rinse the interior surfaces well with hexane. Pour the solvent rinse into the separatory funnel containing the sample. Repeat this Step.

10.2.3 For the MB, LCS/LCSD and MS/MSD QC samples, add 30mL hexane to each separatory funnel.

10.2.4 Re-fill the sample bottle to the mark with tap water, then pour the tap water into a graduated cylinder and measure what the volume of the original sample was. Record the volume (Vs in liters) on the benchsheet.

10.2.5 Extract the sample in the separatory funnel by shaking for two minutes, vent as needed to minimize pressure buildup.

10.2.6 Allow the organic phase (top solvent layer) to separate from the aqueous phase for a minimum of 10 minutes.

If an emulsion forms between the two phases, that is greater than ⅓ the volume of the solvent layer, break the emulsion using one of the following mechanical techniques:

- gentle stirring
- addition of sodium chloride
- filtration through glass wool
- drain emulsion into a glass centrifuge tube, spin to break emulsion
- use an ultrasonic bath cooled with ice

The optimum technique to employ depends on the extent of the emulsion formed. Consult Supervisor for details as to how a particular technique should be performed.

10.2.7 Place approximately 10g of anhydrous sodium sulfate into a filter funnel with filter paper and rinse with a small portion of n-hexane. Discard the rinsate appropriately. Place a pre-weighed boiling flask containing boiling chips under the filter funnel.

10.2.8 Drain the water (aqueous phase) from the extracted sample in the separatory funnel, into a 1500mL Erlenmeyer flask and momentarily set aside.

Then, suspend the separatory funnel over the filter funnel containing the pre-wetted sodium sulfate, and drain the n-hexane layer (solvent phase) through the sodium sulfate (drying agent) and into the boiling flask.

Rinse the tip of the separatory funnel with a few mL of hexane, allowing the rinse to pass through the sodium sulfate and into the boiling flask.

10.2.9 Return the sample aqueous phase that was momentarily set aside to the separatory funnel; add 30mL of hexane.

Extract as before by shaking for two minutes, venting as needed to minimize pressure buildup.

Allow the phases to separate for a minimum of 10 minutes; treat emulsion, if formed, as necessary.

Drain the water phase from the separatory funnel into the same 1500mL Erlenmeyer flask and momentarily set aside.

Suspend the separatory funnel over the same filter funnel containing sodium sulfate, and drain the solvent phase through the sodium sulfate into the same boiling flask containing the first extracted solvent portion.

Rinse the tip of the separatory funnel with a few mL of hexane, allowing the rinse to pass through the sodium sulfate and into the boiling flask.

10.2.10 Repeat Step 10.2.8 again, resulting in a total of three extractions of the aqueous sample using 30mL portions of n-hexane, passing the post-extraction solvent portions through the sodium sulfate drying agent, and combining the dried solvent phases into the same pre-weighed boiling flask.

10.2.11 To ensure quantitative transfer of the HEM from the drying column (filter funnel with sodium sulfate), rinse the sodium sulfate with 10mL of hexane, collecting the rinse in the same boiling flask..

10.2.12 A milky extract (i.e., contents of the boiling flask) indicates the presence of water. If the extract is milky, allow the solution to stand for up to one hour to allow the water to settle. Decant the solvent (upper) layer through sodium sulfate (use funnel and filter paper setup as previously described) to remove any excess water. Collect in a clean pre-weighed boiling flask. Rinse the initial boiling flask, filter paper and sodium sulfate, with small portions of n-hexane to ensure a quantitative transfer.

10.3 DETERMINATION

10.3.1 Evaporate the hexane extract contained in the boiling flask on top of the S-Evap unit. The temperature of the S-Evap should be maintained at <85°C to ensure that the more volatile components extracted into the hexane are not lost (note that stearic acid begins to volatilize at 90°C).

10.3.2 Bring flask to dryness. Evacuate remaining hexane vapors using a vacuum pump with hose.

10.3.3 Move the boiling flasks to a desiccator and store for several hours.

10.3.4 Weigh each flask and record on benchsheet. Return flask to desiccator, store again for several hours, then re-weigh. Repeat this step until a constant weight is achieved.

10.3.5 If the residue does not look typical (i.e., affected by watery extract or contaminated with sodium sulfate), then re-dissolve the residue in n-hexane, filter though a fresh drying funnel containing sodium sulfate, ensuring a quantitative transfer, and repeat evaporation process.

10.3.6 Calculate HEM per Section 11 below.

10.4 SILICA GEL TREATED HEM (SGT-HEM)

Silica gel cleanup is generally not performed unless the client specifies the need for separate data for HEM and SGT-HEM analytes. Also, if no HEM is detected, then there is no reason to proceed with the silica gel treatment.

10.4.1 If silica gel treatment is needed, then the MB and LCS (LCSD) must also be carried through the silica gel treatment. If the sample associated with the MS/MSD does not require silica gel treatment, then there is also no need to perform the silica gel treatment on the MS/MSD.

10.4.2 Re-dissolve the HEM in 80-90mL of n-hexane; swirl as necessary.

10.4.3 The amount of silica gel to use for treatment can be adjusted (up to 30g) based on the known weight of HEM. A 3.0g amount of silica gel can adsorb approximately 100mg of HEM. Add 3.0±0.3g of silica gel to the boiling flask for every 100mg of HEM measured. Add a PTFE-coated stir bar and stir on a magnetic stirrer for approximately 5 minutes.

10.4.4 Filter the solution through hexane-rinsed filter paper, into a pre-weighed boiling flask containing a few boiling chips. Rinse the sample flask, filter paper and funnel with a few aliquots of hexane (up to about 15mL total); evaporate the hexane on the S-Evap unit as described previously.

10.4.5 Cool in desiccator and determine constant weight as described previously (Steps 10.3.3. and 10.3.4).

10.4.6 Calculate SGT-HEM per Section 11 below.

11.0 CALCULATIONS

11.1 Calculate HEM as follows:

$$\text{SampleHEMConc.}(\text{mg/L}) = \frac{W_h\,(\text{mg})}{V_s\,(\text{L})}$$

where:

W_h = weight of extractable material (Step 10.3.4)

Vs = sample volume (Step 10.2.3)

11.2 Calculate the recovery of the OPR QC spike using the following equation:

$$\text{Recovery (\%R)} = \frac{\text{measuredconc.of HEM}}{\text{spikedconc.of HEM}} \text{ X } 100$$

See attached QC Table. Note that Method EPA 1664A provides different ongoing precision and recovery limits for the HEM vs SGT-HEM laboratory control sample.

11.3 Calculate the recovery of the MS/MSD QC samples as follows:

$$\text{Recovery (\%R)} = \frac{HEM_{Found} - HEM_{Sample}}{HEM_{Target}} \text{ X } 100$$

where:

HEM_{Found} = calculated HEM concentration in the MS or MSD

HEM_{Sample} = calculated HEM concentration in the field sample

HEM_{Target} = the target concentration of the added HEM spike

11.4 Calculate the Relative Percent Deviation (RPD) of the MS/MSD QC samples using the following equation:

$$\text{RPD (\%)} = \frac{\left|HEM_{MS} - HEM_{MSD}\right|}{\left(\frac{HEM_{MS} + HEM_{MSD}}{2}\right)} \text{ X } 100$$

where:

HEM_{MS} = calculated HEM concentration in the MS

HEM_{MSD} = calculated HEM concentration in the MSD

11.5 Calculate the concentration of SGT-HEM as follows:

$$\text{Sample SGT} - \text{HEM Conc.}(\text{mg} / \text{L}) = \frac{W_h\,(\text{mg})}{V_s\,(\text{L})}$$

where:

W_h = weight of silica gel treated extractable material (Step 10.4.5)

Vs = sample volume (Step 10.2.3)

12.0 QUALITY CONTROL

12.1 DEFINITION OF BATCH

A batch is defined as a group of ≤20 field samples of like matrix that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the MB, LCS (LCSD) and matrix spike and duplicate (MS/MSD). All QC samples must be carried through all stages of the sample preparation and measurement steps.

12.2 METHOD BLANK

Method blanks are aliquots of clean matrix (i.e., laboratory DI water) that have been prepared and analyzed in the same manner as the associated field samples. To be acceptable, concentrations of analytes of interest detected (if any) in the MB must be below the analyte reporting limit, or as otherwise specified in the LIMS program specification. If this criterion is not met, analyses should be halted and the source of the contamination found and corrected. See also attached QC Table.

12.3 OPR QC SAMPLE

This sample is comprised of a known concentration of target analyte contained in a clean matrix. This laboratory control sample (LCS) is analyzed to measure the accuracy of the analytical system. LCS recovery is calculated as shown in Section 11. See QC Table for evaluation criteria.

12.4 MS AND DUPLICATE

Matrix spikes consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection and recovery. MS recovery is calculated as shown in Section 11, see QC Table for evaluation criteria.

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this analysis, either a field sample may be analyzed in duplicate (DUP), or the laboratory control sample (LCSD) or matrix spike analysis (MSD) can be performed in duplicate. Recovery is calculated as

shown in Section 11, and precision (see Section 11 for calculation) is evaluated in terms of RPD. See QC Table for acceptance limits.

Possible causes for matrix spiked failure include:

- sample heterogeneity
- a sample matrix which inhibits extraction of spiked compounds
- high levels of HEM that "swamp out" the small amount of extractable materials added with the OPR spike.

NOTE: Typically, one MS and MS Duplicate pair is analyzed per batch. In the event that not enough sample volume is provided to generate MS and duplicate analyses, the requirement to perform these analyses is waived and an explanatory notation is made in the data package narrative.

For projects in which the client designates the MS/MSD samples, an analysis batch may not contain an MS/MSD pair because the required spikes were included in another batch. Where this occurs, a notation will be made in the data package narrative.

12.5 A METHOD DETECTION LIMIT (MDL) STUDY shall consist of the analysis of a minimum of seven replicate analyses for a target analyte at a concentration level near to the capabilities of the method. The MDL study is performed as needed, at a minimum, annually, following the guidance of SOP 329.

13.0 DEVIATIONS FROM METHOD

This procedure complies with the requirements of Methods EPA 1664A and SW9070A. There are no known deviations from the Methods.

14.0 SAFETY, HAZARDS AND WASTE DISPOSAL

14.1 SAFETY AND HAZARDS

14.1.1 The building is equipped with a safety shower, eye wash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

14.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

14.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

14.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

14.1.5 All flammable compounds (i.e., hexane) must be kept away from ignition sources.

14.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) should be labeled at a minimum with compound name, NFPA Health, Flammability and Reactivity ratings, and date.

14.1.7 Food and drink are prohibited in all lab areas.

14.2 WASTE DISPOSAL

14.2.1 The aqueous solution left over from the original sample container shall be disposed of in the Aqueous Laboratory Waste or Radioactive Aqueous Lab Waste, as appropriate.

14.2.2 All empty solvent bottles shall be disposed of appropriately; note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

STANDARD OPERATING PROCEDURE 672 REVISION 3

TITLE **EXTRACTION AND GRAVIMETRIC DETERMINATION OF LIPIDS IN TISSUES**

FORMS: **603** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8.17.07

QUALITY ASSURANCE MANAGER _____ DATE 8/16/07

LABORATORY MANAGER _____ DATE 8-20-07

HISTORY: Rev0, 1/8/03; Rev1, 3/6/04; Rev2, 2/27/06; Rev3, 8/16/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes procedures for determining the lipid content of tissues. This SOP is applicable to the determination of animal fats, vegetable oils, relatively nonvolatile hydrocarbons, waxes, soaps, greases, and related matter.

2. SUMMARY

A representative portion of solid tissue sample is mixed with a drying agent. The sample is then extracted with methylene chloride using a Soxhlet apparatus. The methylene chloride is evaporated from the sample and the dry residues recovered are measured gravimetrically and reported as the "lipids" from the tissue sample.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this procedure. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of an unknown proficiency test sample.

3.3 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the analytical review sheets, logbook or case narrative indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Organic residues on glassware, as well as dust or other particulate matter can interfere with this procedure - tongs or clean gloves should be used at all times when handling flasks. This method is strictly empirical, and meaningful results can be obtained only by strict adherence to all details of the process.

The presence of non-oily extractable substances such as sulfur compounds, organic dyes, and chlorophyll may result in a positive bias. For the purpose of this method, all materials extracted and retained during this procedure are defined as lipids.

5. APPARATUS AND MATERIALS

5.1 analytical balance, 0.0001g sensitivity; verified per SOP 305

5.2 desiccating cabinets with viable Drierite® desiccant

5.3 steam generator and evaporator, Organomation S-Evap Model 120 or equivalent

5.4 laboratory tongs

5.5 Soxhlet apparatus consisting of the following:

- 500mL round flat-bottom flasks
- Soxhlet extractors
- fritted glass thimbles
- condensers with circulating cooling water

5.6 boiling chips, Teflon®, pre-cleaned with methylene chloride

5.7 beakers, sized as appropriate

5.8 lint-free wipes (i.e., KimWipes®)

5.9 vacuum pump with hose

6. SOLVENTS - Only pesticide grade or better solvents shall be used

6.1 methylene chloride (CH_2Cl_2), Burdick & Jackson #299-4 or equivalent

6.2 acetone

7. REAGENTS - Only reagent grade or better chemicals shall be used

7.1 sodium sulfate (Na_2SO_4), anhydrous, granular, EMD #SX0760E-5 or equivalent: purify by heating at approximately 400°C (i.e., kilning) for a minimum of four hours in a shallow tray.

7.2 Ottawa sand, EMD #SX0075-3 or equivalent

8. STANDARDS

8.1 All standards are maintained per PAR SOP 300 and are documented in Paragon's Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials, documents the concentration of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis for each standard are maintained by the applicable laboratory Department.

8.2 corn oil reference standard, Mazola® or equivalent: dilute in acetone to appropriate concentration, typically 0.1g/mL.

9. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

9.1 Samples should be collected according to an approved sampling plan.

9.2 Tissue samples should be collected in wide mouth glass jars, aluminum foil or resealable (Ziploc®) plastic bags and frozen as soon as possible after collection.

9.3 No holding time has been established for this test. Paragon follows a holding time for tissue samples of 28 days from collection to extraction.

10. PROCEDURE

10.1 For each field sample, add a few boiling chips to a uniquely identified, kilned flask. Use a dry, lint-free wipe to remove any dust or particulate matter present on the outside of the flask. Place flask in the dessicator and weigh to constant weight. Record weight on the benchsheet (Form 603).

10.2 For each field sample, weigh an appropriate mass of tissue (2-5g) into a suitably sized beaker. Add an equal or greater amount of granular sodium sulfate and stir until completely dry. Addition of more sodium sulfate may be needed. If enough sample material is present, then prepare one sample from each batch in duplicate (for duplicate analysis).

10.3 For each batch of 20 or fewer samples, prepare a method blank and a laboratory control sample (LCS) (see Section 11). If no sample duplicate will be prepared, prepare the LCS in duplicate (LCSD).

10.4 Transfer each prepared field and quality control (QC) sample to a Soxhlet thimble. Rinse the beaker into the thimble with methylene chloride to effect a full quantitative transfer. Spike the LCS/D with corn oil solution, typically 1mL of 0.1g/mL solution.

10.5 Assemble the Soxhlet apparatus and apply heat to the round bottom flask. Reflux for 18±2 hours.

10.6 Transfer the flask to the S-Evap and evaporate the extract to dryness. Evacuate

remaining solvent vapors using a vacuum pump with hose.

10.7 Place each flask in the desiccator and allow to sit – this process can take anywhere from several hours to several days.

10.8 Remove each flask from the desiccator. Weigh each flask on the analytical balance and record the weight on the laboratory benchsheet. Return each flask to the desiccator and allow to sit – again for a period of time from several hours to several days. Repeat this Step until a constant weight is achieved (note that if the flask hasn't achieved constant weight, it may still contain residual solvent vapors or moisture).

10.9 Calculate the lipid content as shown below:

$$lipids\ (mg/kg) = \frac{gain\ in\ weight\ of\ \ flask\ (mg)}{weight\ of\ \ tissue\ extracted\ (kg)}$$

11. QUALITY CONTROL

11.1 DEFINITION OF A BATCH

A batch is defined as a group of $\leq$20 field samples of like matrix that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS) and duplicate (Sample DUP or LCSD). All QC samples must be carried through all stages of the sample preparation and measurement steps.

11.2 METHOD BLANK

The method blank is an aliquot of clean matrix (i.e., Ottawa sand) that has been prepared and analyzed in the same manner as the associated field samples. To be acceptable, concentrations of lipids in the MB must be below the analyte reporting limit, or as otherwise specified in the LIMS program specification. If this criterion is not met, analyses should be halted and the source of the contamination found and corrected. See QC Table for further details.

11.3 LABORATORY CONTROL SAMPLE

The laboratory control sample is an aliquot of clean matrix (i.e., Ottawa sand) that has been "spiked" with a known concentration of target analyte, and is analyzed to demonstrate the accuracy of the analytical test. The recovery of target analyte (calculation shown below) should be within 80-120% of the expected (known) concentration of lipids:

$$\text{Percent Recovery (\%R)} = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Expected}}} \times 100$$

See QC Table for further details.

11.4 LABORATORY DUPLICATE

A laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. To accomplish this, either a field sample or the laboratory control sample (LCS) is performed in duplicate. Precision is evaluated in terms of Relative Percent Difference (RPD):

$$RPD\ (\%) = \frac{|\ Result_x - Result_{Dup}\ |}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

The RPD should be <20%. See QC Table for further details.

11.5 A METHOD DETECTION LIMIT (MDL) STUDY is performed as needed, at a minimum, annually, following the guidance of SOP 329. The MDL study shall consist of the analysis of a minimum of seven replicate analyses for a target analyte at a concentration level near to the capabilities of the method. The MDL generated by such a study must be less than the reporting limit (RL) of the method. See QC Table for further details.

12. DEVIATIONS FROM METHOD

This SOP is based on SW-846 Method 9071B. This is a confidential, proprietary procedure developed by Paragon.

13. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Solid sample remnants shall be disposed of in the Contaminated Soils and Solids satellite collection vessel. Radioactive solids require special disposal, as do mixed wastes.

11.2.2 All empty solvent bottles are disposed of according to the appropriate procedures. All labels and markings must be defaced prior to disposal.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 673 REVISION 2

TITLE: **EXTRACTION OF POLYCHLORINATED BIPHENYLS FROM WIPES USING ULTRASONIC BATH AGITATION**

FORMS: **616** **(use current iteration)**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 8.17.07
QUALITY ASSURANCE MANAGER _____ DATE 8/16/07
LABORATORY MANAGER _____ DATE 8-20-07

HISTORY: Rev0, 6/10/03; Rev1,7/26/05; Rev2, 8/16/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes Paragon's in-house procedure used to extract polychlorinated biphenyls (PCBs, Arochlors) from wipes. The procedure described is modified from SW-846 Method 3550 and is intended to extract removable PCBs from wipes used in assessing surface contamination on buildings and equipment.

2. SUMMARY

Environmental and laboratory quality control (QC) wipe samples are extracted with hexane for two hours using an ultrasonically agitated water bath after addition of surrogates or other standards. Extracts are then concentrated by nitrogen blowdown (SOP 637). Sulfuric acid cleanup (SOP 651) is then performed. The extracts are then ready for analysis by Method SW8082 (SOP 409).

3. RESPONSIBILITIES

3.1 It is the responsibility of the individual performing this procedure to prepare the samples according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of a proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the benchsheet indicates that this review for precision,

accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Corrective action must be taken and documented for any discrepancies noted.

4. INTERFERENCES

Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences upon analysis. Only scrupulously cleaned glassware (SOP 334), reagent grade (or better) chemicals and pesticide grade (or better) solvents may be used. These materials and the analytical system are demonstrated to be free from interferences by the preparation and analysis of method blanks.

5. APPARATUS AND MATERIALS

5.1 sample vials with screw-tops, 40mL, glass, disposable, or equivalent

5.2 ultrasonic agitator water bath, Branson 8210 or equivalent

5.3 solvent dispensers, pump-style or equivalent

5.4 metal spatula

5.5 pipets, transfer, 10mL

5.6 Pasteur pipets, glass, disposable

5.7 extract vials with screw-tops, glass, or equivalent

5.8 gastight syringes, 1mL, or as needed

5.9 cotton gauze pads; Accolade 2”x2” Gauze Pads #908112 or equivalent

6. REAGENTS - Only pesticide residue grade (or better) solvents shall be used

Hexane (C_6H_{14}), Burdick & Jackson #216-4 or equivalent

7. STANDARDS

7.1 All standards are maintained per PAR SOP 300 and are documented in Paragon’s Standards and Solutions database. The information recorded in the database facilitates reordering, provides documentation of purity or concentration of purchased materials, documents the concentration of each intermediate dilution (as well as the analyst who prepared the dilution), and ensures traceability to the manufacturer. Additionally, Certificates of Analysis for each standard are maintained by the applicable laboratory Department.

7.2 The surrogate and spiking solutions are prepared by the Organics - Pesticides Group. The components and concentrations depicted below are provided as examples. Other surrogate compounds may be used or other Arochlors spiked per client project specifications. Refer to the applicable LIMS program specification, LIMS test code, or the Standards and Solutions database for specific information. *Allow all spiking solutions to come to room temperature before use.*

7.2.1 surrogate solution - tetrachloro-m-xylene (TCM) and decachlorobiphenyl (DCB), 500ng/mL

7.2.2 Arochlor spiking solution - Arochlors 1016 and 1260, 5000ng/mL

8. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

8.1 All samples should be collected using an appropriate sampling plan.

8.2 The wipes are frequently provided to the client by the laboratory. The wipes must be placed in glass containers with Teflon-lined lids after sampling. The wipes should be moist with the solvent used in the extraction process (hexane).

8.3 The wipe samples should be extracted within 14 days of collection. The extraction process can be thought of as being initiated at the time of sampling since the wipes are typically in hexane from that time until the extraction is completed.

9. PROCEDURE

9.1 Note all abnormal conditions on the extraction benchsheet (Form 616). Examples of notable items include: absence of a wipe in the jar, completely dry wipe, very oily wipe.

9.2 The wipes are generally extracted in the vials in which they were submitted to the laboratory. If a wipe must be transferred to a different vial for extraction, then any particles or liquid in the original vial must also be carefully transferred to the new vial. Complete the transfer by rinsing the original vial with several small aliquots of hexane and adding the rinsate to the new vial.

9.3 One method blank (MB) must be prepared for each batch of twenty (or less) environmental samples processed. Place an unused wipe into a labeled 40mL glass vial with a screw-top cap for use as the method blank.

9.4 One laboratory control sample/laboratory control sample duplicate (LCS/LCSD) must be prepared for each batch of twenty (or fewer) wipe samples processed. Place one wipe into each of two 40mL glass vials with screw-top caps for use as the LCS/LCSD pair.

9.5 Add the appropriate amount of surrogate solution (typically 1.0mL) to each

prepared vial of environmental or QC sample.

9.6 Add the appropriate amount of Arochlor spiking solution (typically 1.0mL) to both the LCS and LCSD.

9.7 Add enough hexane to each vial to completely cover the wipe being extracted. Addition of 10-20mL of hexane is generally sufficient to cover each wipe completely. Generally, the vials already contain a small volume of hexane that was used for sampling. This hexane should always be included in the total volume of hexane used, as the extraction is considered to have been started at the time of sampling. A spatula may be used to compress and submerge the wipe into the hexane – *make sure to rinse the spatula with hexane (into the vial) after this is done.*

9.8 Close the seal tightly on each vial after addition of the solvent. Place the vials in racks in the ultrasonic agitator bath. If necessary, add water to the bath so that the level of water is at or slightly above the solvent level in the vials.

9.9 Turn on the cold water tap that circulates cooling water to the bath.

9.10 Turn on the ultrasonic agitation power. After 2 hours have elapsed (±15min.), turn the power off and remove the vials from the agitator bath.

9.11 Transfer each extract to a concentrator tube or 40mL VOA vial prior to blowdown. A Pasteur pipet can be used to gently compress the wipe as the extract is pipetted into the concentrator tube. Rinse the vial (and again use the Pasteur pipet to compress the wipe) a minimum of three times to achieve an effective transfer, adding each rinsate to the concentrator tube.

9.12 Bring the extracts to final volume (10mL) per SOP 637.

9.13 Follow the instructions in SOP 651 (sulfuric acid cleanup) to clean up the extracts for analysis.

9.14 Observing proper internal chain-of-custody (SOP 318), deliver the extracts to the designated refrigerator for analysis by the Pesticides Group.

10. QUALITY CONTROL

10.1 DEFINITION OF A BATCH

For this method, a preparation batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS) and laboratory control sample duplicate (LCSD). An LCSD is always performed as each sample is extracted in its entirety as no

matrix spike or matrix spike duplicate can be performed. All quality control samples must be carried through all stages of the sample preparation and measurement steps.

10.2 METHOD BLANK

A method blank (MB) is analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the blank consists of one wipe. For the method blank to be acceptable, the concentration of target compounds must be less than the reporting limit, or as otherwise specified in the applicable LIMS program specification.

10.3 LABORATORY CONTROL SAMPLE AND LABORATORY CONTROL SAMPLE DUPLICATE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method; the LCSD is analyzed (as a laboratory duplicate) to measure precision. A known amount of target analyte is added to a blank laboratory wipe, which is then prepared and analyzed. For this procedure, one wipe is used for the LCS and one for the LCSD. Results obtained are compared to results expected. To be acceptable, LCS/LCSD recoveries must be within the acceptance limits established by the applicable LIMS program specification or test code.

11. DEVIATIONS FROM THE METHOD

The extraction procedures documented in this SOP have been developed in-house. This procedure is modified from Method SW3550 as no documented procedures are known to be available for extraction of removable Arochlor contamination from wipes.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents for the first time.

12.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

12.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). Hexane TLV = 50ppm.

12.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with

compound name, NFPA Health, Flammability and Reactivity ratings, and date.

12.2 WASTE DISPOSAL

12.2.1 Hexane may be disposed of in the Acetonitrile/Non-halogenated Waste.

12.2.2 Extract vials and associated extracts are disposed by the analytical group into the appropriate extract and vial waste container.

12.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Note that all labels and markings must be defaced prior to disposal.

HISTORY: Rev0, 9/18/92; Rev1, 12/26/92; Rev2, PCN #145, 2/28/94; Rev3, PCN #333, 1/19/95; Rev4, 4/10/98; Rev5, 3/24/00; Rev6, 6/29/01; Rev7, 3/13/02; Rev8, 4/4/03; Rev9, 9/22/03 and 2/9/05 (no revisions); Rev10, 4/26/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the preparation of environmental and drinking waters for the quantitative measurement of tritium. This SOP is compliant with EPA Drinking Water Method 906.0.

2. SUMMARY

Environmental and drinking water samples are distilled in order to separate the water from any positive interferences and from dissolved or suspended materials which would cause "quenching" in the liquid scintillation process. Radioiodine and radiocarbon interferences are eliminated by distillation in an alkaline medium in the presence of potassium permanganate. Distillate aliquots are transferred to scintillation vials and mixed with liquid scintillation cocktail. The resulting emulsion is analyzed in a liquid scintillation counter calibrated against NIST-traceable tritiated water in the same geometry and cocktail as the samples.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or designee. Initialing and dating the workorder file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the preparation or analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Remember that the target nuclide is an isotope of hydrogen (^3H) labeled on water molecules. Addition of water, acid or any other materials containing significant quantities of hydrogen can significantly alter the hydrogen concentration in the sample and could potentially compromise sample integrity.

4.2 Samples must be made basic (pH ~10) to prevent co-distillation of other radioactive analytes, such as carbon and iodine.

4.3 The sample is distilled in an oxidizing environment to break down organic sample constituents, which may cause quenching interference.

4.4 All glassware must be cleaned according to the glassware washing SOP 720, and thoroughly dried prior to use. The condenser columns are rinsed with DI water and dried with a small amount of anhydrous acetone between distillations. Distillation flasks should be thoroughly cleaned with aqua regia, as needed, to remove buildup of visible residues in the flasks.

4.5 Approximately every month, or as needed, the anhydrous $CaSO_4$ desiccant should be renewed. Remove the drying tube located on the top of the condenser and replace the spent $CaSO_4$, with fresh anhydrous $CaSO_4$.

NOTE: It may be necessary to use DI water to dislodge the $CaSO_4$ from the drying tube. Gently fill the drying tube with DI water; the $CaSO_4$ will dissolve. Be sure to allow the drying tube to dry fully before repacking.

4.6 The scintillation vial is an optical surface. Any markings or material on the

outside of the scintillation vial will interfere with the detection of scintillation. These marks should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. All labeling must be done on the cap of the vial.

4.7 The presence of visible coloration in the distillate will act as an 'inner filter'. This effect, known as 'color quenching' is an interference to the detection of the scintillation. The quench indicating parameter (QIP, usually H-number or SQP(E)), should be monitored and variations in quench that could correspond to greater than 10% (or +/-15 number) relative bias in the efficiency should be addressed by using standard additions to determine a sample-specific efficiency.

4.8 The presence of particulate contaminant in the final water distillate may interfere with the detection of the scintillation. This effect is known as 'physical quenching'. The quench indicating parameter (QIP, usually H-number or SQP(E)), should be monitored and variations in quench which could correspond to greater than 10% relative bias in the efficiency should be addressed by using standard additions to determine a sample-specific efficiency.

4.9 The presence of chemical contaminants in the final water distillate may inhibit scintillation. This effect is known as 'chemical quenching'. The quench indicating parameter (QIP, usually H-number or SQP(E)) should be monitored and variations in quench which could correspond to greater than 10% relative bias in the efficiency should be addressed by using standard additions to determine a sample-specific efficiency.

4.10 The presence of volatile beta- (or alpha-) emitting materials (low boiling organics, etc.) that could co-distill with water is a positive interference to this method. The initial fraction of distillate is therefore discarded to remove the lightest potential interferences. The sample spectrum is subsequently monitored (window 2) for evidence of higher energy species in the distillate (especially ^{14}C) and corrective action taken when significant interference is observed.

4.11 The distillation apparatus (flask and still) used for each sample and the order of distillation are recorded to enable checking for potential cross-contamination in the case of a sample with significantly elevated activity. Experience indicates that using cleaning procedures defined in this procedure will achieve satisfactory decontamination of the apparatus to assure at least 100-fold differential between successive distillations. Successive samples showing activity differences greater than two orders of magnitude should be examined to ensure that results are not compromised by carry-over in the distillation apparatus. Evidence of contamination or carry-over will lead to re-preparation of the affected sample(s).

5. APPARATUS AND MATERIALS

5.1 Scintillation vials, low-potassium borosilicate glass, Wheaton™ or equivalent, 20mL

5.2 Condenser, Pyrex™ or equivalent, 400mm length, 24/40 ground glass joints

5.3 Receiver, Barrett type, graduated, Pyrex™ or equivalent, 20mL, 24/40 ground glass joints

5.4 Flask, round-bottom, Pyrex™ or equivalent, 500mL, 24/40 ground glass neck

5.5 Drying tube, polyethylene: Place a small amount of glass wool in the cap of the column. Fill the tube with Drierite™. Place the cap on the tube and place bottom of the tube into the stopper.

5.6 Heating mantle assembly to fit 500mL flasks

5.7 Spatula, stainless steel

5.8 Bottle-top dispenser, 10mL or adjustable repeat pippettor, 1-20mL, with disposable tips

5.9 Graduated cylinder, 50mL

5.10 Nalgene™ tubing for cooling water, attached to condenser inlet and outlet

5.11 One-hole stopper, for drying tube

5.12 Glass wool, for drying tube

5.13 Wide range indicating pH paper

5.14 Boiling beads, glass

5.15 Lubricant, silicon-based, used to seal ground glass joints

6. REAGENTS - only reagent grade or better chemicals may be used

NOTE: TLV and other hazard information may be given here. As stated in Section 13.6 below, any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not mean that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Anhydrous calcium sulfate ($CaSO_4$), or indicating Drierite™

6.2 Hydrochloric acid (HCl), concentrated, 12N. TLV = 5ppm (ceiling)

6.3 Nitric acid (HNO_3), concentrated, 16N. TLV = 2ppm (TWA); irritant, corrosive

6.4 Liquid scintillation cocktail, Ultima-Gold LLT™ or equivalent brand (Packard)

6.5 Potassium permanganate ($KMnO_4$), crystals. No TLV; Caution: strong oxidizer

6.6 Sodium hydroxide (NaOH), pellets. TLV = $2mg/m^3$ = 1.2ppm (ceiling); irritant

6.7 Tritium-free water: Water from a deep well, distilled or deionized, or other reagent water (e.g., deionized water) that shows activity indistinguishable from the method background. Historical data indicate that Paragon laboratory water is consistently free of contamination and may be used as tritium-free water. Activity levels measured for the reagent blank are tracked, and results deviating from historical values are identified with appropriate actions taken to remediate results or re-prepare samples.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Environmental and drinking water samples for tritium analysis should be collected in glass containers. *Tritium samples should not be preserved.*

7.2 Keep all sample containers tightly closed. If samples are to be stored for an extended period of time, refrigeration is recommended to prevent biological growth in the sample.

7.3 At the current time, there is no regulatory holding time for tritium. Many sampling and analysis plans, however, apply a default holding time of 180 days for this analysis. If samples are analyzed more than 180 days after collection, this fact should be noted in the data package case narrative.

8. PROCEDURE

8.1 WATER SAMPLE DISTILLATION

8.1.1 Verify and record the pH of the sample on a liquid sample condition form (Form 631) according to SOP 733.

8.1.2 Label (on the top of the lid) a glass scintillation vial for each sample to be distilled.

8.1.3 Remove all necessary glassware (round-bottom flask, Barrett receiver, and stopcock) from the oven and allow to cool for several minutes. Do not add samples to hot glassware, as tritium may be lost from the sample due to evaporation.

8.1.4 Use a clean and dry graduated cylinder to measure approximately 50mL of each water sample. Record the actual volume to the nearest graduation on the benchsheet.

8.1.5 Transfer the aliquot of each water sample into a labeled round bottom flask.

8.1.6 Prepare the appropriate batch quality (QC) samples as required in Section 9.2 of this SOP or as required to meet project-specific requirements. Note that the spikes are to be added after the samples have been transferred to a round bottom flask.

8.1.7 Make the sample basic as follows (see also comments in Sections 4.1 and 4.2):

8.1.7.1 Add approximately 0.1g (1 pellet) of sodium hydroxide to the round bottom flask.

8.1.7.2 If there is no unpreserved sample available for the tritium analysis, then an acid preserved sample may be used. However, enough NaOH pellets must be added to make the sample basic.

Samples with pH 1 will require roughly 0.2g NaOH (2 or 3 pellets), and those at pH 0 will require approximately 2g NaOH to be added.

Measure the pH of the preserved sample with pH paper and slowly add NaOH pellets accordingly. Verify that the pH of the sample after base addition is approximately 10. Record base addition and final pH on the sample condition form (Form 631). Also, submit a Quality Assurance Summary Sheet (QASS, Form 302) noting the use of a preserved sample.

8.1.8 Add ~0.01-0.05g of potassium permanganate to the round bottom flask. This can be accomplished by using a pair of forceps or a lab spatula.

8.1.9 Add 2 glass boiling beads to the flask. Swirl to dissolve the sodium hydroxide and potassium permanganate.

8.1.10 Lubricate all glass joints and stopcock with silicone-based lubricant as needed.

8.1.11 Place the flask into a heating mantle.

8.1.12 Attach the Barrett receiver (graduated) to the flask.

8.1.13 Attach the condenser to the top of the receiver.

8.1.14 Ensure that the drying tube is in place on the top of the condenser and that the desiccant does not need to be replaced.

NOTE: The desiccant appears caked, rather than having a bead-type appearance, when in need of replacement. Indicating type desiccant will turn pink when expended. Replace when the entire tube has turned pink.

8.1.15 Make sure the stopcock on the receiver is closed.

8.1.16 Record the appropriate information concerning the distillation apparatus used for each sample in the tritium run log (Form 1306).

8.1.17 Turn on the water to cool the condensers.

8.1.18 Turn on the mantle assembly to about 7. The water should come to a slow boil.

8.1.19 Allow the sample to start distilling.

NOTE: Some samples may become foamy or reactive while distilling. If this occurs, turn down the heat on the mantle to ensure that the sample does not boil over or contaminate the collected distillate.

8.1.20 Discard the first 5mL of distillate that has collected.

NOTE: It is important that the first 5mL of sample distillate be discarded to avoid low boiling contaminants from being included in the distillate taken for analysis.

8.1.21 Collect the next 20mL of distillate in the receiver.

8.1.22 Drain the distillate from the receiver into a labeled scintillation vial.

8.1.23 Cap the vial with the properly labeled lid until ready to aliquot.

8.1.24 After collecting 20mL from each sample distillation, turn off the mantle assembly.

8.1.25 Allow the flasks to cool.

8.1.26 Remove the flask from the mantle and clean.

8.2 LIQUID SCINTILLATION VIAL PREPARATION

8.2.1 Label (on each lid) a scintillation vial for each sample in the batch. Label one vial per batch for the reagent blank. Label with the batch ID and "CBX" (where CB is an identifier for calibration blanks and X denotes a sequential designation which will provide for a unique ID for this blank).

8.2.2 Pipet a 10.0mL (or an appropriate volume to match calibration geometry) aliquot of the sample distillate into the scintillation vial using a previously calibrated pipette with a fresh tip. Save the

remainder of the sample distillate for reserve.

8.2.3 Add 10.0mL (or an appropriate volume to match calibration geometry) of liquid scintillation cocktail to the sample vial with the bottle-top dispenser. Record the type of cocktail used, as well as the lot number, and dispenser ID on the benchsheet. If inadequate volume of distillate is available to match the calibration geometry, add the available volume and dilute to 10mL (or the appropriate calibration geometry volume) with tritium-free water.

8.2.4 Record the actual volume of distillate (mL or grams) added to each vial on the benchsheet as the analytical aliquot. In cases where volume is not measured using a calibrated 10mL pipettor, the aliquot volume may be measured gravimetrically assuming a density of 1 g/mL.

8.2.5 Cap the sample vial with its corresponding labeled lid and shake the sample thoroughly.

8.2.6 Clean the outside of scintillation vial using a lint-free lab wipe and alcohol to remove dust, smudges, and fingerprints.

8.2.7 Place the scintillation vials in racks.

8.2.8 Deliver the samples to the Counting Lab with the necessary documents. Place the racks in the liquid scintillation counter and allow at least 3 hours for the samples to "dark adapt" prior to counting. The Counting Lab will analyze and ultimately dispose of the scintillation vials in the manner described in SOP 704.

9. QUALITY CONTROL

9.1 CALIBRATION

9.1.1 Bottle-top dispenser calibration. The bottle-top dispenser is checked monthly, by dispensing a 10mL aliquot of scintillation cocktail into an appropriate volumetric measurement apparatus, typically a 10mL Class A volumetric flask. The volume dispensed should be 10mL +/- 0.1mL; if not, adjust the dispenser and re-check. Record the calibration check in the pipet calibration logbook.

9.1.2 Efficiency calibration source preparation. A one-point calibration source is prepared as follows: Prepare three 50mL aliquots of deionized water containing approximately 5000dpm of NIST-traceable tritium standard. This solution is then distilled and prepared for counting as described in Sections 8.1 and 8.2.

A one-point efficiency is highly accurate and will be used for the calculation of all results showing QIP results corresponding to the

average observed for the calibration standard (within +/- 10 % relative efficiency or lacking this calibrated range, +/- 15 of mean H-numbers). Any sample falling outside this range will be calibrated by sample-specific addition of a minimum known volume (< 200 µL) of NIST-traceable tritiated water. The efficiency from sample-specific standard additions is calculated as defined in Section 10.7.

9.1.3 Background calibration (calibration blank). An aliquot of tritium-free water equivalent to the calibration geometry is transferred to a scintillation vial, independent of the preparation process and cocktail added, such that the calibration geometry is reproduced. One calibration blank is submitted for each preparation batch and counted for a time period equal to or longer than the longest sample count. For samples counted in the default calibration geometry (10mL water + 10mL cocktail), cpm results (as well as blank ID, batch, and QIP result) of the calibration blank count are entered into a spreadsheet (H3_RB.xls) which tracks the running mean of the last seven calibration blanks, and compares each blank to historical control limits established from the first 20 data points in the population (+/- 3 sigma). The current running mean of the calibration blank cpm is used as the background in the calculation of associated results for the associated prep batch.

9.2 BATCH QC SAMPLE PREPARATION

Quality control samples are processed and results calculated in the same manner as the associated field samples, with the exception that Laboratory Control Samples (LCS) and matrix spikes are spiked after being transferred to the round bottom flask.

9.2.1 Blanks Process a method blank at a frequency of one per batch of 20 samples or 5%, whichever is greater. 50mL of 'tritium-free' water is transferred into a flask.

9.2.2 Laboratory Control Samples (LCS) Process an LCS at a frequency of one per batch of 20 samples or 5%, whichever is greater. Appropriate spiking levels are 5-50 times the requested minimum detectable concentration (MDC).

NOTE: Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of the lab's internally derived acceptance criteria.

9.2.3 Sample Duplicates Process a sample duplicate at a minimum frequency of two per batch of 20 samples or 10%, whichever is greater.

If sample volumes are limited, an LCS duplicate may be substituted for duplicate sample analysis. The discrepancy should be noted in a QASS (Form 302) and in the data package narrative.

9.2.4 Matrix Spikes Process a matrix spike sample at a frequency of one per batch of 20 or 5%, whichever is greater. Appropriate spiking levels are five to ten times the native sample activity. If sample volumes are limited, an LCS duplicate may be substituted for matrix spike analysis. The discrepancy should be noted in a QASS (Form 302) and in the data package narrative.

10. CALCULATIONS

10.1 The sample activity is calculated as follows:

$$\text{Activity} = \frac{(\text{SmplGrCPM}) - (\text{BkgCPM})}{\text{Denom}}$$

10.2 The activity calculation denominator is calculated as follows:

$$\text{Denom} = \text{FinAli} * \text{Dec} * \text{ActCnv} * \text{DetEff}$$

10.3 As defined in SOP 743, the following uncertainty factors (1σ) are applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU):

10.3.1 Calculate the one-sigma counting uncertainty (CU) as follows:

$$\text{CU} = \frac{\sqrt{(\text{SmplGrCPM}/\text{SmplTime}) + (\text{BkgCPM}/\text{BkgTime})}}{\text{Denom}}$$

10.3.2 The one-sigma preparation uncertainty (PU) is 5.1%. This is based on one gross aliquotting, one volumetric measurement, one pipetting, and one reagent addition.

10.3.3 The one-sigma instrument uncertainty (IU) is 5.6%, based on the in-house preparation of calibration standards.

10.3.4 Calculate the one-sigma total propagated uncertainty (TPU) as follows:

$$\text{TPU}(\text{pCi/unit}) = \sqrt{\text{CU}^2 + (\text{Activity} * \text{PU})^2 + (\text{Activity} * \text{IU})^2}$$

10.4 The Minimum Detectable Concentration (MDC) is calculated as follows:

$$MDC = \frac{4.65 * \sqrt{BkgCPM * SmplTime} + 2.71}{SmplTime * Denom}$$

10.5 The Decision Level (DL) activity is calculated as follows:

$$DL = \frac{2.33 * \sqrt{(BkgCPM * SmplTime)}}{SmplTime * Denom}$$

10.6 The efficiency used for calculation of sample results is calculated as shown in the equation below:

$$DetEff = \frac{Net\,Cpm}{SpkDPM}$$

NOTE: Multiple standards are prepared and the measured values averaged for use in sample calculations.

10.7 The sample-specific efficiency is measured following addition of a known quantity of tritiated water (< 0.20mL) as follows:

$$Deteff = \frac{((SSGrCPM - BkgCPM) - (SmplGrCPM - BkgCPM))}{SpkDpm}$$

where:

Activity = Tritium activity corrected for decay to date of collection (default units pCi/L)

SmplGrCPM = Analyte gross count rate (cpm)

SmplTime = sample count time (min)

BkgCPM = Background count rate (cpm)

BkgTime = Background count time (min)

Denom = Activity calculation denominator

DetEff = sample detection efficiency for sample geometry / quench level

Counting Unc. = Counting Uncertainty (pCi/L)

FinAli = Final dilution/preparation adjusted aliquot (Note: dilution factor is included in this number to reflect the quantity of original sample taken for analysis (L)

ActCnv = Activity conversion factor from DPM to desired units (2.22 for pCi, 60 for Bq)

Dec = decay factor $e^{(-\lambda t)}$ (fractional)

$\lambda = \ln 2 / t_{1/2}$

$t_{1/2}$ = half-life for tritium in same units as decay time

t = decay time in same units as half-life

SSGrCPM = Spiked Sample Gross CPM

SpkDPM = Spike addition DPM decay corrected to count date

11. DEVIATIONS FROM METHOD

11.1 This procedure is compliant with EPA Drinking Water Method 906.0. There are no known deviations from the method.

11.2 This procedure is compliant with Eastern Environmental Radiation Facility (EERF) Procedures Manual Method H-02.

11.3 This procedure is compliant with Standard Methods for the Examination of Water and Wastewater, 18th Edition.

12. SAFETY HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Read the MSDSs prior to preparing standards or using any solvents or reagents.

12.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

12.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles), shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.1.5 Care should be taken when working with the heating mantles and boiling water to prevent thermal burns. Occasionally, pressure will build up in the condenser and pop the drying tube off the top.

12.2 WASTE DISPOSAL

12.2.1 All empty radionuclide standard solutions are disposed of by rinsing the standard container with tap water a minimum of three times. The container must be surveyed prior to release. Please note that all labels and markings must be defaced or removed prior to disposal.

12.2.2 The tritium analytical process effluent has been determined to not be hazardous in any other way than corrosivity. This material may be

discharged into Paragon's wastewater treatment facility. Here the solution will be neutralized prior to discharge, and the radionuclide concentration will be monitored to ensure compliance with Colorado Rules and Regulations pertaining to Radiation Control, Part 4, regarding discharges to sanitary sewers.

12.2.3 Consult with waste management staff for the disposal of scintillation cocktail.

12.2.4 Vials of sample/cocktail mixture may be accumulated (intact) in a container provided by waste management staff.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references, EPA 900.0 and SW-846 Method 9310, describe the procedure used to determine non-volatile gross alpha and beta activity of waters, liquids, soils, non-soil solids, air filters and air filter composites, and certain non-aqueous liquids. The solids procedure is amenable to the preparation of suspended solids that have been removed by filtration from waters or other liquid matrices.

The gross alpha and gross beta activity are determined simultaneously in the same sample preparation by counting on the beta plateau. The raw count results are corrected for detector background, efficiency (referenced to ^{241}Am for alpha -or ^{230}Th to meet National Primary Drinking Water Standards using Method EPA 900.0- and ^{90}Sr/Y for beta), mass attenuation (sample self-absorption), and alpha and beta cross-talk. Default reporting units are picoCuries per liter (pCi/L) on an unfiltered basis, (waters), or per gram (pCi/g) on a dry weight basis (solids), or per filter or composite as appropriate to meet the client's data quality objectives.

This procedure is substantially compliant with methods EPA 900.0, SW-846 Method 9310, and Standard Methods (SM) Method 7110B for aqueous matrices.

2. SUMMARY

2.1 WATERS

Waters samples are routinely analyzed on a "filtered" or "unfiltered" basis. Samples containing visible sediment are routinely filtered prior to preparation according to SOP 721 unless EPA drinking water protocols are requested by the client. In this case, the sample must not be filtered so that the actual consumer

dose can be accurately measured. The aliquot size is determined for each sample by gravimetric measurement of the total solids. This aliquot is then evaporated to near dryness and a small volume (i.e., <5mL) is quantitatively transferred into a tared stainless steel planchet. The contents of the planchet are evaporated on a hot plate and cooled in a desiccator. After cooling, the planchet is weighed to determine the residual mass of nitrated sample solids. If the mass of solids is greater than 100 milligrams for alpha-only and simultaneous alpha/beta measurements, or greater than 200 milligrams for beta-only measurements, the sample is re-prepared using a proportionately smaller aliquot. Planchets containing solids in the acceptable range are sent to the Radiochemistry Instrument Group for analysis per SOP 724.

2.2 LEACHATES OR DIGESTATES

Following preparation, sample leachates or digestates are determined as described in Section 2.1 above for waters. The total solids spot check may be omitted at the analyst's discretion. The sample aliquot is adjusted to reflect the equivalent sample concentration (grams or mL sample per gram or mL leachate).

2.3 NON-AQUEOUS OR MIXED PHASE LIQUIDS

Non-aqueous liquids are analyzed and reported on an "as received" basis. They may be treated as waters as long as the physical or chemical characteristics of the sample are amenable to safe evaporation with the eventual addition of nitric acid. Questionable cases should be addressed to the Senior Scientist, Technical Manager, Project Manager, or Health and Safety Officer prior to initiation of analysis.

2.4 SOILS AND NON-SOIL SOLIDS (hereafter referred to as "solids")

Solids are analyzed on a "dry weight" basis. Routinely, a 3g aliquot (or other appropriate quantity) of the solid is digested in a known volume (usually 30mL) of 8N nitric acid in a 50mL centrifuge tube. The sample is then centrifuged. A volume aliquot which yields <100mg of nitrated solid residue is determined gravimetrically. This aliquot is then evaporated onto a tared stainless steel planchet, dried, flamed, and weighed. The planchet is then sent to the Radiochemistry Instrumentation Group for analysis. Results are reported on a default basis of pCi/g dried solids.

2.5 AIR FILTERS

Air Filters are processed in a manner similar to solids except they need not be weighed and the units are reported on a default basis as "per filter".

2.6 SUSPENDED SOLIDS

Solids suspended in aqueous solutions are filtered from a known quantity of sample onto tared glass fiber filters. The filters are dried and weighed to determine the mass of the suspended fraction. The entire filtered suspended solid

sample, up to 5 grams, is then treated as a solids sample. Results are reported on a default basis as pCi/g dried solids.

2.7 SWIPES
Swipes and some filters that are counted directly, or on an "as received" basis, are placed onto a clean stainless steel planchet and relinquished to the Radiochemistry Instrument Group for counting. Results are typically reported on a per sample basis, but may also be reported as pCi/air volume for filters at the client's request.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. The demonstration may come in the form of supervisory/training review, precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off on the data are performed by the Department Supervisor or designee. Initialing and dating the file indicate that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events. Any discrepancies must be noted and brought to the attention of a Senior Scientist or Manager. Corrective actions taken must be approved, and promptly and thoroughly documented.

4. INTERFERENCES

4.1 Radionuclides that are volatile during evaporation in nitric acid or flaming of

planchets will not be dependably measured. This method is not applicable to the determination of Tritium (^{3}H) or Carbon 14 (^{14}C). Other problematic nuclides include Technetium 99 (^{99}Tc) and radioisotopes of iodine, cesium, and polonium.

4.2 If the radionuclides are not separated from the solids of the sample, the solids concentration is a primary limiting factor in the sensitivity of the method for any given water sample. Also, for samples with very low concentrations of radioactivity, it is essential to analyze as large a sample aliquot as possible to allow reasonable counting times.

4.3 The largest sample aliquot that should be counted for gross alpha activity is that size aliquot which gives a solids density thickness of $5mg/cm^2$ in the counting planchet. For a 2in diameter counting planchet, an aliquot containing 100mg of nitrated (sample evaporated with nitric acid present) dissolved solids would be the maximum aliquot size for that sample which should be evaporated and counted for gross alpha activity.

4.4 The largest sample aliquot that should be counted for gross beta activity is that size aliquot which gives a solids density thickness of $10mg/cm^2$ in the counting planchet. For a 2in diameter counting planchet, an aliquot containing 200mg of nitrated dissolved solids would be the maximum aliquot size for that sample which should be evaporated and counted for gross beta activity.

4.5 In some areas of the country, the nitrated water solids will not remain at a constant mass after being brought to dryness. Those types of water samples need to be heated to a dull red heat for a few minutes to convert the salts to oxides. Sample masses are then usually sufficiently stable to give consistent counting rates, and a correct counting efficiency can then be assigned. Some radioactive species, such as the cesium radioisotopes, may be lost when samples are heated to a dull red color. Such losses are limitations of the method.

4.6 This method is applicable to the measurement of alpha emitters having energies above 3.9MeV and beta emitters having maximum energies above 0.1MeV. Lower detection efficiency for emitters such as ^{99}Tc or ^{63}Ni will lead to an underestimation of the actual isotopic concentration for these species, if present in the sample.

4.7 Non-uniform distribution of the sample residue in the counting planchet interferes with the accuracy and precision of the method.

4.8 Moisture absorbed by the sample residue may interfere because it may change the sample residue mass affecting self-absorption characteristics. While the presence of hydrated solids is non-problematic to counting, residue mass should be stable enough to allow application of self-absorption corrections which meet the precision and accuracy requirements of the work being performed.

4.9 The minimum detectable concentration (MDC), applicable to this method, depends on sample size, counting system characteristics, background, and counting time. The formula for calculating an MDC is derived from ANSI N42.23 (rev. February 10, 1995). Due to industry-wide practice, and the need to demonstrate compliance with regulatory requirements, the "sample specific MDC" is routinely calculated and often reported in conjunction with sample activity and total propagated uncertainty values. The sample specific MDC makes a priori assumptions regarding the variance in the background count rate, but also reflects the actual conditions employed for the analysis, including aliquot, detection efficiency, solids residue, and count time. The routine solids digestion procedure will not completely remove radioactive elements from silica or absorbed radioactive materials. More aggressive digestion procedures may be necessary if determination of matrix constituents is required (see SOP 721).

4.10 Non-aqueous liquid, non-soil solids, and samples with high organic content may not be amenable to this procedure.

4.11 The presence of significant quantities of chloride salts in aqueous samples may lead to corrosion of the stainless steel planchet if the solution is not fully converted to a nitrate system prior to transfer. Repeated additions of concentrated nitric acid followed by evaporation are usually sufficient to address the problem.

4.12 Sample solution should be slowly evaporated to near dryness (≤5mL). Avoid evaporating the sample to complete or hard dryness that could lead to analyte loss resulting from poorly soluble residues in the beaker.

5. APPARATUS AND MATERIALS

5.1 2in stainless steel ringed planchets. Prior to use, the planchets are placed in a beaker and muffled at approximately 550°C for a minimum of 2 hours. This is done as a cleaning procedure.

5.2 pipettors, Eppendorf™ or equivalent

5.3 centrifuge tubes with caps, plastic, 50mL

5.4 polypropylene beakers, 250mL

5.5 balance, top loading, 0.1g sensitivity

5.6 balance, analytical, 0.1mg sensitivity

5.7 pleated filter paper

5.8 plastic funnels

5.9 hot plate

5.10 wash bottles

5.11 drying oven

5.12 graduated cylinders

5.13 desiccator

5.14 Meeker burner

5.15 tongs

5.16 glass rods

5.17 rubber policeman

5.18 disposable transfer pipettes, plastic, ~3mL and disposable pipette tips

5.19 filtering apparatus and 47mm glass fiber filters

6. REAGENTS - TLV and other hazard information may also be given here. Any chemical with a TLV below 50ppm must be worked with in a laboratory fume hood. The absence of this information does not imply that the substance is non-hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Deionized (DI) water, ASTM Type II, minimum

6.2 Nitric acid, concentrated, 16N, ACS grade
TLV = 2 ppm (TWA) Irritant, corrosive

6.3 Nitric acid, 8N: Cautiously add 500mL of reagent grade concentrated HNO_3 to approximately 400mL of DI water and dilute to 1.0L.

6.4 Nitric acid, 1N: Cautiously add 62.5mL of reagent grade concentrated HNO_3 to approximately 500mL of DI water and dilute to 1.0L.

6.5 ^{90}Sr spiking solution, NIST-traceable. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.6 ^{241}Am spiking solution, NIST-traceable. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.7 ^{230}Th spiking solution, NIST-traceable. A second source should be used, independent of the source used for calibration (*required* for DOD samples per LIMS program specification).

6.8 Modified USGS Simulated River Water Reagent (salt solution): Dissolve 3.72g $MgSO_4$, 3.10g NaCl, and 3.24g $CaCl_2$ in 200mL 1N HNO_3.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 Although the client is responsible for conducting the sampling process, it is emphasized that water samples be collected in a manner that addresses the considerations discussed in EPA 900.0 Section Three or Chapter Nine of EPA SW-846, as appropriate. Also, it is recommended that samples be preserved at the time of collection by adding enough 1N HNO_3 to the sample to bring it to pH 2 (15mL of 1N HNO_3 per liter of sample is usually sufficient). If water samples are collected without preservation, they should be brought to the laboratory within 5 days, and then be preserved and held in the original container for a minimum of 24 hours before analysis or transfer of the sample.

7.2 The container should be plastic rather than glass to prevent loss due to breakage during transportation and handling.

7.3 SW-846 specifies the holding time for Method 9310 as 180 days.

8. PROCEDURE

8.1 PREPARATION OF CALIBRATION STANDARDS

8.1.1 EFFICIENCY CALIBRATIONS

8.1.1.1 Gross Alpha Efficiency Planchets: Spike five ringed stainless steel planchets directly with ~8,000 to 15,000 dpm each of NIST-traceable ^{241}Am. Submit to the Radiochemistry Instrument Group with appropriate documentation.

8.1.1.2 Gross Alpha Efficiency Planchets for Drinking Water Protocols: Spike five ringed stainless steel planchets directly with ~8,000 to 15,000 dpm each of NIST-traceable ^{230}Th. Submit to the Radiochemistry Instrument Group with appropriate documentation.

8.1.1.3 Gross Beta Efficiency Planchets: Spike five ringed stainless steel planchets directly with ~8,000 to 15,000 dpm each of NIST-traceable ^{90}Sr. Submit to the Radiochemistry Instrument Group with appropriate documentation.

NOTE: If the standard matrix is HCl, convert to the nitrate system before planchetting to avoid corroding the planchet.

8.1.2 MASS ATTENUATION CALIBRATION

8.1.2.1 Supply the Radiochemistry Instrument Group with a series of planchets containing a range of mass from ~10mg to ~145mg, including a duplicate for each mass. The

approximate target masses in mg are: 10, 25, 40, 55, 70, 85, 100, 115, 130, and 145.

NOTE: A separate set of planchets must be prepared for gross alpha, gross alpha for drinking water protocol, and for gross beta calibrations

8.1.2.2 Label and tare weigh 10 stainless steel ringed planchets. Label a plastic disposable cup for each sample.

8.1.2.3 Add the appropriate amount of Simulated River Water Reagent to give the target mass to each cup (1mL of reagent typically gives 35-40mg dried mass on the planchet).

8.1.2.4 Spike each sample cup with ~8,000 to ~15,000dpm of the appropriate NIST-traceable radionuclide (routinely ^{241}Am for gross alpha and ^{90}Sr for gross beta).

8.1.2.5 Add ~5mL of concentrated nitric acid to each to convert chloride salts to nitrate salts.

8.1.2.6 Take to near dryness on a steam bath.

8.1.2.7 Transfer with at least three rinses of 1N nitric acid to a tared stainless steel planchet.

8.1.2.8 Dry on a hot plate set at 3.

8.1.2.9 Once dry, continue heating for 20-30 minutes with the hot plate set at 10.

8.1.2.10 Cool in a desiccator.

8.1.2.11 Weigh on an analytical balance and record the data on a benchsheet

8.1.2.12 Submit to the Radiochemistry Instrument Group with the appropriate documentation, where the planchets will be analyzed per SOP 724.

8.2 CALIBRATION PROCEDURES

8.2.1 Efficiency and Attenuation Calibration: Analysis systems will be calibrated at least annually or as indicated by routine instrument response check results.

8.2.2 Gross Alpha measurements are routinely referenced to ^{241}Am.

8.2.3 Gross Beta measurements are routinely referenced to ^{90}Sr/Y.

8.2.4 EPA drinking water compliance testing for gross alpha requires that the gross alpha measurement be referenced to ^{230}Th instead of ^{241}Am. (EPA 816-D-00-002, December 2000).

8.2.5 All standards used to develop efficiency and attenuation curves shall be traceable to the National Institute for Standards and Technology (NIST).

8.2.6 Detectors must be calibrated to obtain the ratio of net count rate to disintegration rate. ^{241}Am has higher alpha particle energy (5.49MeV) than those emitted by the naturally occurring uranium and ^{226}Ra radionuclides, but is close to the energy of the alpha particles emitted by naturally occurring ^{228}Th and ^{224}Ra.

8.2.7 ^{90}Sr/Y and ^{137}Cs have both been used quite extensively as standards for gross beta activity. Cesium, however, may become volatile at elevated temperatures (above 450ºC) and may volatilize at temperatures observed while flaming a sample containing hygroscopic salts.

8.2.8 Each instrument used for the analysis of gross alpha and beta shall be calibrated to correct for alpha and beta sample self-absorption (residue mass vs. zero mass normalized efficiency). Mass attenuation curves will be prepared for this purpose. The mass stable standards should be alpha or beta counted (as appropriate) until 10,000 counts have been accumulated. A single set of standards for each nuclide (^{241}Am, ^{230}Th, and ^{90}Sr/Yis suitable for calibration of instruments and re-verification of curves, whenever needed.

8.2.9 Data acquisition is conducted according to instrument manufacturer instructions.

8.2.10 Calculations for attenuation and crosstalk are defined in Section 9. Meticulously document steps taken to produce calibration data.

8.3 PROCEDURE FOR WATERS

8.3.1 Verify with pH paper that the sample has been properly preserved to a pH <2. Record the pH on the sample condition form (Form 631).

8.3.1.1 If the pH is > 2, notify the appropriate Project Manger to determine if further analysis will be acceptable to the client and whether the sample should be (re-)preserved prior to

continuing with analysis. If the Project Manager determines that the situation is acceptable to the client's DQOs, acidify to pH<2 with conc. HNO_3. Wait for two (2) minutes and retest pH. Record the acid addition and the final pH on a Quality Assurance Summary Sheet (QASS) or NCR form (Form 313), as appropriate. The date and time of acidification must be noted.

8.3.1.2 Return the sample to storage for at least 24 hours before proceeding. Record the beginning date and time on a Sample Condition Form. If twenty-four (24) hours causes a scheduling difficulty, notify the Project Manager to determine if a deviation from this requirement is acceptable. Document any deviations thoroughly on a QASS that accompanies the project file.

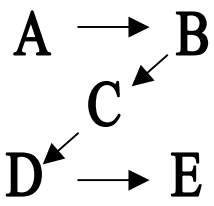
8.3.1.3 When resuming the analysis, record the date/time of resumption on the Sample Condition form. Also, calculate and record the number of elapsed hours since acidification.

8.3.2 To determine the mass of solids in 10mL of the sample, proceed as follows:

8.3.2.1 Place all planchets to be used onto a steel desiccator tray. Each space on the tray is numbered and that number corresponds with the sample ID on the mass benchsheet.

8.3.2.2 Label and tare a planchet on an analytical balance to nearest 0.1mg. Record the mass in the appropriate column on the mass benchsheet.

8.3.2.3 Place the planchets in the following order on the hotplate:



Where 'A' corresponds to the first planchet, 'B' to the second, and so on.

8.3.2.4 Shake the sample well and pipet 10.0mL of sample into the labeled, tared planchet using a calibrated pipettor. Place on

hotplate set at 3.

8.3.2.5 When dry, turn the hotplate setting to 10 and maintain at this heat for 20-30 minutes.

8.3.2.6 Transfer the planchets to the steel tray, making sure that each sample is returned to its proper numbered space, and place the tray directly in the desiccator to cool. Be sure to note which numbered space in the pan corresponds to which sample on the benchsheet.

8.3.2.7 When the planchets are cool, weigh each one to the nearest ±0.1mg. Record the mass in the appropriate column on the mass benchsheet.

8.3.2.8 The solid mass and volume aliquot will be calculated using Equation 1 (shown below), and the results will be shown in the respective cells in the "Init Mass" and "Sugg. Alq" columns in the Mass section of the electronic benchsheet. The "Sugg. Alq" column shows the calculated aliquot plus the 10mL used for aliquot determination as final aliquot used. (V is the volume of the spot check used, in mL and W is the mass calculated in the "Init Mass" column, in g.)

$$V(g) = \frac{0.75}{W(g)}$$

EQUATION 1

8.3.2.9 If the planchet mass is unstable, flame the 10mL planchet and recalculate. If that is done, the resultant sample planchet needs to be flamed also.

8.3.2.10 The default maximum aliquot size for water samples is 200mL. If the calculated aliquot volume is greater than 200mL, use the default aliquot size unless DQOs demand a higher aliquot to achieve required detection limits.

8.3.2.11 If the predicted final residue mass for a sample is estimated to be below 20 milligrams (1.0mg residue for 10mL spot check), simulated river water reagent is added, in Step 8.3.4 below, to provide between 20 and 100 milligrams equivalent of final residue.

8.3.2.12 1mL of simulated river water reagent is added to provide

between 20 and 100 milligrams equivalent of final residue for each of the batch QC samples (Method Blank and LCS).

8.3.3 Measure the calculated sample aliquot from a well-shaken sample container into a labeled disposable poly beaker. If DQOs demand the use of a larger sample size, a glass beaker may be used and taken to near dryness on a hotplate.

NOTE: The same planchet will be used for the sample as was used for the determination of the residue. Thus only 190 additional mL would be necessary to make up the final volume to 200mL.

8.3.4 Add the appropriate spike and amount of spike per Section 10. Add simulated river water reagent to the blank, LCS, and any samples that require it (see Section 8.3.2.11). Typically, 1mL of simulated river water reagent is added for waters analysis to produce 35-40mg of nitrated solids on the planchet.

8.3.5 Add concentrated HNO_3 in the ratio of 1/10th the sample volume. (e.g., 19mL acid per 190mL of sample). The samples may be diluted to a single volume (e.g., to the largest volume of any sample in the batch).

8.3.6 Slowly evaporate the sample solution to near dryness (≤5mL). Avoid evaporating the sample to complete or hard dryness that could lead to analyte loss resulting from poorly soluble residues in the beaker.

8.3.7 If significant concentrations of chlorides are suspected to be present, a second 5mL portion of concentrated nitric acid may be added to complete conversion of the sample to a nitrate system. The sample is once again evaporated to near dryness.

8.3.8 Using a disposable plastic transfer pipet, quantitatively transfer the solution to the labeled stainless steel planchet used for the 10mL aliquot determination. If solid residues are present, it may be necessary to use a rubber policeman to effect the transfer.

NOTE: Any rubber policeman that shows signs of deterioration should not be used.

8.3.9 Rinse the beaker with three successive 2mL portions of 1N HNO_3 transferring each of the rinses to the appropriate planchet on a hotplate in a fume hood. If the planchet cannot hold all rinses, add them as planchet volume is evaporated in the next Step.

8.3.10 Take the solution to dryness as in Step 8.3.6. Avoid excess heating that can cause spattering or boiling during drying. Turn the hotplate setting to highest and maintain at this heat for 20-30 minutes.

8.3.11 Flame the planchet if the 10mL planchet was flamed.

NOTE: Be sure the sample is well distributed on the planchet. This will assure proper counting efficiency.

8.3.12 When all the planchets are dry, remove and cool in a desiccator for at least 30 minutes. Note the time and date of the desiccation in the Notes section on the benchsheet.

8.3.13 Remove the samples from the desiccator and weigh them on an analytical balance. Record the mass to the nearest 0.1mg in the designated cell mass benchsheet. If the planchet mass is unstable on the balance and noticeably gains weight proceed with Step 8.3.15.

8.3.14 Let planchet stand outside of the desiccator for 15 minutes. If the samples are not noticeably hygroscopic, they are ready for counting; (if they are hygroscopic, proceed with Step 8.3.15.

8.3.15 If the samples demonstrate hygroscopicity, cautiously flame planchet to dull redness over a Meeker burner. Avoid popping and spattering. Maintain heat for at least one minute. Cool in a desiccator. Reweigh to nearest 0.1mg and reenter the new mass in the electronic benchsheet. Submit the planchets and any necessary documentation to the Radiochemistry Instrument Group. The Radiochemistry Instrument Group will analyze and ultimately dispose of the planchets in a manner described in SOP 724.

8.3.16 Store the samples in a desiccator for at least 72 hours before counting. Where EPA methodologies are not required, such as for non-water matrices, etc., the samples should be desiccated overnight or until they are ready for counting.

8.4 PROCEDURE FOR SOLIDS

8.4.1 Analysis is routinely reported on a dry weight basis. The use of oven dried solid samples allow direct calculation of aliquot mass without the need to correct for sample moisture content. Rocky, coarse or non-homogeneous solids should be milled or ground to pass a No. 4 sieve before taking an aliquot for analysis. See SOP 721 for soil preparation procedure.

8.4.2 Weigh 3g of solid sample to the nearest 0.1g into a labeled 50mL centrifuge tube.

8.4.3 Add the appropriate spike and amount of spike per Section 10. Add 2mL of simulated river water reagent to the blank and LCS.

NOTE: It is important protocol to always add QC spikes *before* any chemical treatments applied during sample processing.

8.4.4 Slowly add 8N HNO_3 to give a total volume of 30mL. Be sure to account for the volume of salt solution and spiking solutions. (i.e., the LCS would receive only 26mL of nitric acid if it already contains 2mL of salt solution and 2mL of spiking solution). Some samples may react vigorously with the acid, so it may be necessary to add the acid in small increments.

8.4.5 Mix to break up clumps.

8.4.6 Heat on a steam bath with caps on loosely for (1) one hour. Allow samples to cool and mix by vortexing.

8.4.7 Centrifuge for 10 minutes and filter the supernatant using VWR Grade 313 pleated paper, or equivalent, into a new, labeled centrifuge tube.

8.4.8 Determine the mass of solids as in Section 8.3.3, except use 5mL instead of 10mL. **The planchet should be flamed for all solid samples unless otherwise indicated by applicable DQO's or the client.** Calculate and record the required aliquot volume of solution using Equation 2 shown below:

$$V(mL) = \frac{0.375}{W(g)}$$

EQUATION 2

8.4.8.1 If the calculated aliquot exceeds 20mL, use a 20mL aliquot. Aliquots should be in increments of 5 up to 20mL. Directly transfer the additional aliquot to the planchet used for the 5mL aliquot. Proceed with Step 8.4.9.

8.4.8.2 If the mass of the residue from the 5mL aliquot is more than 100mg, calculate the required amount less than 5mL. Aliquots should be calculated in increments of 1mL (unless an aliquot smaller than 1mL is appropriate). Directly transfer the calculated aliquot to a clean, labeled, and tared

planchet.

8.4.9 Dry the sample on a hot plate set to 3. Once the sample is dry, turn the hot plate up to 10 for 20-30 minutes. After the sample has been heated for 20-30 minutes, cautiously flame the planchet to a dull redness over a Meeker burner. Avoid popping and spattering. Maintain heat for at least one minute.

8.4.10 When all planchets are dry, remove and cool in a desiccator for at least 30 minutes. Note the date and time of the desiccation in the Notes section on the benchsheet. Also, in the Notes section, note that all samples were flamed.

8.4.11 Remove the samples from the desiccator and weigh the planchets on an analytical balance. Record the mass to the nearest 0.1mg in the designated cell of the mass benchsheet.

8.4.12 Submit the planchets and any necessary documentation to the Radiochemistry Instrument Group. The Radiochemistry Instrument Group will analyze and ultimately dispose of the planchets in a manner described in SOP 724. Store the planchets in a desiccator at least overnight or until they are ready for counting. Be sure to note the date and time the samples were placed in the desiccator on the benchsheet.

8.5 PROCEDURE FOR SUSPENDED SOLIDS

8.5.1 Label a 2in stainless steel planchet for each sample. Tare each planchet with a 47mm glass fiber filter. Record the tare weights on a QASS.

8.5.2 Filter a known volume of aqueous sample through the tared glass fiber filter. Record the volume of sample filtered on the benchsheet. Return the filter to the labeled planchet.

8.5.3 Reweigh the planchet/filter and record on the QASS.

NOTE: If the samples that have been submitted are already filtered on a glass fiber filter, the analyst may omit Section 8.5.2 and 8.5.3 and enter the procedure at this point.

8.5.4 Subtract the tare weight in Section 8.5.1 from the gross weight in Section 8.5.3 to determine the mass of suspended solids. If results are requested on a dry weight basis, the filters must be dried overnight prior to re-weighing in Section 8.5.3. Samples yielding over 5 grams of suspended material should be scraped down gently with a spatula until the mass is approximately 5 grams. Record the final mass of suspended solids in the sample weight column of the soils benchsheet.

8.5.5 The sample preparation now proceeds as a solid in Section 8.4. The entire sample on the filter, including the filter, is transferred to the centrifuge tube in Section 8.4.1. Submit the QASS with the benchsheet and note on the benchsheet that the analysis is for suspended solids rather than solids.

9. CALCULATIONS

9.1 Calculate the mass of solid deposited by subtracting the tare weight (g) from the gross weight (g). This gives the solids deposit weight in grams. To convert to mg, multiply the grams by 1000.

9.2 Calculate the alpha and beta activity, counting uncertainty, TPU, MDC and crosstalk factors in activity units per aliquot unit following SOP 708.

9.2.1 TPU FACTORS. As defined in SOP 708, the following one-sigma preparation uncertainty factors should be applied during the final reporting stage of the analysis as a component of the Total Propagated Uncertainty (TPU):

Water samples require a preparation uncertainty factor of 0.0565. This is based on one gross aliquoting (sample homogeneity), one quantitative transfer, one pipetting, two mass measurements and one volumetric measurement. See the following equation:

$$0.0565 = \sqrt{0.05^2 + 0.025^2 + 0.004^2 + 0.003^2 + 0.003^2 + 0.006^2}$$

Solid samples require a preparation uncertainty factor of 0.0567. This is based on one gross aliquoting (sample homogeneity), one quantitative transfer, two pipetting, two mass measurements, and one reagent addition. See the following equation:

$$0.0567 = \sqrt{0.05^2 + 0.025^2 + 0.004^2 + 0.004^2 + 0.003^2 + 0.003^2 + 0.006^2}$$

In practice, these two TPU factors are statistically equivalent. To simplify the data reporting procedure, the greater of the two (0.0567) may be used for both matrices.

9.2.2 Calculate the alpha and beta activity according to SOP 708, except for solids, the final sample aliquot is calculated as:

$$\text{Final Sample Aliquot} = \frac{\text{SampMass} * \%\text{Sol} * \text{AnalAliqVol}}{\text{DigTotVol}}$$

where:

SampMass = Initial Sample mass taken for digestion

%**Sol** = percent solids for sample

AnalAliqVol = Volume of digestate taken for analysis

DigTotVol = Total Volume of Digestate

10. QUALITY CONTROL

10.1 Method blanks will be run at a frequency of five-percent (i.e., one per 20 field samples) with a minimum of one per batch. Method blanks for water consist of deionized (DI) water and match the largest sample volume used. Nitric acid is added to the method blank, as it is to the samples, prior to evaporation. Method blanks for solids are 2mL of salt solution brought up to 30mL with 8N nitric acid.

10.2 Laboratory Control Samples (LCS) will be run at a frequency of five-percent with a minimum of one per batch. Known quantities of NIST-traceable alpha (e.g., ^{230}Th for Drinking Water Compliance using Method EPA 900.0 and ^{241}Am for any others) and beta (^{90}Sr/Y) emitters are spiked into DI water at the start of the procedures. The spiking levels are determined according to specific data quality objectives for the work being performed, but will generally be 5-50 times the required minimum detectable concentration for the respective analyte or at an activity level roughly equivalent to levels expected to be observed in the samples. The volume for the LCS is as large as the largest sample volume. The LCS consists of deionized water at the correct volume and the appropriate spike and spike volume. The LCS for solids consists of 2mL of salt, the appropriate spikes and spike volume, brought up to 30mL with 8N nitric acid.

10.3 Duplicate samples will be run at a frequency of ten percent with a minimum of one per batch. Client requested duplicate analyses shall be run as required and may count as the QC replicates for that batch.

10.4 Matrix Spike (MS) will be run at a frequency of five-percent with a minimum of one per batch. Known quantities of NIST-traceable alpha (i.e., ^{230}Th for Drinking Water Compliance using Method EPA 900.0 or ^{241}Am for any others) and beta (^{90}Sr/Y) emitters are spiked into a representative sample at the start of the procedures. The spiking levels are generally 5-50 times the analyte activity level expected to be observed in the samples.

10.5 The LIMS Standards Database should be consulted for the identification of the proper ^{241}Am or ^{230}Th, and ^{90}Sr working standards and spike activities.

10.6 Method blanks for air filter and suspended solids samples may be prepared to reflect the proper background contribution of the filter medium used for analysis. Method blanks for suspended solids consist of clean glass fiber filter medium

from the same batch used for capturing the solids. Air filter blanks, if supplied by the client, may be used as a "reagent" blank. Otherwise, a blank planchet is usually the best representation of the sampling medium background.

10.7 LCS for filter-mounted samples consists of a planchet containing a known amount of standard ^{241}Am and ^{90}Sr.

11. DEVIATIONS FROM METHOD

This SOP is substantially compliant with SW-846 Method 9310 and EPA Method 900.0. The following information states deviations from and distinctions between the two reference methods as well as other regulatory issues that should be considered.

11.1 In this procedure, alpha and beta activities are determined simultaneously on the beta plateau. Crosstalk calibration of the proportional counter allows for correction of the contribution of "crosstalk" into respective opposing channels (beta-to-alpha and alpha-to-beta). Methods 9310 and 900.0 instruct the counting of alpha and beta at their respective plateaus. By setting the alpha/beta discriminators such that there is negligible contribution of beta events to the alpha energy region, there is no advantage for counting on the respective voltage plateaus. However, there are significant disadvantages to counting on the two plateaus independently: (1) The count time required immediately doubles and (2) the alpha efficiency is lower at the alpha plateau such that analysis time may need to be increased more to reach the same required detection limit.

11.2 This procedure has been modified to accommodate matrices other than drinking waters. The procedure treats solubilized radioactive constituents in digestate or leachate solutions as a water sample.

11.3 Implementation Guidance for Radionuclides (December 2000) indicates that ^{230}Th is to be used for purposes of demonstrating compliance with the standard. Unless otherwise specified, all other results are completed using ^{241}Am as the reference nuclide for gross alpha.

11.4 SW-846 defines sampling and preservation protocols that may diverge from the requirements of Method 900.0. The sampling process is completed prior to receipt and processing of water samples by the laboratory and does not directly affect laboratory operations. SW-846 does specify a holding time of 180 days. The SOP references both protocols that are to be used to ensure compliance with applicable regulation.

11.5 A second deviation between the two methods is the Method 900.0 requirement that a minimum 10,000cts/detector and standard be accumulated during the absorption curve calibration. This SOP requires that 10,000 counts be accumulated, satisfying both methods.

11.6 Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike recovery acceptance criteria shall be ±20%, irrespective of the laboratory's internally derived acceptance criteria.

11.7 Methods 9310 and 900.0 are otherwise substantially identical. This SOP meets or exceeds the requirements of the methods for the analysis of water samples.

12. SAFETY HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Safety glasses, lab coats and gloves should be worn in the laboratory at all times.

12.1.2 Use care when handling strong acids (e.g., HNO_3, HCl, etc.). Work only in a fume hood with adequate ventilation and wear appropriate eye, face, and body protection.

12.2 WASTE DISPOSAL

12.2.1 The Gross Alpha/Beta analytical process liquid effluent, from the solid procedure, has been determined to not be hazardous other than corrosivity. This material may discharged into the Paragon wastewater treatment facility. Here the solution will be neutralized prior to discharge and the activity will be monitored to ensure compliance with Colorado Rules and Regulations pertaining to Radiation Control Part 4 regarding discharges to sanitary discharges to sanitary sewers.

12.2.2 Solids and filtered residues should be accumulated in a 2 liter wide-mouth container. The accumulated solids may be disposed of in the proper solids waste stream when it is determined that the pH is between 5 and 12 units. If the pH of the accumulated solids is determined to be <pH 5, the pH should be adjusted to between 5-12 units using NaOH solution. All free liquids must be drained prior to transfer to the appropriate waste accumulation container. Consult with the Heath and Safety Coordinator or with the lab Supervisor for proper procedures for testing and disposing of solid wastes.

DOCUMENT REVISION HISTORY

2/27/07: Slight title change for rev18 (SW-846 METHOD 9310 to SW9310). Added DOCUMENT REVISION HISTORY Section and Forms.

8/31/07: Added LIMS program specification language (RESPONSIBILITIES). Clarified use of second independent source for spiking (SECTION 6). Updated sample hold in original container from 16 to 24hrs when pH adjusted, for consistency with updated CFR metals requirement (Federal Register, 3/26/07, Volume 72, Number 57), Sections 7.1 and 8.3.1.2. Added note, 8.4.3, that it is important protocol to add spikes before any chemical processing. Removed activity calculations from SECTION 9 and referenced SOP 708 instead.

STANDARD OPERATING PROCEDURE 703 REVISION 8

TITLE: SAMPLE PRESCREENING

FORMS: 214, 796 **use current iteration**

APPROVED BY:

TECHNICAL MANAGER Renee Hallegos DATE 7/21/08
QUALITY ASSURANCE MANAGER Deb Schert DATE 7/20/08
LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: Rev0, 9/18/92; Rev1, PCN #40, 12/13/93; Rev2, PCN #338, 1/24/95; Rev3, 10/08/99; Rev4, 3/17/00; Rev5, 4/26/02; Rev6, 10/3/03 and 2/9/05 (no revisions); Rev7, 8/18/06; Rev8, 7/17/08.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the semi-quantitative determination (i.e., prescreening) of non-volatile gross alpha and beta activity in samples. Prescreen results enable the Radiation Safety Officer (RSO) to determine what precautions are necessary in order to process the samples in the laboratory safely.

2. SUMMARY

2.1 The RSO develops protocols for deciding which samples need to be prescreened. Where sufficient prior knowledge regarding a client's samples exists, a determination of "always prescreen" or "prescreening not required" may be made in advance. Where previous knowledge about a client's samples is insufficient, the RSO uses prescreen results to determine what precautions are necessary for processing the samples in a manner that is safe to laboratory personnel.

If it is known in advance that incoming samples require prescreening, the Project Manager (PM) can use an Incoming Project Notice Form (Form 214, or equivalent) to inform Sample Control and other laboratory staff before the samples arrive. Samples that need to be prescreened may also be determined as a result of the sample login survey performed by Sample Control staff upon sample receipt (SOP 202).

Regardless of which mechanism triggers the prescreen test, Sample Control staff are responsible for notifying the RSO or designee when prescreening is required.

2.2 Liquid samples are prepared for prescreening by drying an aliquot of liquid on a planchet. The mass of solid residue is determined, and the planchet is counted in a proportional counter. Solid samples are prepared for prescreening by transferring a known mass (approximately 100mg) to a stainless steel planchet, adding nitric acid, then evaporating the planchet's contents to dryness on a hotplate. If a high degree of sample inhomogeneity is expected (consult RSO or

Radiochemistry Supervisor), the samples may alternately be leached with nitric acid, and after the suspended solids are allowed to settle, an aliquot of the resulting leachate may be tested as previously described for liquids. The prescreening of other sample matrices, such as non-aqueous liquids, must be handled on a case-by-case basis.

2.3 Gross alpha prescreen measurements are referenced to ^{241}Am; gross beta prescreen measurements are referenced to ^{90}Sr/Y.

3. RESPONSIBILITIES

3.1 This procedure is to be performed only by personnel who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review or the successful completion of precision and accuracy tests performed.

3.2 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. All personnel who work with samples involving this method are responsible for noting any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Emitters that are volatile in hot acidic solution are not amenable to measurement by this method.

5. APPARATUS

5.1 Low-level gas flow proportional counter

5.2 Stainless steel planchets, two inch, ringed bottom

5.3 Beaker, 50 or 100 mL, Pyrex™

5.4 Pipettors, Eppendorf™ or equivalent, 1 and 5 mL, with disposable tips

5.5 Transfer pipets, disposable

5.6 Balance, analytical, 0.0001g sensitivity

5.7 Petri dishes

5.8 Hot plate and steam bath

5.9 Infrared lamp

5.10 Tweezers

5.11 Tongue depressors

5.12 Centrifuge tube, 50mL

5.13 Rubber policeman

5.14 Centrifuge

6. REAGENTS

6.1 Deionized (DI) water, obtainable from the laboratory's deionized water system

6.2 Nitric acid (HNO_3), concentrated. TLV = 2ppm (TWA); irritant, corrosive

6.3 Nitric acid, 8N: Cautiously add 500mL conc. HNO_3 to approximately 400mL DI water, dilute to 1 L. TLV = 2ppm (TWA); irritant, corrosive

6.4 Nitric acid, 3N: Cautiously add 190mL conc. HNO_3 to approximately 700mL DI water, dilute to 1 L. TLV = 2ppm (TWA); irritant, corrosive

6.5 ^{241}Am spiking solution, NIST-traceable, independent second source

6.6 ^{90}Sr spiking solution, NIST-traceable, independent second source

Note: All spiking solutions are from a source that is different than that used for calibration.

6.7 Modified USGS Simulated River Water Reagent (salt solution): Dissolve 3.72g $MgSO_4$, 3.10g NaCl, and 3.24g $CaCl_2$ in 200mL 1N HNO_3.

6.8 Anhydrous calcium chloride ($CaCO_4$) or indicating Drierite™, for desiccator

7. SAMPLE COLLECTION, PRESERVATION, AND HANDLING

Store samples to be prescreened in the Sample Control walk-in cooler RU #20. Sample containers may be taken to the Prescreen Lab for aliquotting, but must be returned to the walk-in cooler as soon as the aliquots are obtained.

NOTE: Samples designated for prescreening are NOT to be prepared in normal sample preparation areas without specific permission from a Radiochemistry Supervisor.

8. PROCEDURE

8.1 GROSS SCREEN PREPARATION WORKSHEET

Initiate a Gross Screen Preparation Worksheet (Form 796) for each group of samples to be prescreened. Use the information on the chain of custody (COC) or workorder to fill out the Sample ID. Locate one of the containers for each sample and transfer them to the Prescreen Lab. Return these samples to the cooler as soon as the aliquots have been obtained.

8.2 PREPARATION OF LIQUIDS FOR PRESCREENING

8.2.1 Label and tare a clean, dry planchet for each sample to be prescreened. Record the weight on the worksheet (Form 796) to the nearest 0.0001g. Prepare quality control (QC) samples per Section 9.

8.2.2 Use a calibrated pipettor (SOP 321) with a clean pipet tip to acquire a 10mL aliquot of sample from the container.

NOTE: A reduced aliquot may be taken for samples with expected activities above 5000cpm. The RSO will determine when a reduced aliquot is used. Also, aliquot sizes should be decreased for samples with significant quantities of suspended solids.

8.2.3 If the sample is unpreserved, or preserved with anything other than HCl, proceed to Step 8.2.5.

8.2.4 If the sample has been preserved with HCl, it will corrode the planchet. Convert to a nitrate system as follows:

8.2.4.1 Place the aliquot (Step 8.2.2 above), in a labeled 50mL beaker and add 5mL conc. HNO_3.

8.2.4.2 Slowly evaporate to near dryness on a hot plate, avoiding spattering.

8.2.4.3 Add 1mL of conc. HNO_3 to the residue and repeat evaporation.

8.2.4.4 Dissolve the residue in 1-2mL of 3N HNO_3, slurry any undissolved solids.

8.2.4.5 Quantitatively transfer the beaker's contents to a labeled, tared planchet using 3N HNO_3. Rinse the beaker 3 times with small portions (≈1mL) of 3N HNO_3. Transfer all rinses to the planchet. Use a rubber policeman to help transfer solids.

8.2.5 Add the sample to the planchet and dry the planchet on a hot plate.

8.2.6 Remove the planchet and allow to cool for about 15 minutes.

8.2.7 Weigh the planchet and record the weight on the worksheet. This weight will later be used in determining the solids present during counting.

NOTE: The amount of solids should be within the range of the instrument calibration, so as to reduce self-absorption losses in activity measurements. If the solids are greater than the range of the instrument calibration, a proportionately smaller aliquot will have to be processed as above per Steps 8.2.1.

The proportionate amount of reduced aliquot to use may be estimated using the following equation:

$$V\ (mL) = \frac{0.95}{W\ (g)}$$

where:

V (mL) = volume of reduced aliquot
W (g) = mass of solids present in the original 10mL aliquot

Note that if a 1mL aliquot was originally used, divide the V(mL) in the equation above by ten to get the correct new aliquot.

8.2.8 Transfer the planchets to a clean petri dish.

8.2.9 Proceed to Section 8.5.

NOTE: Prepare oils as described in section 8.3 for solids. Be aware to avoid spattering. Due to the nature of the matrix (oil), extra drying time may be required. Consult Supervisor with any questions.

8.3 PREPARATION OF SOLIDS FOR PRESCREENING (DIRECT DEPOSITION)

8.3.1 Label and tare a clean, dry planchet for each sample to be prescreened. Record the weight on the worksheet (Form 796) to the nearest 0.0001g. Prepare QC samples per Section 9.

8.3.2 Transfer approximately 100mg of sample directly to the tared planchet. Record the mass to the nearest 0.0001g on the benchsheet.

NOTE: Some samples may contain standing water at the top of the container. Homogenize these samples thoroughly (i.e., mix-in the water) before obtaining an aliquot.

8.3.3 Place the planchet on a hotplate. Set the heat to low-medium. Carefully add 5mL conc. HNO_3.

8.3.4 Slowly evaporate to dryness, avoiding spattering.

8.3.5 Remove the planchet from the hotplate and allow to cool for about 15 minutes.

8.3.6 Weigh the planchet and record the weight on the worksheet. This weight will later be used in determining the solids present during counting. **See NOTE, Step 8.2.7 above.**

8.3.7 Transfer the planchets to a clean petri dish.

8.3.8 Proceed to Section 8.5.

8.4 PREPARATION OF SOLIDS FOR PRESCREENING (LEACHING) - **Consult with a Radiochemistry Supervisor before preparing samples in this manner!**

8.4.1 Weigh 2 grams or 0.5 grams (see note below) of solid, on an analytical balance whose calibration has been previously verified (SOP 305), into a 50mL centrifuge tube. Record the weight on the worksheet (Form 796).

NOTE: Two (2) grams of sample should be aliquoted for samples with expected activities less than 5000cpm. An aliquot of 0.5 grams or less, may be used for samples with higher expected activities.

8.4.2 Add 8mL concentrated nitric acid to the centrifuge tube.

8.4.3 Leach the sample fifteen minutes on a steam bath.

8.4.4 Remove the sample from the steam bath and allow to cool.

8.4.5 Add 17mL of 8N HNO_3 to bring the digest volume to 25mL. Swirl sample to mix completely.

8.4.6 Centrifuge the samples at 3500rpm for 15 minutes.

8.4.7 Prepare QC samples per Section 9.

8.4.8 Take a 2mL aliquot of the leachate and deposit this onto a labeled, tared planchet.

NOTE: The proportionate amount of solid aliquot used may be calculated using the following equation:

$$W_{aliquot}\,(g) = \frac{W_{total}\,(g) \times V_{aliquot}\,(mL)}{V_{total}\,(mL)}$$

where:

Valiquot (mL) = volume of aliquot used

Vtotal (mL) = total volume of leachate

Waliquot (g) = mass of solids present in the original 2 mL aliquot

Wtotal (g) = mass of sample recorded from step 8.4.1.

8.4.9 Follow Steps 8.2.1 to 8.2.7, as for liquids.

8.5 COUNTING OF PRESCREEN SAMPLES

8.5.1 Determine the mass of solids (i.e., residue), in mg, per Section 8.6 below.

8.5.2 Samples are counted in the Prescreen Lab per SOP 724.

8.5.3 Verify that all information has been recorded on the Gross Screen Preparation Worksheet where needed, and is legible. Sign your initials in the space at the top of the form provided for "Analyst".

8.5.4 Give a copy of the prescreen results, including the blank and LCS, to the appropriate PM or the RSO.

8.6 CALCULATIONS

Amount of solids (mg) = [Gross wt of planchet (g) - tare wt of planchet (g)] x 1000 mg/g

NOTE: Activity, uncertainty, and minimum detectable concentration (MDC) calculation formulae may be found in SOP 708.

9. QUALITY ASSURANCE/QUALITY CONTROL

9.1 One blank is to be prepared and analyzed each day prescreen samples are processed. This one blank will be used for all matrices prepared that day. Prepare the blank by pipetting 5.0mL of concentrated nitric acid onto a labeled planchet; add 1mL of salt solution and dry on a hotplate. This blank is subject to the same acceptance criteria specified in the Gross α/β procedure (SOP 724).

9.2 One laboratory control sample (LCS) is to be prepared and analyzed each day prescreen samples are processed. This one LCS will be used for all matrices prepared that day. The LCS consists of approximately 100dpm of ^{90}Sr and 100dpm of ^{241}Am spiked onto a tared planchet, containing approximately 5mL of conc. nitric acid. ***If the spike solution was made in HCl, the solution must be converted to a nitrate system prior to planchetting in order to prevent corrosion of the stainless steel planchet.*** One (1) mL of salt solution is added to the planchet prior to drying. The LCS is acceptable if the value yielded is +/-30 % of the expected value. If this criterion is not met, notify a Radiochemistry Supervisor immediately for possible corrective actions.

10. DEVIATIONS FROM METHOD

This is a proprietary method, developed by Paragon. Therefore, there are no deviations from promulgated methods.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Safety glasses should be worn when working with nitric acid.

11.1.2 When working with large amounts of acid, a plastic apron should be worn and use of a face shield is highly recommended.

11.1.3 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in laboratory fume hood (e.g., solvents and acids). TLVs may be found in the reference cited in Section 12.2 below.

11.2 WASTE DISPOSAL

11.2.1 The prescreen liquid analytical process effluent has been determined to not be hazardous in any other way than corrosivity. This material may, therefore, be discharged to the Paragon wastewater treatment facility. Here the solution will be neutralized and the radionuclide concentration will be monitored to ensure compliance with Colorado Rules and Regulations.

11.2.2 Disposal of solids should be in an appropriate waste carboy and stored for further evaluation under the direction of the RSO.

DOCUMENT REVISION HISTORY

8/18/06: Clerical corrections. Updated Form references and added Form attachments. Added missing items to equipment list. Included NOTE regarding oils. Added DOCUMENT REVISION HISTORY section.

7/17/08: Added 6.6 note that all spiking solutions are from a source that is different than that used for calibration. Changed volume used from 5mL to 10mL under Note in Section 8.2.7. Added note and calculation in Step 8.4.3.

STANDARD OPERATING PROCEDURE 704 REVISION 9

TITLE: ANALYSIS OF TRITIUM AND OTHER BETA-EMITTING NUCLIDES BY LIQUID SCINTILLATION COUNTING -- METHOD EPA 906.0

FORMS: 700_Quantulusr1.xls (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9/4/07

QUALITY ASSURANCE MANAGER _____ DATE 9/4/07

LABORATORY MANAGER _____ DATE 9-4-07

HISTORY: Rev0, 9/18/92; Rev1, 3/8/93; Rev2, 5/10/93; Rev3, 7/27/93; Rev4, PCN #148, 3/2/94; Rev5, 10/8/99; Reviewed and distributed without revision, 3/14/02; Rev6, 4/7/03; Rev7, 12/13/04; Rev8, 9/1/06; Rev9, 8/31/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary to perform analysis of samples of various media using Paragon's one Wallac Quantulus 1220 and two Beckman LS6000 and LS6500 liquid scintillation counters (LSCs). Samples will normally be liquids in a 20mL scintillation vial, which may represent the sample directly (water samples) or indirectly (extracts from soil samples, silica gels, etc.).

This procedure provides the analysis portions of EPA Method 906.0. This procedure is applicable to the determination of tritium (^{3}H), as well as ^{14}C, ^{63}Ni, ^{99}Tc, ^{241}Pu, ^{210}Pb, ^{147}Pm, and other radionuclides.

2. SUMMARY

Beta emissions are detected by a fluor (i.e., a fluorescing molecule) mixed with the sample in a 20mL liquid scintillation vial, which in turn emits light in direct proportion to the beta emission energy and intensity. This light pulse is converted to an electronic pulse and recorded as a beta emission event on the instrument's multi-channel analyzer (MCA). The data collected by the MCA are subsequently interpreted by a software program, generating results in units of radioactivity per unit sample volume.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review. Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.2 It is the responsibility of the instrument operator to perform the analyses within

the specified hold time for the method to ensure timely analysis of samples with short-lived radionuclides or other time-sensitive concerns. The instrument analyst must ensure optimum instrument capacity through the timely performance and documentation of calibrations, daily performance checks, routine maintenance, etc., as described in Table 1.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the workorder file indicates that this review for precision, accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples utilizing this method to note any anomalous or out-of-control events associated with the preparation and analysis of the samples. Any discrepancies must be noted and corrective action taken, documented, and approved by the Department Manager.

4. INTERFERENCES

4.1 The scintillation vial is an optical surface. Any markings or material on the outside of the scintillation vial will interfere with the detection of scintillation. These should be removed prior to analysis by wiping the vial with a lint-free lab wipe and alcohol. All labeling must be done on the cap of the vial.

4.2 The quench indicating parameter (QIP, usually H-number or SQP(E)) must be within the established calibration range for the specific analysis. Refer to Table 1 for evaluation of QIPs. Nitromethane, or other suitable quenching agent, is added to samples that are not sufficiently quenched to bring them within the calibrated range. Consult with the Radiochemistry Manager for guidance if quenching is necessary.

4.3 The QIP should be monitored and variations in quench that could correspond to greater than 10% (or +15 H or SQP(E) numbers) relative bias in the efficiency, should be addressed by using standard additions to determine a sample-specific efficiency.

4.4 The presence of visible coloration in the distillate will act as an 'inner filter'. This

effect, known as 'color quenching' is an interference to the detection of the scintillation.

4.5 The presence of particulate contaminant in the final water distillate may interfere with the detection of the scintillation. This effect is known as 'physical quenching'.

4.6 The presence of chemical contaminants in the final water distillate may inhibit scintillation. This effect is known as 'chemical quenching'.

4.7 The scintillation cocktail contains a fluorescing molecule that is subject to excitation in the presence of light. Samples must be "dark adapted" for at least 3 hours prior to counting to minimize this effect. For instruments that do not allow an accurate luminescence correction (i.e., the LS6500 and Quantulus), the sample luminescence should be monitored and appropriate corrective action taken as described in Table 1.

4.8 Sample luminescence (LUMEX) interferes with the analysis of low-energy beta activity, and is monitored by the instruments. Sample LUMEX should be less than 5% for routine analyses on instruments that do not perform an automatic LUMEX correction. In instruments that perform an automatic LUMEX correction to the data, the sample LUMEX should be less than 10% in routine analyses. LUMEX values above 10% may be acceptable, with approval from the Department Manager.

4.9 The Window 2 count rate is monitored for high-energy beta contamination. Control limits are calculated as the mean of the Window 2 count rates for the sources in the efficiency calibration ± three standard deviations of those count rates. Counts outside of the derived control limits should be evaluated and appropriate corrective action taken. Corrective action may include the re-preparation of the sample, reanalysis, or the qualification of the data based on the analyst's judgment of the impact on the sample data quality.

5. APPARATUS AND MATERIALS

This procedure is conducted with the use of installed beta detection and analysis equipment, consisting of a liquid scintillation counter (LSC), analysis software, and associated nuclear electronics and cabling. In the case of the LS6000, the data may be transferred directly to a floppy disk using a PC with the appropriate interface hardware and software. The LS6500 has these features built-in and can write to a floppy disk with an internal disk drive.

6. REAGENTS

NOTE: TLV and other hazard information may be given here. Any chemical with a Threshold Limit Value (TLV) or Permissible Exposure Limit (PEL) below 50ppm must be worked with in a laboratory fume hood. The absence of this

information does not imply that the substance is not hazardous. The employee should be familiar with all pertinent MSDSs before proceeding.

6.1 Nitromethane, reagent grade
TLV = 20 ppm (TWA). Extremely hazardous, highly reactive, highly flammable, flashback hazard, carcinogen.

6.2 Methanol, reagent grade
TLV = 200 ppm (TWA).

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Chemical preparation steps performed for this analysis are detailed in the appropriate Paragon preparation SOPs. Samples to be analyzed by this procedure will have been prepared by radiochemical procedures that include distillation of liquids, or azeotropic distillation of soils/solids.

7.2 The prepared scintillation vials for Total Activity are prone to building up pressure and rupturing in storage. It is the responsibility of the instrument analyst to dispose of the scintillation vials as soon as is practical after review and verification of the data, preferably within 60 days after preparation.

7.3 Certain analyses are prone to interference from either short-lived radionuclides (e.g. ^{99m}Tc, ^{222}Rn) or rapidly ingrowing progeny (e.g. ^{210}Bi). Time-sensitive counting constraints are specified in the individual preparation SOPs.

7.4 Certain analyses are prone to rapid quenching after preparation (e.g. ^{63}Ni). These samples must be counted as soon as possible after preparation, before the QIP drifts outside the calibration range.

8. PROCEDURE

8.1 OPERATING CONDITIONS

The LSC shall be operated according to the instructions provided by the manufacturer. All instrument settings shall be determined during instrument installation and/or calibration. The operating conditions shall be verified daily by performance of the daily quality control (QC) checks (discussed subsequently in this SOP). *Be sure the samples have been allowed to dark-adapt for a period of at least 3 hours prior to analysis.*

8.2 SAMPLE LOADING FOR BECKMAN INSTRUMENTS

8.2.1 Normally, the samples will be placed in the rack in the order they are listed on the benchsheet. Place the rack(s) in the counter with the front (i.e., side with rack number and/or user number) facing *away* from the operator.

The first rack to be counted must have a user number (see below) installed in the left (looking at the front of the rack) card slot.

Subsequent racks will not have a user number card unless a different analysis is required for that rack.

Ensure that the counting position of each sample is correctly recorded on the benchsheet and that the user number has the correct settings.

8.2.2 USER NUMBERS

User numbers provide the count and data output parameters. User number programs can be set by pressing the "Main Menu" button, then using the cursor arrows to highlight "Review and Edit User Programs". Using the cursor arrows, highlight the user number to be edited, then highlight the parameter to be set, and follow any prompts given at the bottom of the screen. For more details on setting the user number parameters, see the instrument's operating manual.

Default settings for all of the user numbers are:

- Count Blank: NO
- Two Phase: NO
- Scintillator: LIQUID
- Low Level: YES
- H#: YES
- IC#: NO
- LUMEX: YES (This option is available only on the LS6000. The LS6500 doesn't correct for luminescence.)
- Half Life Correction Date: NONE
- Sample Repeats: 1
- Cycle Repeats: 1
- Cycle Repeats: 1
- Low Sample Reject: 0
- Printer: STD
- RS232: STD

Other parameters may vary for each user number. These are:

8.2.2.1 MANUAL WINDOW SETTINGS

In order to determine the manual window settings, a source (count long enough to achieve approximately 10,000 counts) and blank (count for approximately 90 minutes or as long as the longest count time typically observed for the method of interest) are counted on the instrument.

The user number is set with Window 1 at WIDE, and the raw data output is set for Spectral Data, to give a channel-by-channel output. Once the data are collected, a Figure of Merit (FOM) is calculated to optimize the window settings in order to minimize the MDC (minimum detectable concentration). Windows are set for each analysis type (i.e., ^{3}H, ^{14}C, etc.). For analyses with multiple counting geometries (i.e., 10mL or 5mL) a single, optimized window setting is preferred.

A FOM determination should be performed following replacement of any major instrument hardware or bi-annually, whichever comes first.

$$FOM = \frac{(\text{Source Counts})^2}{\text{Background Counts}}$$

The FOM should be maximized by changing the window settings to determine the greatest efficiency and the lowest background.

8.2.2.2 COUNT TIME

The count time should be determined taking into consideration the required MDC and sample volume. Samples should not be counted for longer than 2-3x the normal count time for a standard aliquot size unless contractual requirements are in place. For most analyses, the standard count time is approximately 60 minutes.

8.2.2.3 COUNTING PRECISION

The instrument can be set to stop counting once a required numbers of counts have been accumulated. For the analyte of interest window, the precision is generally set to 1.75% to 2.5%.

8.3 SAMPLE LOADING FOR QUANTULUS INSTRUMENT

8.3.1 The Quantulus contains three “racks” each having four rows of five positions. The first rack contains positions 1 through 20, the second rack positions 21 through 40 and the third rack 41-60. Positions 57 through 60 are reserved for daily check vials. Position numbers are arranged as shown below:

1	2	3	4	5
6	7	8	9	10
11	12	13	14	15
16	17	18	19	20

Ensure that the counting position is correctly recorded on the benchsheet.

8.3.2 PROTOCOL SELECTION

8.3.2.1 From the Windows Program Manager, select the "WinQ" icon. There will be two buttons at the top of the screen.

8.3.2.2 Select the button marked "Users." Three columns will appear on the screen: "Users," "Protocols," and "Queue."

8.3.2.3 Highlight the nuclide of interest (e.g., H3-5mL for tritium analysis in a 5mL geometry) in the "Users" column.

8.3.2.4 Protocols for the nuclide of interest will appear in the "Protocols" column. There are three screens within each Protocol.

- In the first screen "General Parameters," enter the folder name and save path. For example, one would enter "C:\H3-5ML\H-0406" for a tritium analysis in a 5mL geometry that was the first of such analyses loaded on the sixth of April.

  For the second of such analyses loaded on the same day, the folder name and save path would be:"C:\H3-5ML\H-0406a".

- On the "Sample Parameters" screen within the protocol, enter the identification of the samples to be counted, the sample position, the count time and the specifications as listed below:

  COUNTS: No Lim
  CUCNTS: No Lim
  MCW: 1
  REP: 1

ST: Y
STMS: 1/1
STIME: 00:30

- On the "MCA & Window Settings" screen within the protocol, specifications are made for each analysis as described below:

DAILY PERFORMANCE CHECKS

Configuration: 3H
Send Spectra: 11, 12
Coincidence Bias: Low
PAC: n/a
PSA: n/a

TRITIUM (and other low-energy beta emitters)

Configuration: 3H
Send Spectra: 11, 12
Coincidence Bias: Low
PAC: 1
PSA: n/a

CARBON-14

Configuration: 14C
Send Spectra: 12
Coincidence Bias: High
PAC: 1
PSA: n/a

ALPHA/BETA DISCRIMINATION

Configuration: Alpha/Beta
Send Spectra: 11, 12
Coincidence Bias: Low
PAC: 1
PSA: The default setting is 100, the optimum PSA value should be determined experimentally as it depends on the quench of the sample and the nuclides being analyzed.

8.3.3 PROTOCOL DELETION

CAUTION: Protocols should only be deleted with the approval of the Department Manager.

8.3.3.1 From the "Users" screen (accessed by clicking the "Users" button at the top left of the screen at any time), entire protocols may be deleted by highlighting the protocol in the center of the screen and clicking the "Delete" button.

8.3.3.2 A protocol may be removed from the queue (i.e., be removed from the counting line-up but not actually deleted) by highlighting the protocol in the "Queue" column at the right of the screen and pressing the DELETE key on the keyboard.

8.4 DATA COLLECTION

8.4.1 THE FOLLOWING PROCEDURE IS FOR THE LS6000 *ONLY*
To use this option, the user number used to count the samples must have the STD RS232 Format selected.

8.4.1.1 From the Main Menu of the support computer for the LS6000, choose "Tritium Data Capture" and press <Enter>. When the Data Capture software starts, choose "1. LS6000" <Enter>, then "1. RECEIVE data from instrument" <Enter>.

The program will provide a table with the header "Drive and Subdirectory"; press <Enter>. Send the data to the b:\ drive (be sure that a disk is inserted into the b drive). The upper left corner of the display will read "Awaiting Response".

8.4.1.2 Press the "Main Menu" key on the front panel of the counter. Use the cursor arrows to highlight "Automatic Counting", then press "Start" to begin counting.

The counter will analyze each sample and generate results in CPM for each vial counted. The Data Capture software will have a message in the upper left corner which reads: "Status: Receiving Record XXXX", where XXXX is the number of the data record which will increase as samples are analyzed.

The Data Capture software will now also display the filename in which the data is stored in the center of the screen. This file is named "\TRITIUM\UNXX-YYY.BSF", where XX is the user number, YYY is the next sequential number for files created with that user number, and .BSF is the default extension for Beckman Standard Format files. *Note this file name in the filename section of the benchsheet.*

8.4.1.3 When the count is complete (i.e., LS6000 Main Menu has returned to the display), complete the liquid scintillation run log.

To process the data, press <Esc> on the LS6000 support computer. The Status message in the upper left corner of the display, will read "Capture Completed". Press <Esc> twice to return to the Data Capture software main menu. Remove the disk from the b:\ drive and take the disk to the tritium reporting PC.

Copy the correct file to the c:\ drive of the reporting PC. Open the “dc” program on the c:\ drive by typing “dc” then <Enter>. Use the cursor arrows to move the highlight bar to "DATA CAPTURE SUPPORT", press <Enter> to choose this option, then choose "3. Convert BSF to dBASE File", then press <Enter>. Press 1 (Convert); the software will then prompt for "Input Filename (.BSF)" and "Output Filename (.DBF)". Type the name of the file recorded on the benchsheet, without an extension (for example, "UN01-001"), and press <Enter> for each prompt. The software will then present a default format titled "Tritium"; press <Enter> to accept this format.

A message at the bottom of the screen will read "Use actual dBase file structure (Y/N) [Y]"; press <Enter> to accept the default "Y". Then data will then be converted and displayed on the screen, with the message "Conversion Completed !".

Press <Esc> 4 times to return to the PC's Main Menu. Copy the new file to the r:\tritium directory. The data may now be accessed from any PC that is a part of the Paragon network.

8.4.2 THE FOLLOWING PROCEDURE IS FOR THE LS6500 *ONLY*

8.4.2.1 To start the sample count, press the "Main Menu" key on the front panel of the counter. Use the cursor arrows to highlight "Automatic Counting", then press "Start" to begin counting. The counter will analyze each sample and generate results in CPM for each vial counted.

8.4.2.2 When the count is complete (LS6500 Main Menu has returned to the display), complete the liquid scintillation run log.

8.4.2.3 To create a disk to transfer run information from the LSC to the tritium reporting PC, select “Data Management” from the

main menu on the LS6500. Next, select "Access Data Buffer/Disk", then select "Move Files to Disk". Enter the user number for the files that you want to move.

8.4.3 THE FOLLOWING PROCEDURE IS FOR THE QUANTULUS *ONLY*

8.4.3.1 After the protocol has been modified for the specific desired analysis, click the "OK" button on the left of the screen. Highlight the protocol in the center of the screen and click on the "Queue" button to add the protocol to the queue to be counted. If the instrument is currently running, the protocol will automatically count after all protocols listed before it in the queue have counted. If the instrument is not currently running, it is necessary to click on the "Counters" button at the top left of the screen. When the "Counters" screen appears, press the "play" (►) at the bottom center of the screen.

8.4.3.2 QUANTULUS LOGBOOK
Samples are recorded in the logbook (Form 700_ Quantulusr1.xls) at the start of analysis. The "Count Time (minutes)" and "Position Check" will be completed after the samples have been counted.

8.4.3.3 When the data collection is complete, the protocol will disappear from the queue. The sample data may be accessed by one of two ways -- through the registry, or through the software analysis program EASY view.

- REGISTRY SAMPLE DATA
  This is the data stored as a text file. To access the registry, use Windows Explorer to access the folder chosen as described in Section 8.3.2. Double-click the file named REGISTRY.TXT within that folder and the file may be printed.

- EASY VIEW SOFTWARE ANALYSIS
  From the main menu of the support computer for the Quantulus, select Programs→Wallac→ EasyView. At the top left of the screen, right-click the word "spectra" and select the option "New".

  Navigate to the folder of interest and choose the desired files. Note: the files are named "QXXYYZZ", where Q refers to the instrument designation, XX is the count order, YY is the

sample position, and ZZ is the repetition (usually 01).

Next, at the top left of the screen, right-click the word "Setup" and select the option "Properties". The "Window Settings" window will appear. Select the channels of interest for the given nuclide. For ^{14}Carbon, spectrum 12 only need be chosen. For all other analyses, both spectra 11 and 12 need to be chosen for each window. After selecting the desired windows, click "Close".

To print the data, choose File→Print and click the printer icon at the top of the page.

8.5 SAMPLE ANALYSIS

Data from all instruments may be entered manually into LIMS. Alternately, data from the LS6000 and LS6500 may be automatically uploaded, as described below:

8.5.1 On the LS6000 or LS6500, move the desired .ASC file into "I:\Operations\LSC\LIMS Data." When the file is moved, add the letter "Y" in front of the file name to denote that the file is from instrument LS6500 or add the letter "X" in front of the file name to denote that the file is from instrument LS6000. The text file should be reviewed to ensure that the correct file has been chosen.

8.5.2 Instructions for processing and reporting radioanalytical data are found in the Paragon LIMS Manual, which is available as a reference on the network.

9. CALIBRATION

9.1 EFFICIENCY CALIBRATION

Standards for calibration shall be traceable to the National Institute for Standards and Technology (NIST). Standards for tritium counting will normally be prepared from commercially available NIST-traceable stock solutions. The analysis system shall be calibrated at least annually. Instructions for the preparation of calibration sources are provided in the individual preparation SOPs.

9.1.1 In cases where a quench curve calibration is performed, a review of the data and the fitted curves may indicate one or more outlying data points that prevent an adequate fit of the data. At the analyst's discretion, one or more data points may be removed as outliers, provided that the number of remaining data points is at least twice the order of the polynomial used to fit the curve. The fitted curve should be re-

generated after the removal of outlying data points. In all cases the effective range of the quench curve will be bounded by the upper and lower data points used to fit the curve.

9.1.2 In cases where a single-point efficiency calibration is performed (i.e. the method of constant quench), the QIP for sample analyses will correspond to the average observed for the calibration standard (within ±10 % relative efficiency or, lacking this calibrated range, ±15 of mean H-numbers).

9.1.3 Any sample falling outside this range will be calibrated by sample specific addition of a minimum known volume (<200µL) of NIST-traceable standard. The efficiency from sample specific standard additions is calculated as defined below:

$$\text{Deteff} = \frac{(\text{SSGrCPM} - \text{SmplGrCPM})}{\text{SpkDpm}}$$

In cases where the method of standard addition is employed, a calibration blank must be deliberately quenched to approximately the quench factor of the sample, so that an appropriate background determination can be made.

9.2 BATCH-SPECIFIC BACKGROUND CALIBRATIONS (REAGENT BLANKS)

9.2.1 Instructions for the preparation and analysis of background determinations are provided in the individual preparation SOPs.

9.2.2 For methods that require the preparation and analysis of batch-specific background determinations, three reagent blanks will be prepared for analysis with the sample batch. The blanks will preferentially be distributed among the beginning, middle, and end of the count batch and should be counted as long as the longest sample count duration in the batch.

9.2.3 For single-point calibrations (method of constant quench) the average count rate of the three reagent blanks will be used directly as the method background determination.

Interim acceptance criteria for the reagent blanks will be derived initially from the blanks used in the efficiency calibration and verification. Interim limits background calibrations will be +/- (3 times the Poisson uncertainty of the initial measurements). After sufficient batches are analyzed to produce reliable statistical control limits from the population of previously analyzed reagent blanks, those interim

control limits will be replaced with limits that are ±3 standard deviations about the mean value.

9.2.4 For methods utilizing a quench curve, three reagent blanks will be analyzed, as described above. The reagent blanks will, ideally, have quench factors approximately at the middle part of the curve, though unquenched reagent blanks are acceptable as long as the quench factors lie within the calibration curve.

The average difference between the individual observed values and the expected values from the quench curve coefficients will be used to adjust the existing quench curve along the dependent axis (i.e. adjust the curve up or down by adding the average difference value to the curve equation).

Interim acceptance criteria for the reagent blanks may be derived initially from either the expected uncertainty in the initial calibration, or from the three reagent blanks used in the analysis of the first sample batch. After sufficient batches are analyzed to produce reliable statistical control limits from the population of previously analyzed reagent blanks, those interim control limits will be replaced with limits that are ± 3 standard deviations about the mean value.

9.2.5 Historical reagent blank results are maintained in the following spreadsheets:

- R:\INST\LSC\ has one subdirectory for each instrument; \LS6500\ , \LS6000\ , \QUANTULUS\
- Each instrument directory has a \CBs_BKG_WIND2_CHKS\ directory with the following files, where appropriate:

RB_C14.XLS
RB_FE55.XLS
RB_H3_5ML.XLS
RB_H3_10ML.XLS
RB_NI63.XLS
RB_TC99.XLS
RB_TOTA.XLS
RB_P241.XLS
and RB_C14_NaOH.XLS

9.3 GAIN CALIBRATIONS

For liquid scintillation counters in which the gain adjustment needs to be calibrated manually, the gain calibration will be performed at least monthly by

placing a sealed, unquenched C-14 source into a rack and initiating the manufacturer's AUTOCAL program.

10. QUALITY CONTROL

10.1 GENERAL

Where EPA drinking water methodologies are required by the client, the LCS and Matrix Spike (MS) recovery acceptance criteria shall be ±20%, irrespective of the laboratory's internally derived acceptance criteria.

10.2 DAILY QA CHECKS ON THE BECKMAN INSTRUMENTS

Standards for Daily QA Checks consist of unquenched ^{3}H and ^{14}C standards (NIST-traceable), a flame-sealed, vendor-supplied background, and an in-house prepared blank sample.

10.2.1 Place the unquenched ^{3}H calibration standard in position 1, the unquenched ^{14}C calibration standard in position 2, the blank in position 3, and the vendor-supplied background in position 4 of the sample rack labeled "User No. 1".

10.2.2 Place the rack in the right front position in the counter. Place the "HALT" (red) rack immediately after the "User No. 1" rack.

10.2.3 Start the Daily checks by pressing "Main Menu", selecting "Automatic Counting" from the menu with the cursor arrows, then pressing "Start" to begin the counting sequence. The QA Check process will initiate a 10 minute count of the ^{3}H standard, the ^{14}C calibration standard, the blank, and the vendor-supplied background. At least 100,000 counts should be acquired for the ^{3}H and ^{14}C check sources.

10.2.4 When the count is complete, enter the count results for the standards and blank in the LSQA spreadsheet (located at R:\inst\ls6000\daily QC\ lsqa6000.xls or R:\inst\ls6500\daily QC\lsqa6500.xls) using a network computer.

Count results from Window 1 are used for the ^{3}H standard, count results from Window 2 are used for the ^{14}C standard, and count results from Window 1 are used for the blank and vendor-supplied background.

The spreadsheet compares each count result to historical control limits established from the first 60 data points in the population. Sixty data point are used for these systems due to the potential for long-period variance in the instrument response. Control limits are set at ± 3 standard deviations (above and below) the means for the standards and blank.

In the absence of a sufficient number of data point to generate reliable historical control limits, interim limits may be used. Interim limits for daily check sources will be +/- 5% of the initial measurements for H-3, C-14 and H#. Interim limits for quenched background checks will be +/-(3 times the poisson uncertainty of the initial measurements).

If any of the Daily QC results fall outside the defined control limits, re-analyze the samples. If the current data points are still outside of control limits, do not operate the instrument until notifying the Supervisor and resolving the problem. *Note that Paragon does not control on the results of the flame sealed vendor-supplied background sample.*

10.3 DAILY QA CHECKS ON THE WALLAC INSTRUMENT

10.3.1 Place the unquenched ^{3}H calibration standard, the unquenched ^{14}C calibration standard, the blank, and the vendor-supplied background in the sample rack and note the positions.

10.3.2 Count the daily check samples, as described in Section 8.3.2, selecting the Daily QC user option.

10.3.3 In the "General Parameters" tab, enter the folder name and save path as "C:\DAILYQC\QC-*mmdda*", where *mm* is the month, *dd* is the day, and *a* is a sequential identifier, if needed, when multiple counts are performed in a single day.

10.3.4 In the "Sample Parameters" tab, enter the sample IDs as "3H", "14C", "Reagent Blank", and "BKG STD".

10.3.5 For each vial, specify the sample position, enter the count time as 10 minutes, and verify that the other settings are set as described in Section 8.3.2.

10.3.6 Click the "OK" icon to save.

10.3.7 Make sure the current protocol is highlighted. Click on the "Queue" icon, select the "Counters" icon, then press "Play" (►) to start the counts.

10.3.8 When the count is complete, enter the count results for the standards and blank in the LSQA spreadsheet (located at R:\inst\quantulus\daily QC\dqaquantulus.xls using a network computer.

The spreadsheet compares each count result to historical control limits established from the first 30 data points in the population. Control limits are set at +3 standard deviations (above and below) the means for

the standards and blank.

If any of the current data points fall outside the default control limits of ±10% of the mean, re-analyze the QC samples. If the current data points are still outside of control limits, do not operate the instrument until notifying the Supervisor and resolving the problem. *Note that Paragon does not control on the results of the flame sealed vendor-supplied background sample.*

10.4 SCINTILLATION COCKTAIL VERIFICATION BY LOT NUMBER

10.4.1 Scintillation cocktail performance for each manufacturing lot must be verified prior to use. The background count rate, counting efficiency, luminescence, and quench factor must be demonstrated to be equivalent to the previous lot of cocktail used for each analytical method.
