VOC	Volatile Organic Compound

1.0 PROJECT MANAGEMENT

This Quality Assurance Project Plan (QAPP) describes the project organization established to ensure attainment of quality data; data quality objectives; the quality assurance and quality control methods employed for sample collection, handling, and testing; documentation requirements; assessment and oversight activities including audits and reports to management; and data validation. The QAPP is the project document that establishes the data quality required for attainment of project data quality objectives, which are in turn determined by site cleanup levels dictated by regulatory authorities. The official approved QAPP is kept in the Project File and is maintained by the Project Chemist, Brian Tucker.

1.1 PROJECT ORGANIZATION

This section of the Chemical Data Quality Management Plan (CDQMP) summarizes the project organization for the Formerly Utilized Sites Remedial Action Program (FUSRAP) Maywood Superfund Site (FMSS) project. It provides specific Shaw Environmental, Inc. (Shaw) and subcontractor personnel responsibilities and lines of authority and communication. Names of personnel fulfilling these responsibilities are also provided.

1.1.1 Quality Assurance / Quality Control Organization

Project Quality Assurance (QA) will be maintained under the direction of the Contract Quality Control System Manager (CQCSM) in accordance with the CDQMP and the Contractor Quality Control Plan (CQCP) (USACE 1999). In addition, the CQCSM will direct field audits. Quality Control (QC) for the following tasks will be the responsibility of the individuals and organizations listed in **Table 1-1**.

Table 1-1
QC Responsibilities

General Responsibility	General Tasks	Responsibility for Quality Control
Field Sampling	Environmental sampling of soil, water, and building materials	Shaw
Sample Management	Maintenance of correct custody and proper preservation of environmental samples	Shaw
Radiological Investigations	Radiological investigations	Shaw and Subcontractors
Laboratory Analyses	Radiological and chemical analysis of soil, water, air, and building materials	Analytical Laboratory(ies) and Shaw and Subcontractors
Data Validation	Validation of laboratory data using USACE guidelines	Data Validator and Shaw
Field Measurement Activities	Performance of QA measurements on Field Measurement units.	Shaw and Subcontractors
Laboratory Audits	Performance of systems and performance audits of laboratory(ies)	Shaw, USACE, NJDEP, and/or Subcontractor auditors
Field Audits	Performance of field quality control audits	Shaw and USACE Personnel

The USACE Contracting Officer and the Corporate Vice President for Quality will be notified prior to any deviation from the approved CDQMP.

1.1.2 Personnel, Responsibilities, and Qualifications

The organizational chart shown in **Figure 1-1** outlines the management structure that will be used to implement the project's sampling and analysis activities. Shaw is the designated USACE contractor responsible for conducting the remedial action at the FMSS. The functional responsibilities of key personnel are described in this section. These roles will be filled by a combination of Shaw staff and subcontractors. The assignment of personnel to each position will be based on a combination of:

1. Experience in the type of work to be performed.
2. Experience working with USACE personnel and procedures.
3. A demonstrated commitment to high-quality and timely job performance.
4. Staff availability.

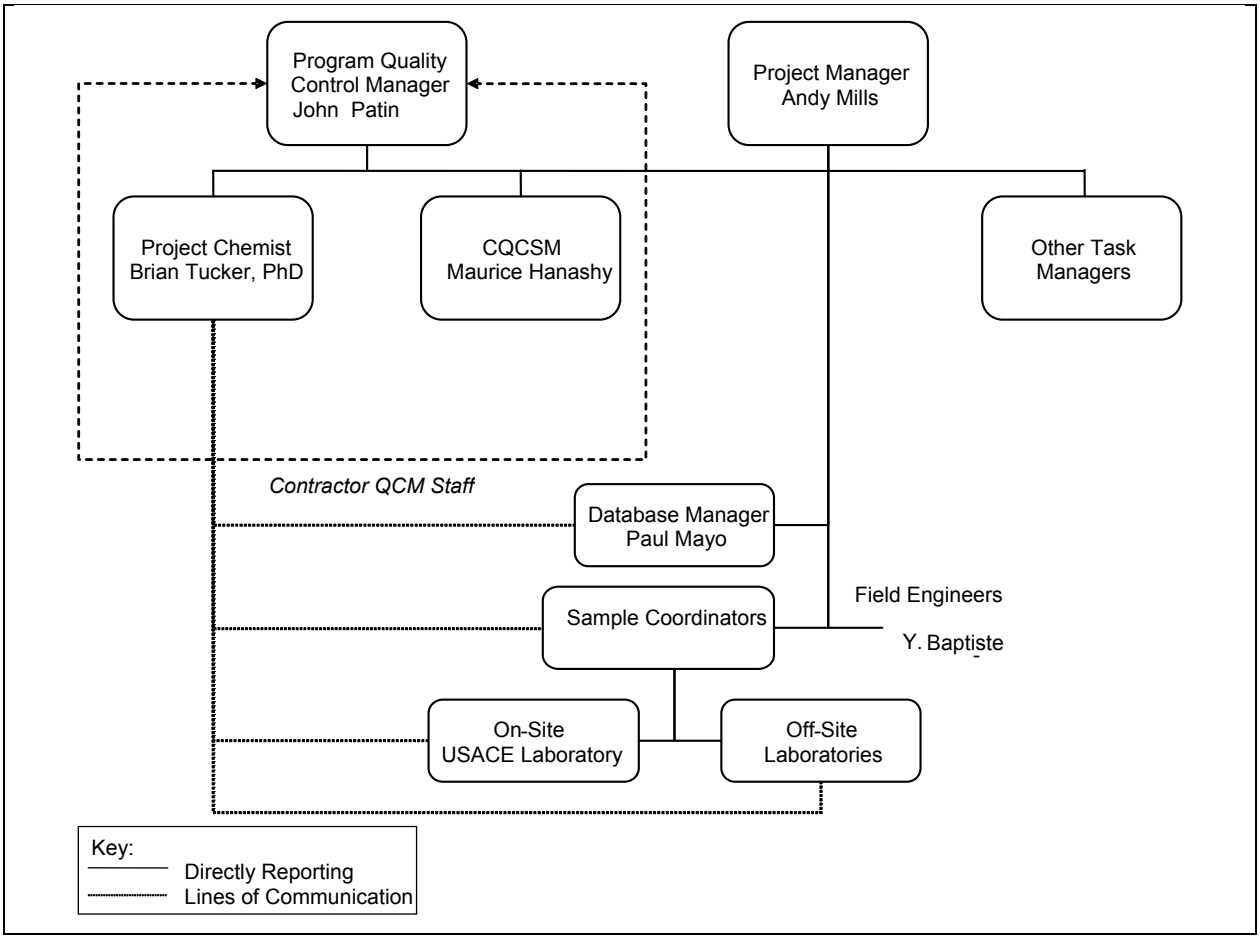

Figure 1-1
Chemical Data Quality Control Organization

1.1.2.1 Project Manager

The Project Manager ensures the overall management and quality of Shaw work on the FMSS project. This individual will ensure that all project goals and objectives are met in a high quality and timely manner. Project QA and nonconformance issues will be addressed by this individual for corrective action.

1.1.2.2 Project Environmental Engineer

The Project Environmental Engineer shall ensure that remediation goals, including required analytical data, are obtained consistent with applicable environmental laws and regulations. The Project Environmental Engineer reports directly to the Project Manager.

1.1.2.3 Task Managers

Task Managers will be assigned to the project to implement specific tasks. They will have direct responsibility for implementing the CDQMP, including all phases of work plan development, field activities, data management, and report preparation. These individuals will also provide the overall management of the tasks, and serve as the points of contact with the USACE. These activities will involve coordinating all personnel working on the assigned tasks, interfacing with USACE personnel, and tracking task budgets and schedules. Task Managers are responsible for ensuring proper technical performance of drilling operations and field sampling activities, adherence to required sample custody and other related QA/QC field procedures, coordination of field personnel activities, management of investigation-derived wastes, checks of all field documentation, and preparation of Field Change Orders (FCOs), if required. The Task Managers will also develop, monitor, and fill task staffing needs; delegate specific responsibilities to task team members; and coordinate with administrative staff to maintain a coordinated and timely flow of all project activities. The Task Managers report directly to the Project Manager, or designee.

1.1.2.4 Field Personnel

In addition to the Task Managers, other field personnel participating in the implementation of field activities are geologists, geotechnical engineers, environmental engineers, hydrogeologists, and sampling technicians. These individuals, in coordination with field subcontractor personnel, will be responsible for performance of drilling operations; collection of soil, groundwater, sediment, surface water, and air samples; radiation monitoring; and preparation of field logbooks and other required documentation. These individuals will be responsible for performing all field activities in accordance with the CDQMP, and will report directly to the Task Managers.

1.1.2.5 Contracted Field Support

Several team subcontractors provide support to the FMSS Project relating to the areas of data generation and quality. Many of the services are competitively bid on an annual basis so that the identified subcontractors may change over time. Within these areas, a few of the subcontractors currently supporting the project are listed is Table 1-2.

Table 1-2
Subcontractors Supporting the Project

Subcontractor	Support Service
Safety & Ecology Corporation 2800 Solway Road Knoxville, Tennessee 37931	Field Radiological Technicians, Laboratory Technicians, and Professional Support Services
Southern University CEES 315 Baranco Hall PO Box 9764 Baton Rouge, LA 70813	Offsite laboratory analysis of samples for chemical parameters
Kestrel Environmental Services 295 Lower Flying Point Road Freeport, ME 04032	Data Validation
Analytics 1380 Seaboard Industrial Blvd. Atlanta, GA 30318	Radiological Tracers and Standards
Ortec/Ametek 801 South Illinois Avenue Oak Ridge, TN 37830	Gamma spectrometer and alpha spectrometer systems
Protean Instrument Corporation 231 Sam Rayburn Parkway Lenoir City, TN 37771	Gas proportional detectors

Other subcontractors may also provide support on an as needed basis.

1.1.2.5.1 Subcontractor Field Personnel

Subcontractor field personnel, under the supervision of the Task Managers, will be responsible for performing their specific scopes of work that have been derived from the task-specific work plan. These individuals will be required to review the sampling sections of the work plan and the entire FMSS *Site Safety and Health Plan* (SSHP) (USACE 2006a) prior to field mobilization. All subcontractor field personnel report directly to the Task Managers who will be responsible for ensuring that all subcontractor activities comply with project requirements.

1.1.2.6 Subcontracted Laboratory Support

Analytical laboratory support specific to these investigations and remedial actions will be obtained from on-site testing and screening and one or more off-site laboratories.

On-site testing and screening for radiological parameters will be performed in the onsite laboratory (USACE FMSS Maywood Laboratory, or UFML) operated for USACE by Shaw and Safety and Ecology Corporation (SEC). UFML has the ability to dry and grind soil samples during the sample preparation phase. They can perform gamma spectrometry on these samples using one Canberra 30% germanium and two Canberra 40% Germanium one-hole detector systems. They can also take gamma counts on wet samples using a cross-correlation between dry equilibrated and wet unequilibrated samples. The on-site laboratory analyzes water samples for isotopic uranium (iso-uranium), isotopic thorium (iso-thorium), and radium-226 (Ra-226) using alpha spectrometry, and gross alpha, gross beta, and radium-228 (Ra-228) using a Protean Low-Background Gas Flow Proportional Counter. They can also analyze water samples using kinetic phosphorescence analysis (KPA). This laboratory also performs gross air sample and swipe counting using a combination of a gas proportional detector counting system and several Ludlum 2000/2929 alpha-beta scalers. The on-site laboratory is currently certified by the New Jersey Department

of Environmental Protection (NJDEP) to analyze soil samples by gamma spectrometry, and water samples by alpha spectrometry, gas proportional counting, and KPA. Sample testing by UFML reduces overall laboratory costs and improves turnaround time. This laboratory prepares and analyzes samples and generates data in accordance with the 600 series Standard Operating Procedures (SOPs) (located in the Electronic Document Management System (EDMS); see Section 4.7 of this QAPP) and uses the quality assurance principles described within their Quality Manual (USACE 2006b).

At this time, Test America Laboratories, Inc. of Earth City, Missouri (for QA split samples only) and ALS Laboratory Group (formerly Paragon) of Fort Collins, Colorado (subcontractor to Southern University for chemical testing) are the off-site contract laboratories for the FMSS tasks.

All current and future subcontract laboratories will be certified by the State of New Jersey to perform the pertinent tests. The subcontract labs are required to implement and maintain a QA/QC program in accordance with USACE and NJDEP guidelines. In addition, each subcontract laboratory must hold National Environmental Laboratory Accreditation Program (NELAP) accreditation. The Maywood onsite radiological laboratory must maintain State of New Jersey certification in their Environmental Laboratory Certification Program.

A relevant QA Manual, laboratory qualification statements, certifications, and license documentation will be made available upon request. Geotechnical laboratory support will be designated to a separate subcontractor certified by the State of New Jersey.

Organization charts outlining the key laboratory personnel and organization will be identified in their QA Plans. The responsibilities of key personnel are described in the following paragraphs. The assignment of personnel to each position will be based on a combination of

1. Experience in the type of work being performed.
2. Experience working with USACE personnel and procedures.
3. A demonstrated commitment to high quality and timely job performance.

Prior to commencement of project field activities for the project, Shaw will send a complete copy of the CDQMP to all subcontracted laboratories.

1.1.2.6.1 Laboratory Quality Assurance / Quality Control Manager

The subcontractor laboratory QA/QC Manager is responsible for the laboratory QA/QC in accordance with the requirements of this QAPP in conjunction with the established laboratory QA Program. In coordination with the Shaw CQCSM and Project Chemist, the laboratory QA/QC Manager will be responsible for documenting sample analysis in accordance with required methodologies. In addition, the laboratory QA/QC Manager will be responsible for documenting instrument calibration; field and internal laboratory QC sample analysis; and that analytical results for both field and QC samples are reported to the USACE and Shaw in the format required in the laboratory scope of work, this QAPP, and the task-specific Work Plans. Further, the laboratory QA/QC Manager is responsible for processing laboratory Nonconformance Reports (NCRs) in a timely manner and for implementing Corrective Action Report recommendations and requirements. The Subcontractor Laboratory Project Manager reports directly to the Shaw CQCSM and Project Chemist for issues related to this project.

1.1.2.6.2 Laboratory Project Manager

The responsibilities of each laboratory Project Manager include the following: initiation and maintenance of contact with Shaw on individual job tasks; preparation of laboratory-associated work plans, schedules,

and resource allocations; initiation of laboratory-associated procurement for the project; provision of day-to-day direction of the laboratory project team including analytical department managers, supervisors, QA personnel, and data management personnel; coordination of laboratory related financial and contractual aspects of the project; provision of formatting and technical review for laboratory reports; provision of day-to-day communication with Shaw; provision of final review and approval on all laboratory analytical reports to Shaw; and response to all post project inquiries.

1.1.2.6.3 Laboratory Manager

The responsibilities of the Laboratory Manager include the following: coordination of all analytical production activities conducted within the analytical departments; working with the Laboratory Project Manager to ensure all project objectives are met; provision of guidance to analytical department managers; and facilitation of transfer of data produced by the analytical departments to the report preparation and review staff for final delivery to the client.

1.1.2.6.4 Laboratory Section Heads, Department Managers, and Technical Leads

The responsibilities of each laboratory section or department include the following: coordination of all analytical functions related to specific analytical areas; provision of technical information to and oversight of all analyses being performed; review and approval of all analytical results produced by their specific analytical area of expertise; and maintenance of all analytical records and information pertaining to the analysis being performed.

1.1.2.7 Program Quality Control Manager

The Program Quality Control Manager (PQCM), John Patin, consults with the Shaw Director of Quality Assurance, Bryan Koehler, as required for direction on all quality matters. The PQCM is responsible for the planning, development, implementation, and effectiveness of the project-specific QC program included in the CQCP (USACE 2005). The effectiveness of the program is measured through the use of audits, surveillances, document reviews, and other QA monitoring activities defined throughout this document.

The PQCM's duties include, but are not limited to, reviewing and approving the project-specific CQCP (USACE 2005) and all revisions thereto, reviewing and approving supporting QC procedures, evaluating the effectiveness of the quality program, assigning qualified QC personnel to projects, directing and supporting project QC management staff, training and qualifications oversight, and ensuring the necessary QC resources are provided consistent with project needs.

1.1.2.8 Contractor Quality Control System Manager

The CQCSM, Maurice Hanashy, is responsible for implementation and documentation of all project QA/QC protocols during field activities. In this capacity the CQCSM will direct and implement the various components of the Contractor Chemical Quality Control (CCQC) program as identified in USACE Engineering Manual (EM) 200-1-3. This will include but not be limited to: documentation of QAPP instructions to field personnel; oversight of field sampling and analytical activities; documentation of field QC activities; and completion of Daily Quality Control Reports (DQCRs). The CQCSM reports directly to the Project Manager and consults with the PQCM and other project personnel as required to keep them informed and support their activities. The QC organization is also discussed in the CQCP (USACE 2005).

1.1.2.9 Site Safety and Health Officer and Radiation Safety Officer

The Site Safety and Health Officer (SSHO), Chad Miller, and Radiation Safety Officer (RSO), Mike Winters, are responsible for ensuring that health and safety procedures designed to protect personnel are maintained throughout the field activities. This will be accomplished by strict adherence to the project SSHP (USACE 2006a), which has been prepared as a separate document for this project. These individuals will have the authority to halt fieldwork if health or safety issues arise that are not immediately resolvable in accordance with the project SSHP (USACE 2006a). The SSHO and RSO report directly to the Project Manager.

1.1.2.10 Project Chemist

The Project Chemist, Brian Tucker, together with the CQCSM, will oversee the field sampling and sample handling activities, as well as laboratory quality control, to ensure that the requirements of the CDQMP are met. In particular, the Project Chemist is responsible for oversight of chemical and radiochemical analysis and reporting performed by the subcontract laboratory(ies), in accordance with the requirements defined in the CDQMP. The Project Chemist will also resolve questions the laboratory may have regarding QAPP requirements and deliverables, and will coordinate data reduction, validation, and documentation activities related to sample data package deliverables received from the laboratories. The Project Chemist is responsible for writing or overseeing the writing of the Quality Control Summary Reports (QCSRs) for each task, and for periodically revising the CDQMP. The Project Chemist reports directly to the Project Manager.

The Project Chemist is also currently identified as the QA Officer of UFML, as required under the certification designation of the NJDEP. The responsibilities of the QA Officer are defined under NJAC 7:18 of the NJDEP Office of Quality Assurance.

1.1.2.11 Sample Coordinator

The Sample Coordinators are responsible for coordination of sample shipment to the analytical laboratory(ies), and verification of the accuracy of chain-of-custodies. The Sample Coordinators will also coordinate the shipment of samples to the USACE QA Laboratory(ies), which will be designated by the USACE for the project. A Sample Coordinator is assigned to each task. These individuals are responsible for obtaining required sample containers from the laboratory(ies) for use during field sample collection. Along with the Project Chemist, the Sample Coordinators ensure that off-site laboratories understand the FMSS project QC requirements, and that quality concerns and problems are resolved in a timely manner. The Sample Coordinators also track the samples of a given task from shipment to the laboratory through delivery of results and transmittal to a data validation subcontractor, if required.

1.1.2.12 Project Environmental Sampler

The Project Environmental Sampler must be familiar with all of the SOPs pertaining to sampling in this CDQMP. Specifically, the sampler must be familiar with methods of collecting various matrices; the types of containers and preservatives required; how and how often to collect field sample quality control samples; safety guidelines described in the FMSS Site Safety and Health Plan; documentation including how to fill out a Field Notebook and Chain-of-Custody; and labeling, packaging, and shipping requirements as per project guidelines. The Project Environmental Sampler interacts with the Sampling Coordinator on a regular basis.

1.1.2.13 USACE QA Laboratory

The USACE QA Laboratory for this project will be assigned by the USACE Kansas City District (KCD) Project Chemist in Kansas City, MO. This laboratory is responsible for analyzing designated project QA samples. The QA laboratory designated by the KCD for testing of QA split samples is Test America Laboratories, Inc., at 13715 Rider Trail North, Earth City, Missouri 63415 (referred to as Test America-St. Louis), for both chemical and radiological parameters. The point of contact at the Test America-St. Louis facility is Terry Romanko (314-298-8566).

1.2 PROBLEM DEFINITION / BACKGROUND

1.2.1 Problem Definition

Shaw will perform remedial actions at the FMSS, a FUSRAP site under the jurisdiction of the USACE Kansas City and New York Districts. Task-specific Work Plans will contain a problem definition section that describes the problem to be solved and project goals. Site-specific maps, diagrams, existing data, and possible regulatory requirements shall be discussed.

Soils located on the FMSS contain thorium and radium, and to a lesser degree uranium, above the site-specific cleanup levels established for the FMSS. Deposition of radionuclides was either by soil and sediment transport along the former Lodi Brook and Westerly Brook channels, by emplacement of fill containing radionuclides, or by past waste disposal practices. Properties with FUSRAP waste include 88 designated commercial, government, and residential tracts. Sixty-four (64) of these properties have previously been remediated by removal actions as authorized under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). The Maywood Feasibility Study addresses soil and building contamination meeting the definition of FUSRAP waste at the remaining 24 properties (including the MISS and the Stepan Company) within the FMSS. Maximum concentrations of these radionuclides of approximately 37500 picoCuries per gram (pCi/g) ^{232}Th, 609 pCi/g ^{226}Ra, and 7600 pCi/g ^{238}U have been detected in buried residues or soils.

Chemicals are also known to be present on some of these properties. In particular, the soils have exhibited elevated concentrations of volatile organics (methylene chloride, acetone, methyl ethyl ketone [MEK], benzene, toluene, and ethylbenzene in the parts per million [ppm] range); acid extractables; and metals (aluminum, arsenic, barium, cadmium, chromium, copper, cobalt, lead, manganese, mercury, beryllium, silver, thallium, zinc, and nickel varying in concentrations from 1 ppm to several hundred ppm). In addition, all of the target compound list (TCL) pesticides have been detected infrequently in the low part-per-billion (ppb) range. Some soil borings also exhibited the presence of gasoline and fuel oil components, various methylated benzenes, caffeine, and the essential oils alpha-pinene and d-limonene.

Groundwater analyses have detected volatile organic compounds (VOCs) and semi-volatile organic compounds (SVOCs), including but not limited to benzenes, toluene, xylenes, 1,2-dichloroethene, and phenol; the pesticide gamma-BHC at a maximum concentration of 0.03 ppb; and metal contaminants including aluminum, arsenic, lead, chromium, copper, cobalt, nickel, vanadium, and barium.

The USACE is responsible for FUSRAP waste as defined in the Federal Facilities Agreement that states:

- All radioactive and chemical contamination, whether commingled or not, occurring on the MISS.
- All radioactive contamination exceeding the action levels agreed to in the Record of Decision and related to thorium processing at the Maywood Chemical Works (MCW), occurring on a vicinity property.

- Non-radioactive chemical contamination that occurs on vicinity properties if the contamination is mixed or commingled with radioactive contamination that exceeds cleanup criteria.
- Non-radioactive contamination that originated at the MISS or is associated with specific thorium manufacturing or processing activities at (MCW) that resulted in the radioactive contamination.

Detection of these chemicals in various matrices has been accomplished as part of several tasks. Much of this effort was focused on characterization of soils and groundwater, as well as evaluation of a soil sorting and rinsing operation as a mechanism for reducing the volume of soil to be shipped and thus reducing cost.

The tasks completed to date on this project include:

- Pre-design investigations to delineate soil excavation limits at all commercial / government vicinity properties.
- On-site field demonstrations of gravel separation and rinsing and radiological sorting of soil technologies.
- Development and implementation of a work plan for the FMSS groundwater remedial investigation.
- Time critical removal action of contaminated sediments in the West Howcroft Road drainage swale, following heavy rains deposited by Hurricane Floyd on September 16-17, 1999.
- Characterization of radiological contamination in Stepan buildings.
- Remediation of the 72 Sidney Street, 170 Gregg Street, 150/160/174 Essex Street, 80 Hancock, 100 Hancock Street, former I-80 Right-of-Way, 167 NJ Route 17N, 8 Mill Street, 239 NJ Route 17N, 23 West Howcroft Road, 85-103 NJ Route 17N, 200 NJ Route 17N, 137 NJ Route 17N, and Ballod properties including shipment and off-site disposal of the contaminated soils.
- Construction of an on-site radiological laboratory.
- Ongoing water treatment of groundwater encountered during excavation and storm water runoff.
- On going work plan and report preparation associated with PRAR/CCOR, Master Construction Work Plan, Site Safety & Health Plan, Quality Control Plan, etc.

The tasks currently in progress are:

- Remediation at the 149-151 Maywood Avenue and 100 West Hunter Avenue properties and final restoration of 99 Essex Street and 113 Essex Street properties
- Associated soil load-out evolutions and wastewater processing

The scope of future work currently planned for this project includes the follow:

- General
  - Design, remediation, and restoration of MISS, Stepan, and remaining commercial / government vicinity properties.
  - Excavation, handling, sampling, analysis, and disposal of buried drums and contents currently located on the 149-151 property.
  - Excavation, handling, transportation, and off-site disposal of the remaining accessible radiological contaminated soils exceeding cleanup standards; and backfill and restoration at the commercial / government vicinity properties and MISS and Stepan properties.

  - Verification sampling of remaining excavations during final status surveys (FSS) using Environmental Protection Agency (EPA) document 402-R-97-016, *Multi-Agency Radiation Survey and Site Investigation Manual* (*MARSSIM*) (EPA 2000b).

- Structures
  - Further characterization of radiological contamination in buildings.
  - Demolition of Building 76, the pumphouse, and the reservoir on the MISS to allow access to contaminated soils.
  - Potential demolition of Buildings 11, 13, 15, 20, 67, and 78 on the Stepan property to allow access to contaminated soils.
  - Demolition and/or decontamination of Buildings 4, 10, 13, 15, 20, 67, and 78 to remediate contamination in buildings.

For each delivery order involving sampling and analysis of environmental media, the corresponding task-specific Work Plans will contain sampling and analysis sections. They will address the site- and task-specific issues that are not discussed in this CDQMP. A narrative describing the task will be included that will state the specific problem to be solved or the decision to be made. The goal of the investigation will be clearly stated. A description of the work site, including an area map, location map, site map, site history as it relates to the current work, and any unusual conditions will be included. The text will include diagrams detailing areas to be sampled as relevant to the definition of the investigation goals. These sections will also contain a summary of site geology / hydrogeology as known, prepared to a level of detail such as to provide a comprehensive description of the site. The discussion will include enough information about the problem, the past history, any previous work or data, the regulatory or legal context, and any relevant regulatory requirements to present a clear description of the project objectives. It also should specify rationale for selection of sampling locations and test methods and frequencies.

1.2.2 Goals of the Investigation and Remediation

Remedial action has been and will continue to be conducted at the FMSS to ensure that risks to human health or the environment from potential exposure to impacted materials are either eliminated or reduced to prescribed safe levels. Media of concern will be remediated to these levels.

To meet the overall project objective, procedures for sampling, chain-of-custody, laboratory instrument calibration, laboratory analysis, reporting of data, internal QC, audits, preventive maintenance of field equipment, and corrective action have been developed and implemented and are described in other sections of this CDQMP. They will provide information for site evaluation and assessment leading to remediation. The procedures will ensure technically sound and legally defensible data. Each task-specific Work Plan will be used to identify specific task objectives as they relate to site action levels and remediation. The task-specific Work Plan for each FMSS task or activity will also provide the details, in tabular form, of the analytical parameters, methods, and quantitation levels.

General objectives of this CDQMP are as follows:

- To provide data of sufficient quality and quantity to support ongoing remedial efforts and further define the project contaminants of concern, if possible.
- To provide data of sufficient quality to meet applicable State of New Jersey and federal concerns (e.g., reporting requirements) as identified in the FMSS *General Environmental Protection Plan* (GEPP) (USACE 1999).
- To ensure samples are collected using approved techniques and are representative of existing site conditions.

- To specify QA/QC procedures for both field and laboratory methodology to meet the USACE and other applicable guidance document requirements such as:
  - EPA SW-846, *Test Methods for Evaluating Solid Waste: Physical/Chemical Methods*, Version 2 (EPA 1997).
  - EPA, QA/R-5, *Requirements for Quality Assurance Project Plans for Environmental Data Operations*, March 2001 (EPA 2001).
  - USACE, EM 200-1-6, *Chemical Quality Assurance for HTRW Projects*, October 1997 (USACE 1997).
  - DoD Quality Systems Manual for Environmental Laboratories, Version 1, October 2000
  - USACE, *Radionuclide Data Quality Evaluation Guidance*. May 2009 (USACE 2009).

1.2.3 Work Sites Description

The FMSS is located in Bergen County, New Jersey, approximately 20 kilometers (km) (12 miles [mi]) north-northwest of New York City and 21 km (13 mi) northeast of Newark, New Jersey. It is described in detail in the GEPP (USACE 1999). The reader is directed there.

1.2.4 Site History

The MCW was constructed in 1895. In 1916, the plant began extracting thorium and rare earth metals from monazite sands, by an acidic process, for use in manufacturing industrial products such as mantles for gas lanterns. The plant also produced a variety of other materials, including lithium compounds, detergents, alkaloids, and oils. The plant stopped accepting monazite sands for extraction of thorium in 1956, but it processed stockpiled materials until 1959. Based on available historical information and knowledge of the chemical processes involved, the chemicals identified as having been used in the thorium extraction process include sulfuric acid, nitric acid, ammonium hydroxide, and ammonium oxalate. Oxalic acid was also used at the site in the production of higher-grade thorium.

A detailed discussion of the site history is given in the GEPP (USACE 1999) and the reader is directed to the GEPP for follow-up.

1.3 PROJECT DESCRIPTION

Each task-specific Work Plan provides a description of the work that will be performed in order to provide an overall picture of how the project will resolve the problem or questions described in Section 1.2.1 (Problem Definition). A general description of the sampling will be included. Anticipated task start and completion dates will be included in addition to the following:

- Measurements that are expected during the course of the task and the approach that will be used.
- Applicable technical, regulatory, or program-specific quality standards, criteria, or objectives if they differ from those in this CDQMP.
- Any special personnel and equipment requirements that may indicate the complexity of the project.
- Assessment tools that will be employed for the task (program technical reviews, peer reviews, surveillance, technical audits, etc.).
- Project schedule or a sequence of milestones and their expected durations. If individual sampling plans will be developed for discrete task plans, their preparation schedule will be included.

This page intentionally left blank.

2.0 DATA QUALITY OBJECTIVES (DQO)

Data Quality Objectives (DQOs) are qualitative and quantitative statements that specify the quality of data required to support decisions made during investigation activities, and are based on the end uses of the data being collected. Detailed, site-specific DQOs shall be provided in the task-specific Work Plans and shall clearly describe what data are needed and how that data will be used to satisfy project DQOs.

For radiological samples, analytical test methods will be selected that have Minimum Detectable Activities (MDA) that meet the DQOs for the project. Similarly, for chemical analyses, methods shall be chosen that have Practical Quantitation Limits (PQLs) lower than the established Data Quality Objectives to the greatest extent practicable. Such test method pre-selection provides the highest probability that generated data is useful in making project decisions.

The DQO process is designed to provide a means to determine what type of data need to be collected, as well as to ensure that the data collected are scientifically sound, legally defensible, and of known, documented quality. The DQO process used for this remedial action follows the method outlined in MARSSIM (EPA 2000b) and the *Guidance for the Data Quality Objectives Process* (EPA 2000c) and in EM-200-1-2, *Technical Project Planning Process* (USACE 1998). The DQO process was chosen because it is an established process that identifies quality of data required for decisions.

An analytical DQO summary for these investigations is presented in the form of quality control limits for precision and accuracy in Appendix B. Any deviations or exceptions will be detailed in the task-specific Work Plan. All QC parameters stated in the specific SW-846 methods (i.e., percent recoveries) will be adhered to for each chemical listed.

Laboratories are required to comply with all methods as written. Laboratories selected will be required to submit all lab method SOPs and references, and the actual method detection limits (MDLs) to be achieved in all chemical analyses to Shaw and the USACE. For radiological parameters in soil, Shaw and the USACE will set the MDA to comply with the project requirements and the selected laboratory will be required to meet these limits.

In accordance with EPA guidance (EPA 2000c) and USACE guidance (USACE 1997), a combination of Screening Level and Definitive Level data will be required for each project. Definitive data is typically data generated under laboratory conditions using EPA-approved procedures. Data of this type, both qualitative and quantitative, are used for determination of source, extent, or characterization and to support evaluation of remedial technologies and preliminary assessment memorandum. The elements in the DQO process are as follows:

- Statement of the problem / Data Uses
- Identification of the decisions
- Data needed to meet objectives
- Definition of study boundaries
- Determination of decision rules
- Placement of limits on decision errors
- Optimization of design

The ability of a data generation process to meet the DQOs is provided through the establishment of data quality criteria, which include precision, accuracy, representativeness, comparability, completeness, and sensitivity (PARCCS) parameters. DQOs are also met by meeting certain goals for the PQL concentrations. Laboratory and field sampling activity documentation will be used to assess the PARCCS parameters. To provide for reliability of field sampling procedures and materials, QC samples will be collected or prepared at a defined frequency for each medium sampled, sample shipment, and each sampling event.

In addition to the collection of QC samples, QA samples will be collected at a frequency of five percent of the field samples collected for FSS samples and environmental monitoring samples only. There are no QA split samples collected for air, excavation control, and document control samples. QA split samples will be submitted to a separate USACE QA lab. The QA laboratory will be assigned by the USACE KCD.

The following subsections present the development of the DQOs for the FMSS investigations, remedial designs, and remedial actions.

2.1 STATEMENT OF THE PROBLEM / DATA USES

The FMSS vicinity property soils have been impacted primarily by radionuclides, specifically ^{226}Ra, ^{232}Th, and ^{238}U. If certain FMSS property soils and debris are contaminated with these radionuclides, or any other parameters listed in the final Record of Decision (ROD), at concentrations that exceed acceptable risk levels, they will be removed and transported off-site for disposal. Additionally, it will be necessary to show that remedial activities do not result in contaminant concentrations in the air, surface, and/or groundwater that exceed regulatory limits for on-site or off-site impact to workers, members of the public, and the environment.

The problem is to identify the types, quality, and quantity of data that will be used to support the remedial action within the planned project schedule.

The remainder of chapter two addresses DQOs for soil and groundwater remediation.

2.2 IDENTIFICATION OF DECISIONS

There are four key decisions that must be made to support project objectives. The key questions are:

1. **Work Area Remediation**—Do post-remedial site soil concentrations meet the appropriate cleanup criteria?
2. **Verification of Remedial Action**—Are there sufficient data to demonstrate that the FMSS vicinity properties have been remediated as specified in the ROD?
3. **Groundwater Remedial Investigation**—Have enough groundwater sample data been generated to adequately characterize groundwater contamination and thus allow for informed groundwater treatment decisions to be made? Is there enough data to allow us to assert that wastewater collected during remediation activities and treated on-site are below the discharge limits established by the Bergen County POTW?
4. **Transportation/Disposal—**Are the concentrations of contaminants of concern below the maximum concentrations allowed by a given soil disposal facility?

Associated with each of the key decisions are intermediate or follow-on decisions termed decision elements. The key decisions and decision elements are discussed in the following sections.

2.2.1 Work Area Remediation

The primary decision for work area remediation is whether soil concentrations for radionuclides and selected metals are reduced to levels that are less than the appropriate cleanup criteria. Decision elements are associated with individual soil excavation areas within each of the identified work areas. The decision as to whether all contaminated soils have been removed, and therefore that remaining soil analyte concentrations meet cleanup action levels, will be made for each excavation. The following are actions that would be taken to help answer the study questions:

- The excavation area is backfilled
- Additional soils are excavated

Inputs to this decision are discussed in Section 2.3.

The key decision for the demonstration of clean closure is whether there is sufficient site data to demonstrate that all accessible contaminated soils have been removed. The following are actions that would be taken to help answer the study questions:

- The FMSS properties are qualified as remediated via the radioisotopic results of a final status survey (FSS).
- Additional excavation of soil is required for successful remediation.

Sampling activities described in this document are used to support preparation of excavations for clean closure. Final verification surveys and verification sampling will be described in property-specific final status survey work plans.

2.2.2 Groundwater Remedial Investigation

The key question concerning the adequacy of groundwater sampling is whether groundwater characterization is sufficient to determine whether groundwater contaminant concentrations exceed action levels, and whether the exceedances can be attributed to historical site operations, or other off-site sources. To some extent, the answers to these questions will depend on the accuracy of groundwater modeling in predicting contaminant distribution. This will likely be an iterative process, in which initial sampling guidance, which may be provided by numerical models, will be succeeded by follow up sampling events. The actions that could be taken to help answer the study questions are that:

- Groundwater has been adequately characterized to determine:
  - Whether remediation is required, and if required, to develop preliminary remediation goals by evaluating the feasibility of remedial alternatives.
  - Whether contamination can be attributed to historical operations, or to off-site sources.
- More samples are needed.
- The model needs to be revised or a new model employed.

In addition, as part of the groundwater program, wastewater (excavation water, storm water runoff, etc.) shall be tested periodically. The accuracy of this data relative to Publicly Owned Water Treatment facility (POTW) requirements shall be considered in deciding whether to discharge these waters to the POTW.

2.2.3 Transportation and Disposal

The key question concerning the adequacy of sampling of soils destined for off-site disposal depends on the following:

- Whether sampled soils are representative of the soil quantity being shipped.
- The accuracy and precision of test data relative to the landfill disposal criteria and permitting requirements for contaminant concentrations.
- Possible changes in the concentration of contaminants over time.

The actions that may result are:

- Additional soil samples are collected from the disposal pile.
- Soil is shipped to the off-site disposal facility.

2.3 DATA NEEDED TO MEET OBJECTIVES

One major input decision is assurance that an individual work area has been remediated. This will be demonstrated through the use of field screening methods, in situ field measurements, and laboratory analytical methods for measurement of radiological constituents, which are stored in the EDMS (see Section 4.7). Inorganic and organic concentrations have been and will continue to be determined by laboratory analysis. These measurements will be used in nonparametric statistical tests as part of the final status surveys to demonstrate successful remediation for all contaminants of concern at the FMSS properties (^{238}U, ^{226}Ra, and ^{232}Th, plus any other contaminants listed in the ROD) or that may be discovered during a given site investigation.

A second major input decision is the conclusion that groundwater has been characterized adequately enough to determine the source of the contamination and the feasibility of treatment. PQLs (see Section 2.8.3 for definition of PQLs, also known as reporting limits [RLs]) for groundwater testing, must be lower than the proposed Maximum Contaminant Levels (MCLs) and New Jersey Groundwater Quality Criteria for chemicals and the National Primary Drinking Water Regulations for radionuclides. The groundwater program has adequately characterized the nature and extent of all chemical and radiological contamination in groundwater. Several groundwater plumes within the MISS, notably a benzene, lithium, and arsenic plume have been delineated. The remedial investigation determined that tetrachloroethene, trichloroethene, and dichloroethene plumes in Rochelle Park are derived from an offsite source; i.e., they are not associated with waste derived from the MCW. A baseline risk assessment is presently being prepared to determine the risk to various receptors within the FMSS due to contaminants present in groundwater, surface water, and sediment. Additionally, initial stages of the Feasibility Study have been initiated. Monitored Natural Attenuation (MNA) is being evaluated in conjunction with groundwater modeling efforts to determine if a reduction of benzene to below cleanup standards is likely due to the presence of aerobic and anaerobic bacteria present in the groundwater system. Two other chemicals, lithium and arsenic, exhibit concentrations well above cleanup action levels. The source of these two chemicals is believed to be the retention ponds on the MISS. No treatment schemes have been proposed yet for these chemicals.

2.4 DEFINITION OF STUDY BOUNDARIES

The study boundaries for the FMSS vicinity properties are defined in the ROD (USACE 2003d). The FMSS consists of properties in the boroughs of Maywood and Lodi and the township of Rochelle Park, New Jersey that became contaminated by thorium processing operations at the former MCW. The ROD

states that these remedial actions are limited to hazardous substances released during the aforementioned thorium processing operations. More specifically, the Federal Facilities Agreement (FFA) states that USACE is responsible for FUSRAP waste, defined as:

- All radioactive and chemically impacted materials, whether mixed together or not, occurring on MISS.
- All radioactive impacted materials from past thorium processing at the MCW site above action levels on any nearby property.
- Any chemically impacted material on nearby properties that is mixed with radioactivity above cleanup criteria.
- Impacted material that originated at MISS or was associated with specific thorium manufacturing or processing at MCW.

The remedial actions are to remove and dispose of all accessible soils that are above the cleanup criteria, and to treat and discharge groundwater and excavation water that is contaminated with radionuclides of concern or chemicals above acceptance criteria.

2.5 DEVELOPMENT OF DECISION RULES

2.5.1 Work Area Remediation

The cleanup criteria for radionuclides, SVOCs, VOCs, metals, etc. are contained in Appendix A of this CDQMP.

During excavation activities, a combination of exposure rate monitoring and remedial support soil sampling will be conducted to determine if radiological contaminants have been removed to a level below established clean-up goals. When remedial support data suggests that the appropriate cleanup level has been attained, final status survey measurements will be collected and evaluated against defined clean-up criteria. These will consist of soil samples collected and analyzed by a state-certified radioanalytical laboratory (gamma/alpha spectroscopy) and collection of gamma walkover survey data. Section 2.1.3 of the FSP discusses the final status surveys to be performed. FSS and associated clearance evaluations are conducted based on guidance provided in NUREG 1575 (MARSSIM, EPA 2000b) and according to the requirements of the Master Final Status Survey (FSS) Plan (USACE 2001a).

2.5.2 Groundwater Remediation

For the groundwater program, the upper 95% confidence limit of the mean of each chemical and radiological contaminant data set shall be compared to the most stringent (lowest) groundwater and soil action levels. The action levels used for this project are the MCL and New Jersey Groundwater Quality Criteria for water and the soil impact to groundwater and New Jersey direct contact residential criteria for soils. If the upper 95% confidence limit is less than the action level, no cleanup action will be required. If the upper 95% confidence limit is greater than the action level, a treatment scheme shall be developed. The radiological cleanup levels for groundwater and surface water are as follows:

Table 2-1
Radiological Cleanup Levels for Groundwater and Surface Water

Ra-226 plus Ra-228	5 pCi/L
Total uranium	30 μg/L
Gross alpha	15 pCi/L (excluding uranium and radon)
Gross beta	50 pCi/L

As stated earlier, the cleanup criteria for chemical parameters are listed in Appendix A of this CDQMP.

2.6 SPECIFY THE LIMITS ON DECISION ERRORS

Because decisions pertaining to remediation will be based on analytical data, an attempt is made to define, and if possible, limit decision errors that may result from the limitations of the sampling and analyses. To limit decision errors, analytical method data indicator objectives have been established and are presented in Section 2.8.

Limits on decision errors will be controlled through development of a sampling and analytical methodology to demonstrate that sufficient data have been generated for a decision. Methodology described in MARSSIM (EPA 2000b) will be followed to determine the number of measurements needed for final status surveys. This methodology consists of a statistical determination of the number of required sampling points. Statistical determination of the number of sampling points will also be used for the groundwater and material transportation and disposal programs. Determination of the number of samples depends on:

- The difference between the mean value of a contaminant of concern and the cleanup level.
- The precision of the mean values for a given parameter as determined by the standard deviation of the mean.
- The distribution of past and more recent data (e.g., normal, lognormal, non-parametric, etc.).
- Values established for decision errors.

Analysis of soil samples could potentially result in the incorrect reporting of the concentration of a contaminant. The two types of decision errors that could result are the reporting of false positives (Type I) and the reporting of false negatives (Type II). False positives and false negative decision errors are defined in the context of hypothesis testing, where the terms are defined with respect to a null hypothesis. The null hypothesis states that the concentration of a given contaminant of concern is above the cleanup action level. A false positive decision error occurs when the null hypothesis is rejected when it is true and corresponds with an analytical false negative (or more accurately, the analytical result is biased so low that the incorrect decision is made that the contaminant concentration is below the cleanup action level). A false negative decision occurs when the null hypothesis is not rejected when it is false and corresponds with an analytical false positive (the analytical result is biased so high that the incorrect decision is made that the contaminant concentration is above the cleanup action level).

Potential consequences of an analytical false positive (for establishment of soil remediation design limits and remedial support sampling decisions) are as follows:

- Unnecessary excavation and disposal of soils that meet cleanup criteria.
- Incorrect identification of additional areas as exceeding cleanup criteria when in reality they meet cleanup criteria.

Potential consequences of an analytical false negative (for establishment of soil remediation design limits and remedial support sampling decisions) are as follows:

- Failure to remove soils that exceed the cleanup criteria.
- Failure to identify additional areas within the FMSS properties that require remediation.

- Verifying that the property under consideration is remediated when in fact accessible soils exceeding the cleanup criteria remain.

Potential consequences of an analytical false negative (for FSS) are as follows:

- Failure to remove soils that exceed the cleanup criteria.

Potential consequences of an analytical false positive (for FSS) are as follows:

- Unnecessary excavation and disposal of soils that meet cleanup criteria.

Potential consequences of an analytical false positive (for the groundwater treatment decision) are:

- Unnecessary treatment of FMSS groundwater that is below cleanup standards.
- Possible incorrect interpretation that contaminated groundwater is migrating off-site.

Potential consequences of an analytical false negative (for the groundwater treatment decision) are:

- Failure to treat groundwater that is contaminated above specific parameter action levels.
- Failure to notify adjacent property owners that groundwater migrating onto their property is contaminated.

Potential consequences of an analytical false positive (for the soil disposal decision) are:

- Unnecessary shipment of below cleanup criteria soils to the soil disposal facility.

Potential consequences of an analytical false negative (for the soil disposal decision) are:

- Failure to ship soils that are contaminated above cleanup criteria to a disposal facility.

Definitive data are required for supporting project decisions. It is assumed that if the precision, accuracy, and completeness requirements specified in this section are met, and the minimum number of samples are collected in accordance with appropriate statistical tests, then definitive data will be obtained and can be used for performing remedial actions and monitoring. The limits on the magnitudes of decision errors selected for the FMSS site radiological data will be 5% for false positive (α) decision errors (corresponding to an analytical false negative; see consequences on previous page) and 10% for false negative (β) decision errors (corresponding to an analytical false positive; see consequences on previous page. Decision error rates may be set lower in coordination with USACE. A decision level will be established for each sample count and/or count protocol so that there is 5% probability of a false positive result. This decision level is defined as the Critical Level, or L_c. The count result shall be reported as the sample activity where the sample counts are greater than the L_c. The Minimum Detectable Activity (MDA) will be reported in place of the sample activity for those sample results that are less than the L_c - except where unbiased results are permitted. The MDA shall be equal to or less than the DQO for those cases where the count results are less than the L_c, - except where it is permitted that the DQO be exceeded.

For chemical data, the decision error limits shall be 5% for false positive (α) and 15% for false negative (β) decision errors.

2.7 OPTIMIZATION OF THE DESIGN

As a result of the DQO process, the optimum sampling design is derived for this remedial action. While all of the properties have been sampled, the quality and quantity of existing data do not enable completion of accurate designs. Two types of survey data will be collected to optimize the design. Characterization data for radionuclides will be collected at all accessible FMSS properties for which the quality and quantity of existing data do not enable completion of accurate designs. Remedial support survey data will be collected to guide the excavations such that all soils containing radionuclide concentrations that exceed the cleanup criteria are removed.

To optimize the design for the groundwater characterization effort, additional data shall be collected from areas of known contamination to better define contamination plumes and sources.

2.8 STANDARDS / CONTROLS TO ENSURE OBJECTIVES ARE MET

The analytical data used as inputs to the DQO process must be of known and sufficient quality to support the end use of the data. Analytical data of known and acceptable quality for the intended use are generated by the implementation of carefully chosen QA/QC protocols, both in the field and in the laboratory. QA/QC goals are set for:

- Each single measurement.
- The entire data set of which the single measurement is a part.

Each individual measurement should be precise, accurate, representative, comparable, and part of a complete data set. Precision, accuracy, representativeness, comparability, and completeness are often referred to by the acronym PARCC, and are known as the PARCC parameters. The PARCC parameters of precision and accuracy can be quantified for a single measurement and for a complete data set. Representativeness and comparability are not as quantifiable as precision and accuracy, although there is necessarily some overlap between the parameters of representativeness, precision, and accuracy. Analytical completeness is assessed by comparing the total number of analytical results expected for a data set (based on the number of samples collected) with the total number of usable (i.e., not qualified R, or rejected) analytical results. The test measurement method must be sensitive enough to ensure that method detection limits are less than project cleanup criteria. The count time for radiological samples will be set so that the Minimum Detectable Activity (MDA) for a typical sample type meets the DQOs for the project. Similarly, for chemical parameters, the method chosen will be, to the greatest extent practicable, the one that achieves reporting limits that are below cleanup levels. Methods may require modifications to achieve project DQOs.

The goal for analytical precision and accuracy is that each measurement should be associated with laboratory QC that is within limits. QC limits for both chemical and radiological parameters are those required by the requested analytical method. This CDQMP sets forth the QC limits (see Appendix A) required for the FMSS properties remediation for radiological and chemical analyses. Matrix samples including matrix spike (MS) and matrix spike duplicate (MSD) samples (MS/MSD for organics and MS/MD (matrix duplicate) for inorganics), will be used to assess the effect of matrix on the measurement process. Laboratory control samples (LCS), or blank spikes, will be used to assess the accuracy and precision of the measurement process in the absence of effects from field samples. Method blanks will be used to assess possible laboratory contamination, and field blanks – such as trip blanks and equipment rinseate blanks – will be used to determine sources of contamination from the sampling location, the sample container, the sampling equipment, or sample transport.

Requirements for precision and accuracy to meet data quality goals are identified in Appendix B. Requirements for completeness are noted in Section 2.8.4.

Data quality indicators are percent differences between replicate or duplicate sample (precision), percent recoveries of blank or matrix spike results (accuracy), and MDLs or MDAs, and PQLs (sensitivity). Data indicator objectives are established to ensure the quality of the analytical data produced by the laboratory. A general description of each of the data indicator objectives is given below along with the data assessment procedures. All data must meet or exceed limits for precision and accuracy stated in the individual analytical methods.

2.8.1 Precision

Precision is the degree to which the measurement is reproducible and is frequently determined by comparison of laboratory designated duplicates or designated laboratory MS/MSDs. Precision is important because it represents the ability of the laboratory to produce consistent results. Precision of analyte concentrations in field samples is typically measured by the collection and testing of field duplicate samples. In that case, precision is calculated by the percent difference (%D) between the field duplicate results. That is:

$$\%D = (A - B)/[(A + B)/2] \times 100$$

where: A = *first sample result*
B = *second sample result*

Standard deviation (S) is calculated as follows:

$$S = \left(\sum_{i=1}^{n} \frac{(x_i - \bar{x})^2}{n-1} \right)^{1/2}$$

x_i = *measured value of the* i^{th} *replicate*
$\bar{x}$ = *average of replicate measurements*
n = *number of replicates*

If more than two samples are collected at the same location and at the same time, precision will be calculated as % relative standard deviation (%RSD). %RSD may be calculated as follows:

$$\%RSD = \frac{S}{\bar{X}} \times 100\%$$

$\bar{X}$ = *average of replicate measurements*
S = *standard deviation*

For radiological laboratory replicate and field duplicate results, the absolute difference $|X_1 - X_2|$, provides an indication of precision if the average value of the two replicates is less than the action level. If the average value of the two replicates is greater than the action level, the relative percent difference (RPD), 100 x $|X_1 - X_2| / \overline{X}$ provides an indication of precision

See Appendix D of this QAPP, USACE Radionuclide Data Quality Evaluation Guidance for additional details on acceptance criteria for laboratory replicate and field duplicate results.

2.8.2 Accuracy

For chemical parameters, accuracy is reported as the percent recovery (%R) of a parameter from a laboratory or field sample spiked with a known value of the parameter for a given analytical procedure. Accuracy is important because it is a measure of the true concentration of a parameter for a given analytical procedure. The determination of the accuracy of a measurement requires knowledge of the true or accepted value for the parameter being measured and the value of the parameter for the unspiked sample. Accuracy is monitored for each matrix type. The %R may be calculated as follows:

$$\%R = \frac{X_s - X_u}{K} x\ 100\%$$

where: X_s = *measured value for spiked sample*
X_u = *measured value of unspiked sample*
K = *known value of the spike in the sample*

For radiological parameters, the percent difference (%D) is used to assess the accuracy of laboratory control sample (LCS), or blank spike results, and the Z score (EPA 2004) is used to assess the accuracy of matrix spiked sample results. Tracers, which are known spikes of either an isotope of the same element as the isotope of interest, or an element that is chemically very similar to the isotope of interest, are added to all field samples and batch QC samples and so provide a recovery value for each sample which is indicative of any losses or method anomalies that might have affected the isotope of interest. The %D is defined as:

$$\%D = \frac{SSR - SA}{SA} x100$$

Where:

%D is the percent difference
SSR is the measured result (spiked result)
SA is the spike activity (or concentration) added.

For matrix spike results, the Z score statistic is defined as follows:

$$\text{Z-Score} = \frac{SSR - SR - SA}{\phi_{MR}\sqrt{SSR^2 + \max(SR, UBGR)^2}}$$

Where:
max (x,y) denotes the maximum of x and y
φ_{MR} is the maximum allowable (relative) standard deviation at the UBGR
SSR is the spiked sample result
SR is the sample result

SA is the activity spiked into the sample

The terms φ_{MR} and UBGR are defined within Appendix D of this QAPP. Accuracy may also be impacted by blank contamination. The potential impacts of LCS, matrix spike, and blank results on sample results are evaluated within Appendix D of this QAPP.

2.8.3 Method Detection Limits and Reporting Limits

RLs will be based on MDLs, except that the RLs for samples analyzed under the Toxicity Characteristic Leachate Procedure (TCLP) will be the regulatory limits for individual compounds as listed in 40 CFR, Part 261.24, Table 1. The RL is often called the PQL.

MDL is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from the analyses of seven blanks, each spiked in an identical fashion with the analytes of interest, so that the final concentration of the spiked solution is approximately two to five times the expected method detection limit. Following analyses, the mean and standard deviation of the seven results is calculated. The MDL may be calculated as follows:

$$MDL = t_{(n-1,\ \alpha = 0.99)} \times S$$

where: S = *standard deviation of the replicate analyses*
$t_{(n-1,\alpha=0.99)}$ = *one-sided 99% t-statistic*
n = *number of measurements of analyte*

Typical RLs are provided in Appendix A of this QAPP. They are typically 2 to 10 times the MDL.

It should be recognized that MDLs and RLs are sample matrix dependent and may be raised due to matrix interferences and/or dilution factors.

Several parameters unique to radiochemical analyses are used to describe the sensitivity of the detection systems. These parameters are lifted directly out of the NUREG/MARSSIM guidance (EPA 2000b). They include the critical level (L_c), detection limit (L_d), and MDA.

L_c is the net response level (in counts) at which the detector output can be considered above background. It may be calculated as follows:

$$L_c = k\sqrt{2B} = 2.33\sqrt{B} \quad \text{for } \alpha, \beta = 0.05$$

L_d is the net response level (in counts) that can be expected to be seen with a detector with a fixed level of certainty. It may be calculated as follows:

$$L_d = k^2 + 2k\sqrt{2B} = 3 + 4.65\sqrt{B} \quad \text{for } \alpha, \beta = 0.05$$

where: k = *Poisson probability sum for* α *and* β *(assuming* α *and* β *are equal)*
B = *number of background counts that are expected to occur while performing an actual measurement*

The MDA is the a priori net activity level above the L_c that an instrument can be expected to detect 95% of the time. It may be calculated as follows:

$$MDA = C \times (3 + 4.65\sqrt{B})$$

where: *C = factor to convert from counts to concentration*
B = number of background counts that are expected to occur while performing an actual measurement

2.8.4 Data Completeness

Completeness refers to the amount of valid data obtainable (by the specific method the laboratory used with the instrument to be employed) from a measurement system compared to the expected amount of data, and is usually expressed as a percentage. Completeness may be calculated as follows:

$$Completeness = \frac{amount\ of\ valid\ data}{expected\ amount\ of\ data}\ X\ 100\ \%$$

Valid data can be defined as either acceptable data or quality data. Quality data are data that passed all QC indicators. Acceptable data are data that are either quality data or data for which corrective actions have been performed. The minimum completeness for acceptable data required for this project is 95%. The minimum completeness is 98% for each of the analytical methods employed in the task-specific Sampling and Analysis Plans (SAPs). Completeness for quality data shall be 80%.

Analytical data will be divided into two categories:

- Non-critical measurements
- Critical measurements

Non-critical measurements are defined as organic and wet chemistry (e.g., anions, alkalinity, Total Kjeldahl Nitrogen (TKN), etc.) soil and water quality parameters, while critical measurements are defined as radiological constituents, metals, and TCLP. Non-attainment of QA objectives for non-critical measurements will have a minor impact on project objectives. The most important objective for critical measurements is completeness because it is based on data validity and directly impacts project decisions. Non-attainment of completeness may result in the need for resampling at specific locations. Water quality parameters may be critical if one is considering discharge of groundwater, storm water, or decontamination water.

3.0 DOCUMENTATION AND RECORDS

3.1 DATA REDUCTION, VALIDATION, AND DOCUMENTATION

3.1.1 Calculations

All FMSS samples requiring radiological testing, including waters, soils, air filters and smears are routinely analyzed by UFML, except for USACE QA split samples, which are analyzed by Test America Laboratories in Earth City, MO. The analyses of water and soil samples, as well as smears that are used as equipment blanks, are described below. The air filters and all other smear analyses are discussed in the Radiation Protection Plan, a component of the Site Safety & Health Plan (USACE 2006a).

Soils

The UFML method to be used for routine detection of ^{232}Th, ^{226}Ra and ^{238}U in soils is gamma spectrometry. The method is based upon the HASL-300 Method Ga-01-R, Gamma Radioassay (HASL-300, 28th Ed., Feb. 1997, US DOE Environmental Measurements Laboratory).

Soil loadout soil samples are analyzed "as is" (i.e., without drying and grinding) since knowing the exact radionuclide activity in these samples is not as critical as other types of samples. For FSS, document control, and backfill samples, the samples are dried 4 to 10 hours (or overnight) in a 105°C oven. Each dried sample is placed in a pulverizer and pulverized, then transferred to a Marinelli or tuna can container for counting using gamma spectrometry. Excavation control samples are also dried, but are sometimes first counted wet. Such measurements quantify the ^{232}Th, ^{226}Ra and ^{238}U activities by counting the gamma-emitting decay products ^{228}Ac, ^{214}Pb, and ^{234}Th, respectively. Since in each case the two radionuclides are assumed to be in equilibrium, the activity of the parent radionuclide equals the activity for the daughter radionuclide. Correction factors for wet-dry analysis (i.e., to account for the presence of moisture in soil sample undergoing gamma spectrometry) have been developed for the project. An additional correction factor has been developed for Ra-226 gamma spectrometry analyses (applicable to dried soil samples that have had insufficient time to allow for the in-growth of the photon emitting daughters in the Ra-226 decay chain.

The equation for calculation of the activity of each isotope in picoCuries (pCi) per gram (pCi/g) is:

$$C\ (pCi/g) = \frac{CF \times (Cpm\ of\ sample\ peak - Cpm\ background\ peak)}{(2.22\ dpm/pCi) \times D \times W}$$

where: *CF=Applicable correction factor(s)*
D = efficiency of counting for the gamma spectrometer (cpm/dpm)
W = weight of solid (grams)

Isotopic uranium, isotopic thorium, Ra-226, and Ra-228 in soil can be measured by the onsite laboratory. The equations for calculation of the activities of these isotopes are discussed in the Waters Section below.

Waters

Wastewater samples are collected and analyzed in accordance with the requirements established by the Bergen County POTW. Currently, wastewater samples are collected after 125,000 gallons have been processed. The sample collected after 125,000 gallons of wastewater have been processed is analyzed for gross alpha (GA) and gross beta (GB). After every 500,000 gallons have been processed, a sample is

collected and analyzed for not only GA and GB, but also iso-thorium, iso-uranium, Ra-226, and Ra-228. The GA method used depends upon the amount of total solids (dissolved plus suspended) in the sample. If there are less than 500 parts-per-million (ppm) of total solids, EPA Method 900.0, Gross Alpha and Gross Beta radioactivity in Drinking Water is used. If the total solids is greater than 500 ppm, Method 7110C (Standard Methods Ref.), Coprecipitation Method for Gross Alpha Radioactivity in Drinking Water, is utilized. EPA Method 900.0 is always used for GB.

Measurement of iso-thorium, iso-uranium, and Ra-226, utilizes an isotopic tracer spike followed by acid digestion. Measurement of Ra-228 relies upon barium sulfate carrier recovery to estimate the Ra-228 recovery. The SOPs for these methods are equivalent to Eichrom methods ACW02, Revision 1.3 for iso-uranium and ACW10, Revision 1.0 for iso-thorium (Horwitz 1993); EPA 903.0, Alpha-Emitting Radium Isotopes in Drinking Water (modified)(EPA 1980) and HASL-300 method Se-02, Isotopic Uranium, Isotopic Thorium, and Radium-226 (modified) for Ra-226 (DOE 1997); and EPA Method 9320 (modified), Ra-228 in Drinking Water, for Ra-228 (EPA 1997). These SOPs are located in the EDMS (see Section 4.7). For iso-uranium and iso-thorium, an aliquot of a homogenous sample is digested with an acid mixture. Uranium-232 and thorium-229, man-made isotopes, are added to the samples, as required, in known quantities as tracers. The solution is subsequently passed through an ion exchange resin column that separates the elements of interest, each of which are subsequently coprecipitated as tetrafluorides with neodymium fluoride. The activity of each thorium isotope, C (pCi/l), is calculated from the alpha spectrometry count as follows:

$$C\ (pCi/l) = \frac{\text{Cpm of sample (thorium isotope peak) - Cpm background (thorium isotope peak)}}{(2.22\ dpm/pCi) \times D \times V \times Y}$$

where: D = *efficiency of counting for the alpha spectrometer (cpm/dpm)*
V = *volume of water (liters)*
Y = *fractional recovery of the Th-229 (^{229}Th) tracer.*

The conversion value of 2.22 disintegrations per minute (dpm) per picocurie (pCi) is based on the standard value for 1 curie of 3.700E10 disintegrations per second (dps) (CRC 1974-75). 3.7E10 dps/curie X 60 sec/min X (1 curie / 10^{12} pCi) = 2.22 dpm/pCi.

The activity of a given uranium isotope in a water sample, F (pCi/L), is calculated from the alpha spectrometry count as follows:

$$F\ (pCi/L) = \frac{\text{cpm of sample (^{238}U peak) - cpm background (^{238}U peak)}}{(2.22\ dpm/pCi) \times D \times V \times Y}$$

where: D = *efficiency of counting for the alpha spectrometer (cpm/dpm)*
V = *volume of water (liters)*
Y = *fractional recovery of the U-232 (^{232}U) tracer*

For ^{226}Ra, the method coprecipitates radium with barium and lead sulfate, and purifies it by re-precipitation from EDTA solution. Barium-133 (Ba-133) tracer is added to the sample during the initial sample preparation. Citric acid is added to the sample to ensure that complete interchange occurs before the first precipitation step. The final $BaSO_4$ precipitate, which includes Ba-133, Ra-226, radium-224 (Ra-224), and radium-223 (Ra-223) is counted by alpha spectroscopy for Ra-226. The activity of Ra-226, A (pCi/L) is calculated from the alpha spectrometry count as follows:

$$A\ (pCi/L) = \frac{\text{cpm of sample (^{226}Ra peak) - cpm background (^{226}Ra peak)}}{(2.22\ dpm/pCi) \times E \times V \times R)}$$

Where:
E = predetermined counter efficiency for Ra-226 in $BaSO_4$
V = volume of sample aliquot in liters
R = fractional chemical yield (Ba-133 activity recovered / Ba-133 added)

For Ra-228, radium in the sample is collected by coprecipitation with barium and lead sulfate, and purified by reprecipitation from an EDTA solution. After an in-growth of 36 hours, equal to approximately 6 half-lives of Ac-228 and allowing for the transient equilibrium of the Ra-228 to Ac-228, the actinium is coprecipitated with yttrium oxalate, purified, and beta counted. The initial chemical separation process isolates radium from potential beta emitters such as cesium, strontium, and lead. The actinium yttrium oxalate is counted in a gas proportional counter for gross beta. Since the Ac-228 was in equilibrium with Ra-228 at the time it was precipitated as the oxalate, the gross beta count equals the Ra-228 activity. The activity of Ra-228, D (pCi/L) is calculated from the gas proportional detector count as follows:

$$D = \frac{C}{2.22 * E * V * R} \; X \; \frac{\lambda * t_2}{\left(1 - e^{-\lambda t_2}\right)} \; X \; \frac{1}{\left(1 - e^{-\lambda t_3}\right)} \; X \; \frac{1}{e^{-\lambda t_1}}$$

where:
C = average net count rate, cpm
E = efficiency of detector, for Ac-228 or comparable average beta energy nuclide
V = volume of the sample in mL or g
R = fractional chemical yield of the yttrium carrier (R_Y) X fractional chemical yield of the barium carrier (R_{BaSO4})
λ = decay constant for Ac-228 = 0.001884 min^{-1}
t_1 = time interval between first Yttrium Hydroxide step (11.80) and start of counting time
t_2 = time interval of the count of the sample = 30 minutes
t_3 = the in-growth time of the actinium in minutes measured from the last barium precipitation

The fractional chemical yield of the yttrium carrier, R_Y, is determined from the weight of yttrium oxalate recovered and the mass of yttrium added (step 11.59). The mass of yttrium oxalate precipitate is converted to mass of yttrium by multiplying by the ratio of yttrium in one mole of $Y_2(C_2O_4)_3\ H_2O$.

$$R_Y = \frac{\left(M_{YOx}\right)\left(\frac{2 * Z_Y}{MW_{YOx}}\right)}{M_Y}$$

where:
M_{YOx} = mass of yttrium oxalate recovered
M_Y = mass of yttrium added
Z_Y = atomic weight of yttrium
MW_{YOx} = molecular weight of yttrium oxalate ($Y_2(C_2O_4)_3\ H_2O$)
The atomic weight of yttrium is multiplied by two because there are two moles of yttrium in one mole of yttrium oxalate.

The fractional chemical yield of the barium carrier R_{BaSO4}, is determined by weighing the $BaSO_4$ precipitate, converting that weight to the weight of barium, and dividing it by the weight of barium added.

For SW-846 methods, the procedures to be used for calculation of the concentration of organics can be found in Sections 7.7 of both Method 8260B and 8270C for volatile and semivolatile organics, respectively, Sections 7.5.6 and 7.6 of Method 8081A for pesticides, and Sections 7.8 and 7.9 of Method 8082 for PCBs. For metals by Method 6010B, there is no calculation for aqueous samples; that is, the instrument response, which is based on a method acceptable calibration, provides the analyte concentration. If a dilution is required, the instrument response must be multiplied by the dilution factor to obtain the analyte concentration in the original sample. For metals in soils by 6010B, the dilution factor incurred by sample preparation is approximately 100 (depends on actual sample weight and percent moisture). The instrument response is then multiplied by the dilution factor to obtain the analyte concentration in the sample. For solid samples, the result is also divided by the weight fraction of dry solids in the sample to obtain the final result.

3.1.2 Procedures to Ensure Data Integrity

The principal criteria to assure data integrity during collection and reporting shall include the following:

- For collection, the number of samples to be collected will be statistically determined to provide the highest probability that the data quality objectives outlined in this CDQMP will be met.
- For testing, both field and laboratory QC samples will be analyzed in order to evaluate potential blank contamination, analyte recovery from the sample matrix, laboratory and field sample testing precision, and proper instrument calibration. The laboratory will be instructed how to proceed when recoveries are outside of established QC limits, blank contamination is present, or other unforeseen problems arise. These instructions, entitled Guiding Principles, are contained within the first two pages of Appendix E of this QAPP.

3.1.3 Treatment of Outliers

Outliers are extreme high or low measurements that are set apart from most of the data. They may arise from matrix interferences, errors in transcription, sample preparation, analytical method, or regional variations in the background geochemistry. Apparent outliers may also represent areas with unusually high concentrations.

Outliers that are obvious mistakes should be corrected, otherwise they will disproportionately affect the statistical descriptors of the data set. Outlier statistical tests, however, should only be used to identify potential outliers that require further evaluation (EPA 2000a). EPA 2000a recommends 1 of 4 types of statistical tests: Dixon's Extreme Value test (when sample size is less than or equal to 25), Discordance test, Walsh's test (non-parametric test), or Rosner's test. After identification as a potential outlier, consideration should be given to the magnitude of the observation with respect to the assumed distribution for the data set. It is important to note that no datum should be discarded as an outlier based solely upon the results of these statistical tests. The chosen statistical test should be performed on the original data set and the truncated data set.

Decisions on the use or rejection of outlier data will be aided by the laboratory supplying information justifying an extreme result, especially when associated with QC results that exceed criteria.

3.1.4 Data Management

The laboratory will employ a three-phase review. First, the analyst reviews the data, then the analyst's supervisor reviews the data, and finally a QA person checks for proper QA/QC protocol as well as any results that appear unusual.

3.1.5 Data Archive

Sample data is saved electronically within the laboratory database, project database, and project shared hard drive. Hardcopies are retained for 6 months in file cabinets within the laboratory building. After the 6-month period, data is stored in boxes in a different location onsite or disposed as directed by USACE. Electronic data packages and data validation reports received by the FMSS Project Chemist or Sample Coordinator are scanned and the scanned files moved into Documentum, an electronic data and document repository for the FMSS project. Hardcopy data will be stored for the duration of the project.

This page intentionally left blank.

4.0 MEASUREMENT / DATA ACQUISITION

4.1 SAMPLING PROCESS DESIGN

Systematic evaluation of the objectives of the investigation, the use of the data to be collected, and an evaluation of the data quality requirements form a methodology for designing an adequate and appropriate sampling plan. The following discussion presents three approaches to defining the sampling requirements: the Observational Approach, which focuses on the data needed to define and evaluate site conditions based on source / pathway / receptor evaluation; Technical Project Planning, which breaks down project planning into distinct phases; and EPA's DQO process, which focuses on a need/ decision/ action evaluation for the site. Each of these planning methodologies is used to define the minimum acceptable and necessary data set for each investigative area or media type. Once the minimum data set is defined, refinements and additions are made to fulfill all identified and anticipated data requirements, and to resolve or constrain uncertainty. These approaches require systematic identification of the end use of the data. If there is no identifiable action to be taken or decision to be made based on a given proposed data set, then these data are deleted from the sampling plan. The systematic evaluation of collected data and the decision / action process result in collecting only needed data in a cost-effective and expedited manner.

This Section describes the approach that will be employed in the task-specific Work Plans for defining sampling requirements. Shaw shall follow EM 200-1-2, Technical Project Planning Guidance for HTRW Data Quality Design, for defining data needs and data quality objectives for FMSS project tasks in those Work Plans.

4.1.1 Observational Approach

The Observational Approach assesses the site's "probable conditions" based on the available data. It is intended that the "probable conditions" be understood to the extent necessary to meet the sampling objectives (i.e., evaluate potential risks and resolve data gaps).

As part of the approach, a detailed conceptual model is developed based on the current understanding of site conditions including:

- Primary Sources.
- Primary release mechanisms.
- Secondary sources.
- Secondary release mechanisms.
- Pathway of migration.
- Exposure routes.
- Potential receptors.

The primary release mechanisms for the primary contaminants of concern (PCOCs) are:

- Erosion.
- Wind-blown dust.
- Surface water runoff.
- Operation activities / construction disturbances.
- Infiltration / percolation to adjacent and underlying soils.

- Solubility or suspension in ground water.
- Ground-water infiltration / discharge to surface water.

Secondary sources of PCOCs include surface water and features receiving surface water such as drainageways and sediments, groundwater, soils surrounding and underlying storage and disposal areas, and on-site and off-site sediments. Secondary sources may also include receptors, which consume contaminated biotic or abiotic matrices.

Secondary release mechanisms include:

- Channel flow / surface water transport
- Sediment deposition (in-channel and over-bank)
- Sediment traps
- Dredging of sediments from drainageways
- Overland flow / storm water runoff
- Infiltration to subsurface soil
- Fugitive dust
- Potential ground-water movement from source areas

Potential contaminant of concern (COC) exposure routes for human and ecological receptors include:

- Inhalation of dust
- Ingestion of soil, surface water, ground water, contaminated fish, plants, or animals
- External exposure
- Dermal contact with soil, surface water, sediments, or ground water

The Observational Approach uses "decision rules" (as does the DQO process) for the purpose of linking data needs and uses. This approach helps to focus the sampling plan and sampling strategies by developing a conceptual model that identifies sources, pathways, and potential receptors. To augment the conceptual model, a DQO discussion that follows EPA's guidance is presented in Section 2.0.

4.1.2 Technical Project Planning

The Technical Project Planning approach (USACE 1998) occurs in several phases. In Phase I, the team identifies the site approach, including site objectives, regulator and stakeholder perspectives; and then prepares a Phase I Memorandum for Record to document the team's findings and decisions during Phase I.

In Phase II, one defines and documents data needs by determining the role of the data user, and evaluating the use of existing data.

In Phase III, one plans the sampling and analysis approach, including various data collection options.

In Phase IV, the description of the data collection program is finalized. This includes communicating with the customer and the regulators, encouraging participation by all stakeholders, preparing a Final Scope of Work or Work Plan, and preparing a cost estimate.

Phase V is the actual implementation of the data collection program. During and after the program, the project team will assess the data collection effort, including whether or not project data quality objectives have been attained. It will use this information to guide and plan future data collection efforts.

4.1.3 Data Quality Objective Process

The DQO process is discussed in Section 2.0.

4.1.4 Sampling Network

For soils, the line transect method will be used to locate areas of contamination. The types of samples required will include all matrices known or having the potential to be contaminated including surface and subsurface soils, concrete, building interior and exterior surfaces, groundwater, surface water, sediments, and storm water.

4.2 SAMPLING METHODS REQUIREMENTS

Field screening and sampling covers all sampling activities at the FMSS properties including sampling of soils, building materials, backfill materials, air, groundwater, surface water, sediments, and wastewater. Additionally, it covers radiological background determination (downhole logging, gamma walkover surveys, soil gas surveys for VOC screening, meteorological monitoring, and air monitoring for industrial hygiene requirements). Section 2.0 of the FSP describes the methods and techniques to be used for sampling / monitoring all applicable media and parameters. Sampling protocols will follow USACE Environmental Sampling Instructions (EM-200-1-3). The task-specific Work Plans will describe specific soil sampling activities for the various tasks such as pre-design investigation, remedial confirmation / final status surveys, groundwater remedial investigation, wastewater treatment, and materials handling in preparation for transport and disposal. In the FSP, **Tables 3-1** and **3-2** provide bottle requirements, preservation, and holding times to extraction and/or analysis for all analytical parameters and matrices. Support facilities will be required and will include:

1. Area where hand-held field surveying equipment can be properly calibrated and kept periodically charged.
2. Decontamination area for cleaning of sampling equipment, including drill bits and sampling tools.
3. Area for storing / stocking sampling supplies such as tape, foil, solvents, bailers, paper towels, etc.
4. Clean area for sample management.

4.2.1 Corrective Actions

Technical staff and project personnel will be responsible for reporting all suspected technical and QA nonconformances or suspected deficiencies of any activity or issued document by reporting the situation to the Project Manager or his / her designee and the CQCSM. The Project Manager will be responsible for assessing the suspected problems in consultation with the CQCSM and Sampling Coordinator to make a decision based on the potential for the situation to impact the quality of the data. When it is determined that the situation warrants a reportable nonconformance and corrective action, then the CQCSM will initiate a NCR, or Corrective Action Report (CAR) in accordance with the CQCP (USACE 2005). The CQCSM will be responsible for ensuring that corrective actions for nonconformances are initiated by:

- Evaluating all reported nonconformances
- Controlling additional work on nonconforming items
- Determining disposition or action to be taken
- Maintaining a log of nonconformances
- Reviewing NCRs and corrective actions taken

- Ensuring that NCRs are included in the final site documentation project files

If appropriate, the CQCSM will ensure that no additional work dependent on the nonconforming activity is performed until the corrective actions are completed.

Corrective action for field measurements may include:

- Repeating the measurement to check the error
- Checking for all proper adjustments for ambient conditions such as temperature
- Checking the batteries
- Re-calibrating equipment
- Checking the calibration
- Modifying the analytical method including documentation and notification (e.g., standard additions)
- Replacing the instrument or measurement devices
- Stopping work (if necessary)

The Project Manager or designee is responsible for all site activities. In this role, the Project Manager may at times be required to adjust the site activities to accommodate activity-specific needs. When it becomes necessary to modify an activity, the responsible person notifies the Project Manager of the anticipated change and implements the necessary changes after obtaining the approval of the Project Manager and the USACE Task / Technical Lead, as required. All such changes will be documented on USACE Field Change Request Form (FCRF, see **Figure 4-1**) that will be signed by the initiators and the Project Manager and USACE Task / Technical Lead. The FCRF for each document will be numbered serially as required. The FCRF will be attached to the file copy of the affected document. The Project Manager must approve the change in writing or verbally before field implementation. If unacceptable, the action taken during the period of deviation will be evaluated in order to determine the significance of any departure from established program practices and action taken.

The Project Manager for the site is responsible for controlling, tracking, and implementing the identified changes. Reports on all changes will be distributed to all affected parties, including the USACE Task / Technical Lead. USACE will be notified whenever significant program changes in the field are made.

4.3 SAMPLE HANDLING AND CUSTODY REQUIREMENTS

Once the samples have been received, the sample custodian must inspect the samples against the chain of custody and any other documentation for nonconformances. Any discrepancies are documented on the sample receipt verification form and communicated to the laboratory project manager immediately, in the case of the offsite laboratory. The laboratory project manager shall contact the Project Chemist to resolve the issue. Once the paperwork from the sample receipt is completed and reviewed, it is given to the laboratory project manager for log-in to the Laboratory Information Management System (LIMS) computer system. For UFML, any discrepancies are resolved immediately with the field person delivering the samples to the lab, or the Maywood Task Manager for the activity pertaining to the collected sample(s). The sample information from the hardcopy COC is entered into the UFML database by one of the laboratory technicians.

4.4 ANALYTICAL METHODS REQUIREMENTS

4.4.1 Analytical Procedures

The following text provides detailed information on analytical procedures. The task-specific Work Plans shall contain tabular summaries of analyses required for each site or project. These summaries shall contain the number of samples to be collected for each method including field and laboratory QC samples. The actual quality assurance methods and procedures employed in the subcontractor laboratories' daily activities are provided in EDMS (see Section 4.7).

4.4.1.1 Laboratory Analytical Procedures

All samples shall be prepared and analyzed in accordance with laboratory test methods, copies of which are stored in EDMS (see Section 4.7). These procedures contain detailed descriptions of the sample preparation and analyte detection steps, including instrumentation and other laboratory apparatus, reagent and standards preparation, and calibration. It also includes discussions of interferences, sample collection (including containers and preservation), QC samples, calculations, and reporting of results. Each individual task Work Plan shall reference one or more of these analytical methods. Use of alternate procedures or modified procedures must be pre-approved by the Contracting Officer (CO), or designee.

4.4.1.2 Field Measurement Methods

Initial field measurements may consist of geophysical surveys, gamma walkover surveys, building surveys, soil gas surveys, organic screening or inorganic screening.

The geophysical survey will be used primarily to define subsurface features to be considered during the remedial work. Geophysical screening techniques are presented within the 200 series SOPs in EDMS (see Section 4.7).

Radiological testing of soils by gamma spectrometry is employed using UFML (see description in Section 1.1.2.6).

Soil gas surveys will be conducted as appropriate. The SOP for conducting soil gas surveys is SOP 105, a copy of which is found in EDMS (see Section 4.7).

Data collected from these field reconnaissance activities has been used to establish the boundaries, soil sample locations, and well locations for site investigations and remedial actions.

Organic and inorganic screening methods including hand-held monitors or real time soil analyses by an on-site laboratory may be utilized to help determine extent and location of non-radiological contaminants.

4.4.2 Analytical / Statistical / Control Parameters

Section 5.3.5 of the DOD Quality System Manual (DOD 2000) discusses when laboratories must implement corrective actions. Refer to the Guiding Principles, contained within Appendix E of this QAPP (the Guidance), for specific corrective actions to be taken when QC control limits are exceeded.

4.4.2.1 Accuracy - Organics

Accuracy shall be evaluated by requiring the laboratory to treat no less than 10% of all FMSS samples (per matrix) as MS/MSD pairs, to analyze at least one blank spike (or LCS) with the entire analyte list for a given method (analyte lists are shown in **Table A-1** of Appendix A for the FMSS project) per matrix per sample batch (a sample batch contains a maximum of 20 environmental samples), to add surrogate spikes to all samples as required by the method, and to analyze method blanks every 12 hours of analysis time or every batch, whichever is more frequent. The field sample coordinator will clearly identify the sample chosen for matrix spiking and the equipment rinsate blanks on the sample chain of custody. Under no circumstances will trip blanks or equipment rinsate blanks be analyzed as MS/MSD pairs. The sample designated for MS/MSD analyses will have approximately triple the volume of a normal sample. Triple volume is required for aqueous samples, not soil samples. For FMSS, it is practical to batch samples and assign MS/MSDs per investigation or remediation site. Obviously, for large sites multiple batches may be necessary. MS/MSD samples should be spiked by the laboratory with those compounds that have been detected in FMSS property soils most frequently. Lists of MS/MSD compounds for the various test methods are provided in **Table B-1** of Appendix B of this QAPP. Both the MS and MSD samples must be reanalyzed if the recoveries are outside of laboratory-derived acceptable recovery ranges listed in **Table B-1** of Appendix B. Specific off-site laboratory corrective action guidelines are provided in Appendix E.

If analysis results show surrogate recoveries outside laboratory-derived acceptable ranges (in-house limits established as per SW-846 guidance [Method 8000, section 8.7]) the laboratory shall take corrective action in accordance with the Guiding Principles, contained within Appendix E of this QAPP. If method blanks are consistently out of control (see Chapter One of SW-846) for one or more analytes, the laboratory will be required to stop analysis of field samples and find and eliminate the source of contamination. If the source of contamination cannot be found in a timely fashion, Shaw shall procure another laboratory subcontractor for those analyses.

LCS samples are clean matrices, such as organic-free water or high purity sodium sulfate spiked with all of the analytes for a given method as listed in **Table A-1** of Appendix A. LCS samples will be analyzed with each batch. If there are aqueous and solid samples within the same batch, the laboratory must run an aqueous LCS for the aqueous samples and a solid LCS for the solid samples. The LCS provides method performance data for samples free from interferences. As such, they serve as a warning for laboratory methods that are out of control. Like surrogate spikes, control limits must be established for LCS results using SW-846 Method 8000, Section 8.7. If an LCS result falls outside QC recovery limits, the LCS should be reanalyzed in real time with respect to sample analyses, to see if the failure represents a transient instrumental condition. A second failure indicates a fundamental problem that must be corrected before sample analysis can restart. All of the sample results associated with that LCS (only for those analytes that failed LCS recovery) must be reanalyzed after the method performance problem has been corrected. The corrective actions taken by the laboratory must follow the corrective action procedures described in the Guiding Principles (Appendix E). If a laboratory is in the process of implementing a new GC/MS method, and LCS recovery limits have not yet been established, the temporary percent recovery

limits shall be 80 to 120% for water and 70 to 130% for solids. For Gas Chromatography (GC), High Performance Liquid Chromatography (HPLC), and Total Recoverable Petroleum Hydrocarbons (TRPH) (413.2, 418.1, and/or 1664) methods, QC limits may be established by the laboratory for surrogate, LCS, and MS/MSD recoveries, as appropriate. If not, a default recovery range of 65-135% may be used.

In all cases, construction of control charts or QC limit ranges should eliminate outliers, which are defined as those exceeding the mean plus or minus three standard deviations. In addition, reanalysis as a result of QC recovery exceedances as described here, may not be required if the spike signal is obscured by gross contamination. In such cases, the laboratory **must** substantiate its case for not reanalyzing or following the Guidance by providing the proper chromatograms or other pertinent raw data. The final decision as to the acceptability of a laboratory deviating from the requirements of this CDQMP will be made by the USACE CO.

4.4.2.2 Accuracy - Inorganics (non-radiological) and General Chemistry

Accuracy shall be evaluated by requiring the laboratory to treat no less than 5% of all FMSS samples (per matrix or per batch) as a MS sample, to analyze LCSs with the entire analyte list for a given method, and to analyze method blanks as required by the selected analytical method. Shaw will coordinate field sample collection with the laboratory so that batch size is maximized and the frequency of MS sample designation is not too high. The sample chosen for matrix spiking should be similar to other samples in the batch. The field sample coordinator will clearly identify the sample chosen for matrix spiking and the equipment rinsate blanks on the sample chain of custody. Under no circumstances will equipment rinsate blanks be analyzed as MS/MD pairs. The sample designated for MS/MD analyses will have approximately triple the volume of a normal sample. Triple volume is required for aqueous samples, not soil samples. For FMSS, it is practical to batch samples and assign MS samples per investigation or remediation site.

MS inorganic samples should be spiked with the complete analyte target list for a given method at a concentration per analyte of about 3 to 5 times the expected background. The percent recovery of the spiked compounds will provide a measure of accuracy. The MS must be reanalyzed if any of the analyte recoveries are outside of acceptable recovery ranges. The default QC recovery range typically used for inorganics and general chemistry parameters is 75 to 125%. Prior to any redigestion / reanalysis, sample preparation and test data must be reviewed to see if the cause of the spike recovery exceedance can be determined. If an out-of-control condition is discovered in this process, it must be corrected prior to the redigestion / reanalysis.

Similar to organics, the LCS should be performed for each sample batch up to a maximum of 20 samples per batch. If there are aqueous and solid samples within the same batch, the laboratory must run an aqueous LCS for the aqueous samples and a solid LCS for the solid samples. If the LCS recovery falls outside of the QC criteria (default range is 80 to 120%), the LCS must be reanalyzed for the analyte(s) falling outside criteria. If the LCS recovery fails a second time, corrective action must be taken to improve test measurement performance for the analyte(s) of concern. All samples associated with the faulty LCS must be reanalyzed (only for those analytes that failed LCS recovery) after the problem has been corrected.

The post-digestion spike sample recovery test described in Section 8.5 of Method 6010B of SW-846 must be performed on one representative sample from a given analytical batch whenever new or unusual matrices are encountered. It is the responsibility of the analyst to look at the samples prior to digestion and select the representative sample in a conservative manner, such that in his or her judgment, the selected sample is the one most likely to contribute interference. If the results of the interference tests are outside the QC limits provided in Section 8.5, these results must be discussed in the case narrative. For

SW-846 Series 7000 methods, spiked samples may be analyzed as described in Section 8.6.2. If the results are outside of the QC limits stipulated in Section 8.6.2, the method of standard additions (Section 8.7) must be employed.

QC criteria for metals analysis will conform to the requirements of SW-846 and Appendix B of this CDQMP QAPP.

4.4.2.3 Accuracy - Radionuclides

The accuracy described here applies to isotopic radium, thorium, uranium, and gross alpha and beta. Accuracy shall be evaluated by requiring the laboratory to analyze a method blank and LCS at a minimum frequency of 5% of field samples per matrix or per sample preparation batch, whichever is more frequent. For alpha spectroscopy, isotopic tracers shall be added to every sample to evaluate matrix effects. Shaw will coordinate field sample collection with the laboratory so that batch size is maximized. In addition, a field duplicate shall be collected at a minimum frequency of 10% for FSS and environmental monitoring field samples. The field sample coordinator will clearly identify the sample chosen for the equipment wipe sample blank on the sample chain of custody.

The LCS should be performed for each sample batch up to a maximum of 20 samples per batch. If there are aqueous and solid samples within the same batch, the laboratory must run an aqueous LCS for the aqueous samples and a solid LCS for the solid samples. If any of the LCS or isotopic tracer analyte recoveries fall outside of the current control limits established by the laboratory (default limits are 80 to 120% for aqueous samples and 70 to 130% for solid samples, and should only be used if laboratory-established limits are not available), the LCS and/or tracer spike solution must be reprepared and reanalyzed for the analyte(s) falling outside criteria (see the Guidance in Appendix D of this QAPP). All samples associated with a faulty LCS must be reanalyzed (only for those analytes that failed LCS recovery) after the problem has been corrected. The LCS should mimic the nominal activity of samples of interest. Recommended LCS activity levels for the radionuclides of interest in soils are 2 to 3 pCi/g each of ^{226}Ra and ^{232}Th, and 5 to 15 pCi/g for ^{238}U. Recommended LCS activity levels for the radionuclides of interest in waters are 10 to 15 pCi/L for GA, 35 to 50 pCi/L for GB, 3-6 for Ra-226, 3-6 for Ra-228, 5-10 each for U-234 and U-238, and 3-6 for Th-230.

For alpha spectrometry measurements, chemical separation specificity shall be verified. The observed peak energy of each radionuclide shall be within 40 keV of the actual radionuclide energy.

For gamma spectroscopy measurements, a target radionuclide list must be provided. It must contain an example calculation plus uncertainties for all quantitated radionuclides. Positive identification shall be achieved by the following:

1. The observed peak energy is within 2 keV of the target energy.
2. There are no radionuclide gamma peaks interfering with the radionuclide of interest. If an interference is present, the peak for the radionuclide of interest must be corrected to remove the contribution from the interferent.
3. Calibration standards will have been run at the frequency specified in the approved SOP.

4.4.2.4 Sensitivity

The offsite laboratory will have developed MDLs in accordance with 40 CFR 136 Appendix B. The PQL, also known as the reporting limit, shall be set at 3 to 5 times the MDL. It is understood that PQLs are subject to approval by the USACE Contracting Officer. MDLs should be consistent with the MDLs shown in SW-846. **Table A-1** of Appendix A contains the most current Contract Laboratory PQLs for all

analyses. All results for dilution runs must be provided. A discussion as to which values are to be reported must also be provided in the Case Narrative.

For UFML, radionuclide quantitation must be calculated according to project-approved SOPs. Minimum Detectable Activities (MDAs) specified in the SOPs and in Appendix A of this QAPP must be met. Analytical uncertainties shall be reported with all results, including all uncertainties associated with the analyses.

Matrix effects caused by highly contaminated samples will be reviewed to assess the laboratory's ability to meet sensitivity requirements. A detailed analysis of all failures to meet sensitivity requirements must be provided in the Case Narrative.

4.4.2.5 Precision

Precision is defined in DQOs Section 2.8.1 of this QAPP. It is represented by the Percent Difference (%D) between duplicate sample results, and the relative standard deviation for more than two results. The results of many laboratory control sample (LCS) results can be used to determine the mean precision (from the relative standard deviation of the average percent recovery) and accuracy (from the average percent recovery) for a given analyte since there are no matrix effects. For metals and radionuclides, laboratory duplicates (replicates of 1 field sample) will be analyzed at a rate of at least 1 in 20 or 1 per batch, whichever frequency is greater. Laboratory duplicates not meeting QC criteria must be reextracted / reanalyzed once. For organics, precision may be calculated from spiked and unspiked (if present) analyte results obtained from analysis of MS/MSD samples. Field duplicate results are used for both metals and organics to provide a measure of precision. Field duplicate samples are collected at a frequency of 5% for organic and inorganic, and 10% for radiological of the total number of samples of a given matrix or site, or one per batch, whichever is more frequent.

4.4.2.6 Laboratory Internal QC Checks

1. The analytical batch is defined by the group of samples that are prepared (extracted, digested, etc.) together and analyzed sequentially on a single instrument.
2. The Laboratory shall analyze internal QC samples at a frequency consistent with a given method. These shall include method blanks, MS/MSD (MS and laboratory duplicates for inorganic analyses) and LCS. The matrix used for LCS samples will be reagent grade water for aqueous samples and reagent sand for soils and sediments. Failure to analyze a matrix spike, LCS, or method blank will result in rejection of data.
3. One method blank will be analyzed per analytical batch. At a minimum, a method blank must be analyzed for every 12 hours analysis time for GC / mass spectrometry analyses. Chronic blank contamination from one or more analytes shall result in reselection of the Laboratory Subcontractor.
4. Second column confirmation will be required for all GC analyses except when results are between the MDL and PQL. The results obtained from the two columns should be less than 40% different.
5. The Laboratory should have control charts for surrogate recoveries and LCS at a minimum. These charts should be updated at least quarterly. The Laboratory Quality Assurance Plan must have detailed procedures describing corrective actions to be taken if QC criteria are exceeded for LCS, method blanks, surrogate recoveries, etc. for each method and matrix. It must also describe changes made to laboratory protocols or operations to prevent such exceedances from reoccurring.

4.5 ANALYTICAL QUALITY CONTROL REQUIREMENTS

4.5.1 Completeness

Completeness shall be evaluated both qualitatively and quantitatively. The project goals for completeness, expressed in percent, are provided in DQO Section 2.8.4 of this CDQMP. The qualitative determination will be a function of sample handling (in the field and in the lab), labeling, shipping, etc. The quantitative description will depend on the number of sample results that are rejected due to gross exceedances of QC criteria.

The completeness requirement for holding times is 95%. Samples exceeding holding times must be resampled and reanalyzed. Results from samples with proven matrix effects will not be used in calculating completeness.

4.5.2 Representativeness

Shaw accepts responsibility for ensuring that all field samples, including blind duplicates and QA splits, are representative of field conditions and are properly preserved. Samples with results that are rejected due to lack of preservation must be resampled and reanalyzed.

Laboratory procedures must detail the steps taken to ensure that the sample aliquot collected for analysis is representative of the whole sample.

4.5.3 Data Comparability

To ensure data comparability, laboratory procedures shall include, but not be limited to the following:

- Use of standard approved methodologies
- Methodologies for quantitation within test procedures, as appropriate
- Use of standard units and report format
- Use of standard measures of accuracy and precision for QC samples

Samples collected as QA split samples should be analyzed by the same or equivalent analytical methods with comparable MDLs/PQLs.

All final solid sample results shall be reported on a dry weight basis, and the percent moisture will be reported. If QA split samples sent to an independent laboratory yield results that are significantly different from the Contract Laboratory results, Shaw will investigate the discrepancies. If errors in sampling or testing are discovered, samples will be resampled / reanalyzed.

4.5.4 Preventive Maintenance

4.5.4.1 Field Instruments and Equipment

The field equipment for this project may include temperature probes, pH meters, conductivity meters, turbidimeter, platinum Eh electrode, dissolved oxygen meter, alpha / beta and gamma survey meters, organic vapor detectors (flame or photoionization detector), and geophysical equipment. Specific preventative maintenance procedures to be followed for field equipment are those recommended by the manufacturers. These procedures are included in the technical procedures governing the use of these instruments.

Field instruments will be checked and/or calibrated before they are shipped or carried to the field. Each field instrument will be checked for good condition and operability prior to use. Items such as frayed cords, loose components, or cracked casings shall be cause for not using the instrument. Operational checks against a traceable standard or reference with a known value shall be performed prior to use to ensure that the instrument is in proper calibration. Reference standards used in the field for calibration checks should be labeled with an expiration date and recorded in the log. Instruments found to be out of calibration or improperly responding to instrument checks will be recalibrated before use in the field. If the instrument cannot be calibrated, it will be returned to the supplier or manufacturer for recalibration, and a backup instrument will be used in its place. Calibration checks and calibrations will be documented on the Field Meter / Calibration Log Sheets in the Equipment Logbook. Any maintenance conducted on field equipment must be documented in the Equipment Logbook and the process documented, including the results of the check / calibration and any adjustments required. Any significant adjustment shall be cause for recalibration by the manufacturer or approved calibration facility.

Critical spare parts such as tapes, papers, pH probes, electrodes, and batteries will be kept on site to minimize down time of malfunctioning instruments. Backup instruments and equipment should be available on site or within one day shipment to avoid delays in the field schedules.

4.5.4.2 Laboratory Instruments

As part of their QA/QC Program, a routine preventive maintenance program will be conducted by all investigation-associated laboratories to minimize the occurrence of instrument failure and other system malfunctions. All laboratory instruments will be maintained in accordance with manufacturers' specifications and the requirements of the specific method employed. This maintenance will be carried out on a regular, scheduled basis and will be documented in the laboratory instrument service logbook for each instrument. The laboratory shall maintain an inventory of expendable parts and supplies to minimize downtime. Emergency repair or scheduled manufacturer's maintenance should be provided under a repair and maintenance contract with the manufacturer or authorized factory representatives.

4.5.5 Performance Evaluation Samples

Testing of performance evaluation (PE) samples by USACE laboratories may be part of a laboratory performance audit. The performance evaluation program may also include a maximum of two blind PE samples (provided by the USACE) for each matrix and analysis. PE samples provide an ongoing assessment of laboratory precision and accuracy. The analytical results of the analysis of performance evaluation samples are evaluated by USACE Kansas City District to ensure that laboratories maintain an acceptable performance.

Radiological PEs will be identified and supplied as required by the NJDEP pertinent to the regulations set forth in NJAC 7:18. These PEs may consist of EPA regulated PEs for Drinking Water analysis and US DOE PEs for Solid Hazardous Waste.

4.6 INSTRUMENT CALIBRATION AND FREQUENCY

This section describes procedures for maintaining the accuracy of all the instruments and measuring equipment used for conducting field tests and laboratory analyses. These instruments and equipment shall be calibrated before each use or on a scheduled, periodic basis according to manufacturer instructions using certified equipment or standards traceable to nationally recognized standards (as applicable).

4.6.1 Field Instruments / Equipment

Instruments and equipment used to gather, generate, or measure environmental data will be calibrated with sufficient frequency (and at least annually) and in such a manner that accuracy and reproducibility of results are consistent with the manufacturer's specifications. All field instruments for this purpose will have unique identifiers and each instrument will be entered into the Equipment Logbook before use in the field. The SSHO, Project Environmental Sampler, designee, or other assigned responsible individual will be responsible for performing and documenting daily calibration / checkout records for instruments used in the field.

Equipment to be used during the field sampling will be examined to certify that it is in operating condition. This will include checking the manufacturer's operating manual and instructions for each instrument to ensure that all maintenance requirements are being observed. Field notes from previous sampling trips will be reviewed so that the notation on any prior equipment problems will not be overlooked, and all necessary repairs to equipment will be carried out. Spare parts or duplication of equipment will be available to the sampling effort.

Calibration of field instruments is governed by the specific SOP for the applicable field analysis method, and it will be performed at the intervals specified in the SOP. If no SOP is available, calibration of field instruments will be performed at intervals specified by the manufacturer or more frequently as conditions dictate. Calibration procedures and frequency will be recorded in a field logbook.

Field instruments may include a pH meter; temperature probe; specific conductivity meter; respirable dust meter; turbidimeter; platinum Eh electrode; dissolved oxygen meter; hand held scintillation, Geiger-Muller, or proportional detectors for radioactivity screening levels; photoionization and flame ionization detectors for organic vapor detection; low/high volume air samplers; geophysical equipment, etc. If an internally calibrated field instrument fails to meet calibration / checkout procedures, it will be returned to the manufacturer for service and a back-up instrument will be calibrated and used in its place. Field instrument uses, detection levels, and calibration are summarized in **Table 4-1**.

Table 4-1
Field Instrument Uses, Detection Limits, and Calibration

Instrument	Uses	Detection Limits	Calibration	Comments
Total organic vapor meters	Sample screening for VOCs	PID - 0.2 ppm benzene or	1 point - PID benzene daily	Action level must be stated in Health and Safety Plan
	Health and safety screening	FID - 1.0 ppm methane	1 point - FID methane daily	Instrument cannot differentiate naturally occurring compounds from contaminants
			Verification check every 20 samples	PID cannot detect compounds with ionization potentials > 11 eV
Radiological monitoring	Monitoring of beta-gamma surface, gross gamma, alpha surface contamination levels	Daily calibration check varies by equipment	Daily source check per manufacturer	Action level must be stated in Health and Safety Plan
pH meters	Field screening of waters	N/A	2 point with standards at pH 7.0 and 4.0 or pH 7.0 and 10.0 daily	Accuracy is to within 0.5 pH units
Temperature	Determining water	N/A	To manufacturer	

(in-line)	temperature		instructions	
Conductivity meter	Determining conductivity of water	N/A	1 point in KCL solution	Calculations and acceptance criteria must be available in the field
Membrane electrode meter	Determining dissolved oxygen levels	N/A	1 point using calculated value for water at ATP at least once every 3 hours	Accuracy is to within 0.01 ppm
Gamma Spectroscopy System	Analysis of soil samples for general isotopic conditions	≤ 0.2 pCi/g for ROIs	Yearly at a minimum using a multi-gamma source from 60 - 1840 keV	Requires a low-background condition to enable proper detection conditions

Notes:
PID = photoionization detector
FID = flame ionization detector
N/A = not applicable
ATP = Ambient temperature and pressure
ROI = radionuclides of interest

4.6.1.1 pH Meter Calibration

The pH meter will be calibrated according to SOP 409, Onsite Water Quality Testing (see UFML SOPs in EDMS; see Section 4.7)

4.6.1.2 Temperature Calibration

Temperature measurement will be calibrated according to SOP 409, Onsite Water Quality Testing (see UFML SOPs in EDMS; see Section 4.7).

4.6.1.3 Conductivity Meter Calibration

A specific conductivity meter will be calibrated according to SOP 409, Onsite Water Quality Testing (see UFML SOPs in EDMS; see Section 4.7).

4.6.1.4 Organic Vapor Detection

Organic vapor detectors will be checked according to SOP 401, Operation of the MultiRAE Plus Multi-Gas Monitor and SOP 402, Operation of the TVA-1000 Photoionization / Flame Ionization Detectors.

4.6.1.5 Radiation Testing

Several types of radiation detection instrumentation will be used by Radiation Protection Technicians (RPTs) during the course of the project activities. They include sodium iodide (NaI) detectors used to monitor exposure rates and collect downhole gross gamma logging data, Geiger Muller detectors used for screening measurements, and scintillation detectors used to quantify levels of surface radioactivity on miscellaneous materials. Proper use of these instruments includes a series of QC measurements that will be reviewed as part of the data validation process. These are described below.

Each detector / meter combination will be calibrated no less than annually at a licensed calibration facility. At a minimum of once per day during use, each instrument utilized in the field will undergo the

following: source check, battery check, voltage check, and background check. Results will be recorded in a dedicated notebook in the form of a QC log. Instruments found to be operationally deficient will be tagged "out of service" and sent to an appropriate facility for repair and recalibration. Procedures for the operation and management of portable radiation survey instruments are established in the Radiation Protection Program (*Site Safety & Health Plan*, Appendix C, USACE 2006a).

4.6.2 Laboratory Instruments

Calibration of laboratory equipment will be based on approved written procedures. Records of calibration, repairs, or replacement will be filed and maintained by laboratory personnel performing QC activities. These records will be filed at the location where the work is performed and will be subject to QA audit. Procedures and records of calibration will follow USACE and Shaw-reviewed laboratory-specific QA Plans.

In all cases where analyses are conducted according to the EPA Region 2 or SW-846 protocols, the calibration procedures and frequencies specified in the applicable EPA Region 2 SOPs or SW-846 methods shall be followed, or be more stringent. For analyses governed by SOPs, refer to the appropriate SOP for the required calibration procedures and frequencies.

Records of calibration will be kept as follows:

- Each instrument will have a record of calibration with an assigned record number.
- A label will be affixed to each instrument showing identification numbers, manufacturer, model numbers, date of last calibration, signature of calibrating analyst, and due date of next calibration. Reports and compensation or correction figures will be maintained traceable to the instrument.
- A written step-wise calibration procedure will be available for each piece of test and measurement equipment.
- Any instrument that is not calibrated to the manufacturer's original specification or equivalent procedure shall be tagged out of service and not utilized for this project.

4.7 ELECTRONIC DOCUMENT MANAGEMENT SYSTEM (EDMS)

4.7.1 EDMS in use at FMSS

Two electronic systems are used by the Maywood Project to capture the permanent project record: an electronic document control system, Documentum, and the Maywood Site Sample Database (MSSDB). A quality program with strict controls is in place to ensure quality (USACE 2005).

Documentum is the integrated, computer-based document and information control system. It is used as the repository for records including the base contract, contract modifications, cost and schedule reports, QA/QC records, minutes of meetings, and reports and deliverables submitted to the client. Records are entered as files and sub-files under broad functional categories called "cabinets" which include Correspondence, Contract Management, Engineering, Construction, Procurement, Historic and Background Records, Community Relations, and Quality Control. Documentum provides multiple attribute search capabilities and is accessible to project members on site as well as from remote locations. Ultimately, at the conclusion of the project, the Documentum electronic record will be submitted to our client in accordance with the terms of our contract.

The MSSDB (based upon Microsoft™ Access) is used to capture field investigation and laboratory data and provides the capability to query and prepare data tables. Specific information captured includes field

related sampling and monitoring data including final status survey results, waste soil load out information that includes rail car number and verification sample results, and occupational training records. The field data includes descriptions of sampling locations, such as coordinates of sample locations, GW well development and purge data, and environmental monitoring data. The database also generates sequential sample labels /numbers prior to sampling events and incorporates sample tracking from collection through laboratory analytical result reporting and validation. Select USEPA and NJDEP regulatory criteria are loaded in the database, thereby permitting comparison of analytical results against the criteria. Data in the Access database can be linked to associated reports captured in Documentum.

4.7.2 Responsible Personnel

An on-site document control administrator is responsible for entering records and assisting users in retrieving records. This person is supported on an as-needed basis by Shaw corporate IT and Documentum specialists. The Maywood Project technical staff are responsible for identification of work products to be captured in Documentum, and determining the applicable attributes. Documentum is accessible by project personnel and the Documentum administrator.

An off-site Database Manager, who enters electronic laboratory data, administers the Access database. Field personnel enter field-related data directly. The database is also accessible by project personnel, the database manager, and the client.

4.7.3 Documented Procedures for use of EDMS

An electronic project record is a requirement of the prime contract. Documentum use is described in the Contract Management Procedures CMP 2, Management Information System as well as the Maywood Project Procedures PP 6-1-0 Project File Index; PP 6-2-0 Task File Maintenance; PP 6-4-0 Project Records Management Plan; and PP 7-5-0 Document Control.

The Access Database system use is described in the Database Documentation Manual, which includes a User's Guide.

4.7.4 Advantages and Limitations of the System

Documentum is a searchable, multi-attribute electronic project record, and will be a highly usable system to the USACE, USEPA, and DOJ when delivered following project conclusion. This advantage was emphasized to the USACE when attempts were made to take the earlier FUSRAP microfilm project records consisting of more than 7 million records and assign basis attributes to enable query and sorting capabilities. Documentum is available to project employees and the use of the system is easily learned.

Similarly, the MSSDB is available to designated Shaw employees and can be accessed from any location in the United States. This system is searchable, user friendly, and holds capability for USACE connection via a DSL line. Furthermore, the relational database permits preparation of project reports relating to sample information.

An advantage of the MSSDB is that it manages sample number assignment (automated) and tracking. There is a semi-automated process for importing electronic data deliverables from laboratories, minimizing data entry errors.

The MSSDB has a built in quality control in that the database enforces preferential integrity. Sample results must be linked to a specific sampling location, sampling number, and any other field related to that specific sample, or else it flags the entry. This provides a check against error in laboratory data reports.

As the MSSDB is MS-Access based and easily copied, it can be provided to the client in a usable format. It will be an end product deliverable as part of the project record.

Both Documentum and the MSSDB are secured by password protection and differing levels of authorized access, data entry, editing, changes, and utilization of data. Disadvantages of both systems are that they require administrators with an associated cost, and they require training for users.

4.7.5 Purpose of EDMS

Documentum contains some historical reports relating to the Maywood site. Further, the administrative record is contained on the Maywood project website and is linked to Documentum.

The MSSDB is used for historical measurement data. Shaw has integrated certain amounts of historical soil and water data from Bechtel as well as other investigations, into the MSSDB. This historical data helps us characterize areas with greater time depth. Note that the data entered are not comprehensive because of the labor-intensive effort required to manually enter it.

4.7.6 System Backup

Documentum is run on a dedicated Maywood project server. The server records are backed up daily on tapes. Additionally, monthly backup tapes are made and permanently stored.

The MSSDB is run on a Shaw corporate network system. This system is backed up daily by the secure Shaw corporate network.

4.7.7 Description of Quality Program

The MSSDB has built in quality controls designed to ensure data quality by employing cross-checks of relational attributes. The data is also frequently being used and reviewed by the Project Chemist, project engineers, and the Database Manager.

This page intentionally left blank.

5.0 ASSESSMENT / OVERSIGHT

Shaw will maintain an aggressive oversight program and implement a three-phase inspection process. These programs are addressed in detail in the CQCP (USACE 2005). The task-specific Work Plans shall describe the specific three-phase control procedures with particular emphasis on execution of field operations relating to sampling and analysis. Checklists to be used for implementation of three-phase control shall also be included in the task-specific Work Plans.

5.1 ASSESSMENTS AND RESPONSE ACTIONS

Performance and system audits of both field and laboratory activities will be conducted to verify that sampling and analysis activities are performed in accordance with the procedures established in the CDQMP and task-specific Work Plans. Audits of laboratory activities will include both internal and external audits. Field audits are described in the CQCP (USACE 2005).

5.1.1 Laboratory Audits

Laboratories that possess the appropriate State certification, are compliant with the most recently published version of the DOD Quality Systems Manual (QSM) (including the NELAC Standard Chapter 5 and Appendix requirements), and that successfully test performance evaluation samples (performance audits) are qualified to perform USACE environmental analysis (USACE 2001b).

Internal performance and system audits of laboratories will be conducted by the Laboratory QA Officer as directed in the laboratory QA Management Plan (see copies of the UFML and offsite laboratory Plans within EDMS). System audits are conducted annually by the laboratory or corporate QA manager and shall include examination of laboratory documentation of sample receiving, sample log-in, sample storage, chain-of-custody procedures, sample preparation and analysis, and instrument operating records. Internal performance audits are also conducted at a minimum frequency of twice per year. The UFML participates annually, and the offsite laboratory twice per year in PE studies conducted by outside agencies. The double blind format ensures that samples are introduced into the laboratory without their knowledge. Criteria for success of laboratory audits will be compliance with the QC requirements outlined in this QAPP.

Shaw is not contracted to perform laboratory audits; however, additional audits of laboratories may be planned and budgeted within specific USACE task scopes. These project-specific laboratory performance review audits would be conducted by Shaw on an as-needed basis to ensure laboratory compliance.

External audits may be conducted in conjunction with or at the direction of EPA Region 2 or the State of New Jersey Department of Environmental Protection.

5.2 REPORTS TO MANAGEMENT

5.2.1 Daily Quality Control Reports

During the field investigation activities performed for this project, Shaw will prepare DQCRs as delineated in the CQCP (USACE 2005).

5.2.2 Quality Control Summary Reports (QCSRs)

At the conclusion of field investigation activities and laboratory analysis for each major task, Shaw, in addition to any review conducted by the laboratory, will prepare a QCSR, which will be included as an appendix to the final report. This report will be submitted to the USACE Task/Technical Lead as determined by the project schedule and included in any regulatory deliverables. The contents of the QCSR will include data validation documentation and discussion of all data that may have been compromised or influenced by aberrations in the sampling and analytical processes. Both field and laboratory sampling and analysis QC activities will be summarized, and relevant DQCR information will be consolidated. Problems encountered, corrective actions taken, and their impact on project DQOs will be discussed.

Specific elements to be addressed within the QCSR include the following. Note that only deviations from these elements, as described in the CDQMP or the task-specific Work Plan, are included in the QCSR. The effect of deviations on the data and the rationale for occurrence of the deviations should also be provided.

- Data collection – This will include deviations from sampling procedures, sample handling and custody, equipment calibration and maintenance procedures, and analytical procedures. If new methods or modified standard methods were used, but not described in the QAPP, they should be described in the QCSR. The description of the modified analytical method must include method applicability; detection limit; the presence of interferences and attempts to minimize them; and changes in instrumentation, operating parameters, calibration standard type and concentration, and procedures.
- Data Analysis and Validation – This will include a discussion of how data was analyzed. Typically this will be done according to Section 6.0 of this QAPP. This Section will discuss deviations from the guidance provided in Section 6.0. Treatment of outliers shall be discussed. The typical process for treatment of outliers is described in Section 3.1.3 of this QAPP.
- Chemical Analytical and QA/QC Problems Encountered – This Section will summarize those instances for which project DQOs were not met. A discussion of how the problem was discovered, and how/if it was resolved, should be included. Examples include but are not limited to the following:
    1. Unexpected Tentatively Identified Compounds (TICs) that were detected
    2. Compounds that should have been included on a method analyte list, but were not
    3. Analytical methods that were inadequate or that required modification to satisfy project DQOs
    4. Safety problems that might have been avoided if the chemistry of a sample preparation or other test method procedure had been better understood
    5. Higher than expected data variability and their cause, such as erratic instrument performance
    6. Improved strategies for the type, number, or frequency of QC sample testing

5.2.3 Non-Routine Occurrences Reports

Shaw will send the USACE CO, or designee, written reports of all significant non-routine occurrences within 48 hours of the event. These shall include non-routine events in both the laboratory and the field relative to data quality. The reports shall describe the occurrence, corrective action(s) taken, and if

available, any instructions provided by the USACE CO to resolve the problem. Significant events are defined as those that adversely impact project cost or schedule, or the quality of the analytical data.

5.2.4 Data Report to the QA Laboratory

Shaw will provide the KCD Project Chemist with a copy of QA/QC results summaries. The primary and QA samples of each split sample pair shall be identified. Depending on the absolute difference or relative absolute difference between split sample results, Shaw and the Laboratory Subcontractor may be asked to resample and reanalyze at the direction of the USACE Project Chemist and the CO. The data report shall be sent to:

6.0 DATA VALIDATION AND USABILITY

6.1 DATA REVIEW, VALIDATION, AND VERIFICATION REQUIREMENTS

A systematic process for data verification and validation will be performed to ensure that the precision and accuracy of the analytical data are adequate for their intended use. The greatest uncertainty in a measurement is often a result of the sampling process and inherent variability in the environmental media rather than the analytical measurement. Therefore, analytical data validation will be performed only to the level necessary to minimize the potential of using false positive or false negative results in the decision-making process (i.e., to ensure accurate identification of detected versus non-detected compounds). This approach is consistent with the DQOs for the project, with the analytical methods, and for determining contaminants of concern and calculating risk.

Samples will be analyzed through implementation of definitive analytical methods. Definitive data will be reported consistent with the deliverables identified in the Subcontractor laboratories contracts and shown in **Tables 6-1** and **6-2**. This report content typically contains data forms including laboratory QC and calibration information. These definitive data will then be validated through the review process presented here. DQOs identified in Section 2.0 and certain method-specified criteria will be validated. Data from groundwater, environmental monitoring, final status survey, and backfill material to be added to excavated areas shall be validated. Currently, there are no plans to validate sample results associated with soil transportation & disposal, wastewater treatment, remedial support surveys, or document control sampling activities. Comprehensive analytical information will be retained by the subcontract laboratories.

Laboratories will prepare and submit analytical and QC data reports to USACE and the contractor in accordance with the requirements of this CDQMP and the task-specific Work Plans, including data forms listed in **Table 6-1**. An electronic copy of data will be provided in Microsoft® Access format and complying with the New Jersey DEP EDD requirements and **Table 6-2** for entry into the database.

Table 6-1
Summary of Analytical Hard-copy Data Deliverables

Method Requirements	Deliverables
Requirements for all methods:	
Holding time and preservation information	Signed chain-of-custody forms; Run logs and sample prep. Sheets with dates and times; Sample receipt log with temperature and pH
Discussion of laboratory analysis, including any laboratory problems	Case narratives
Percent solids calculation for soil/sediments	Appropriate calculation
Organics: GC / Mass Spectrometry analysis	
Sample results and reporting limits	CLP Form 1 or equivalent
Surrogate recoveries	CLP Form 2 or equivalent
Matrix spike/spike duplicate and blank spike data	CLP Form 3 or equivalent, with control criteria
Method blank data	CLP Form 4 or equivalent
GC / Mass Spectrometry initial calibration data	CLP Form 6 or equivalent
GC / Mass Spectrometry continuing calibration data	CLP Form 7 or equivalent
Organics: GC analysis	
Sample results and reporting limits	CLP Form 1 or equivalent
Surrogate recoveries	CLP Form 2 or equivalent
Matrix spike/spike duplicate and blank spike data	CLP Form 3 or equivalent
Method blank data	CLP Form 4 or equivalent
Initial calibration and continuing calibration data	CLP Form 6 or equivalent
If calibration factors are used	A form listing each analyte, the concentration of each standard, the relative calibration factor, the mean calibration factor, and %RSD
Calibration curve if used	Calibration curve and correlation coefficient
Analytical test sequence	CLP Form 8 or equivalent
Positive identification (second column confirmation; Only if mentioned as a problem in the Case Narrative)	CLP Form 10 or equivalent
Metals	
Sample results and reporting limits	CLP Form 1 or equivalent
Initial and continuing calibration	CLP Forms 2A and 2B or equivalent, dates of analysis and calibration curve, and the correlation coefficient factor
Method blanks	CLP Form 3 or equivalent and dates of analyses
Spike sample recovery	CLP Form 5A or equivalent
Post digestion spike sample recovery for ICP metals	CLP Form 5B or equivalent
Lab Duplicates	CLP Form 6 or equivalent
LCS	CLP Form 7 or equivalent that includes acceptable range or window
Method of Standard additions (when implemented)	CLP Form 8 or equivalent
Serial Dilution (required when analyte concentration is > 25 times the MDL)	CLP Form 9 or equivalent
Holding times (prep. and analysis run logs)	CLP Forms 13 and 14 or equivalent
Wet Chemistry	
Sample results and reporting limits	Report result and reporting limits
Matrix spike recovery	%Recovery
Matrix spike duplicate or duplicate	%Recovery and %RPD
Method blank	Report results
Initial calibration	Calibration curve and correlation coefficient

Method Requirements	Deliverables
Continuing calibration check	Recovery and % difference
LCS	LCS result and control criteria
Run log	Copy of run log
Radiochemical Analysis	
Sample results	Report results with uncertainties (errors)
Initial calibration (submitted annually, typically near the beginning of the calendar year, to the data validator)	Energy, Efficiency & Activity determination (alpha spec); Full Energy and Shape Cal., Peak-to-Compton Ratio & Efficiency Cal. (gamma spec); average activities and standard deviations on control charts (gas proportional detectors)
Continuing Calibration	Daily pulser and monthly calibration checks (alpha spec); daily calibration checks (gamma spec and gas proportional detectors)
Blanks and Background determinations	Report results with uncertainties, plus mean ± 3σ control limits for daily blanks and backgrounds; and mean ± 3μ control limits for method blanks.
Sample Specific Chemical Tracer recovery Matrix Spike Z score results	Report results, spike concentration added, and %recovery (alpha spec for iso-U and iso-Th tracers; Ba-133 by gamma spec for Ra-226 method; $BaSO_4$ [gravimetric] for Ra-228, and matrix spike Z score for GA/GB) as well as mean ± 3σ control limits for tracer percent recoveries, and the Z score control limits of ±3 for matrix spike results
Duplicate results	Report results and either the absolute difference between the results (if they are < action level) or the relative difference between the results (if they are > action level) as well as lab-derived control limits
LCS	LCS results and percent differences (%Ds) as well as a control chart or a range of acceptable values based upon the mean %D and the warning limits of ±3φ
Sample Tracking Form (STF) Run Logs	Copies of STF Run Logs
Minimum detectable activity (MDA)	MDA value for each radionuclide for each sample specific result
Radionuclide energies	Theoretical (target) and observed peak energies
Matrix density variability	Densities (or weights and volumes) of calibration standards and samples (gamma spec only)

Notes:

CLP	contract laboratory program	LCS	laboratory control sample
GC	gas chromatography	RPD	relative percent difference
ICP	inductively coupled plasma	RSD	relative standard deviation

Refer to Appendix D of this QAPP, Radionuclide Data Evaluation Guidance for definitions of required method uncertainty, μ , relative method uncertainty, φ, and Z score.

Table 6-2a
Standardized Electronic Data Deliverables for Chemical Analyses

Field No.	Field Name	Data Type	Field Length/Type	Comments
1	S&W Sample ID	Text	11	Shaw Sample ID - Format exactly as follows: 12B-079999: No additional characters
2	Date of Sample Collection	Date/Time	Short Date	Date of Sample Collection (MM/DD/YY)
3	Time of Sample Collection	Date/Time	Short Time	Time of Sample Collection (HH:MM military format)
4	Lab Batch Number	Text	12	Laboratory Analytical Batch/Sample Delivery Group (SDG) Number
5	Sample Matrix	Text	8	Sample Matrix, e.g., Soil, Water, etc.
6	Lab Sample ID Number	Text	20	Laboratory Sample Identification Number
7	Extraction/Prep Date	Date/Time	Short Date	Sample Preparation/Extraction Date (MM/DD/YY)
8	Sample Analysis Date	Date/Time	Short Date	Sample Analysis Date (MM/DD/YY)
9	Sample Analysis Time	Date/Time	Short Time	Sample Analysis Time (HH:MM military format)
10	Result Type	Text	10	REG = Regular Analysis; DUP = Duplicate; DIL = Dilution; REN = Re-analysis
11	CAS Number	Text	12	Chemical Abstract Services (CAS) Number
12	Analyte	Text	40	Chemical Name
13	Analysis Method*	Text	25	Analysis Method (Method numbers shall be the EPA, SW-846, NIOSH, etc. method number)
14	Result	Number	Single	Results (Report PQL if not detected)
15	Result Qualifier	Text	5	Result Qualifier (U, J, etc.)
16	Unit of Measure	Text	12	Unit of Measure
17	PQL**	Text	10	Practical Quantitation Limit
18	Percent Solids	Text	5	Percent Solids (Report “0” for water matrices)
19	Sample Weight/Volume	Text	10	Sample Weight/Volume
20	Sample Weight/Volume Unit	Text	5	Sample Weight/Volume Units
21	Dilution	Text	10	Dilution factor
22	LABNAME	Text	20	Laboratory name performing the analysis
23	RESULTTYPE	Text	1	“A” for Analyte; “P” for Parameter; “T” for Tentatively Identified Compound
24	NJDLABCERT	Text	5	New Jersey Laboratory Certification Number
25	FILTUNFILT	Text	1	“F” for Filtered; “U” for Unfiltered

*If test method follows TCLP leaching procedure, method used should read, 1311/8260B, 1311/8270C, etc.

**For metals, the IDL or MDL shall be substituted for the PQL

Table 6-2b
Standardized Electronic Data Deliverables for Radiological Analyses

Field No.	Field Name	Data Type	Field Length/Type	Comments
1	S&W Sample ID	Text	11	Shaw Sample ID - Format exactly as follows: 12B-079999: No additional characters
2	Date of Sample Collection	Date/Time	Short Date	Date of Sample Collection (MM/DD/YY
3	Sample Analysis Date	Date/Time	Short Date	Sample Analysis Date (MM/DD/YY)
4	Lab Batch Number	Text	12	Laboratory Analytical Batch/Sample Delivery Group (SDG) Number
5	Lab Sample ID Number	Text	12	Laboratory Sample Identification Number
6	Sample Volume	Number	Single	Sample Volume
7	W/D	Text	4	"Wet" = analysis on wet sample or "Dry" = analysis on dried sample
8	Sample Type	Text	10	REG = Regular Analysis; DUP = Duplicate; DIL = Dilution; REN = Re-analysis
9	CAS Number	Text	12	Chemical Abstract Services (CAS) Number
10	Analyte	Text	40	Chemical Name
11	Result	Number	Single	Results (Report reporting limit if not detected)
12	Error	Number	Single	Total measurement error[1]
13	Unit of Measure	Text	12	Unit of Measure
14	Result Qualifier	Text	5	Result Qualifier (U, J, etc.)
15	Analysis Method	Text	25	Analysis Method
16	MDA	Text	10	Minimum Detectable Activity
17	Reporting Limit	Number	Single	Reporting Limit is typically 3 to 5 times the MDA
18	Sample Matrix	Text	8	Sample Matrix, e.g., Soil, Water, etc.
19	FILTUNFILT	Text	1	"F" for Filtered; "U" for Unfiltered sample
20	TOP_DEPTH	Number	Single	Top of sample depth, ft
21	BOT_DEPTH	Number	Single	Bottom of sample depth, ft
22	LABNAME	Text	20	Laboratory name performing the analysis
23	RESULTTYPE	Text	1	"A" for Analyte; "P" for Parameter; "T" for Tentatively Identified Compound
24	NJDLABCERT	Text	5	New Jersey Laboratory Certification Number
25	Date Received	Date/Time	Short Date	Date sample was received by laboratory (MM/DD/YY)

[1]Prior to receiving FMSS samples, the Subcontractor must provide the Contractor with a description of what is included in the total measurement error.

The laboratory will be required to confirm sample receipt and log-in information. The laboratory will return a copy of the completed chain-of-custody and confirmation of the laboratory's analytical log-in to the contractor on a daily basis (see Section 3.2.3 of the FSP).

The subcontract analytical laboratories will prepare and retain full analytical and QC documentation. Such retained documentation will include all data, both QC summaries and raw data, in hardcopy or electronic form. As needed, the subcontract analytical laboratories will make available all retained analytical data information.

Validation will be accomplished by comparing the contents of the data packages and QA/QC results to requirements contained in the requested analytical methods. Validation support staff will be responsible for these activities. For final status survey results, the protocol for organic and inorganic analyte data validation is presented in the EPA Region 2 SOPs for data review of specific organic and inorganic parameters.

For all other organic and inorganic analyte data, the DOD Quality System Manual shall be used.

There are no Contract Laboratory Program (CLP) protocols for radiological data. Radiological data validation will be performed on data collected during final status surveys according to the USACE Radionuclide Data Quality Evaluation Guidance (USACE 2009; see Appendix D).

Validation support staff will conduct a systematic review of chemical data for compliance with the established QC criteria based on the following categories:

- Holding times and preservation
- Method (or preparation) blanks, trip blanks, equipment rinseate blanks, and initial / continuing calibration blanks
- LCS
- Surrogate recovery (organic methods)
- MS/MSD and MS/MD percent recoveries and RPDs; MS Z scores for radiological data
- Field Duplicates and Lab Replicates
- Calibration
- Pulser checks (alpha spectroscopy only)
- Second column confirmation (only if mentioned as a problem in the Case Narrative)
- Postdigestion spike sample recovery for ICP metals (inorganic only)
- Interference check sample and CRDL standard recoveries (metals only)
- Method of standard additions (inorganic only, when implemented)
- Sample specific chemical recoveries (radionuclides)
- Chemical separation specificity (tracer recovery; radionuclides only)
- Target radionuclide list
- Peak energies (alpha spectroscopy only)
- Run log
- Minimum detectable activity (MDA) and/or analyte / instrument MDLS
- Radionuclide energies (gamma spectroscopy only)
- Matrix density variability (gamma spectroscopy only)
- Laboratory case narrative
- GC/MS tuning
- Percent moisture

Consistent with the data quality requirements as defined in the DQOs, all project data and associated QC will be evaluated on these categories and qualified as per the outcome of the review. Data validation reports will be completed and presented with the QCSR.

6.2 VALIDATION AND VERIFICATION METHODS

The QC items in the following Region 2 SOPs will be reviewed as part of the data validation task for chemical data. For radiological data, the QC items described within the Radionuclide Data Evaluation Guidance (see Appendix D of this QAPP) will be reviewed as part of the data validation task. These QC items apply to all sample types unless noted otherwise:

Table 6-3
EPA Region 2 SOPs

SOP No.	Title	Date
SOP HW-2 Rev.13, ILM05.3	Evaluation of Metals Data for the CLP Program	September 2006
SOP HW-6 Revision 14	CLP Organic Data Review and Preliminary Review	September 2006
SOP HW-13 Rev. 3, OLC03.2	Organic Data Review for Low Concentration Water	September 2006
SOP HW-17 Revision 2	Validating Chlorinated Herbicides by GC	September 2006
SOP HW-22 Revision 3	Validating Semivolatile Organic Compounds by SW-846 Method 8270	October 2006
SOP HW-24 Revision 2	Validating Volatile Organic Compounds by SW-846 Method 8260B	October 2006
SOP HW-44 Revision 1	Data Validation SOP of Organochlorine Pesticides by Gas Chromatography SW-846 Method 8081B	October 2006
SOP HW-45 Revision 1	Data Validation SOP of Organic Analysis of PCBs by Gas Chromatography SW-846 Method 8082A	October 2006

In addition, checks will be made of how results were obtained from the raw data (only for those data being validated using Region 2 protocols) to verify proper calculation and transcription of results (EPA 1999 and 2002). Data review will verify PQLs to be the same as those agreed upon in the CDQMP (see references EPA 1999 and 2002 for data review guidelines; PQLs shall be obtained from the current subcontract laboratory and compared to the Project Action levels in Appendix A).

The data validation will review field notes to confirm that correct sampling and excavation decisions were made based on screening and on-site testing data.

Shaw will perform statistical treatment tests to determine the degree of attainment of DQOs and potential elimination of outliers as per Section 3.1.3.

6.3 RECONCILIATION WITH DATA QUALITY OBJECTIVES

The primary criterion for satisfying DQOs is to maximize the number of analyte PQLs that are below applicable cleanup action levels. This will give us confidence that we can detect contaminants of concern below the action levels. Cleanup levels for radiological contaminants are discussed in Section 2.3. Standard laboratory radiochemical techniques and in situ gamma spectroscopy can easily attain minimum detectable levels, which are significantly less than the cleanup criteria. Screening levels for chemical contaminants of concern are taken from the New Jersey cleanup criteria in Appendix A. If standard methods cannot produce PQLs that are less than screening levels, the methods may need to be modified or non-standard methods should be utilized if possible. Even using modified or substitute methods, there may be analytes with screening levels that fall between the PQL and MDL, or below the MDL. These analytes are indicated in footnotes at the end of **Table A-1** of Appendix A. For these analytes, there will likely be negotiations with stakeholders and regulators to agree upon a satisfactory approach to test for these analytes.

For each task (Field Demonstration, groundwater remedial investigation, remediation of a given property, etc.), sample results will be grouped according to matrix and action level cleanup categories. For example, if the soil cleanup action levels differ depending on depth, separate groupings of sample results will be made according to depth. All test results for samples within a given category will be compared to the appropriate action level. If the results are all below the action level, no further action will be required. If one or more results are above the action level, the mean and standard deviation of the sample grouping will be calculated and compared to the analogous background results. If the comparison, using an appropriate statistical technique, indicates that the two sample populations are indistinguishable, then no further action will be required. If the comparison indicates that the sample grouping is higher than the background population, then remedial action will be undertaken. For Final Status Surveys of property soils, MARSSIM (EPA 2000b) will be employed.

Thorium 228, 230, 232	none	0.2		see Ra-226	0.1	
Uranium 234, 235, 238	Total Uranium 50 pCi/L	0.2		50 pCi/g U-238; 100 pCi/g total U	0.1	
Gross Alpha and gross beta	15 pCi/L for alpha; 50 pCi/L for beta	3 for gross alpha 4 for gross beta		NA	3 for gross alpha 4 for gross beta	
Radium 228	See Ra-226	1.0		NA	1.0 by Gamma	
Radium 226	5 pCi/L (w/ Ra-228)	1.0		5 pCi/g	1.0 by Gamma	

Notes:

NA = Not Available for this Constituent, if shown in an Action level column; Not Applicable if shown in a PQL column since samples do not need to be analyzed for this parameter, or the parameter does not have a PQL, such as Grain Size

TBP = To be provided

a. Soil chemical action levels are the most stringent (lowest) of the 3 soil action levels; namely, nonresidential direct contact, residential direct contact, and soil impact to groundwater cleanup criteria from the NJDEP proposed rule, Cleanup Standards for Contaminated Sites, N.J.A.C. 7:26D, dated February 3, 1992, last revised May 12, 1999. Parameter specific notes shall be added to these footnotes. Water action levels are the more stringent of the NJ Groundwater Quality Criteria and the Maximum Contaminant Level (MCL) for groundwater as taken from the NJDEP Ground Water Quality Standards, N.J.A.C. 7:9-6. These values are provided for comparison to detection and quantitation limits. Additional ARAPS are discussed in the Environmental Protection Plan (Stone & Webster 1999)

b. All solids will be reported on a dry weight basis, with the associated sample percent moisture reported separately.

c. Soxhlet extraction must be used during the sample preparation step on clay or clay-like soils.

d. PCB action level is for total PCBs.

e. Samples do not need to be analyzed for this parameter for the matrix indicated.

f. Present soil action level is 5 pCi/g for combined Ra-226 plus Th-232; and 50 pCi/g for U-238. Instead of PQLs, the radionuclide minimum detectable activities (MDAs) for low level activity samples are provided in pCi/g for soil and pCi/L for water.

g. Volatile organic analyses for aqueous samples is performed using a 25 ml purge

h.These compounds have action levels that are lower than their corresponding PQLs. In all cases, however, except for ADD COMPOUND LIST, the corresponding MDLs were lower than the action levels.

i. Paragon PQLs apply to all chemical parameters; UFML MDAs apply to radiological parameters only.

This table does not cover wastewater parameters, the limits for which are provided in Table A-2.

j. Lithium, thallium and boron (soil) are analyzed by ICP/MS, Method 6020B which has lower reporting limits and can therefore meet the regulatory action levels for water. All other metals except mercury are analyzed by Method 6010B. Mercury is analyzed by 7470A and 7471A for water and soil samples, respectively.

Notes:

1. For Maywood wastewater samples, only the compounds acrylonitrile and 1,2-dichlorobenzene are required as MS/MSD analytes.
2. These compounds are not on the VOC TCL list, but are part of the select list of VOCs for which Maywood wastewater samples are analyzed.
3. For metals and Rad parameters, the acceptance criterion for precision of aqueous replicate pairs is a RPD of less than 20% when sample results are greater than 5 times the PQL; when one or both results are less than 5 times the PQL, the absolute difference between the two replicate results must be less than the PQL
4. MS and LCS limits are the same.

NA – not applicable; NE – not established

APPENDIX C
FORMS

Note: The Sample Receipt Checklist shown in this Appendix is typical of an off-site lab checklist. The USACE FUSRAP Maywood laboratory has a Sample Receiving Log shown as Attachment 22.1 of SOP 641.

Chapter 1
Introduction

This document is designed to offer guidance in laboratory data quality evaluation of radiological data and is based, in part, on the Multi-Agency Radiological Laboratory Analytical Protocols Manual (MARLAP, 2004). The MARLAP Manual addresses the need for a nationally consistent approach to producing radioanalytical laboratory data that meet a project's or program's data requirements. MARLAP was developed collaboratively by the following federal agencies; the Environmental Protection Agency (EPA), the Department of Energy (DOE), the Department of Homeland Security (DHS), the Nuclear Regulatory Commission (NRC), the Department of Defense (DOD), the National Institute of Standards and Technology (NIST), the United States Geological Survey (USGS), and the Food and Drug Administration (FDA).

MARLAP provides guidance for the planning, implementation, and assessment phases of those projects that require the laboratory analysis of radionuclides and is both scientifically rigorous and flexible enough to be applied to a diversity of projects and programs. The MARLAP manual is divided into two main parts. Part I is primarily for project planners and managers and provides guidance on project planning with emphasis on analytical planning issues and analytical data requirements. Part II is intended for laboratory personnel and provides guidance in the relevant areas of radioanalytical laboratory work. This document is limited to the application of MARLAP Chapters 1, 7, 8, and 9 and Appendix C of Part I, and Chapters 15, 16, 18, 19, and 20 of Part II.

The purpose of this document is to provide data quality guidelines to personnel involved in the testing of radiologically contaminated environmental media, and the interpretation and possible qualification of the results. The scope of the document includes discussions of the quality criteria, corrective actions, and data qualifications that should be used or applied during the data acquisition, verification and validation processes. This document shall be used by laboratory personnel to obtain guidance on how to establish quality control parameter control charts, how and when to employ corrective actions, and which laboratory qualifiers to apply under certain circumstances. It shall be used by project chemists to establish project data quality guidelines and oversight of laboratory operations. It shall also be used by independent third party validators to apply data qualifiers when necessary. This document, in conjunction with MARLAP, shall take precedence in the validation process over contracted labs QA/QC procedures

One of the most important factors considered when using the MARLAP approach is the issue of uncertainty. The term "uncertainty" refers to a lack of complete knowledge about something of interest. In this document, the term "measurement uncertainty" will often be used and is defined in the *Guide to the Expression of Uncertainty in Measurement* (GUM) (ISO 1995) as a "parameter, associated with the result of a measurement, that characterizes the dispersion of values that could reasonably be attributed to the measurand." MARLAP recommends the methods of GUM for describing, evaluating, and reporting measurement uncertainty. The uncertainty of a measured value is typically expressed as an estimated standard deviation, called a "standard uncertainty" or one-σ uncertainty. The topic of measurement uncertainty goes into greater detail in Chapter 3 of MARLAP (Attachment 3A, pg 3-29).

As per MARLAP, this document establishes method quality objectives (MQO) for method uncertainty for every appropriate analyte/matrix combination. The required method uncertainty, μ_{MR}, at the upper bound of the gray region (UBGR) is defined as:

$$\mu_{MR} = \Delta / 10$$

where Δ is the width of the gray region (UBGR – lower bound of the gray region (LBGR)). The UBGR is synonymous with the action level for those analytes that have an action level. For sample results that fall at or above the UBGR, the relative method uncertainty, φ_{MR}, is used to establish quality control parameter acceptance criteria. The quantity φ_{MR} is defined as:

$$\varphi_{MR} = \mu_{MR} / \text{UBGR}$$

The quality control parameters described within this document and employed during sample batch testing at USACE remedial investigation project sites help ensure that MQOs are met.

The validation process involves three steps; criteria, verification, and validation:

a. Criteria is the required quality control action that must be performed to be in compliance with the data quality objectives (DQO).

b. Verification assures that laboratory conditions and operations were compliant with the contractual Scope of Work (SOW) and the project plan. Verification compares the data package to these requirements (contract compliance) and checks for consistency and comparability of the data throughout the data package and completeness of the results to ensure all necessary documentation is available.

c. Validation addresses the reliability of the data, where the degree of confidence in the reported analytical data are considered. Data validation criteria and procedures should be established during the planning process and captured in the project plan documents (and SOW for the validation contractor). Data validation qualifiers may be applied based upon qualify control exceedances. A list of these qualifiers are shown in Table 14-1 (see MARLAP Section 8.3.3).

This document will cover the following quality control criteria:

- Holding Times and Preservation
- Calibration
- Blank Analysis
- Tracer Recoveries
- Laboratory Control Sample Analysis
- Matrix Spike Sample Analysis
- Standards and Reagents
- Laboratory Replicate Analysis
- Field Duplicate Analysis
- Spectrometry Resolution

- Radionuclide Quantitation and Detection Limits
- Matrix Density

This document may be used to establish quality control acceptance criteria for any radiological parameters, however specific control limits are provided for parameters of interest associated with the Formerly Utilized Sites Remedial Action Program (FUSRAP) Maywood Superfund Site in Maywood, New Jersey. Table 1-1 provides the Maywood project parameters, the results of which are validated and unvalidated, for each radioanalytical instrument type. Generally, this document covers sample matrices with analysis results for the parameters that require validation.

Table 1-1. Maywood Project Parameters

	VALIDATED PARAMETERS		
	Gamma Spectrometry	Alpha Spectrometry	Gas Proportional Detection
Surface water; groundwater	NA	Ra-226, iso-uranium, and iso-thorium	GA, GB, and Ra-228
Soils and sediments	Th-232, Ra-226, U-238 in backfill and FSS soils	None	NA
	UNVALIDATED PARAMETERS		
Wastewaters	NA	Ra-226, iso-uranium, and iso-thorium	GA, GB, and Ra-228
Air filters, wipes and smears	NA	NA	GA, GB
Soil	Th-232, Ra-226, U-238 in document control, excavation control and soil loadout samples	Ra-226, iso-thorium, and iso-uranium	NA

Chapter 2
Holding Times and Preservation

2.1 Criteria

Aqueous sample holding times for all Maywood project analytes, including Ra-226, Ra-228, isotopic uranium, isotopic thorium, gross alpha (GA) and gross beta (GB) are six months, when preserved to pH <2 in nitric or hydrochloric acid (EPA, 1997).

Due to limited information regarding the holding times for soil samples, it is left to the professional judgment of the Project Manager of the regulatory authority (New Jersey Department of Environmental Protection (NJDEP) in the case of Maywood) how to apply holding times to soil samples. For the Maywood project, soil samples are routinely analyzed for Th-232, Ra-226, and U-238 by gamma spectrometry. Long-lived radionuclides in a soil matrix should not have a holding time if they are chemically stable and stored properly. Proper storage means the sample is stored in a chemically compatible (i.e., non-reactive with the analytes of interest) container in a secure area either within the laboratory or a storage trailer.

2.2 Verification (MARLAP, Chapter 8, Radiochemical Data Verification and Validation)

Actual holding times are established by comparing the sampling date in the sampling logbook, or Chain-of-Custody (COC) with the dates of analysis found in the laboratory raw data (digestion logs and instrument run logs).

Analyte Holding Times (days) = Analysis Date - Sampling Date

For water samples, the pH is checked using pH paper (range of 0-3 pH units) to verify that samples are properly preserved to a pH of <2.

Physical characteristics and half-lives must also be considered when evaluating holding times. It is important that radionuclides with short half-lives and low action levels or relatively high MDAs be analyzed as quickly as possible. For example, suppose radionuclide X has the following characteristics:

- Method MDA: 1.5 pCi/g
- Action level: 5 pCi/g
- Activity at time of collection: 5.2 pCi/g
- Half-life: 4 days

If a sample containing X at 5 pCi/g is analyzed 8 days after collection, the activity of X will have decayed through two half-lives, and will therefore be 1.3 pCi/g. Since this activity is less than the MDA, it will most likely be qualified non-detect. Thus, a sample that exceeded the action level would be incorrectly interpreted as being less than the action level. Please note that as long as the result is not non-detect, the sample activity at the time of collection can be calculated from the decay

equation. Thus decay to less than MDA levels for radionuclides with low action levels must be avoided.

2.3 Validation

If exceptions to the holding times and preservation criteria are noted, the validator shall qualify the data corresponding to samples analyzed outside of holding time, or to samples improperly preserved estimated, J.. In cases where the improper preservation severely impacts data quality or defensibility, the validator should qualify the data rejected,R. The validator may still deem the data usable, but he or she must provide the rationale for their decision in the assessment report.

If holding times are exceeded, the reviewer shall use professional judgment to estimate the potential effects of additional storage on the sample results. The expected bias would be low.

Please note that all qualifiers are defined in Chapter 14.

Chapter 3
Calibration

3.1 Gamma Spectroscopy

3.1.1 Initial Calibration – Energies and Efficiencies (MARLAP, Chapter Sections 15.2, 15.6 and 18.5.6)

3.1.1.1 Criteria

A full energy and shape calibration, Peak-to-Compton ratio calibration, and efficiency calibration, the three of which are called an initial calibration, is performed annually and after hardware replacement or significant instrument repairs. The initial calibration must be performed with a NIST-traceable mixed gamma standard, typically a radioactive source with 8 to 10 radionuclides having gamma ray emissions at energies from approximately 60 keV to 2000 keV.

Energy Calibration

A plot of the true energy versus the observed energy (expressed as channel number) must be a straight line. The difference between the true energy and the observed energy of any radionuclide gamma emission line must be less than 1.0% ([(true energy – observed energy)/true energy] X 100 < 1%). For a 660 keV energy (Cs-137), 1% is 6.6 keV. To ensure proper resolution, the Full Width Half Maximum (FWHM) value is checked and must be less than 3% of the observed energy.

Peak-to-Compton Ratio Calibration

The Peak-to-Compton ratio, an important characteristic of the detector, shall be performed on the ^{60}Co 1332 keV peak, then compared with the manufacturer's specification. This ratio is defined as follows:

(Counts in the peak centroid channel of the full energy peak (1332 keV peak)) ÷ (Average number of counts in the Compton region)

The Compton region typically falls between 1040 keV and 1096 keV for ^{60}Co.

Efficiency Calibration

After the efficiency calibration has been performed and the parameters for the equation of the line calculated, the Delta and Fit values are observed. The Fit value is the efficiency value of the best fit line at a given energy. The Delta value, in percent, equals the difference between the Fit value and the actual efficiency, divided by the actual efficiency, all times 100.

Delta value = [(Fit Value – Actual Efficiency)/ Actual Efficiency] X 100

The actual efficiency is calculated from the activity of the standard and the counts observed. For the best fit polynomial, linear, or quadratic equation, the Delta values must each be less than 5%.

The full width tenth maximum to full width half maximum (FWTM-FWHM) ratio will also be checked quarterly. The FWTM-FWHM ratio will be determined for Co-60. The values are documented on a spreadsheet file that is kept on the laboratory shared drive. The acceptance range for this ratio will be based upon the detector specification for this ratio as well as the observed variability in the ratio over the past few years (mean ± std. deviation).

3.1.1.2 Verification

Check that the energy and efficiency determination, including calibration curves and instrument background are included in the analytical data package. Since the initial calibration is typically prepared only once per year, this documentation only must be submitted once to the validator each year; i.e., it does not have to be submitted with every data package. Typically, the initial calibration documentation is submitted to the validator at the beginning of the project, and then each time the detectors are recalibrated. If the documentation is missing, the validator shall request that the laboratory provide the missing information.

For the energy calibration, verify that a plot of the observed energies versus the channel number is a straight line. The difference between the observed energy and the true energy of any radionuclide must be less than 1.0%. If it is greater than 1% for 2 or more radionuclides, verify that the instrument gain was adjusted and the instrument recalibrated. Verify that the FWHM value for a given energy peak is less than 3% of the observed energy.

For the peak-to-Compton ratio calibration, verify that the ratio is at least as high as the following manufacturer's specifications for the three gamma spectrometer detectors:

Detector 1(30%): 58.4:1 Detector 2 (40%): 63:1 Detector 3 (40%): 64:1

For the efficiency calibration, verify that it was performed and that the delta values, as described above in 3.1.1.1, are less than 5%.

3.1.1.3 Validation

If the initial calibration data is not provided to the validator within a reasonable period of time, all data associated with the initial calibration shall be qualified rejected, R.

The data associated with the calibration shall be deemed unusable if one or more of the following criteria are exceeded:

- The energy percent difference (described above in the Energy Calibration paragraph) from the energy calibration plot is greater than 1% for two or more radionuclides (and the instrument was not recalibrated after gain adjustment);
- The efficiency calibration delta values are greater than 5% for any one radionuclide;
- The FWHM for any one energy peak is > 3%.

If only one radionuclide has an energy percent difference greater than 1%, that radionuclide can be removed and the instrument calibrated without it, unless it is Cs-137 (661.66 keV) which is a critical radionuclide.

3.1.2 Continuing Calibration (daily) – Energy and Activities

3.1.2.1 Criteria

Continuing calibrations are to be performed daily, or every day that a gamma spectroscopy detector analyzes samples and/or standards. The same NIST-traceable mixed gamma standard employed for the initial calibration, is used for continuing calibrations. The activity of each radioisotope in the calibration standard must be within 10% relative of the true, decay-corrected activity. The energy of each isotope must be within 1% of the true energy. The FWHM value will be monitored and must be less than 3% of the observed energy for one low energy, one mid-energy, and one high energy calibration radionuclide.

3.1.2.2 Verification

Check that the continuing calibration standard was analyzed on each day for which field and batch QC samples were analyzed, and that the calibration standard was analyzed before analysis of any samples. Default control limits of ± 10% (relative) and default warning limits of ± 7% (relative) of the true activity of each radionuclide must also be provided. If the control limits for one or more radionuclides, or if the warning limits for two or more radionuclides are exceeded, verify that the continuing calibration standard was reanalyzed before analysis of any samples or batch QC. Verify that the mixed gamma standard contains 8 to 10 radionuclides with energies that span the energy spectrum (approximately 60 keV to 2000 keV). Sources should provide at least 10,000 counts at each energy so counting uncertainty is less than 1%. The Full Width Half Maximum (FWHM) value will be monitored and must be less than 3% of the observed energy for one low energy, one mid-energy, and one high energy calibration radionuclide.

3.1.2.3 Validation

If any continuing calibration standard results are missing, the validator must reject all sample results generated on that day or on those days. Check all continuing calibration standard radionuclide activities to ensure they fall within ±10% relative of the true activity. If any control limits (as noted in 3.1.2.2) were exceeded and the continuing calibration standard was not reanalyzed or the reanalysis results were also unacceptable, all sample results associated with that standard (essentially all results generated on that day) shall be qualified rejected, R. Typically, the standard results are checked and it is reanalyzed if necessary. Qualify all results associated with a calibration rejected, R if one or more of the following occurs:

- The difference between the true energy and the observed energy of any radionuclide gamma emission line is > 1%;
- The FWHM value is greater than 3% of the observed energy for one low energy, one mid-energy, or one high energy calibration radionuclide, and the calibration was not reanalyzed, or if it was reanalyzed and there was still an exceedance.

3.2 Alpha Spectroscopy

3.2.1 Initial Calibration (annual) – Energy and efficiencies (MARLAP, Chapter Section 15.4)

For both initial and continuing calibrations, a pulser check must be run before the calibration on the same day of the calibration run. For the pulser check, the following QC acceptance criteria apply to each detector:

- Full Width Half Maximum (FWHM): within the mean ± 3σ; the mean and 3σ are established using 20 or more pulser check values.
- Pulser Energy Center: 5500 ± 50 keV
- Efficiency: within the mean ± 3σ; the mean and the ± 3σ control limits are established using 20 or more pulser check values

3.2.1.1 Criteria

The alpha spectrometer system is calibrated with a NIST-traceable standard containing five (5) isotopes: U-238, U-234, Th-230, Pu-239, and Am-241. The detector response created by three of these radioisotopes, U-238, Pu-239, and Am-241, are used to calibrate the instrument. The manufacturer has indicated that three radionuclides are sufficient to calibrate the alpha spectrometer detectors. An initial energy and efficiency calibration is performed annually, or whenever significant equipment changes occurs, such as replacement of a detector. The following QC acceptance criteria are established for the initial calibration for each detector.

Table 3-1. QC Acceptance Criteria Established for the Initial Calibration for each Detector

	Calibration Radioisotope		
QC CRITERION	U-238	Pu-239	Am-241
Efficiency (detector specific)	(see Note 1)	(see Note 1)	(see Note 1)
Maximum Peak Energy (keV)	4196 ± 10	5155 ± 10	5486 ± 10
Activity (%R of true value)	90-110%	90-110%	90-110%

Note 1: Average Efficiency for the 3 Radionuclides of 20.72% – 23.20%

3.2.1.2 Verification

Verify that an initial calibration has been performed within one year ± 30 days of the last initial calibration, and that the efficiency, activity (with %R values), and calibration isotope maximum peak energies have been provided in the data package. The pulser check resolution (FWHM), pulser energy center, and efficiency values must also be provided along with the acceptance criteria (mean ± 3σ for FWHM and efficiency; 5500 ± 50 for pulser energy center) for these QC parameters. Sources should provide at least 10,000 counts at each energy so counting uncertainty is less than 1%. Since the initial calibration is typically prepared only once per year, this documentation only must be submitted once to the validator each year; i.e., it does not have to be submitted with every data package.

3.2.1.3 Validation

Check the initial calibration isotope efficiency, activity and maximum peak energy values as well as pulser check acceptance criteria to see if they fall within the criteria stated in 3.2.1 and 3.2.1.1. If they do not, and the initial calibration standard was not reanalyzed or the reanalysis results were also unacceptable, all data associated with the initial calibration is deemed unusable and shall be rejected.

3.2.2 Continuing Calibration (daily) – Energy and Activities

3.2.2.1 Criteria

For alpha spectroscopy, an energy and efficiency calibration is performed monthly using the same isotopic mixture as that used for the initial calibration. For the calibration isotopes, the maximum peak energy, activity and efficiency must be within the limits provided in Table 3-1. At no time shall the maximum peak energy value vary by more than 10 keV from the theoretical peak energy.

3.2.2.2 Verification

Check that the latest (the most recent relative to the sample analyses) energy and efficiency calibrations are included in the analytical data package and that the average efficiency, maximum peak energies, and activities fall within the limits specified within Table 3-1. If the documentation is missing, the validator shall request the data from the laboratory. If the laboratory does not have a record of the continuing calibration, all data that would have been associated with the calibration is unusable, unless the lab can verify that the calibration has not shifted.

3.2.2.3 Validation

If required factors are missing, or if the QC parameter values exceed the Table 3-1 limits, the validator may elect to qualify affected data estimated J to signify an increased level of uncertainty in the measurement because of the inability to correct the measured value for efficiency. If the calibration was not supplied in the package, and the laboratory cannot verify that the calibration has not shifted, or if the results of a continuing calibration have indicated a shift has occurred, reject all data resulting from the last continuing calibration check.

3.3 Gross Alpha/Gross Beta (Gas Proportional Counter)

See Section 15.4.1.2 and 15.5 of MARLAP.

3.3.1 Initial Calibrations and Daily Calibrations

The gross alpha and gross beta initial instrument calibrations consist of 20 or more analyses each of a single paper filter gross alpha standard containing Th-230 and a single electroplated gross beta standard containing Sr/Y-90. Average activities and standard deviations are then calculated and used on control charts. These are "zero mass" standards, so that there is little or no attenuation of the alpha or beta energies. The control charts are constructed for each detector using the mean and the ±2 sigma (warning) and the ±3 sigma (control) limits. Subsequent continuing calibration standard checks are made on days of instrument operation, and checked against the control chart to ensure acceptable instrument operability prior to measurement of samples. The charts are updated periodically to reflect the most recent calibration checks.

In addition to control charts for the standards, efficiency curves are generated for gross beta and gross alpha analyses by Method 900.0 for each detector to account for self-adsorption of alpha or beta particles within the thickness of evaporated sample solids. To the greatest extent practicable, the salt used for the construction of efficiency curves should simulate the dissolved and suspended salts encountered in actual field samples. A set of standards are prepared which have varying amounts of salt but have the same activity. Each curve is a plot of mass of solids (x-axis) versus the efficiency. The efficiency is the response in counts-per-minute (cpm) divided by the known activity in disintegrations-per-minute (dpm). The efficiency for a given sample is then determined from a detector's efficiency curve by reading the efficiency that corresponds to the weight of the evaporated solids on the planchet. The efficiency taken from the curve, in conjunction with the response in cpm, are used to calculate the activity of a given sample.

The gas proportional detector is also used to measure Ac-228 in the Ra-228 analysis. Ac-228 is the daughter of Ra-228. A separate dedicated calibration is generated annually for this analysis using Sr-89, whose beta decay energy is closer to the Ac-228 decay energy than the Sr/Y-90 standard. The Sr-89 calibration is different than the gross alpha (Th-230) and gross beta (Sr/Y-90) calibrations since it uses several replicate standards instead of one standard and each replicate has a mass of solid that replicates the mass of solid generated for the Ra-228 test method. A mean efficiency is determined by calculating the efficiency of each replicate (by dividing the cpm response by the known dpm activity) and then calculating the average efficiency. It is this mean efficiency, in conjunction with a sample response, which is used to calculate the activity of a sample.

Similar to the Sr-89 calibration, a dedicated calibration is generated for gross alpha by Method 7110C, employed for water samples with high (>500 ppm) total solids. The solid used is a mixed precipitate of ferric hydroxide and barium sulfate, and the mass of the precipitate in each replicate approximates the mass of solid generated in the Method. The radionuclide standard spike is Th-230. All other aspects of the calibration are the same as the one generated with Sr-89

3.3.1.1 Criteria

For the calibration control charts, the Th-230 or Sr/Y-90 activities, which are checked on each day that a gas proportional detector will be used and are in units of cpm or percent recovery, must be within QC limits of the mean ± 3 sigma for a given detector. The calibration control charts are updated periodically, typically every six to nine months.

3.3.1.2 Verification

Verify that the daily calibration results are within the mean ± 3 sigma for a given detector. Also verify that daily calibration checks were performed on every day that a sample and/or standard was analyzed. If a daily calibration check result was outside of QC limits, verify that it was reanalyzed and that the reanalysis results were within QC limits prior to sample analysis.

3.3.1.3 Validation

If the gas proportional gross alpha or gross beta calibration checks are not within the mean ± 3 sigma, and the daily calibration was not successfully reanalyzed, all data associated with that calibration check shall be qualified rejected, R.

Chapter 4
Blanks

For all methods, blank analysis results are assessed to determine the existence and magnitude of contamination problems. The criteria for evaluation of blanks apply to any blank associated with the samples. If problems with any blank exist, all data associated with the case shall be carefully evaluated to determine whether or not there is an inherent variability in the data for the case, or if the problem is an isolated occurrence not affecting other data. (MARLAP Appendix C, Section C.4.2.3)

4.1 Gamma Spectroscopy, Alpha Spectroscopy, and Gas Proportional Counting

4.1.1 Criteria

A daily blank is analyzed on each detector on every day that samples shall be analyzed on that detector (gamma spectroscopy and gas proportional detectors only) A daily blank consists of a detector count of the same length as that of a regular sample, performed with a blank container in the shielding cave (gamma) or counting chamber (gas proportional counter). Daily blanks are not measured for alpha spectroscopy. Warning and control limits for daily blanks are established using the mean $\pm 2\sigma$, and the mean $\pm 3\sigma$, respectively. The symbol σ is the standard deviation of the mean. The mean value is calculated using at least 20 points and often many more. The mean and warning and control limits are recalculated approximately every six months.

In addition, at least one method blank must be analyzed for every matrix, every batch, or for every 20 samples (5% of samples), whichever is more frequent. For solid samples (gamma spectroscopy only), the method blank consists of Ottawa sand, or a material with equivalent physical and radiological properties, that has been dried, ground, and stirred to homogenize in the same or similar manner as field samples. For water samples (alpha spectroscopy and gas proportional detection only), a deionized water blank is prepared or processed in the same manner as the field samples. A deionized water blank is also used as the method blank for alpha spectroscopy soil sample batches. For onsite laboratories, due to the nature of sample flow and the rapid turnaround time requirement (often less than 24 hours), the batch is defined as the samples received by the lab during a given week. Thus the method blank frequency at onsite laboratories is typically weekly, unless more than 20 samples are received in a given week, in which case a new batch is started. Warning and control limits for method blanks are established using $\pm 2\mu_{MR}$ and $\pm 3\mu_{MR}$, respectively for all parameters except Th-228, Th-230, Th-232, and U-235 in water. The variable μ_{MR} is defined in Chapter 1 of this Guidance and μ_{MR} values are taken from all detectors of a given instrument type. Since there are no regulatory action levels for Th-228, Th-230, Th-232 in water and since U-235 contributes an insignificant amount of activity to the total uranium, the control limits for these parameters come from the mean $\pm$ 3σ limits established from historical data. The warning and control limits for the thorium isotopes and U-235 are recalculated approximately every six months. The method blank warning and control limits for gamma spectroscopy, alpha spectroscopy and gas proportional detectors are provided in Table 4-1.

Background counts (12 hours each for gamma and alpha detectors, and 1000 minutes for gas proportional detectors) are conducted weekly for gamma spectrometer and gas proportional detectors and monthly for alpha spectrometer detectors. The background count rate must fall within its control

limits, which are its mean background activity ± 3σ, which is calculated for each detector. The most recent background count rate is subtracted from each sample and batch QC sample count rate. Due to the very low background count rates for alpha spectrometer detectors, an absolute total count value of six counts is used as a control limit for each detector. Six counts in 12 hours, or 720 minutes, is a count rate of 0.0083 counts per minute (cpm), which is one to two orders of magnitude less than the not-to-exceed MDA values for all alpha spectroscopy analytes. The background mean and warning and control limits are recalculated approximately every six to nine months.

The result of all blanks and backgrounds must be reported along with the sample results and must be plotted on a QC chart. Acceptable tolerances must be based on system performance and analytical requirements. The daily blank and background control charts show the mean, the warning limits (+2σ and -2σ lines), and the control limits (+3σ and -3σ lines) while the method blank control charts show the warning limits (+2μ_{MR} and -2μ_{MR} lines), and the control limits (+3μ_{MR} and -3μ_{MR} lines).

Table 4-1. Method Blank Control Limits for Maywood Analytes of Concern

Analyte	Required Method Uncertainty, μ_{MR} (pCi/g)	Warning Limit, ±2μ_{MR} (pCi/g)	Control Limit, ±3μ_{MR} (pCi/g)
	GAMMA MARINELLI		
Ac-228	0.16	0.32	0.49
Pb-214	0.11	0.22	0.33
Th-234	2.0	4.1	6.1
	GAMMA TUNACAN		
Ac-228	0.052	0.103	0.154
Pb-214	0.043	0.086	0.129
Th-234	0.246	0.492	0.738
	GAS PROPORTIONAL (units in pCi/L)		
GA (900.0)	1.44	2.88	4.32
GA (7110C)	1.115	2.23	3.34
GB (900.0)	1.395	2.79	4.18
Ra-228	0.285	0.57	0.86
	ALPHA SPECTROMETER (units in pCi/L)		
U-234	3.38	6.77	10.16
U-235 (*)	0.022	0.043	0.065
U-238	3.20	6.59	9.88
Ra-226	0.275	0.55	0.825
Th-228 (*)	0.125	0.25	0.38
Th-230 (*)	0.70	1.4	2.1
Th-232 (*)	0.10	0.20	0.30

Note: Method blank uncertainties, warning limits and control limits apply to all three detectors (gamma), all 16 detectors (gas proportional) and all 24 detectors (alpha spectrometer).
*: For Th-228, Th-230, Th-232 and U-235, the uncertainty values are the σ values from historical data.

4.1.2 Verification

If a daily blank or method blank was required but not performed, or if the required data are missing, the validator shall request the data from the lab. If the blank(s) was not generated, the field sample data generated on that day (in the case of a missing daily blank) or generated within a given batch (in the case of a missing method blank) shall not be acceptable for use. Review the blank results and

evaluate the blank control charts if available as well as the raw data for all blanks. Verify that the results were accurately reported and that tolerance limits were not exceeded.

4.1.3 Validation

If the blank result does not comply with the established criteria, that is, if a result is outside of the control limits of $\pm 3\mu$ (method blanks), or $\pm 3\sigma$ around the mean (daily blanks or backgrounds), then the qualifier B should be applied with a "+" or "-" (depending upon whether the result is above or below the control limits) to all samples in the batch in the case of method blanks, and to all samples analyzed on a given detector on a given day in the case of the daily blank. If a background activity falls outside $\pm 3\sigma$, it should be reanalyzed.

Chapter 5
Sample Specific Chemical Recovery (Tracer)

The following discussion applies to alpha spectroscopy tracers and Ba-133 measured by gamma spectroscopy. A tracer is either an isotope of the same element as the isotope of interest, or an isotope of an element different from the element of the isotope of interest, but one that behaves chemically very similar to the isotope of interest. Tracers are added to both field samples and batch QC samples prior to sample preparation. Because the tracer is chemically either identical or very similar to the isotope of interest, it provides an indication for every batch QC or field sample of any method anomalies such as sample losses due to absorption, reactivity, spillage, etc. or artifacts specific to the measurement step. Thus the percent recovery of the tracer is used to normalize the measured activity of the isotope of interest.

5.1 Alpha Spectroscopy

5.1.1 Criteria

Each sample chemical tracer percent recovery (%R) must be recorded and should be plotted on a QC chart for each radionuclide and method and fall within the prescribed limits of ±3σ of the mean recovery. There should be at least 30 points used to establish a control chart for each radionuclide and both the ±2σ warning limits and ±3σ control limits must be displayed. **Note that batch QC tracer data should not be used to establish control charts**.

The quantity of tracer material used must be adequate to provide a maximum uncertainty at the 95% confidence level in the measured recovery using the following equation (Golnick, 1994):

$$2\sigma uncertainty = \frac{1.96\sqrt{(C_s / t_s) + (C_b / t_b)}}{(E)(Vol)(R)(2.22)}$$

Where:

C_s = Sample count rate, cpm
C_b = Background count rate, cpm
t_s = Sample count time, minutes
t_b = Background count time, minutes
E = Counting efficiency
Vol = Volume of sample (liters or grams) (NOTE: This factor does not apply for the Ba-133 tracer which is measured as total activity in a centrifuge tube or on a filter disk)
R = Radiochemical recovery
2.22 = Conversion factor from dpm to pCi

5.1.2 Verification

a. Check the raw data to verify that sample specific recoveries are accurately reported. Recalculate up to 10% of the sample specific recoveries (%R) using the following equation:

$\%R = (A_{Found}/A_{True}) \times 100$

Where:
A_{Found} = activity (in pCi/L for aqueous; pCi/g for solid) of each analyte measured in the LCS.
A_{True} = activity (in pCi/L for aqueous; pCi/g for solid) of each analyte in the LCS source.

b. Check spike levels to verify that sufficient activities are used to provide adequate precision, as measured by the 2σ uncertainty equation in 5.1.1, for recovery determination.

c. Evaluate recoveries to verify that they fall within the limits specified in Section 5.1.1.

5.1.3 Validation

For sample specific recoveries, qualify results for the appropriate radionuclides in all associated samples as follows:

a. Within ±2σ of the mean recovery, data is acceptable and no qualifiers are necessary.

b. If data falls between +2σ and + 3σ, or between -2σ and -3σ, or is equal to ±2σ, qualify the data estimated, J

c. If data is greater than or equal to +3σ or less than or equal to -3σ, corrective action must be taken, typically by repreparing and reanalyzing the sample with the poor tracer recovery. If no corrective action is taken, qualify the data rejected, R. If corrective action is taken and the results are within ±3σ, qualify the data estimated, J. If corrective action is taken and the result is still greater than or equal to +3σ or less than or equal to -3σ, qualify the data rejected, R.

d. If significant errors are noted in the calculations, qualify all affected results, specific to that sample rejected, R.

Chapter 6
Laboratory Control Sample (LCS)

6.1 Gamma Spectroscopy

6.1.1 Criteria

The laboratory control sample (LCS) serves as a monitor of the overall accuracy and performance of all steps in the analysis, including the sample preparation. Please note that for the gamma spectroscopy soil LCS, there is no sample preparation. The LCS is a known radionuclide standard in an analysis geometry and containing isotopes of interest consistent with the samples undergoing analysis. For the following limits to apply, the LCS must contain greater than 10 times the radionuclide's detection limit activity. Limits are laboratory-derived using as many points as possible near the action level and must display the mean and the ±2 and $3\varphi_{MR}$ limits of the percent deviation (%D) for the LCS analysis. The statistical parameter φ_{MR} is the relative standard deviation at the UBGR (upper boundary of the gray region) and equals μ_{MR} / UBGR. LCS values must fall within the mean %D ±3 φ_{MR} limits (MARLAP Appendix C, Section C.4.2.1). For the Maywood project, the term UBGR is synonymous with the action level.

As an example, consider the action level of the sum of Th-232 and Ra-226 in soil, which is 5 pCi/g above background. Uncertainties are obtained by looking at historical data of Maywood soils with either Th-232 or Ra-226 around 5 pCi/g. The relative standard deviation values provided in Table 6-1 were calculated by dividing the mean uncertainty of a given set of USACE FUSRAP Maywood Laboratory (UFML) results with values near the action level, μ_{MR}(avg), by the action level value of 5 pCi/g, then multiplying by 100. For example, if a result and one sigma uncertainty are 4.5 and 0.7 pCi/g, respectively, the percent relative standard deviation, φ_{MR}, equals (0.7/5) x 100, or 14%. The average percent relative standard deviation (φ_{MR}) values are found to be approximately 9.75% and 6.57%, respectively for Th-232 and Ra-226 for the Marinelli geometry. For U-238, the action level is 50 pCi/g and its average percent relative standard deviation (φ_{MR}) value is 12.24% for the Marinelli geometry

Table 6-1. LCS Warning and Control Limits for Gamma Spectrometry Maywood Soil Analytes of Concern

Analyte	φMR X 100	Warning Limits (±2φMR X 100)	Control Limits (±3φMR X 100)
Marinelli Geometry			
Th-232	3.25%	6.50%	9.75%
Ra-226	2.19%	4.38%	6.57%
U-238	4.08%	8.16%	12.24%
Tunacan Geometry			
Th-232	3.88%	7.76%	11.64%
Ra-226	1.58%	3.16%	4.74%
U-238	4.08%	8.16%	12.24%

For example, if the mean LCS %D is 7.3% for Th-232 (Marinelli), the control limits are then (7.3% - 9.75%) to (7.3% + 9.75%), or -2.45% to +17.05%. So, if the activity of the Th-232 LCS is 3.3 pCi/g, the LCS limits in pCi/g are 3.22 – 3.86 pCi/g. The mean LCS activities are obtained from the (approximately) 30 most recent results using values obtained from all three gamma detectors. The mean values are updated approximately every six months.

6.1.2 Verification

At least one LCS must be analyzed for every matrix, every batch, or for every 20 samples (5% of samples), whichever is more frequent. All aqueous and solid LCS percent deviation values, as calculated below, must be plotted on a control chart, and must fall within the control limits noted in Table 6-1. :

$$\%D = \frac{SSR - SA}{SA} x100$$

Where:

%D is the percent deviation
SSR is the measured result (spiked result)
SA is the spike activity (or concentration) added.

The control chart will contain the mean %D value and the warning and control limits shown below. The φ_{MR} x 100% values are taken from Table 6-1.
Warning limits: ± $2\varphi_{MR}$ x 100 %
Control limits: ± $3\varphi_{MR}$ x 100%

6.1.3 Validation

Review and verify that results fall within the control limits. Check the raw data (counter printout, strip charts, bench sheets, etc.) to verify the reported recoveries.

a. If any result falls outside control limits, the lab must take corrective action to ensure acceptable LCS results. The corrective action will typically be a reanalysis. If the reanalysis is unsuccessful (i.e., one or more of the LCS reanalysis results fell outside of control limits), then adjustments should be made to instrument settings. The LCS should then be reanalyzed along with any samples associated with the LCS that had already been analyzed.

b. If an acceptable LCS result (within control limits) cannot be generated, all sample results associated with the faulty LCS shall be qualified by the laboratory with an S- or S+ indicating a high or low recovery. The third party validator may apply a U, J, or R qualifier to the LCS and associated regular samples in the analytical batch based on professional judgment and the use of other quality control criteria.

c. If an LCS is not analyzed with a batch, all data associated with the batch shall be qualified rejected, R.

6.2 Alpha Spectroscopy

6.2.1 Criteria

The laboratory control sample (LCS) serves as a monitor of the overall accuracy and performance of all steps in the analysis, including the sample preparation.

6.2.2 Verification

At least one LCS must be analyzed for every matrix, every batch, or for every 20 samples (5% of samples), whichever is more frequent. All aqueous LCS percent deviation values, as calculated using the Equation in Section 6.1.2, must be plotted on a control chart, and must fall within the control limits noted in Table 6-2. [MARLAP (C.4.2.1)].

The control limits are plotted around a mean value for the percent deviation. The mean shall be calculated using the 20-30 most recent LCS percent difference (%D) values obtained from all detectors. The mean value is updated every 12-18 months.

Control limits are determined by first calculating the relative uncertainties (φ_{MR}) of several results of a given isotope by first calculating the average uncertainty, μ_{MR}(avg), then dividing μ_{MR}(avg) by the analyte action level and multiplying the quotient by 100 to obtain the average percent relative uncertainty. If possible, the selected results should fall around the action level for that analyte. The average percent relative uncertainties are then multiplied by 3 to obtain control limits.

Isotopic thorium analytes have no action level. Since thorium-230 (Th-230) is the only thorium isotope in the LCS, the mean %D value and the control limits are derived from existing data (the mean value determines the %D, and the 3σ value is added to and subtracted from the mean %D to yield the control limits). For uranium, the action level is 20 pCi/L for total uranium and most of the contribution to total uranium activity is from U-234 and U-238, which theoretically have equal activities in any given sample. Therefore the uncertainties for U-234 and U-238 activities around 10 pCi/L were considered. There were 15 and 12 points, respectively for U-234 and U-238. Similar to the Th-230, the U-235 mean %D value and the control limits are taken from historical data. Ra-226 is another alpha spectroscopy parameter. The Ra-226 + Ra-228 action level is 5.0 pCi/L. Given these action levels for the Maywood project alpha spectrometry parameters, the mean φ_{MR} values were calculated for the following activity ranges:

- Ra-226, between 0.75 and 2.5 pCi/L.
- U-234, between 7.6 and 11.6 pCi/L.
- U-238, between 7.6 and 10.8 pCi/L

The average relative uncertainties for these parameters were used to establish the control limits shown in Table 6-2. The percent relative standard deviation (φ_{MR} x 100) values provided in Table 6-2 were calculated by dividing the mean uncertainty of a given set of UFML results, μ_{MR}(avg), by the analyte's action level, then multiplying by 100.

Table 6-2. LCS Warning and Control Limit Relative Uncertainties for Alpha Spectrometry Maywood Water Analytes of Concern

Analyte	φMR X 100	Warning Limits (±2φMR X 100)	Control Limits (±3φMR X 100)
U-238	4.42%	± 8.85%	± 13.28%
U-235	12.3%	± 24.6 %	± 36.9%
U-234	7.00%	± 14.0%	± 21.0%
Th-230	6.70%	± 13.4%	± 20.1%
Ra-226	5.50%	± 11.0%	± 16.5%

As far as control limits for soil LCS analyzed by alpha spectrometry, there have been very few samples, perhaps two to four per year, analyzed by alpha spectrometry. Therefore, there is an inadequate number of results available to establish accurate control limits for the three soil parameters with project action levels, namely Th-232, Ra-226, and U-238. Plus, UFML does not analyze a soil LCS with alpha spectrometry soil sample batches; they analyze an aqueous LCS. Therefore, the aqueous control limits provided in Table 6-2 shall also be utilized as acceptance criteria for soil LCS sample results.

6.2.3 Validation

Review and verify that results fall within the control limits. Check the raw data (counter printout, strip charts, bench sheets, etc.) to verify the reported recoveries.

a. If any result falls outside the quality control limits, the lab must take corrective action to ensure acceptable LCS results. The corrective action will typically be a reanalysis. If the reanalysis is unsuccessful, then adjustments should be made to instrument settings and/or a new LCS shall be prepared . The new LCS should then be processed through the sample preparation and analyzed along with all batch samples associated with the LCS for the failed LCS analyte.

b. If an acceptable LCS result cannot be generated, all sample results associated with the faulty LCS shall be qualified by the laboratory with an S- or S+ indicating a high or low recovery. The third party validator may apply a U, J, or R qualifier to the LCS and associated regular samples in the analytical batch based on professional judgment and the use of other quality control criteria.

c. If an LCS is not analyzed with a batch, all data associated within the batch shall be qualified rejected, R.

6.3 Gross Alpha/Gross Beta and Ra-228 (Gas Proportional Counter)

6.3.1 Criteria

The laboratory control sample (LCS) serves as one of the monitors of the overall accuracy and performance of the analysis, including the sample preparation. For the following acceptance criteria to apply, the LCS must contain greater than 10 times the radionuclide's detection limit activity.

6.3.2 Verification

At least one LCS must be analyzed for every matrix, every batch, or for every 20 samples (5% of samples), whichever is more frequent. All aqueous LCS percent deviation values, as calculated in Section 6.1.2, must be plotted on a control chart, and must fall within the control limits noted in Table 6-3. [MARLAP Appendix C, Section C.4.2.1)]. The control limits are plotted around a mean value for the percent deviation. The mean shall be calculated using the 20-30 most recent LCS %D values from all detectors. The mean value is recalculated approximately every six months, or whenever 20 values are accumulated. The relative standard deviation values provided in Table 6-3 were calculated by dividing the average uncertainty of a set of UFML results (preferably) near the analyte's action

level, μ_{MR}(avg), by its associated action level, then multiplying by 100. Every attempt was made to use uncertainty values associated with results near the action levels of 15 pCi/L for GA and 50 pCi/L for GB. There were 37 and 29 results, respectively for GA by Method 900.0 and GA by Method 7110C. There were 33 GB results by Method 900.0 used to establish limits. The Ra-228 action level is described as 5 pCi/L for the sum of the activities of Ra-226 and Ra-228. There were 17 Ra-228 wastewater results (Method 9320) generated by UFML and they ranged from 2.1 to 7.3 pCi/L. The average relative standard deviation was calculated from these 17 values.

Table 6-3. Warning and Control Limits for Gas Proportional Detector Maywood Water Analytes of Concern

Analyte	φMR X 100	Warning Limits (±2φMR X 100)	Control Limits (±3φMR X 100)
Gross Alpha (7110C)	7.44%	± 14.9%	± 22.3%
Gross Alpha (900.0)	9.61%	± 19.2%	± 28.8%
Gross Beta	2.79%	± 5.58%	± 8.37%
Ra-228	9.10%	± 18.2%	± 27.3%

6.3.3 Validation

Review and verify that results fall within the control limits. Check the raw data (counter printout, strip charts, bench sheets, etc.) to verify the reported recoveries.

a. If any result falls outside the quality control limits, the lab must take corrective action to ensure acceptable LCS results. The corrective action will typically be a reanalysis. If the reanalysis is unsuccessful, then adjustments should be made to instrument settings and/or a new LCS shall be prepared. The new LCS should then be processed through the sample preparation and analyzed along with all batch samples associated with the LCS for the failed LCS analyte.

b. If an acceptable LCS result cannot be generated, all sample results associated with the faulty LCS shall be qualified by the laboratory with an S- or S+ indicating a high or low recovery. The third party validator may apply a U, J, or R qualifier to the and regular samples associated with the LCS in the analytical batch based on professional judgment and the use of other quality control criteria.

c. If an LCS is not analyzed with a batch, all data associated within the batch shall be qualified rejected, R.

Chapter 7
Matrix Spike Sample (MSS) Analysis

The matrix spike sample (MSS) analysis provides information about the effect of each sample matrix on the method preparation and measurement. MSS are required when sample specific chemical recoveries (tracers) are not used and the samples undergo a chemical preparation process.

MSS analysis is only performed for Gross Alpha/Gross Beta analyses. The accuracy of the matrix spike analysis is assessed using tracers for alpha spectroscopic analysis and by measuring the gravimetric yield of barium sulfate for Ra-228 measured by gross beta. For gamma spectroscopy soils, there is no matrix spike employed due to the difficulty introducing a homogenous matrix spike. Matrix spikes may also be used for water samples to be analyzed by gamma spectroscopy, although water samples are not analyzed by gamma spectroscopy on the Maywood project.

7.1 Gross Alpha/Gross Beta (Gas Proportional Counter)

7.1.1 Criteria

The acceptance criteria for matrix samples are more complicated than for LCS and method blanks due to the pre-existing activity in the unspiked sample, which must be measured and then subtracted from the activity measured after spiking. The %D warning and control limits are dependent only upon one measured value (spiked result for LCS, and blank result for the method blank), whereas the matrix spike limits are dependant upon two measured values (spiked sample result and sample result), therefore %D is not a good statistic to use for MSS. Instead, a "Z-Score" equation is employed (MARLAP Appendix C, Section C.4.2.4):

$$\text{Z-Score} = \frac{SSR - SR - SA}{\phi_{MR}\sqrt{SSR^2 + \max(SR, UBGR)^2}}$$

Where:
max (x,y) denotes the maximum of x and y,
φ_{MR} is the maximum allowable (relative) standard deviation at the UBGR
SSR is the spiked sample result
SR is the sample result
SA is the activity spiked into the sample
UBGR = 15 pCi/L for GA and 50 pCi/L for GB

A control chart shall be prepared which contains a mean Z score, obtained from 20-30 matrix spike results, as well as warning and control limits. The warning and control limits for the calculated Z-Score statistic are set as follows:

Warning limits: ±2
Control limits: ±3

If a result falls outside of control limits, the sample must be reanalyzed to confirm the exceedance.

7.1.2 Verification

At least one MSS must be analyzed for every matrix, every batch, or for every 20 samples (5% of samples), whichever is more frequent. Samples identified as field blanks must not be used for spiked sample analysis. The calculated Z-Score statistic of the matrix spike must be recorded and plotted on a QC chart and fall within the prescribed limits. Verify that the MS and its associated unspiked sample were reprepared and reanalyzed if the MS result exceeds control limits. If the sample result is > 4 times the spike level, the MSS Z-Score evaluation is not employed.

7.1.3 Validation

Verify that the calculated MSS Z-Score statistic falls within the specified control limits. A calculated Z-Score statistic that falls outside the control limits should be qualified by the laboratory with an S- or S+ indicating a high or low recovery. The third party validator may apply a U, J, or R qualifier to the MSS and associated regular samples in the analytical batch based on professional judgment and the use of other quality control criteria. Generally, if the calculated Z-Score statistic is between -2 and -3, or +2 and +3, the sample result is qualified estimated J. If the Z-Score is <-3 or >+3, the data is qualified R, rejected. Rejection of data for MSS failures requires professional judgment. If a result falls outside of control limits, corrective action may be taken by repreparing and reanalyzing the sample and its matrix spike. If the reanalysis result falls outside control limits the sample result shall be qualified rejected, R. If the reanalysis falls within control limits, the result should be qualified estimated, J.

Chapter 8
Standards and Reagents

8.1 Criteria

The traceability of standards and reference materials to be used during the analysis should be specified in the sampling and analysis plan.

8.2 Verification

Check that criteria related to traceability of reference materials and standards (completed source manufacturer and internal calibration certificates) have been addressed, and pertinent documentation is included in the analytical data package or has been verified during an audit.

8.3 Validation

The validator may factor the absence of the traceability into their evaluation of data quality and usability. At most, this should result in increasing the uncertainty of the determination and the possible assignment of an estimated "J" qualifier to the data. This would not occur normally unless one or more of the standards used in analyzing the samples was shown to be unreliable. The inability to trace a reliable standard to a sample increases the uncertainty of the data points(s).

Chapter 9
Laboratory Replicates

9.1 Criteria

Replicate analyses are indicators of laboratory precision based on each sample matrix. The variability of sample results due to analyte heterogeneity in the sample is also reflected in the replicate result. At least one replicate must be analyzed for every matrix, every batch or for every 20 samples (5% of samples) whichever is more frequent. The laboratory may not be in control of the precision, therefore, replicate results are used to evaluate reproducibility of the complete laboratory process that includes subsampling, preparation, and analytical processes (MARLAP, Appendix C, Sect. C.4.2.2).

Acceptance criteria for replicate analysis results depend on the sample concentration, which is estimated by the average $\overline{X}$ of the two measured results X1 and X2.

$$\overline{X} = \frac{X_1 + X_2}{2}$$

When the $\overline{X}$ < UBGR, the warning limit for the absolute difference $|X_1 - X_2|$ is:

$2\ u_{MR}\sqrt{2} \approx 2.83\ u_{MR}$; and the control limit is: $3\ u_{MR}\sqrt{2} \approx 4.24\ u_{MR}$

Where u_{MR} is the uncertainty at the UBGR.

When the $\overline{X}$ >= UBGR, the warning limit for the relative percent difference (RPD),

100 x $|X_1 - X_2|$ / $\overline{X}$ = 100 X 2.83 φ_{MR} ; and the control limit = 100 X 4.24 φ_{MR} (MARLAP Appendix C, Section C.4.2.2)

For the Maywood project gamma spectrometry parameters, the mean 2σ uncertainties were calculated for the following activity ranges. The mean σ uncertainty is 0.5 of the 2σ uncertainty, and equals u_{MR}:

Marinelli Geometry
Ac-228 (Th-232), between 4.4 and 5.6 pCi/g.
Pb-214 (Ra-226), between 3.9 and 6.0 pCi/g.
Th-234 (U-238), between 45.0 and 53.6 pCi/g

Tunacan Geometry
Ac-228 (Th-232), between 3.0 and 6.5 pCi/g.
Pb-214 (Ra-226), between 2.3 and 3.4 pCi/g.
Th-234 (U-238), there was no data near the action level; therefore, the Marinelli data was used as an approximation.

Table 9-1. Average 2 μ_{MR} Uncertainties, Average μ_{MR} Uncertainties and Average Relative Method Uncertainties (φ_{MR})

	No. of Points	Mean 2μ	Mean μ	φ_{MR} values
		Marinelli Geometry		
Th-232	25	0.325	0.162	3.25%
Ra-226	25	0.219	0.110	2.19%
U-238	26	4.08	2.04	4.08%
		Tunacan Geometry		
Th-232	14	0.388	0.194	3.88%
Ra-226	16	0.158	0.079	1.58%
U-238	26 (See note below)	4.08	2.04	4.08%

NOTE: For U-238 in soil, there are no values at or near the action level of 50 pCi/g for the tunacan geometry. Therefore, the μMR and φMR values for U-238 established for the Marinelli geometry were also used for the tunacan geometry.

The activity ranges for Ac-228 (Th-232) and Pb-214 (Ra-226) were chosen to represent a reasonable estimate of the uncertainty. Determination of the uncertainties for these two parameters is complicated by the fact that the action level, or UBGR, is 5 pCi/g for the sum of the activities of these two radionuclides. The author chose a group of activities around 5 pCi/g for Th-232 and for Ra-226 (if available) and around 50 pCi/g for U-238. The mean σ values are used as the u_{MR} values (see Table 9-1) to determine the warning and control limits for the gamma spectrometry parameters. The warning and control limits for laboratory replicate soils measured by gamma spectrometry are provided in Table 9-2.

Table 9-2 Warning and Control Limits for Laboratory Replicate Soil Results for Maywood Analytes Measured by Gamma Spectrometry

Table 9-2. Warning and Control Limits for Laboratory Replicate Soil Results for Maywood Analytes Measured by Gamma Spectrometry

Analyte	$\overline{X}$ < UBGR Warning Limit, 2.83 uMR	Control Limit, 4.24 uMR	$\overline{X}$ > UBGR Warning Limit, 100 X 2.83 φMR	Control Limit, 100 X 4.24 φMR
		Marinelli Geometry		
Th-232	0.460	0.689	9.20%	13.8%
Ra-226	0.310	0.464	6.20%	9.29%
U-238	5.77	8.65	11.5%	17.3%
		Tunacan Geometry		
Th-232	0.549	0.823	11.0%	16.5%
Ra-226	0.224	0.335	4.47%	6.70%
U-238	5.77 (see note below)	8.65	11.5%	17.3%

NOTE: For U-238 in soil, there are no values at or near the action level of 50 pCi/g for the tunacan geometry. Therefore, the μMR and φMR values for U-238 established for the Marinelli geometry were also used for the tunacan geometry.

For the alpha spectrometry parameters, only the Ra-226 and iso-uranium replicate limits were developed using MARLAP guidance since they are the only alpha spectrometrer parameters that are regulated. The regulatory limit for the sum of the activities of Ra-226 and Ra-228 in water is 5.0 pCi/L. The regulatory limit for total uranium is 20 pCi/L. For the purposes of this discussion, we

consider the sum of the U-234 and U-238 activities as comprising the total iso-uranium activity (U-235 is considered negligible). For the gas proportional multi-detector system (MDS), GA, GB, and Ra-228 are considered. Only GA, GB, and Ra-228 activities generated by UFML (as opposed to an outside lab) are considered and only those that meet the not-to-exceed MDA requirement of 3.0 for GA and 4.0 for GB are considered.

For the Maywood project alpha spectrometry and gas proportional detector parameters, the mean 2σ uncertainties were calculated for the following activity ranges:

- Ra-226, between 0.75 and 2.5 pCi/L.
- Ra-228, between 2.1 and 7.3 pCi/L
- U-234, between 7.6 and 11.6 pCi/L.
- U-238, between 7.6 and 10.8 pCi/L
- GA, between 9.0 and 15.5 pCi/L
- GB, between 39 and 53 pCi/L

Table 9-3. Average Required and Relative Uncertainties for Alpha Spectrometry and Gas Proportional Detector Parameters

	No. of Points	Mean 2 u_{MR}	Mean u_{MR}	φ_{MR} values
Ra-226	6	0.55	0.28	5.5%
Ra-228	17	0.91	0.46	9.1%
U-234	15	1.4	0.70	14%
U-238	12	0.885	0.44	8.85%
GA (900.0)	37	2.88	1.44	28.8%
GB (900.0)	33	2.79	1.40	27.9%
GA (7110C)	29	2.23	1.12	22.3%

The mean σ values are used as the u_{MR} values to determine the warning and control limits for the alpha spectrometry and gas proportional detector parameters. The warning and control limits for laboratory replicate waters measured by alpha spectrometry and gas proportional detection are provided in Table 9-4. As in Section 9.1, the quantity used to construct replicate control charts is $|X_1 - X_2|$ when $\overline{X}$ < UBGR and 100 x $|X_1 - X_2| / \overline{X}$ when $\overline{X}$ > UBGR.

Table 9-4. Warning and Control Limits for Laboratory Replicate Water Results for Maywood Analytes Measured by Alpha Spectrometry and Gas Proportional Detectors

Analyte	$\overline{X}$ < UBGR		$\overline{X}$ > UBGR	
	Warning Limit, 2.83 uMR	Control Limit, 4.24 uMR	Warning Limit, 100 X 2.83 φMR	Control Limit, 100 X 4.24 φMR
Ra-226	0.778	1.17	15.6%	23.3%
Ra-228	1.29	1.93	25.8%	38.9%
U-234	1.98	2.97	19.8%	29.7%
U-238	1.25	1.88	12.5%	18.8%
GA (900.0)	4.08	6.11	27.2%	40.7%
GB (900.0)	3.95	5.91	7.90%	11.8%
GA (7110C)	3.16	4.73	21.0%	31.5%

9.2 Verification

If replicate analyses are required but not performed, or if the required data are not present in the report, the validator should request the data from the laboratory. If they are still not available, their absence should be noted in the data validation report because overall analytical precision may be impacted. The validator must be provided with the warning and control limits as displayed in Tables 9-2 and 9-4 and defined in the beginning of Section 9.1 of this guidance.

9.3 Validation

If replicate values fall between the warning and control limits, all samples of the same matrix in the batch shall be qualified estimated J. If the LREP statistic is outside the control limits, the laboratory shall qualify all samples associated with that replicate using the letter P. The validator shall then use professional judgment to determine whether to J qualify, or to reject the data (i.e., R qualifier). Data shall not be rejected based upon lab replicate results alone.

Chapter 10
Field Duplicate Analysis (see Appendix C, Section C.4.2.2 of MARLAP, titled Duplicate Analyses)

10.1 Criteria

Field duplicate samples shall be taken and analyzed as an indication of overall precision. A field duplicate is a collocated sample that is sent "blind" to the lab by labeling it such that it cannot be determined from which sample it was split.

10.2 Verification

If duplicate analyses are required but not performed, or if the required data are not present in the report, the validator should request the data from the laboratory. If it is not available, this should be noted in the validation report, since overall data precision may be impacted.

10.3 Validation

The same criteria for lab replicates (see section 9 above) apply to field duplicates and are summarized below:

If $\overline{X}$ < UBGR:

Statistic:	$\left\|X_1 - X_2\right\|$
Warning limit:	2.83 u_{MR}
Control limit:	4.24 u_{MR}

If $\overline{X}$ >= UBGR:

Statistic:	RPD = 100 x $\left\|X_1 - X_2\right\|$ / $\overline{X}$
Warning limit:	2.83 φ_{MR} x 100%
Control limit:	4.24 φ_{MR} x 100%

Warning and control limits for the Maywood parameters of interest are provided within Tables 9-2 and 9-4. If duplicate values fall between the warning and control limits, all samples of the same matrix in the batch shall be qualified estimated J. If the field replicate statistic is outside the control limits, the validator shall qualify the results of all samples associated with the field replicate with the letter P. The validator shall then use professional judgment to determine whether to further qualify the results estimated J, or to reject the sample results. Data shall not be rejected based upon field duplicate data alone.

Chapter 11
Spectrometry Resolution

11.1 Gamma Spectroscopy

11.1.1 Criteria

The target radionuclide energy must be within 2 keV of the observed peak (MARLAP 15.6.3). This criteria does not apply for isotopes present at a values less than the MDA.

11.1.2 Verification

a. Check that the peak search algorithm of the instrument is set at 2 keV of the standard library energy for the identified radionuclide.

b. Compare isotope concentrations with equilibrium concentrations. Unless enrichment is suspected, these concentrations should be comparable.

11.1.3 Validation

Qualify the data as follows:

a. For radionuclide peaks that are detected but fail to meet the positive identification criteria; i.e., the peak energy is > 2 keV from the theoretical peak energy, qualify the data as rejected (R).

b. The validator may contact the lab to resolve differences and request additional information in an effort to resolve discrepancies.

11.2 Alpha Spectroscopy

Chemical separation specificity is the contract laboratory's ability to separate various radionuclides by chemical separation techniques. The chemical separation specificity can be verified for alpha spectroscopy measurements by observation of the alpha energy spectrum.

11.2.1 Criteria

The energy of the radionuclide of interest must be within 40 keV of the theoretical peak energy. This criteria does not apply for isotopes present at values less than the MDA.

11.2.2 Verification

Randomly check that the energy of the observed peak of interest is within 40 keV of the theoretical energy for the radionuclide of interest.

11.2.3 Validation

If the energy of the peak of interest is more than 40 keV from the energy for the radionuclide of interest, qualify the results as rejected (R). Corrective actions for this type of exceedance may include careful cleaning of the detector, or changing the amplifier settings. In either case, communication with the instrument manufacturer technical support group is recommended.

Chapter 12
Radionuclide Quantitation and Detection Limits

12.1 Criteria

The objective is to ensure that the reported quantitation results are accurate and that the required detection limits have been met. When detection limit requirements are not met, the data quality objectives may not have been met. All results shall be evaluated relative to the uncertainty associated with the analysis and the sample reports shall report the uncertainty.

Radionuclide quantitation must be calculated according to the appropriate procedures specified in the contractual SOW. Detection limits specified in the specific procedures must be met unless other detection limits are specified in the SOW.

Analytical uncertainties must be reported with all results in order to qualify the data. Results and uncertainties must be reported for all required analyses regardless of the size or sign of the result. The reported uncertainty must include all uncertainties associated with the analysis. An example calculation of the total propagated uncertainty or error must be provided to the data validator if requested.

12.2 Verification

The raw data shall be examined to verify the correct calculation of sample results reported by the laboratory.

a. Examine the raw data for any anomalies (i.e., omissions, legibility, etc.). Recalculate a few of the results if there is a suspicion the results have not been calculated properly. If calculation errors are found, (e.g., if sample results cannot be reproduced through manual calculations), contacting the laboratory may be necessary to resolve the problem. Qualifiers should be placed using professional judgment. Verify that all analytical uncertainties have been propagated and reported or otherwise documented.

b. Verify that uncertainties have been reported for all results. If a sample result is less than its uncertainty (or indistinguishable from background) or falls between its uncertainty and its MDA, the result shall be validated as directed in Section 12.3 below.

12.3 Validation

When significant errors are found in the calculations, qualify all affected results as rejected, R.

a. For net negative results that have uncertainties smaller than their absolute value, qualify the data “R” as rejected. This is an indication of improper blank subtraction or background shift.

b. For negative results that have uncertainties greater than the absolute value of the result, qualify the result U.

c. If a result is greater than its uncertainty, but less than its MDA, the result is non-detect, or less than background, since it is less than the MDA. While there is a finite possibility that the true result is >MDA, there is a greater probability that the result is less than the MDA. Qualify the result non-detect, U.

d. If a result is greater than its MDA, but less than its uncertainty, the probability that the result is >MDA is greater than the probability that it is less than the MDA. The result is accepted but qualified estimated J, since there will likely be significant probability (typ. 15-25%) for <MDA or negative values.

e. If a result is less than both its uncertainty and its MDA, qualify the result non-detect, U. There is a greater probability that the true result is less than its MDA.

f. When analytical uncertainties cannot be obtained from the lab, qualify the results "R" as rejected.

g. If a result is < critical level, qualify the result non-detect, U. The critical level is the upper 95% confidence interval of the background, essentially the background + 2σ

If any discrepancies are found, the laboratory may be contacted by the designated representative to obtain additional information that could resolve any differences. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted based on the reviewer's professional judgment.

Chapter 13
Matrix Density (gamma spectrometry only)

Matrix densities vary from sample to sample. Since analyte signal is dependant to some extent on sample density, this evaluation criterion takes into account the impact of variations in sample density.

13.1. Criteria

The sample density of the dried and ground sample must be within 70 – 130% of the density of the calibration standard.

13.2. Verification

Calculate each sample density by dividing the weight of the dried and ground sample by the volume of the sample within the sample container.

13.3. Validation

If the density of any sample is not within 70 – 130% of the density of the calibration standard, qualify the results for that sample as estimated J.

Chapter 14
Data Qualifier Definitions

Table 14-1. Data Qualifier Definitions

Data Qualifier	Definition
U	A normal, non-detected (< critical value) result
Q	A reported combined standard uncertainty, which exceeds the project's required method uncertainty
J	An unusually uncertain or estimated result
R	A rejected result: the problems (quantitative or qualitative) are severe; rejected data may still be usable depending upon the intended use of the data and the reason for data rejection
S	A result with a related spike result (laboratory control sample [LCS], matrix spike [MS] or matrix spike duplicate [MSD]) that is outside the control limit for recovery (%R); "S+" or "S-" used to indicate high or low recovery
P	A result with an associated replicate result that exceeds the control limit
B	A result with an associated blank result, which is outside the control limit, "B+" or "B-" used to indicate high or low results

Chapter 15
Glossary

Table 15-1. Glossary of Terms

Term	Definition
Calibration Curve	An analytical curve based on the pulse energy, detector efficiency, energy absorbance or other measured characteristic obtained from standard sources and a reagent blank.
Calibration Source	A radionuclide source counted daily to verify the calibration of a counting system.
Case	A finite (usually predetermined) number of samples collected over a given time period for a particular site. A case consists of one or more sample delivery group(s).
Chemical Tracer	A trace quantity of a different radioisotope of the same element or a carrier quantity of an inactive isotope of the same or a chemically similar element
Critical Level (CL)	The net count rate that must be exceeded before there is a specific degree of confidence that the sample contains any measurable radioactive material above background.
Laboratory Replicate	Two aliquots taken from a homogenized sample and analyzed as individual samples. These are used to determine the precision of the method.
Field Blank	A sample of radionuclide-free media which is taken to the field in sealed containers and transferred from one vessel to another at the sampling site and preserved with the appropriate reagents. This serves as a-check on reagent and environmental contamination. These blanks are treated as actual samples but may not be used for matrix spikes or sample replicates.
Field Replicate	A sample that is collected in the field, homogenized, and split into two separate samples, which are then sent to the laboratory as blind splits, or field replicates. These samples are useful for determination of the precision of the sample collection and preparation processes, as well as the analytical testing process.
Full Width at Half Maximum (FWHM)	The width of the distribution at a level that is half the maximum ordinate of the peak.
Holding Times	The time between the date of collection of sample and the date of sample analysis.
Laboratory Control Sample (LCS)	A control sample of known composition. Aqueous and solid laboratory control samples are analyzed using the same sample preparation, reagents and analytical methods employed for the unknown samples being analyzed. The results from the analysis of the controls are plotted and compared to control limits to determine the usability of the data.
Matrix Spike Sample (MSS)	An aliquot of sample spiked with a known concentration of target radionuclide(s). The spiking occurs prior to sample preparation and analysis. A matrix spike is used to document the bias of a method in a given sample matrix. (Some Federal Regulations require that data be corrected for spike recovery prior to reporting. Environmental Protection Agency recommends a minimum of 10 times the method detection Limit or 2 to 4 times the measured quantity.)

Table 15-1. Glossary of Terms

Term	Definition
Method Blank	A radionuclide-free matrix to which all reagents are added in the same volumes or proportions as used in sample processing. The method blank is carried through the complete sample preparation and analytical procedure. The method blank is used to document contamination resulting from the analytical process and should not be used for matrix spikes or sample duplicates.
Method Detection Limit (MDL)	The minimum concentration of a radionuclide that can be measured and reported with a specific degree of confidence that the radionuclide's activity is greater than zero and is determined for analysis of a sample in a given matrix type. MDL is equivalent to LLD, MDA, etc.
Percent Recovery (%R)	The fractional amount of the known activity of the radionuclide of interest that was obtained in the analysis.
Quality Control (QC)	An aggregate of activities designed to ensure adequate quality of analytical data.
QC Chart	A graphic representation on which the values obtained on the analysis of backgrounds, blanks, calibrations, and laboratory control samples are plotted sequentially. The chart usually consists of a central line and two control limit lines parallel to the central line. The distribution of the plotted values with respect to the control limits provides valuable visual and statistical information on the quality of the analyses.
Standard Operating Procedure (SOP)	Established or prescribed methods to be followed routinely for the performance of design area operations or in designated situations.
Scope of Work (SOW)	A detailed description of work to be performed by a contracted laboratory or facility.
Target Radionuclide List (TRL)	A listing of radionuclides for which a quantitative analysis is required. Net quantitation with uncertainties must be provided for all TRL radionuclides whether or not the radionuclide is identified in the computerized peak search and identification routine.

TABLE OF CONTENTS

INTRODUCTION

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to "SW846-Method 8270D" January 1998. Method 8270D is used to determine the concentration of semivolatile organic compounds in extracts prepared from many types of solid waste matrices, soils, air sampling media and water samples. The validation methods and actions discussed in this document are based on the requirements set forth in SW846 Method 8270D, Method 8000C and the "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," January 2005. This document covers technical problems specific to each fraction and sample matrix; however, situations may arise where data limitations must be assessed based on the reviewer's professional judgement.

Summary of Method

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are defined on page 5.

The reviewer must prepare a detailed data assessment to be submitted along with the completed SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data and contract non-compliance.

Reviewer Qualifications

Data reviewers must possess a working knowledge of SW846 Analytical Methods and National Functional Guidelines mentioned above.

DEFINITIONS

Acronyms

BNA - base neutral acid(another name for Semi Volatiles)
CLP - Contract Laboratory Program
CRQL - Contract Required Quantitation Limit
%D - percent difference
DCB -decachlorobiphenyl
DDD - dichlorodiphenyldichloroethane
DDE - dichlorodiphenylethane
DDT - dichlorodiphenyltrichloroethane
DoC - Date of Collection
GC - gas chromatography
GC/ECD - gas chromatograph/electron capture detector
GC/MS - gas chromatograph/mass spectrometer
GPC - gel permeation chromatography
IS - internal standard
kg - kilogram
µg - microgram
MS - matrix spike
MSD - matrix spike duplicate
ℓ - liter
mℓ - milliliter
PCB - Polychlorinated biphenyl
PE - performance evaluation
PEM - Performance Evaluation Mixture
QC - quality control
RAS - Routine Analytical Services
RIC - reconstructed ion chromatogram
RPD - relative percent difference
RRF - relative response factor
RRF - average relative response factor (from initial calibration)
RRT - relative retention time
RSD - relative standard deviation
RT - retention time
RSCC - Regional Sample Control Center
SDG - sample delivery group
SMC - system monitoring compound
SOP - standard operating procedure
SOW - Statement of Work
SVOA - semivolatile organic acid
TCL - Target Compound List
TCLP - Toxicity Characteristics Leachate Procedure

TCX -tetrachloro-m-xylene
TIC - tentatively identified compound
TOPO - Task Order Project Officer
TPO - Technical Project Officer
VOA - Volatile organic
VTSR - Validated Time of Sample Receipt

Data Qualifiers

U - The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

J - The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.

N - The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."

JN - The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

LAB QUALIFIERS:

D - The positive value is the result of an analysis at a secondary dilution factor.

B - The analyte is present in the associated method blank as well as in the sample. This qualifier has a different meaning when validating inorganic data.

YES NO N/A

E - The concentration of this analyte exceeds the calibration range of the instrument.

A - Indicates a Tentatively Identified Compound (TIC) is a suspected adol-condensation product.

X,Y,Z- Laboratory defined flags. The data reviewer must change these qualifiers during validation so that the data user may understand their impact on the data.

I. PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER:_____ LAB:_____

SITE NAME:_____

1.0 Data Completeness and Deliverables

1.1 Has all data been submitted in CLP deliverable format? [ ] ___ ___

ACTION: If not, note the effect on review of the data in the data assessment narrative.

2.0 Cover Letter, SDG Narrative

2.1 Is a laboratory narrative or cover letter present? [ ] ___ ___

2.2 Are case number and SDG number(s) contained in the narrative or cover letter? [ ] ___ ___

YES NO N/A

II. SEMIVOLATILE ANALYSES

1.0 Traffic Reports and Laboratory Narrative

1.1 Are the Traffic Report Forms present for all samples? [ ] ___ ___

ACTION: If no, contact lab for replacement of missing or illegible copies.

1.2 Do the Traffic Reports or Lab Narrative indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data? ___ [ ] ___

ACTION: If any sample analyzed as a soil, other than TCLP, contains 50%-90% water, all data should be flagged as estimated ("J"). If a soil sample, other than TCLP, contains more than 90% water, all non-detects data are qualified as unusable (R), and detects are flagged “J”.

ACTION: If samples were not iced, or if the ice was melted upon arrival at the laboratory and the cooler temperature was elevated (10^{o}C), flag all positive results "J" and all non-detects "UJ".

2.0 Holding Times

2.1 Have any semivolatile technical holding times, determined from date of collection to date of extraction, been exceeded? ___ [ ] ___

Continuous extraction of water samples for semivolatile analysis must be started within **7** days of the date of collection. Soil/sediment samples must be extracted within **14** days of collection. Extracts must be analyzed within

40 days of the date of extraction.

Table of Holding Time Violations

(See Traffic Report)

Sample ID	Sample Matrix	Date Sampled	Date Lab Received	Date Extracted	Date Analyzed

ACTION: If technical holding times are exceeded, flag all positive results as estimated ("J") and sample quantitation limits as estimated ("UJ"), and document in the narrative that holding times were exceeded.

If analyses were done more than 14 days beyond holding time, either on the first analysis or upon re analysis, the reviewer must use professional judgement to determine the reliability of the data and the effects of additional storage on the sample results. At a minimum, all results should be qualified "J", but the reviewer may determine that non-detect data are unusable ("R"). If holding times are exceeded by more than 28 days, all non-detect data are unusable (R).

S))Q

		YES	NO	N/A
3.0	Surrogate Recovery (Form II/Equivalent)			
3.1	Have the semi volatile surrogate recoveries been listed on CLP Surrogate Recovery forms (Form II) for each of the following matrices:			
	a. Low Water	[ ]	___	___
	b. Low/Med Soil	[ ]	___	___
3.2	If so, are all the samples listed on the appropriate Surrogate Recovery Summary forms for each matrix:			
	a. Low Water	[ ]	___	___
	b. Low/Med Soil	[ ]	___	___
	ACTION: If CLP deliverables are unavailable, document the effect(s) in data assessments. In some cases the lab may have to be contacted to obtain the data necessary to complete the validation.			
3.3	Were outliers marked correctly with an asterisk?	[ ]	___	___
	ACTION: Circle all outliers in red.			
3.4	Were two or more base neutral OR acid surrogate recoveries out of specification for any sample or method blank (Reviewer should use lab in house recovery limits. Use surrogate recovery limits from USEPA National Functional Guidlines January 2005 page 130, if in house limits are not available. See Method 8000B-43 or 80000C-24).	[ ]	___	___
	Note: Examine lab in house limits for reasonableness.			
	If yes, were samples re-analyzed?	[ ]	___	___

YES NO N/A

Were method blanks re-analyzed? [ ] ___ ___

ACTION: If all surrogate recoveries are > 10% but two within the base-neutral or acid fraction do not meet method specifications, for the affected fraction only (i.e. either base-neutral or acid compounds):

1. Flag all positive results as estimated ("J").

2. Flag all non-detects as estimated detection limits ("UJ") when recoveries are less than the lower acceptance limit.

3. If recoveries are greater than the upper acceptance limit, do not qualify non-detects.

If any base-neutral or acid surrogate has a recovery of < 10%:

1. Positive results for the fraction with < 10% surrogate recovery are qualified with "J".

2. Non-detects for that fraction should be qualified as unusable (R) .

NOTE: Professional judgement should be used to qualify data that have method blank surrogate recoveries out of specification in both original and reanalyses. Check the internal standard areas.

3.5 Are there any transcription/calculation errors between raw data and Form II? ___ [ ] ___

ACTION: If large errors exist, call lab for explanation/resubmittal, make any necessary corrections and document

YES NO N/A

effect in data assessments.

4.0 Matrix Spikes (Form III/Equivalent)

4.1 Have the semivolatile Matrix Spike and Matrix Spike Duplicate/or duplicate unspiked Sample recoveries been listed on the Recovery Form (Form III)? [ ] ___ ___

NOTE: Method 3500B/page 4 states the spiking compounds:

Base/neutrals	Acids
1,2,4-Trichlorobenzene	Pentachlorophenol
Acenaphthene	Phenol
2,4-Dinitrotoluene	2-Chlorophenol
Pyrene	4-Chloro-3-methylphenol
N-Nitroso-di-n-propylamine	4-Nitrophenol
1,4-Dichlorobenzene	

Note: Some projects may require the spiking of specific compounds of interest.

Note: See Method 8270D-sec 8.4.2 for deciding on whether to prepare and analyze duplicate samples or a martix spike/matrix spike duplicate. If samples are expected to contain target analytes, then laboratory may use one matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, laboratory should use a matrix spike and matrix spike duplicate pair.

4.2 Were matrix spikes analyzed at the required frequency for each of the following matrices:

a. Low Water [ ] ___ ___

b. Low Solid [ ] ___ ___

c. Med Solid [ ] ___ ___

YES NO N/A

ACTION: If any matrix spike data are missing, take the action specified in 3.2 above. It may be necessary to contact the lab to obtain the required data.

NOTE: If the data has not been reported on CLP equivalent form, then the laboratory must provide the information necessary to evaluate the spike recoveries in the MS and MSD. The required data which should have been provided by the lab include the analytes and concentrations used for spiking, background concentrations of the spiked analytes (i.e., concentrations in unspiked sample), methods and equations used to calculate the QC acceptance criteria for the spiked analytes, percent recovery data for all spiked analytes.

The data reviewer must verify that all reported equations and percent recoveries are correct before proceeding to the next section.

4.3 Were matrix spikes performed at concentration equal to 100ug/L for acid compounds, and 200ug/l for base compounds (Method 3500B-4), or those specified in project plan. [ ] ___ ___

4.4 How many semivolatile spike recoveries are outside Laboratory in house MS/MSD recovery limits (use recovery limits values in Method 8270D-43&44 Table 6 if in house values not available).

Water	Solids
____ out of ____	____ out of ____

YES NO N/A

4.5 How many RPD's for matrix spike and matrix spike duplicate recoveries are outside QC limits?

Water	Solids
____ out of ____	____ out of ____

ACTION: Circle all outliers with red pencil.

ACTION: No action is taken on MS/MSD data alone. However, using informed professional judgement, the data reviewer may use the matrix spike and matrix spike duplicate results in conjunction with other QC criteria to determine the need for some qualification of the data.

4.6 Was a Laboratory Control Sample (LCS) analyzed with each analytical batch? [ ] ___ ___

NOTE: When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.

5.0 Blanks (Form IV/Equivalent)

5.1 Is the Method Blank Summary (Form IV) present? [ ] ___ ___

5.2 Frequency of Analysis:

Has a reagent/method blank analysis been reported per 20 samples of similar matrix, or concentration level, and for each extraction batch? [ ] ___ ___

5.3 Has a method blank been analyzed either after

	YES	NO	N/A
the calibration standard or at any other time during the analytical shift for each GC/MS system used ?	[ ]	___	___

ACTION: If any method blank data are missing, call lab for explanation/resubmittal. If not available, use professional judgement to determine if the associated sample data should be qualified.

5.4 Chromatography: review the blank raw data - chromatograms (RICs), quant reports or data system printouts and spectra.			
Is the chromatographic performance (baseline stability) for each instrument acceptable for the semivolatiles?	[ ]	___	___

ACTION: Use professional judgement to determine the effect on the data.

6.0 Contamination

NOTE: "Water blanks", "drill blanks" and "distilled water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC blanks discussed below.

6.1 Do any method/instrument/reagent blanks have positive results for target analytes and/or TICs? When applied as described below, the contaminant concentration in these blanks are multiplied by the sample dilution factor and corrected for percent moisture where necessary.	___	[ ]	___
6.2 Do any field/rinse/ blanks have positive results for target analytes and/or TICs (if required, see section 10 below)?	___	[ ]	___

ACTION: Prepare a list of the samples associated with each of the contaminated blanks. (Attach a separate sheet.)

NOTE: All field blank results associated to a particular group of samples (may exceed one per case) must be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field Blanks must be qualified for outlying surrogates, poor spectra, instrument performance or calibration QC problems.

ACTION: Follow the directions in the table below to qualify sample results due to contamination. Use the largest value from all the associated blanks. If gross contamination exists, all data in the associated samples should be qualified as unusable (R).

Blank Action for Semivolatile Analyses

Blank Type	Blank Result	Sample Result	Action for Samples
Method, Field	Detects	Not detected	No qualification required
	< CRQL *	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	= CRQL *	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	> CRQL *	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank contamination	Report concentration of sample with a U
		≥ CRQL and ≥ blank contamination	No qualification required

NOTE: Analytes qualified "U" for blank contamination are still considered as "hits" when qualifying for calibration criteria.

NOTE: If the laboratory did not report TIC analyses, check the project plans to verify whether or not it was required.

6.3 Are there field/rinse/equipment blanks associated with every sample? [ ] ___ ___

ACTION: For low level samples, note in data assessment that there is no associated field/rinse/equipment blank. Exception: samples taken from a drinking water tap do not have associated field blanks.

6.4 Was a instrument blank analyzed after each sample/dilution which contained a target compound

	YES	NO	N/A
that exceeded the initial calibration range.	[ ]	___	___
6.5 Does the instrument blank have positive results for target analytes and/or TICs?	___	[ ]	___

Note: Use professional judgement to determine if carryover occurred and qualify analytes accordingly.

7.0 GC/MS Apparatus and Materials

	YES	NO	N/A
7.1 Did the lab use the proper gas chromatographic column for analysis of semivolatiles by Method 8270D? Check raw data, instrument logs or contact the lab to determine what type of column was used. The method requires the use of 30 m x 0.25 mm ID (or 0.32 mm ID), silicone-coated, fused silica, capillary column.	[ ]	___	___

ACTION: If the specified column, or equivalent, was not used, document the effects in the data assessment. Use professional judgement to determine the acceptability of the data.

8.0 GC/MS Instrument Performance Check (Form V/Equivalent)

	YES	NO	N/A
8.1 Are the GC/MS Instrument Performance Check Forms (Form V) present for decafluorotriphenylphosphine (DFTPP)?	[ ]	___	___

NOTE: The performance solution should also contain 4,4-DDT, pentachlorophenol, and benzidine to verify injection port inertness and column performance. The degradation of DDT to DDE and DDD must be less than 20% total and the response of pentachlorophenol and benzidine should be within normal ranges for these compounds (based upon lab experience) and show no peak degradation or tailing before samples are analyzed. (see section 5.5

YES NO N/A

page 8270D-12).

8.2 Are the enhanced bar graph spectrum and mass/charge (m/z) listing for the DFTPP provided for each twelve hour shift? [ ] ___ ___

8.3 Has an instrument performance check solution been analyzed for every twelve hours of sample analysis per instrument? [ ] ___ ___

ACTION: List date, time, instrument ID, and sample analyses for which no associated GC/MS tuning data are available.

DATE	TIME	INSTRUMENT	SAMPLE NUMBERS
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____

ACTION: If lab cannot provide missing data, reject ("R") all data generated outside an acceptable twelve hour calibration interval.

ACTION: If mass assignment is in error, flag all associated sample data as unusable (R).

8.4 Have the ion abundances been normalized to m/z 198? [ ] ___ ___

8.5 Have the ion abundance criteria been met for each instrument used? [ ] ___ ___

ACTION: List all data which do not meet ion abundance criteria (attach a separate sheet).

	YES	NO	N/A
ACTION: If ion abundance criteria are not met, take action specified in section 3.2			
8.6 Are there any transcription/calculation errors between mass lists and Form Vs? (Check at least two values but if errors are found, check more.)	___	[ ]	___
8.7 Have the appropriate number of significant figures (two) been reported?	[ ]	___	___
ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and document effect in data assessments.			
8.8 Are the spectra of the mass calibration compound acceptable?	[ ]	___	___
ACTION: Use professional judgement to determine whether associated data should be accepted, qualified, or rejected.			

9.0 Target Analytes

9.1 Are the Organic Analysis Data Sheets (Form I) present with required header information on each page, for each of the following:			
a. Samples and/or fractions as appropriate	[ ]	___	___
b. Matrix spikes and matrix spike duplicates	[ ]	___	___
c. Blanks	[ ]	___	___
9.2 Has any special cleanup, such as GPC, been performed on all soil/sediment sample extracts (see section 7.2, page 8270D-14)?	[ ]	___	___

YES NO N/A

ACTION: If data suggests that extract cleanup was not performed, use professional judgement. Make note in the data assessment narrative.

9.3 Are the Reconstructed Ion Chromatograms, mass spectra for the identified compounds, and the data system printouts (Quant Reports) included in the sample package for each of the following?

a. Samples and/or fractions as appropriate [ ] ___ ___

b. Matrix spikes and matrix spike duplicates (Mass spectra not required) [ ] ____ ___

c. Blanks [ ] ___ ___

ACTION: If any data are missing, take action specified in 3.2 above.

9.4 Are the response factors shown in the Quant Report? [ ] ___ ___

9.5 Is chromatographic performance acceptable with respect to:

Baseline stability? [ ] ___ ___

Resolution? [ ] ___ ___

Peak shape? [ ] ___ ___

Full-scale graph (attenuation)? [ ] ___ ___

Other:_____ [ ] ___ ___

ACTION: Use professional judgement to determine the acceptability of the data.

9.6 Are the lab-generated standard mass spectra of identified semivolatile compounds present for

	YES	NO	N/A
each sample?	[ ]	___	___

ACTION: If any mass spectra are missing, take action specified in 3.2 above. If the lab does not generate their own standard spectra, make a note in the data assessment narrative. If spectra are missing, reject all positive data.

9.7 Is the RRT of each reported compound within 0.06 RRT units of the standard RRT in the continuing calibration?	[ ]	___	___
9.8 Are all ions present in the standard mass spectrum at a relative intensity greater than 10% (of the most abundant ion) also present in the sample mass spectrum?	[ ]	___	___
9.9 Do the relative intensities of the characteristic ions in the sample agree within ± 30% of the corresponding relative intensities in the reference spectrum?	[ ]	___	___

ACTION: Use professional judgement to determine acceptability of data. If it is determined that incorrect identifications were made, all such data should be rejected (R), flagged "N" (Presumptive evidence of the presence of the compound) or changed to not detected (U) at the calculated detection limit. In order to be positively identified, the data must comply with the criteria listed in 9.7, 9.8, and 9.9.

ACTION: When sample carry-over is a possibility, professional judgement should be used to determine if instrument cross-contamination has affected any positive compound identification.

YES NO N/A

10.0 Tentatively Identified Compounds (TIC)

10.1 If Tentatively Identified Compounds were required for this project, are all Form Is, Part B present; and do listed TICs include scan number or retention time, estimated concentration and "JN" qualifier?

NOTE: Review sampling reports to determine if the lab was required to identify non target analytes (refer to section 7.6.2,page 8270D-21).

10.2 Are the mass spectra for the tentatively identified compounds and associated "best match" spectra included in the sample package for each of the following: [ ] ___ ___

a. Samples and/or fractions as appropriate [ ] ___ ___

b. Blanks [ ] ___ ___

ACTION: If any TIC data are missing, take action specified in 3.2 above.

ACTION: Add "JN" qualifier only to analytes identified by CAS #.

10.3 Are any target compounds from one fraction listed as TIC compounds in another (e.g., an acid compound listed as a base neutral TIC)? ___ [ ] ___

ACTION: i. Flag with "R" any target compound listed as a TIC.

ii. Make sure all rejected compounds are properly reported in the other fraction.

10.4 Are all ions present in the reference mass spectrum with a relative intensity greater than 10% (of the most abundant ion) also present in the

	YES	NO	N/A
sample mass spectrum?	[ ]	___	___
10.5 Do TIC and "best match" standard relative ion intensities agree within ± 20%?	[ ]	___	___

ACTION: Use professional judgement to determine acceptability of TIC identifications. If it is determined that an incorrect identification was made, change the identification to "unknown" or to some less specific identification (example: "C3 substituted benzene") as appropriate and remove "JN". Also, when a compound is not found in any blank, but is a suspected artifact of a common laboratory contaminant, the result should be qualified as unusable, "R."

11.0 Compound Quantitation and Reported Detection Limits

	YES	NO	N/A
11.1 Are there any transcription/calculation errors in Form I results? Check at least two positive values. Verify that the correct internal standard, quantitation ion, and RRF were used to calculate Form I result. Were any errors found?	___	[ ]	___

NOTE: Structural isomers with similar mass spectra, but insufficient GC resolution (i.e. percent valley between the two peaks > 25%) should be reported as isomeric pairs. The reviewer should check the raw data to ensure that all such isomers were included in the quantitation (i.e., add the areas of the two coeluting peaks to calculate the total concentration).

	YES	NO	N/A
11.2 Are the method detection limits adjusted to reflect sample dilutions and, for soils, sample moisture?	[ ]	___	___

YES NO N/A

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and document effect in data assessments.

ACTION: When a sample is analyzed at more than one dilution, the lowest detection limits are used (unless a QC exceedance dictates the use of the higher detection limit from the diluted sample data). Replace concentrations that exceed the calibration range in the original analysis by crossing out the "E" and it's associated value on the original Form I (if present) and substituting the data from the analysis of the diluted sample. Specify which Form I is to be used, then draw a red " X" across the entire page of all Form I's that should not be used, including any in the summary package.

12.0 Standards Data (GC/MS)

12.1 Are the Reconstructed Ion Chromatograms, and data system printouts (Quant, Reports) present for initial and continuing calibration? [ ] ___ ___

ACTION: If any calibration standard data are missing, take action specified in 3.2 above.

13.0 GC/MS Initial Calibration (Form VI/Equivalent)

13.1 Is the Initial Calibration Form (Form VI/ Equivalent) present and complete for the semivolatile fraction? [ ] ___ ___

ACTION: If any calibration forms or standard row data are missing, take action specified in 3.2 above.

13.2 Are all base neutral or acid RRFs > 0.050? [ ] ___ ___

YES NO N/A

Check the **average RRFs** of the four System Performance Check Compounds (SPCCs): N-nitroso-di-n-propylamine, hexachlorocyclopentadiene, 2,4-dinitrophenol, and 4-nitrophenol. These compounds must have **average RRFs** greater than or equal to 0.05 before running samples and should not show any peak tailing.

ACTION: Circle all outliers in red.

ACTION: For any target analyte with **average RRF <0.05**

1. "R" all non-detects;

2. "J" all positive results.

13.3 Are response factors for base neutral or acid target analytes stable over the concentration range of the calibration (% Relative standard deviation [%RSD] < 15.0%)? [ ] ___ ___

NOTE: The % RSD for each individual Calibration Check Compound (CCC, Method 8270D-40 see Table 4) must be less than 30% before analysis can begin. If grater 30%, the lab must clean and recalibrate the instrument.

CALIBRATION CHECK COMPOUNDS

Base/Neutral Fraction	Acid Fraction
Acenaphthene	4-Chloro-3-methylphenol
1,4-Dichlorobenzene	2,4-Dichlorophenol
Hexachlorobutadiene	2-Nitrophenol
Diphenylamine	Phenol
Di-n-octyl phthalate	Pentachlorophenol
Fluoranthene	2,4,6-Trichlorophenol

YES NO N/A

Benzo(a)pyrene

ACTION: If the %RSD for any CCC >30% and no corrective action taken, then "J" qualify all positive hits and "UJ" qualify all non-detects.

ACTION: Circle all outliers in red.

ACTION: If the % RSD is $\geq$ 15.0%, qualify positive results for that analyte "J" and non-detects using professional judgement. When RSD > 90%, flag all non- detect results for that analyte "R," unusable. Alternatively, the lab should calculate first or second order regression fit of the calibration curve and select the fit which introduces the least amount of error.

NOTE: Analytes previously qualified "U" due to blank contamination are still considered as "hits" when qualifying for calibration criteria.

13.4 Did the laboratory calculate the calibration curve by the least squares regression fit? ___ [ ] ___

13.5 Are there any transcription/calculation errors in the reporting of average response factors (RRF) or % RSD? (Check at least two values but if errors are found, check more.) ___ [ ] ___

ACTION: Circle Errors in red.

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and note errors in data assessments.

13.5 Do the target compounds for this SDG include Pesticides? [ ] ___ ___

YES NO N/A

13.6 If the pesticide compounds include DDT, was the percent breakdown of DDT to DDD and DDE greater than 20%? ___ [ ] ___

ACTION: If DDT percent breakdown exceeds 20%:

i. Qualify all positive results for DDT with "J". If DDT was not detected, but DDD and DDE results are positive, qualify the quantitation limit for DDT as unusable, "R".

ii. Qualify all positive results for DDD and DDE as presumptively present at an approximate concentration "JN".

14.0 GC/MS Calibration Verification (Form VII/Equivalent)

14.1 Are the Calibration Verification Forms (Form VII) present and complete for all compounds of interest? [ ] ___ ___

14.2 Has a calibration verification standard been analyzed for every twelve hours of sample analysis per instrument? [ ] ___ ___

ACTION: List below all sample analyses that were not within twelve hours of a calibration verification analysis for each instrument used.

_____

_____

_____

ACTION: If any forms are missing or no calibration verification standard has been analyzed within twelve hours of every sample analysis,

YES NO N/A

call lab for explanation/resubmittal. If continuing calibration data are not available, flag all associated sample data as unusable ("R").

14.3 Do any of the SPCCs have an RRF <0.05? ___ [ ] ___

If YES, make a note in data assessment if the lab did not take corrective action specified in section 7.4.4, page 8270D-18. [ ] ___ ___

14.4 Do any of the CCCs have a %D between the initial and continuing RRF which exceeds 20.0%?

ACTION: If yes, make a note in data assessment.

14.5 Do any semivolatile compounds have a % Difference (% D) between the initial and continuing RRF which exceeds 20.0%? ___ [ ] ___

ACTION: Circle all outliers in red.

ACTION: Qualify both positive results and non-detects for the outlier compound(s) as estimated (J). When %D is above 90%, qualify all non-detects for that analyte as "R", unusable.

14.6 Do any semivolatile compounds have a RRF < 0.05? ___ [ ] ___

ACTION: Circle all outliers in red.

ACTION: If RRF < 0.05, qualify as unusable ("R") associated non-detects and "J" associated positive values.

14.7 Are there any transcription/calculation errors in the reporting of average response factors (RRF) or percent difference (%D) between initial and continuing RRFs? (Check at least two values but if errors are found, check more). ___ [ ] ___

YES NO N/A

ACTION: Circle errors in red.

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and document effect(s) in the data assessments.

15.0 Internal Standards (Form VIII)

15.1 Are the internal standard areas (Form VIII) of every sample and blank within the upper and lower limits (-50% to + 100%) for each continuing calibration? [ ] ___ ___

ACTION: List each outlying internal standard below.

Sample ID	IS #	Area	LowerLimit	Upper Limit

(Attach additional sheets if necessary.)

Note: Check Table 5, 8270D-41 for associated analytes.

ACTION: i. If the internal standard area count is outside the upper or lower limit, flag with "J" all positive results and non-detects (U values) quantitated with this internal standard.

ii. Non-detects associated with IS > 100% should not be qualified.

YES NO N/A

iii. If the IS area is below the lower limit (<50%), qualify all associated non-detects (U-values) "J". If extremely low area counts are reported (<25%) or if performance exhibits a major abrupt drop off, flag all associated non-detects as unusable (R).

15.2 Are the retention times of all internal standards within 30 seconds of the associated calibration standard? [ ] ___ ___

ACTION: Professional judgement should be used to qualify data if the retention times differ by more than 30 seconds.

16.0 Laboratory Control Samples (LCS)

16.1 Were any LCS samples run in order to verify analytes which failed criteria for spike recovery? [ ] ___ ___

16.2 Did the lab spike LCS sample spiked with the same analytes and the same concentrations as the matrix spike? [ ] ___ ___

16.3 Were the mean and standard deviation of all analytes within the QC acceptance ranges as shown in Table 6, 8270D-43? [ ] ___ ___

ACTION: If the recovery of any analyte falls out of the designated range, the analytical results for that compound is suspect and should be qualified "J" in the unspiked samples.

17.0 Field Duplicates

17.1 Were any field duplicates submitted for semivolatile analysis? [ ] ___ ___

S))Q
YES NO N/A

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between field duplicate results must be addressed in the reviewer narrative. However, if large differences exist, identification of field duplicates should be confirmed by contacting the sampler.

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to the USEPA SW-846, Method 8260B December 1996. The validation methods and actions discussed in this document are based on the requirements set forth in USEPA SW-846, Method 8260B and Method 8000C, Rev 3, March 2003; and "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," January, 2005. This document covers technical as well as method specific problems; however situations may arise where data limitations must be assessed based on the reviewer's own professional judgement.

Summary

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are defined on page 4.

The reviewer must prepare a detailed data assessment to be submitted along with the complete SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data, and contract non-compliance.

DEFINITIONS

Acronyms

BNA - base neutral acid(another name for Semi Volatiles)
CLP - Contract Laboratory Program
CRQL - Contract Required Quantitation Limit
CF - calibration factor
%D - percent difference
DCB -decachlorobiphenyl
DDD - dichlorodiphenyldichloroethane
DDE - dichlorodiphenylethane
DDT - dichlorodiphenyltrichloroethane
DoC - Date of Collection
GC - gas chromatography
GC/ECD - gas chromatograph/electron capture detector
GC/MS - gas chromatograph/mass spectrometer
GPC - gel permeation chromatography
IS - internal standard
kg - kilogram
µg - microgram
MS - matrix spike
MSD - matrix spike duplicate
ℓ - liter
mℓ - milliliter
PCB - Polychlorinated biphenyl
PE - performance evaluation
PEM - Performance Evaluation Mixture
QC - quality control
RAS - Routine Analytical Services
RIC - reconstructed ion chromatogram
RPD - relative percent difference
RRF - relative response factor
RRF - average relative response factor (from initial calibration)
RRT - relative retention time
RSD - relative standard deviation
RT - retention time
RSCC - Regional Sample Control Center
SDG - sample delivery group
SMC - system monitoring compound
SOP - standard operating procedure
SOW - Statement of Work
SVOA - semivolatile organic acid
TCL - Target Compound List
TCLP - Toxicity Characteristics Leachate Procedure
TCX -tetrachloro-m-xylene
TIC - tentatively identified compound

TOPO - Task Order Project Officer
TPO - Technical Project Officer
VOA - Volatile organic
VTSR - Validated Time of Sample Receipt

Data Qualifiers

U -The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

J -The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.

N -The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."

JN -The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

UJ -The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R -The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

LAB QUALIFIERS:

D - The positive value is the result of an analysis at a secondary dilution factor.

B - The analyte is present in the associated method blank as well as in the sample. This qualifier has a different meaning when validating inorganic data.

E - The concentration of this analyte exceeds the calibration range of the instrument.

A - Indicates a Tentatively Identified Compound (TIC) is a suspected adol-condensation product.

X,Y,Z- Laboratory defined flags. The data reviewer must change these qualifiers during validation so that the data user may understand their impact on the data.

YES NO N/A

I. PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER:_____ LAB:_____

SITE NAME:_____

1.0 Data Completeness and Deliverables

1.1 Has all data been submitted in CLP deliverable format or CLP Forms Equivalent? [ ] ___ ___

ACTION: If not, note the effect on review of the data in the Data Assessment narrative.

2.0 Cover Letter, SDG Narrative

2.1 Is a laboratory narrative, and/or cover letter signed release present? [ ] ___ ___

2.2 Are case number and SDG number(s) contained in the narrative or cover letter? [ ] ___ ___

ACTION: If not, note the effect on review of the data in the Data Assessment narrative.

II. VOLATILE ANALYSES

1.0 Traffic Reports and Laboratory Narrative

1.1 Are the Traffic Reports, and/or Chain of Custodies from the field samplers present for all samples sign release present? [ ] ___ ___

ACTION: If no, contact the laboratory/sampling team for replacement of missing or illegible copies.

1.2 Is a sampling trip report present (if required)? [ ] ___ ___

1.3 Sample Conditions/Problems

YES NO N/A

1.3.1 Do the Traffic Reports, Chain of Custodies, or Lab Narrative indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data? ___ [ ] ___

ACTION: If all the VOA vials for a sample have air bubbles or the VOA vial analyzed had air bubbles, flag all positive results "J" and all non-detects "R".

ACTION: If any sample analyzed as a soil, other than TCLP, contains 50%-90% water, all data should be flagged as estimated ("J"). If a soil sample, other than TCLP, contains more than 90% water, flag all positive results “J” and all non-detects “R”.

ACTION: If samples were not iced or if the ice was melted upon receipt at the laboratory and the temperature of the cooler was elevated (>10°C), flag all positive results "J" and all non-detects non"UJ".

2.0 Holding Times

2.1 Have any volatile holding times, determined from date of collection to date of analysis, been exceeded?

___ [ ] ___

The maximum holding time for aqueous samples is 14 days.

The maximum holding time for soils non aqueous samples is 14 days.

NOTE: If unpreserved, aqueous samples maintained at 4°C for aromatic hydrocarbons analysis must be analyzed within 7 days. If preserved with HCL acid to a pH<2 and stored at 4°C,then aqueous samples must be analyzed within 14 days from time of collection. For non-aqueous samples for volatile components that are frozen (less than 7°C) or are properly cooled (4°C ± 2°C) and perserved with $NaHSO_4$, the maximum holding time is 14 days from sample collection. If

YES NO N/A

uncertain about preservation, contact the laboratory /sampling team to determine whether or not samples were preserved.

ACTION: Qualify sample results according to Table 1:

Table 1. Holding Time Actions for Trace Volatile Analysis

Matrix	Preserved	Criteria	Action	
			Detected Associated Compounds	Non-Detected Associated Compounds
Aqueous	No	≤7 days	No qualifications	
	No	> 7 days	J	R
	Yes	≤14 days	No qualifications	
	Yes	> 14 days	J	R
Non Aqueous	No	≤ 14 days	J	R
	Yes	≤ 14 days	No qualifications	
	Yes/No	> 14 days	J	R

3.0 Surrogate Recovery (CLP Form II Equivalent)

3.1 Have the volatile surrogate recoveries been listed on Surrogate Recovery forms for each of the following matrices:

a. Water [ ] ___ ___

b. Soil [ ] ___ ___

3.2 If so, are all the samples listed on the appropriate Surrogate Recovery forms for each matrix:

a. Water [ ] ___ ___

b. Soil [ ] ___ ___

ACTION: If large errors exist, deliverables are unavailable or information is missing, document the effect(s) in Data

YES NO N/A

Assessments and contact the laboratory/project officer/appropriate official for an explanation /resubmittal,make any necessary corrections and document effect in the Data Assessment.

3.3 Were the surrogate recovery limits followed per Table 2. If Table 2 criteria were not followed, the laboratory may use in-house performance criteria (per SW-846, Method 8000C, sectiom 9.7). Other compounds may be used as surrogates, depending upon the analysis requirements. [ ] ___ ___

Table 2. Surrogate Spike Recovery Limits for Water and Soil/Sediments

DMC	Recovery Limits (%)Water	Recovery Limits Soil/Sediment
4-Bromofluorobenzene	80-120	70-130
Dibromofluoromethane	80-120	70-130
Toluene-d_8	80-120	70-130
Dichloroethane-d_4	80-120	70-130

Note: Use above table if laboratory did not provide in house recovery criteria.

Note: Other compounds may be used as surrogated depending upon the analysis requirements.

3.4 Were outliers marked correctly with an asterisk? [ ] ___ ___

ACTION: Circle all outliers with a red pencil.

3.5 Were one or more volatile surrogate recoveries out of specification for any sample or method blank. Table 2. [ ] ___ ___

If yes, were samples reanalyzed? [ ] ___ ___

Were method blanks reanalyzed? [ ] ___ ___

YES NO N/A

ACTION: If all surrogate recoveries are > 10% but 1 or more compounds do not meet method specifications:

1. Flag all positive results as estimated ("J").
2. Flag all non-detects as estimated detection limits ("UJ") when recoveries are less than the lower acceptance limit.
3. If recoveries are greater than the upper acceptance limit, do not qualify non-detects, but qualify positive results as estimated “J”.

If any surrogate has a recovery of < 10%:

1. Positive results are qualified with ("J").
2. Non-detects for that should be qualified as unusable ("R").

NOTE: Professional judgement should be used to qualify data that have method blank surrogate recoveries out of specification in both original and reanalyses. The basic concern is whether the blank problems represent an isolated problem with the blank alone or whether there is a fundamental problem with the analytical process. If one or more samples in the batch show acceptable surrogate recoveries, the reviewer may choose the blank problem to be an isolated occurrence.

3.6 Are there any transcription/calculation errors between raw data and reported data? [ ] ___ ___

ACTION: If large errors exist, take action as specified in section 3.2 above.

4.0 Laboratory Control Sample(Form III/Equivalent)

4.1 Is the LCS prepared, extracted, analyzed, and reported once for every 20 field samples of a similar matrix, per SDG. [ ] ___ ___

YES NO N/A

Note: LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume.

ACTION: If any Laboratory Control Sample data are missing, call the lab for explanation /resubmittals. Make note in the data assessment.

4.2 Were the Laboratory Control Samples analyzed at the required frequency for each of the following matrices:

A. Water [ ] ___ ___

B. Soil [ ] ___ ___

C. Med Soil [ ] ___ ___

Note: The LCS is spiked with the same analytes at the same concentrations as the matrix spike (SW-846 8000C, Section 9.5). If different make note in data assessment. Matrix/LCS spiking standards should be prepared from volatile organic compounds which are representative of the compounds being investigating. At a minimum, the matrix spike should include 1,1-dichloroethene, trichloroethene, chlorobenzene, toluene, and benzene.

ACTION: If any MS/MD, MS/MSD or replicate data are missing, take the action specified in 3.2 above.

4.3 Have in house LCS recovery limits been developed (Method 8000C, Sect 9.7). [ ] ___ ___

4.4 If in house limits are not developed, are LCS acceptance recovery limits between 70 - 130% (Method 8000c Sect 9.5)? [ ] ___ ___

4.5 Were one or more of the volatile LCS recoveries outside the in house laboratory recovery criteria for spiked analytes? If in house limits are not present use 70 - 130% recovery limits.
[ ] ___ ___

YES NO N/A

Table 3. LCS Actions for Volatile Analysis

Criteria	Action	
	Detected Spiked Compounds	**Non-Detected Spiked Compounds**
%R > Upper Acceptance Limit	J	No Qualifiers
%R < Lower Acceptance Limit	J	UJ
Lower Acceptance Limit ≤ %R	No Qualifications	

5.0 Matrix Spikes(Form III or equivalent)

5.1 Are all data for matrix spike and matrix duplicate or matrix spike duplicate (MS/MD or MS/MSD) present and complete for each matrix? [ ] ___ ___

NOTE: The laboratory should use one matrix spike and a duplicate analysis of an unspiked field sample if target analytes are expected in the sample. If the sample is not expected to contain target analytes, a MS/MSD should be analyzed (SW-846, Method 8260B, Sect 8.4.2).

5.2 Have MS/MD or MS/MSD results been summarized on modified CLP Form III? [ ] ___ ___

ACTION: If any data are missing take action as specified in section 3.2 above.

5.3 Were matrix spikes analyzed at the required frequency for each of the following matrices? (One MS/MD, MS/MSD or laboratory replicate must be performed for every 20 samples

YES NO N/A

of similar matrix or concentration level. Laboratories analyzing one to ten samples per month are required to analyze at least one MS per month [page 8000C, section 9.5.])

a. Water [ ] ___ ___

b. Waste [ ] ___ ___

c. Soil/Solid [ ] ___ ___

Note: The LCS is spiked with the same analytes at the same concentrations as the matrix spike (SW-846 8000C, Section 9.5). If different make note in data assessment. Matrix/LCS spiking standards should be prepared from volatile organic compounds which are representative of the compounds being investigating. At a minimum, the matrix spike should include 1,1-dichloroethene, trichloroethene, chlorobenzene, toluene, and benzene. The concentration of the LCS should be determined as described SW-Method 8000C Section 9.5.

ACTION: If any MS/MD, MS/MSD or replicate data are missing, take the action specified in 3.2 above.

5.4 Have in house MS recovery limits been developed (Method 8000C, Sect 9.7)for each matrix. [ ] ___ ___

5.5 Were one or more of the volatile MS/MSD recoveries outside of the in-house laboratory recovery criteria for spiked analytes? If none are present, then use 70-130% recovery as per SW-846, 8000C, Sect. 9.5.4. [ ] ___ ___

ACTION: Circle all outliers with a red pencil.

NOTE: If any individual % recovery in the MS (or MSD) falls outside the designated range for recovery the reviewer should determine if there is a matrix effect. A matrix effect is indicated if the LCS data are within limits but the MS data exceeds the limits.

YES NO N/A

NOTE: No qualification of data is necessary on MS and MSD data alone. However, using informed professional judgement, the data reviewer may use MS and MSD resuts in conjunction with other QC criteria to determine the need for some qualificatios.

Note: The data reviewer should first try to determine to what extent the results of the MS and MSD affect the associated data. This determination should be made with regard to he MS and MSD sample itself, as welll as specific analytes for all samples associated with the MS and MSD.

Note: In those instances where it can be determned that the results of the MS and MSD affect only the sample spiked, limit qualification to this sample only. However, it may be determined through the MS and MSD results that a laboratory is having a systematic problem in the analysis of one or more analytes that affect all associated samples, and the reviewer must use professional judgement to qualify the data from all associated samples.

Note: The reviewer must use professional judgement to determine the need for qualification of non-spiked compounds.

ACTION: Follow criteria in Table 4 when professional judgement deems qualification of sample.

Table 4. Matrix Spike/Matrix Spike Duplicate (MS/MSD) Actions for Volatile Analysis

Criteria	Action	
	Detected Spiked Compounds	**Non-Detected Spiked Compounds**
%R > Upper Acceptance Limit	J	No Qualifiers
%R < Lower Acceptance Limit	J	UJ
Lower Acceptance Limit ≤ %R	No Qualifications	

YES NO N/A

6.0 Blank (CLP Form IV Equivalent)

6.1 Is the Method Blank Summary form present? [ ] ___ ___

6.2 Frequency of Analysis: Has a method blank been analyzed for every 20 (or less) samples of similar matrix or concentration or each extraction batch? [ ] ___ ___

6.3 Has a method blank been analyzed for each GC/MS system used ? [ ] ___ ___

ACTION: If any blank data are missing, take action as specified above (section 3.2). If blank data is not available, reject (R) all associated positive data. However, using professional judgement, the data reviewer may substitute field blank data for missing method blank data.

6.4 Chromatography: review the blank raw data - chromatograms, quant reports or data system printouts.

Is the chromatographic performance (baseline stability) for each instrument acceptable for volatile organic compounds? [ ] ___ ___

7.0 Contamination

NOTE: "Water blanks", "drill blanks" and "distilled water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC blanks discussed below.

7.1 Do any method/instrument/reagent blanks have positive results for target analytes and/or TICs? When applied as described below, the contaminant concentration in these blanks are multiplied by the sample dilution factor and corrected for percent moisture where necessary.
[ ] ___ ___

YES NO N/A

7.2 Do any field/rinse blanks have positive volatile organic compound results? ___ [ ] ___

ACTION: Prepare a list of the samples associated with each of the contaminated blanks. (Attach a separate sheet.)

NOTE: All field blank results associated to a particular group of samples (may exceed one per case or one per day) may be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field blanks must be qualified forsurrogate, or calibration QC problems.

ACTION: Follow the directions in Table 5 below to qualify sample results due to contamination. Use the largest value from all the associated blanks.

Table 5. Volatile Organic Analysis Blank Contamination Criteria

Blank Type	Blank Result	Sample Result	Action for Samples
Method, Storage, Field, Trip, Instrument**	Detects	Not detected	No qualification
	< CRQL*	< CRQL	Report CRQL value with a U
		≥ CRQL	Use professional judgement
	> CRQL*	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank contamination	Report the concentration for the sample with a U, or quanity the data as unusable R
		≥ CRQL and ≥ blank contamination	Use professional judgement
	= CRQL*	< CRQL	Report CRQL value with a U
		≥ CRQL	Use professional judgement
	Gross contam-ination	Detects	Qualify results as unusable R

* 2x the CRQL for methylene chloride, 2-butanone, and acetone

** Qualifications based on instrument blank results affect only the sample analyzed immediately after the sample that has target compounds that exceed the calibration range or non-target compounds that exceed 100 ug/L.

NOTE: If gross blank contamination exists(e.g., saturated peaks, “hump-o-grams,” “junk” peaks), all affected positive compounds in the associated samples should be qualified as unusable “R”, due to interference. Non-detected volatile organic target compounds do not require qualification unless the contamination is so high that it interferes with the analyses of non-detected compounds.

YES NO N/A

7.3 Are there field/rinse/equipment blanks associated with every sample? [ ] ___ ___

ACTION: For low level samples, note in data assessment that there is no associated field/rinse/equipment blank. Exception: samples taken from a drinking water tap do not have associated field blanks.

8.0 GC/MS Apparatus and Materials

8.1 Did the lab use the proper gas chromatographic column(s) for analysis of volatiles by Method 8260B? Check raw data, instrument logs or contact the lab to determine what type of column(s) was (were) used. [ ] ___ ___

NOTE: For the analysis of volatiles, the method requires requires the use of 60 m. x 0.75 mm capillary column, coated with VOCOL(Supelco) or equivalent column. (see SW-846, page 8260B-7, section 4.9.2)

ACTION: If the specified column, or equivalent, was not used, document the effects in the Data Assessment. Use professional judgement to determine the acceptability of the data.

9.0 GC/MS Instrument Performance Check (CLP Form V Equivalent)

9.1 Are the GC/MS Instrument Performance Check forms present for Bromofluorobenzene (BFB), and do these forms list the associated samples with date/time analyzed? [ ] ___ ___

9.2 Are the enhanced bar graph spectrum and mass/charge (m/z) listing for the BFB provided for each twelve hour shift? [ ] ___ ___

9.3 Has an instrument performance check solution (BFB)

YES NO N/A

been analyzed for every twelve hours of sample analysis per instrument?(see Table 4, SW-846, page 8260B-36) [ ] ___ ___

ACTION: List date, time, instrument ID, and sample analyses for which no associated GC/MS GC/MS tuning data are available.

ACTION: If the laboratory/project officer cannot provide missing data, reject ("R") all data generated outside an acceptable twelve hour calibration interval.

ACTION: If mass assignment is in error, flag all associated sample data as unusable, "R".

9.4 Have the ion abundances been normalized to m/z 95? [ ] ___ ___

9.5 Have the ion abundance criteria been met for each instrument used? [ ] ___ ___

ACTION: List all data which do not meet ion abundance criteria (attach a separate sheet).

ACTION: If ion abundance criteria are not met, take action as specified in section 3.2.

9.6 Are there any transcription/calculation errors between mass lists and reported values? (Check at least two values but if errors are found, check more.) ___ [ ] ___

9.7 Have the appropriate number of significant figures (two) been reported? [ ] ___ ___

ACTION: If large errors exist, take action as specified in section 3.2.

9.8 Are the spectra of the mass calibration compounds acceptable. [ ] ___ ___

ACTION: Use professional judgement to determine wheather associated data should be accepted, qualified, or rejected.

YES NO N/A

10.0 Target Analytes (CLP Form I Equivalent)

10.1 Are the Organic Analysis reporting forms present with required header information on each page, for each of the following:

a. Samples and/or fractions as appropriate [ ] ___ ___

b. Matrix spikes and matrix spike duplicates [ ] ___ ___

c. Blanks [ ] ___ ___

d. Laboratory Control Samples [ ] ___ ___

10.2 Are the reconstructed Ion Chromatograms, mass spectra for the identified compounds, and the data system printouts (Quant Reports) included in the sample package for each of the following?

a. Samples and/or fractions as appropriate [ ] ___ ___

b. Matrix spikes and matrix spike duplicates (Mass spectra not required) [ ] ___ ___

c. Blanks [ ] ___ ___

d. Laboratory Control Samples [ ] ___ ___

ACTION: If any data are missing, take action specified in 3.2 above.

10.3 Is chromatographic performance acceptable with respect to:

Baseline stability? [ ] ___ ___

YES NO N/A

Resolution? [ ] ___ ___

Peak shape? [ ] ___ ___

Full-scale graph (attenuation)? [ ] ___ ___

Other:_____

ACTION: Use professional judgement to determine the acceptability of the data.

10.4 Are the lab-generated standard mass spectra of identified volatile compounds present for each sample? [ ] ___ ___

ACTION: If any mass spectra are missing, take action specified in 3.2 above. If the lab does not generate their own standard spectra, make a note in the Data Assessment. If spectra are missing, contact the lab.

10.5 Is the RRT of each reported compound within 0.06 RRT units of the standard RRT in the continuing calibration? [ ] ___ ___

10.6 Are all ions present in the standard mass spectrum at a relative intensity greater than 10% (of the most abundant ion) also present in the sample mass spectrum? [ ] ___ ___

10.7 Do the relative intensities of the characteristic ions in the sample agree within ± 30% of the corresponding relative intensities in the reference spectrum? [ ] ___ ___

ACTION: Use professional judgement to determine acceptability of data. If it is determined that incorrect identifications were made, all such data should be rejected (“R”), flagged (“N") - Presumptive evidence of the presence of the compound) or changed to non detected (“U”) at the calculated detection limit. In order to be

YES NO N/A

positively identified, the data must comply with the criteria listed in 9.6, 9.7, and 9.8.

ACTION: When sample carry-over is a possibility, professional judgement should be used to determine if instrument cross-contamination has affected any positive compound identification.

11.0 Tentatively Identified Compounds (TIC) (CLP Form I/TIC Equivalent)

11.1 If Tentatively Identified Compound were required for this project, are all Tentatively Identified Compound reporting forms present; and do listed TICs include scan number or retention time, estimated concentration and a qualifier? [ ] ___ ___

NOTE: Add "N" qualifier to all TICs which have CAS number, if missing.

NOTE: Have the project officer/appropriate official check the project plan to determine if lab was required to identify non-target analytes (SW-846, page 8260B-23, Sect. 7.6.2).

11.2 Are the mass spectra for the tentatively identified compounds and associated "best match" spectra included in the sample package for each of the following:

a. Samples and/or fractions as appropriate [ ] ___ ___

b. Blanks [ ] ___ ___

ACTION: If any TIC data are missing, take action specified in 3.2 above.

ACTION: Add "JN" qualifier only to analytes identified by a CAS#.

NOTE: If TICs are present in the associated blanks take action as specified in section 3.2 above.

YES NO N/A

11.3 Are any priority pollutants listed as TIC compounds (i.e., an BNA compound listed as a VOA TIC)? [ ] ___ ___

ACTION: 1. Flag with "R" any target compound listed as a TIC.

2. Make sure all rejected compounds are properly reported if they are target compounds.

11.4 Are all ions present in the reference mass spectrum with a relative intensity greater than 10% (of the most abundant ion) also present in the sample mass spectrum? [ ] ___ ___

11.5 Do TIC and "best match" standard relative ion intensities agree within ± 20%? [ ] ___ ___

ACTION: Use professional judgement to determine acceptability of TIC identifications. If it is determined that an incorrect identification was made, change the identification to "unknown" or to some less specific identification (example: "C3 substituted benzene") as appropriate. Also, when a compound is not found in any blank, but is a suspected artifact of a common laboratory contaminant, the result should be qualified as unusable, "R". (Common lab contaminants: CO_2(M/E 44), Siloxanes (M/E 73), Hexane, Aldol Condensation Products, Solvent Preservatives, and related byproducts).

12.0 Compound Quantitation and Reported Detection Limits

12.1 Are there any transcription/calculation errors in organic analysis reporting form results? Check at least two positive values. Verify that the correct internal standard, quantitation ion, and average initial RRF/CF were used to calculate organic analysis reporting form result. Were any errors found? [ ] ___ ___

NOTE: Structural isomers with similar mass spectra, but insufficient GC resolution (i.e. percent valley between the two peaks > 25%) should be

YES NO N/A

reported as isomeric pairs. The reviewer should check the raw data to ensure that all such isomers were included in the quantitation (i.e., add the areas of the two coeluting peaks to calculate the total concentration).

12.2 Are the method CRQL's adjusted to reflect sample dilutions and, for soils, sample moisture? [ ] ___ ___

ACTION: If errors are large, take action as specified in section 3.2 above.

ACTION: When a sample is analyzed at more than one dilution, the lowest detection limits are used (unless a QC exceedance dictates the use of the higher detection limit from the diluted sample data). Replace concentrations that exceed the calibration range in the original analysis by crossing out the "E" and it's associated value on the original reporting form (if present) and substituting the data from the analysis of the diluted sample. Specify which organic analysis reporting form is to be used, then draw a red "X" across the entire page of all reporting forms that should not be used, including any in the summary package.

13.0 Standards Data (GC/MS)

13.1 Are the Reconstructed Ion Chromatograms, and data system printouts (Quant Reports) present for initial and continuing calibration? [ ] ___ ___

ACTION: If any calibration standard data are missing, take action specified in section 3.2 above.

14.0 GC/MS Initial Calibration (CLP Form VI Equivalent)

YES NO N/A

14.1 Are the Initial Calibration reporting forms present and complete for the volatile fraction? [ ] ___ ___

ACTION: If any calibration forms or standard raw data are missing, take action specified in section 3.2 above.

ACTION: If the percent relative standard deviation (% RSD) is > 20%, (8000C-39)qualify positive results for that analyte “J”. When % RSD > 90%,. Qualify all positive results for that analyte “J” and all non-detects results for that analyte “R”.

14.2 Are all average RRFs > 0.050? [ ] ___ ___

NOTE: (Method Requirement) For SPCC compounds, the individual RRF values must be ≥ the values in the following list. If individual RRF values reported are below the listed values document in the Data Assessment.

Chloromethane	0.10
1,1-Dichloroethane	0.10
Bromoform	0.10
Chlorobenzene	0.30
1,1,2,2-Tetrachloroethane	0.30

ACTION: Circle all outliers with red pencil.

ACTION: For any target analyte with average RRF < 0.05, or for the requirements for the 5 compounds in 14.2 above, qualify all positive results for that analyte "J" and all non-detect results for that analyte "R".

14.3 Are response factors stable over the concentration range of the calibration. [ ] ___ ___

NOTE: (Method Requirement) For the following CCC compounds, the %RSD values must be ≤ 30.0%. If %RSD values reported are > 30.0% document in the Data Assessment.

YES NO N/A

1,1-Dichloroethene
Chloroform
1,2-Dichloropropane
Toluene
Ethylbenzene
Vinyl chloride

ACTION: Circle all outliers with a red pencil.

ACTION: If the % RSD is > 20.0%, or > 30% for the 6 compounds in 14.3 above, qualify positive results for that analyte "J" and non-detects using professional judgement. When RSD > 90%, qualify all positive results for that analyte "J" and all non-detect results for that analyte "R".

NOTE: The above data qualification action applies regardless of method requirements.

NOTE: Analytes previously qualified "U" due to blank contamination are still considered as "hits" when qualifying for calibration criteria.

14.4 Was the % RSD determined using RRF or CF? [ ] ___ ___

If no, what method was used to determine the linearity of the initial calibration? Document any effects to the case in the Data Assessment.

14.5 Are there any transcription/calculation errors in the reporting of RRF or % RSD? (Check at least two values but if errors are found, check more.) [ ] ___ ___

ACTION: Circle errors with a red pencil.

ACTION: If errors are large, take action as specified in section 3.2 above.

15.0 GC/MS Calibration Verification (CLP Form VII Equivalent)

YES NO N/A

15.1 Are the Calibration Verification reporting forms present and complete for all compounds of interest? [ ] ___ ___

15.2 Has a calibration verification standard been analyzed for every twelve hours of sample analysis per instrument? [ ] ___ ___

ACTION: List below all sample analyses that were not within twelve hours of a calibration verification analysis for each instrument used.

_____

ACTION: If any forms are missing or no calibration verification standard has been analyzed twelve hours prior to sample analysis, take action as specified in section 3.2 above. If calibration verification data are not available, flag all associated sample data as unusable ("R").

15.3 Was the % D determined from the calibration verification determined using RRF or CF? [ ] ___ ___

If no, what method was used to determine the calibration verification? Document any effects to the case in the Data Assessment.

15.4 Do any volatile compounds have a % D (difference or drift) between the initial and continuing RRF or CF which exceeds 20% (SW-846, page 8260B-19, section 7.4.5.2). [ ] ___ ___

NOTE: (Method Requirement) For the following CCC compounds, the %D values must be ≤ 20.0%. If %D values reported are > 20.0% document in the Data Assessment.

1,1-Dichloroethene
Chloroform
1,2-Dichloropropane
Toluene
Ethylbenzene
Vinyl chloride

YES NO N/A

ACTION: Circle all outliers with a red pencil.

ACTION: Qualify both positive results and non-detects for the outlier compound(s) as estimated, “J”. When %D is above 90%, qualify all positive results for that analyte "J" and all non-detect results for that analyte "R".

NOTE: The above data qualification action applies regardless of method requirements.

15.5 Do any volatile compounds have a RRF < 0.05? [ ] ___ ___

NOTE: (Method Requirement) For SPCC compounds, the individual RRF values must be ≥ the values in the following list for each calibration verification. If average RRF values reported are below the listed values document in the data assessment.

Chloromethane	0.10
1,1-Dichloroethane	0.10
Bromoform	0.10
Chlorobenzene	0.30
1,1,2,2-Tetrachloroethane	0.30

ACTION: Circle all outliers with a red pencil.

ACTION: If RRF < 0.05, or < the the requirements for the 5 compounds is section 15.5 above, qualify all positive results for that analyte "J" and all non-detect results for that analyte "R".

NOTE: The above data qualification action applies regardless of method requirements.

16.0 Internal Standards (CLP Form VIII Equivalent)

16.1 Are the internal standard (IS) areas on the internal standard reporting forms of every sample and blank within the upper and lower limits (-50% to + 100%) for each initial mid-point calibration (SW-846, 8260B-20, Sect. 7.4.7)? [ ] ___ ___

YES NO N/A

ACTION: If errors are large or information is missing, take action as specified in section 3.2 above.

ACTION: List each outlying internal standard below.

Sample ID	IS #	Area Lower Limit	Area Upper Limit

(Attach additional sheets if necessary.)

ACTION: 1. If the internal standard area count is outside the upper or lower limit, flag with "J" all positive results quantitated with this internal standard.

2. Do not qualify non-detects when the associated IS are counts area > + 100%.

3. If the IS area is below the lower limit (< -50%), qualify all associated non-detects (U-values) "J".

4. If extremely low area counts are reported (< -25%) or if performance exhibits a major abrupt drop off, flag all associated non-detects as unusable “R” and positive results as estimated “J”.

16.2 Are the retention times of all internal standards within 30 seconds of the associated initial mid-point calibration standard (SW-846, 8260B-20, Sect. 7.4.6)? [ ] ___ ___

ACTION: Professional judgement should be used to qualify data if the retention times differ by more than 30 seconds.

YES NO N/A

17.0 Field Duplicates

17.1 Were any field duplicates submitted for volatile analysis? [ ] ___ ___

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between field duplicate results must be addressed in the Data Assessment. However, if large differences exist, take action specified in section 3.2 above.

INTRODUCTION

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to "SW846-Method 8081B November 2000. Method 8081B is used to determine the concentration of pesticide compounds in extracts prepared from many types of solid waste matrices, soils, air sampling media and water samples. The validation methods and actions discussed in this document are based on the requirements set forth in SW846 Method 8081B, Method 8000C and the "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," January 2005. This document covers technical problems specific to each fraction and sample matrix; however, situations may arise where data limitations must be assessed based on the reviewer's professional judgement.

Summary of Method

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are defined on page 4.

The reviewer must prepare a detailed data assessment to be submitted along with the completed SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data and contract non-compliance.

Reviewer Qualifications

Data reviewers must possess a working knowledge of SW846 Analytical Methods and National Functional Guidelines mentioned above.

DEFINITIONS

Acronyms

CLP - Contract Laboratory Program
CRQL - Contract Required Quantitation Limit
%D - percent difference
DCB - decachlorobiphenyl
DoC - Date of Collection
GC - gas chromatography
GC/ECD - gas chromatograph/electron capture detector
GC/MS - gas chromatograph/mass spectrometer
GPC - gel permeation chromatography
IS - internal standard
kg - kilogram
µg - microgram
MS - matrix spike
MSD - matrix spike duplicate
ℓ - liter
mℓ - milliliter
PCB - Polychlorinated biphenyl
PE - performance evaluation
PEM - Performance Evaluation Mixture
QC - quality control
RAS - Routine Analytical Services
RIC - reconstructed ion chromatogram
RPD - relative percent difference
RRF - relative response factor
RRF - average relative response factor (from initial calibration)
RRT - relative retention time
RSD - relative standard deviation
RT - retention time
RSCC - Regional Sample Control Center
SDG - sample delivery group
SMC - system monitoring compound
SOP - standard operating procedure
SOW - Statement of Work
SVOA - semivolatile organic acid
TCL - Target Compound List
TCLP - Toxicity Characteristics Leachate Procedure
TCMX -tetrachloro-m-xylene
TIC - tentatively identified compound
TOPO - Task Order Project Officer
TPO - Technical Project Officer
VOA - Volatile organic
VTSR - Validated Time of Sample Receipt

Data Qualifiers

U- The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

J- The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.

N- The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."

JN- The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

UJ- The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R- The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

LAB QUALIFIERS:

D - The positive value is the result of an analysis at a secondary dilution factor.

B - The analyte is present in the associated method blank as well as in the sample. This qualifier has a different meaning when validating inorganic data.

E - The concentration of this analyte exceeds the calibration range of the instrument.

A - Indicates a Tentatively Identified Compound (TIC) is a suspected adol-condensation product.

X,Y,Z- Laboratory defined flags. The data reviewer must change these qualifiers during validation so that the data user may understand their impact on the data.

PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER:_____ SDG# _____
LAB:_____ SITE:_____

1.0 Data Completeness and Deliverables	YES	NO	N/A
1.1 Has all the data been submitted in CLP deliverable format?	[ ]	___	___
1.2 Have any missing deliverables been received and added to the data package?	[ ]	___	___

ACTION: Call lab for explanation/resubmittal of any missing deliverables. If lab cannot provide them, note the effect on review of the data in the reviewer narrative.

2.0 Cover Letter, SDG Narrative			
2.1 Is a laboratory narrative or cover letter present?	[ ]	___	___
2.2 Are the case number and/or SDG number contained in the narrative or cover letter?	[ ]	___	___

3.0 Data Validation Checklist			
3.1 Does this data package contain:			
Water data?	[ ]	___	___
Waste data?	[ ]	___	___
Soil/solid data?	[ ]	___	___

ORGANOCHLORINE PESTICIDE

YES NO N/A

1.0 Traffic Reports and Laboratory Narrative

1.1 Are traffic report and chain-of-custody forms present for all samples? [ ] ___ ___

ACTION: If no, contact lab for replacement of missing or illegible copies.

1.2 Do the traffic reports, chain-of-custody forms or SDG narrative indicate any problems with sample receipt, condition of the samples, analytical problems or special circumstances affecting the quality of the data? ___ [ ] ___

ACTION: If any sample analyzed as a soil, other than than TCLP, contains 50%-90% water, all data should be qualified as estimated, "J." If a soil sample, other than TCLP, contains more than 90% water, all non detects are qualified as unusable, "R", and positive results flagged “J”.

ACTION: If samples were not iced or if the ice was melted upon arrival at the laboratory and the temperature of the cooler was elevated (> 10° C), flag all positive results "J" and all non-detects "UJ".

2.0 Holding Times

2.1 Have any organochlorine pesticide technical holding times, determined from date of collection to date of extraction, been exceeded? ___ [ ] ___

Water and waste samples for organochlorine pesticide analysis must be extracted within 7 days of the date of collection. Extracts must be analyzed within 40 days of the date of extraction Soils and solid samples must be extracted within 14 days of collection and analyzed within 40 days of extraction.

ACTION: Qualify sample results according to Table 1.

Table 1. Holding Time Criteria

Matrix	Preserved	Criteria	Action	
			Detected compounds	Non-detected compounds
Aqueous	No	≤ 7 days(extraction) ≤ 40 days(analysis)	J*	UJ*
	No	> 7 days(extraction) > 40 days(analysis)	J*	UJ
	Yes	≤ 7 days(extraction) ≤ 40 days(analysis)	No qualification	
	Yes	> 7 days(extraction) > 40 days(analysis)	J	UJ
	Yes/No	> 28 days (gross exceedance)	J	R
Non-aqueous	No	≤ 14days(extraction) ≤ 40 days (analysis)	J*	UJ*
	No	> 14days(extraction) >40 days(analysis)	J	UJ
	Yes	≤ 14days(extraction) ≤ 40 days(analysis)	No qualification	
	Yes	> 14days(extraction) > 40 days(analysis)	J	UJ
	Yes/No	> 28 days (gross exceedance)	J	R

* only if cooler temperature exceeds 10°C; no action required if cooler temperature < 10°C.

YES NO N/A

3.0 Surrogate Recovery (Form II/Equivalent)

3.1 Were the recoveries of tetrachloro-m-xylene (TCMX) and decachlorobiphenyl (DCB) presented on CLP Surrogate Recovery Summary forms (Form II), or equivalent, for each of the following matrices?

a. Water/Waste [ ] ___ ___

b. Soil/Solid [ ] ___ ___

3.2 Are all the pesticide samples listed on the appropriate surrogate recovery form for each of the following matrices?

a. Water [ ] ___ ___

b. Waste [ ] ___ ___

c. Soil/Solid [ ] ___ ___

ACTION: Call lab for explanation/resubmittals. If missing deliverables are unavailable, document the effect in the data assessment.

3.3 Are all recovery limits for the surrogates TCMX and DCB between 30-150% for all samples, including MS and MSDs, LCSs and all blanks? [ ] ___ ___

Note: Reviewer shall use lab in-house recover limits if available. In-house criteria should be examined for reasonableness.

ACTION: Circle all outliers in red. Follow surrogate action Table 2.

3.5 Were surrogate retention times (RT) within the windows established during the initial 5-point analysis? [ ] ___ ___

ACTION: Follow surrogate action, Table 2 below.

YES NO N/A

Table 2. Surrogate Recovery Criteria

Criteria	**Action**	
	Detected Target Compounds	**Non-detected Target Compounds**
%R > 200%	J	Use professional judgement
150% < %R ≤ 200%	J	No qualification
30% ≤ %R ≤ 150%	No qualification	
10% ≤ %R < 30%	J	UJ
%R < 10% (sample dilution not a factor)	J	R
%R < 10% (sample dilution is a factor)	Use professional judgement	
RT out of RT window	Use professional judgement	
RT within RT window	No qualification	

3.6 Are there any transcription/calculation errors between raw data and Form II? [ ] ___ ___

ACTION: If large errors exist, call lab for explanation/resubmittal. Make any necessary corrections and document the effect in data assessments.

4.0 Laboratory Control Sample(LCS)

4.1 Is the LCS prepared, extracted, analyzed, and reported once for every 20 field samples. [ ] ___ ___

ACTION: If any Laboratory Control Sample data are missing, call the lab for explanation /resubmittals. Make note in the data assessment.

YES NO N/A

4.2 Were Laboratory Control Samples analyzed at the required concentration for all analytes of interest as specified in Table 3 below. [ ] ___ ___

Note: Use lab in-house criteria, if available.

Table 3. LCS Spiking Criteria

LCS Spike Compound	Spiking solution ug/l	Amount spiked to 100ml aqueous sample or 30g soil sample ml	Recovery Limits (%)
gamma-BHC	0.05	1	50-120
Heptachor epoxide	0.05	1	50-120
Dieldrin	0.01	1	30-130
4,4'-DDE	0.01	1	50-150
Endrin	0.01	1	50-120
Endosulfan sulfate	0.01	1	50-120
gamma-Chloradane	0.05	1	30-130
Tetrachloro-m-xylene(surrogate)	0.20	3	30-150
Decachlorobiphenyl (surrogate)	0.40	3	30-150

Note: The LCS might be spiked with the same analytes at the same concentration as the matrix spike.

ACTION: If Laboratory Control Samples were not analyzed at the required concentration or the required frequency, make note in the data assessment and use professional judgement to determined the affect on the data.

4.3 Do average recovery for each analyte meet the corresponding QC acceptance criteria listed in table above? [ ] ___ ___

YES NO N/A

ACTION: For LCS % recovery not meeting the required recovery, follow the required action in Table 4 below.

Table 4. LCS Recovery Criteria

Criteria	**Action**	
	Detected Associated Compounds	**Non-Detected Compounds**
%R > Upper Acceptance Limit	J	No qualification
%R < Upper Acceptance Limit	J	R
Lower Acceptance Limit ≤ %R ≤ Upper Acceptance Limit	No qualifications	

5.0 Matrix Spikes (Form III/Equivalent)

5.1 Are all data for matrix spike and matrix duplicate or matrix spike duplicate (MS/MD or MS/MSD) present and complete for each matrix? [ ] ___ ___

NOTE: For soil and waste samples showing detectable amounts of organics, the lab may substitute replicate samples in place of the matrix spike (see page 8000B-40, section 8.5.3).

5.2 Have MS/MD or MS/MSD results been summarized on Form III/Equivalent? [ ] ___ ___

ACTION: If any data are missing take action as specified in section 3.2 above.

5.3 Were matrix spikes analyzed at the required frequency for each of the following matrices? (One MS/MD, MS/MSD or laboratory replicate must be performed for every 20 samples of similar matrix or concentration level. Laboratories analyzing one to ten samples per month are required to analyze at least one MS per month [page 8000B-39, section 8.5.])

YES NO N/A

a. Water [ ] ___ ___

b. Waste [ ] ___ ___

c. Soil/Solid [ ] ___ ___

ACTION: If any MS/MD, MS/MSD or replicate data are missing, take the action specified in 3.2 above.

5.4 We Were Matrix Spike Samples analyzed at the required concentration for all analytes of interest as specified in Table 5 below. [ ] ___ ___

Note: Spiking analytes may differ from those in Table 5. Check QA project plan or task order.

Table 5. Matrix Spiking Criteria

Matrix Spike Compound	Spiking solution ug/l	Amount spiked to 100ml aqueous sample or 30g soil sample ml
gamma-BHC	0.05	1
Heptachor	0.05	1
Aldrin	0.05	1
Dieldrin	1.0	1
Endrin	1.0	1
4,4'-DDT	1.0	1

Note: For aqueous organic extractable, the spike concentration should be:

1) For regulatory compliance monitoring - the regulatory concentration limit or 1 to 5 times the expected background concentration, whichever is higher;

2) For all other aqueous samples - the larger of either 1 to 5 x times the expected background

YES NO N/A

concentration, or the same as the QC check sample concentration (see section 4 above);

3) For soil/solid and waste samples - the recommended concentration is 20 times the estimated quantitation limit (EQL).

No action is taken based on MS or replicate data alone. However, using informed professional judgement, the data reviewer may use the matrix spike or laboratory replicate results in conjunction with other QC criteria and determine the need for some qualification of the data. In some instances it may be determined that only the replicate or spiked samples are affected. Alternatively, the data may suggest that the laboratory is having a systematic problem with one or more analytes, thereby affecting all associated samples.

5.5 Do average recovery for each analyte meet the corresponding QC acceptance criteria listed in Table 6 below. [ ] ___ ___

Note: Use lab in-house criteria, if available.

Table 6. Matrix Spike Recovery Criteria

Compound	% Recovery Water	RPD Water	% Recovery Soil	RPD Soil
gamma-BHC	56-123	0-15	46-127	0-50
Heptachor	40-13	0-20	35-130	0-31
Aldrin	40-120	0-22	34-132	0-43
Dieldrin	52-126	0-18	31-134	0-38
Endrin	56-121	0-21	42-139	0-45
4,4'-DDT	38-127	0-27	23-134	0-50

NOTE: The actual number of MS analytes depends on the number analytes being measured (e.g., total number of MS plus MSD compounds). If only chlordane or toxaphene are the analytes of

YES NO N/A

interest, the spiked sample should contain the most representative multi-component analyte.

ACTION: Follow the matrix spike actions (Table 7) for pesticide analyses.

Table 7. Matrix Spike Qualifying Criteria

Criteria	**Action**	
	Detected Associated Compounds	**Non-Detected Compounds**
%R or RPD > Upper Acceptance Limit	J	No qualification
20% R ≤ %R < Lower Acceptance Limit	J	UJ
%R < 20%	J	Use professional judgement
Lower Acceptance Limit ≤ %R; RPD ≤ Upper Acceptance Limit	No qualifications	

Note: When the results of the matrix spike analyses indicates a potential problem due to the sample matrix itself, the LCS results are used to verify the laboratory can perform analyses in a clean matrix.

6.0 Blanks (Form IV/Equivalent)

6.1 Was reagent blank data reported on Method Blank Summary form(s) (Form IV)?

6.2 Frequency of Analysis: Has a reagent blank been analyzed for every 20 (or less) samples of similar matrix or concentration or each extraction batch? [ ] ___ ___

Note: Method blank should be analyzed, either after the calibration standard or at any other time during the analytical shift.

YES NO N/A

ACTION: If any blank data are missing, take action as specified above (section 3.2). If blank data is not available, reject (R) all associated positive data. However, using professional judgement, the data reviewer may substitute field blank data for missing method blank data.

6.3 Chromatography: review the blank raw data - chromatograms, quant reports or data system printouts.

Is the chromatographic performance (baseline stability) for each instrument acceptable for pesticides? [ ] ___ ___

ACTION: Use professional judgement to determine the effect on the data.

7.0 Contamination

NOTE: "Water blanks", "distilled water blanks" and "drilling water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC blanks discussed below.

7.1 Do any method/instrument/reagent/cleanup blanks have positive results for organochlorine pesticides? When applied as described below, the contaminant concentration in these blanks are multiplied by the sample Dilution Factor and corrected for % moisture when necessary. ___ [ ] ___

7.2 Do any field/rinse blanks have positive organochlorine pesticide results? ___ [ ] ___

ACTION: Prepare a list of the samples associated with each of the contaminated blanks. (Attach a separate sheet.)

NOTE: All field blank results associated to a particular group of samples (may exceed one per case or one per day) may be used to qualify data. Blanks may not be qualified because of contamination in

YES NO N/A

another blank. Field blanks must be qualified for surrogate, or calibration QC problems.

ACTION: Follow the directions in Table 8 below to qualify sample results due to contamination. Use the largest value from all the associated blanks.

Table 8. Blank Contamination Criteria

Blank Type	Blank Result	Sample Result	Action for Samples
Method, Clean up, Instrument, Field	Detects	Not detected	No qualification
	< CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification
	> CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank contamination	Report the concentration for the sample with a U
		≥ CRQL and ≥ blank contamination	No qualification
	= CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification
	Gross contamination	Detects	Qualify results as unusable R

Note: Analytes qualified “U” for blank contamination are treated as “hits” when qualifying the calibration criteria.

Note: When applied as described in Table 8 above, the contaminant concentration in the blank is multiplied by the sample dilution factor.

NOTE: If gross blank contamination exists(e.g., saturated peaks, “hump-o-grams”, “junk peaks”), all affected positive compounds in the associated samples should be qualified as unusable “R”, due to interference.

YES NO N/A

Non-detected pesticide target compounds do not require qualification unless the contamination is so high that it interferes with the analyses of non-detected compounds.

7.3 Are there field/rinse/equipment blanks associated with every sample? [ ] ___ ___

ACTION: For low level samples, note in data assessment that there is no associated field/rinse/equipment blank. Exception: samples taken from a drinking water tap do not have associated field blanks.

8.0 Gas Chromatography with Electron Capture Detector (GC/ECD)Instrument Performance Check (CLP Form VI and Form VII Equivalent)

8.1 Was the proper gas chromatographic column used for the analysis of organochlorine pesticides? Check raw data, instrument logs, or contact the lab to determine what type of columns were used. (See Method 8081B-8, section 4.2) [ ] ___ ___

8.2 If capillary columns were used, were they both wide bore (.53 mm ID) fused silica GC columns, such as DB-608 and DB-1701 or equivalent. Indicate the specific type of column used for:

column 1: _____

column 2: _____

ACTION: Note any changes to the suggested materials in section 8.1 above in the data assessment. Also note the impact (positive or negative) such changes have on the analytical results.

9.0 Calibration and GC Performance

9.1 Are the following Gas Chromatograms and Data Systems Printouts for both columns present for all samples, blanks, MS, replicates?

a. DDT/endrin breakdown check [ ] ___ ___

		YES	NO	N/A
b.	toxaphene	[ ]	___	___
c.	technical chlordane	[ ]	___	___
d.	5 pt. initial calibration standards	[ ]	___	___
e.	calibration verification standards	[ ]	___	___
f.	LCS	[ ]	___	___
g.	Method blanks	[ ]	___	___

ACTION: If no, take action specified in 3.2 above.

9.2 Has a DDT/endrin breakdown check standard (at the mid-concentration level) been analyzed at the beginning of each analytical sequence on both columns (page 8081B-24, section 8.2.3)? [ ] ___ ___

ACTION: If no, take action as specified in 3.2 above.

9.3 Has the individual % breakdown exceeded 20.0% on either column for:

- 4,4' - DDT? ___ [ ] ___
- endrin? ___ [ ] ___

ACTION: If any % breakdown has failed the QC criteria in the breakdown check standard, qualify all sample analyses in the entire analytical sequence as described below.

a. If 4,4'-DDT breakdown is greater than 20.%:

i. Qualify all positive results for DDT with 'J". If DDT was not detected, but DDD and DDE are positive, then qualify the quantitation limit for DDT as unusable ("R").

ii. Qualify positive results for DDD and DDE as presumptively present at an approximated quantity ("NJ").

YES NO N/A

b. If endrin breakdown is greater than 20.0%:

i. Qualify all positive results for endrin with "J". If endrin was not detected, but endrin aldehyde and endrin ketone are positive, then qualify the quantitation limit for endrin as unusable ("R").

ii. Qualify positive results for endrin ketone and endrin aldehyde as presumptively present at an approximated quantity ("NJ").

9.4 Are data summary forms (containing calibration factors or response factors) for the initial 5 pt. calibration and daily calibration verification standards present and complete for each column and each analytical sequence? [ ] ___ ___

NOTE: If internal standard calibration procedure is used (page 8000B-16, section 7.4.2.2), then response factors must be used for %RSD calculations and compound quantitation. If, external standard calibration procedures are used (page 8000B-16, section 7.4.2.1), then calibration factors must be used.

ACTION: If any data are missing or it cannot be determined how the laboratory calculated calibration factors or response factors, contact the lab for explanation/resubmittals. Make necessary corrections and note any problems in the data assessment.

9.5 Are there any transcription/calculation errors between raw data and data summary forms. ___ [ ] ___

ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and document the effect in data assessments.

9.6 Are standard retention time (RT) windows for each analyte of interest presented on modified CLP summary forms? [ ] ___ ___

YES NO N/A

ACTION: If any data are missing, or it cannot be determined how RT windows were calculated, call the lab for explanation/resubmittals. Note any problems in the data assessment.

NOTE: Retention time windows for all pesticides are established using retention times from three calibration standards analyzed during the entire analytical sequence (page 8081B-15, section 7.4.6).

A 72 hr. sequence is not required with this method, however, the method states that best results are obtained using retention times which span the entire sequence; i.e., using the mid level from the 5 pt. calibration, one of the mid-concentration standards analyzed during mid-sequence and one analyzed at the end.

9.7 Were RT windows on the confirmation column established using three standards as described above? [ ] ___ ___

NOTE: RT windows for the confirmation column should be established using a 3 pt. calibration, preferably spanning the entire analytical sequence as described in 9.6 above. If RT windows on one column are tighter than the other, this may result in false negatives when attempting to identify compounds in the samples.

ACTION: Note potential problems, if any, in the data assessment.

9.8 Do all standard retention times in each level of the initial 5 pt. calibrations for pesticides fall within the windows established during the initial calibration sequence?

[ ] ___ ___

ACTION: i. If no, all samples in the entire analytical sequence are potentially affected. Check to see if three standards, spanning the entire sequence were used to obtained RT windows. If the lab used three standards from the 5 pt., RT windows

YES NO N/A

may be too tight. If so, RT windows should be recalculated as per page 8081B-15, section 7.4.6.2

ii. Alternatively, check to see if the chromatograms contain peaks within an expanded window surrounding the expected retention times.

If no peaks are found and the surrogates are visible, non-detects are valid. If peaks are present but cannot be discerned through pattern recognition or by using revised RT windows, qualify all positive results and non-detects as unusable, "R".

ACTION: For toxaphene and chlordane, the RT may be outside the RT window, but these analytes may still be identified from their individual patterns.

9.9 Has the linearity criteria for the initial calibration standards been satisfied for both columns? (% RSD must be < allowable limits* for all analytes). [ ] ___ ___

ACTION: If no, follow the actions in Table 9 below.

Table 9. Initial Calibration Linearity Criteria

Criteria	**Criteria**	
	Detected Associated Compounds	**Non-Detected Associated Compounds**
% RSD exceeds allowable limits*	J	No qualification
% RSD within allowable limits*	NO qualifications	

* %RSD ≤ 20% for single component compounds except alpha-BHC and delta-BHC.
%RSD ≤ 25% for alpha-BHC and delta-BHC
%RSD ≤ 30% for Toxaphene peaks
%RSD ≤ 30% for surrogates(tetrachloro-m-xylene and decachlorobiphenyl).

9.10 Has a calibration verification standard containing all analytes of interest been analyzed on each

YES NO N/A

working day, prior to sample analyses (pages 8081B-15,sections 7.5.2)? [ ] ___ ___

9.11 Has a calibration verification standard also been analyzed after every 10 samples and at the end of each analytical sequence (page 8081B-15, section 7.5.2)? [ ] ___ ___

ACTION: If no, take action as specified in section 3.2 above.

9.12 Has no more than 12 hours elapsed from the injection of the opening CCV and the end of the analytical sequence (closing CCV). Has no more than 72 hours elapsed from the injection of the sample with a Toxaphene detection and the Toxaphene CCV? [ ] ___ ___

ACTION: See Table 10 below.

9.13 Has the percent difference (%D) exceeded ± 20% for any organochlorine pesticide analyte in any calibration verification standard? ___ [ ] ___

9.14 Has a new 5 pt. calibration curve been generated for those analytes which failed in the calibration verification standard (page 8081B-16, section 7.5.2.2), and all samples which followed the out-of-control standard (page 8081B-16, section 7.5.2.3)reinjected? [ ] ___ ___

ACTION: If the %D for any analyte exceeded the ± 20% criterion and the instrument was not recalibrated for those analytes, see table below.

9.15 Have <u>daily</u> retention time windows been properly calculated for each analyte of interest (page 8081B-16, section 7.5.3)), using RTs from the associated mid concentration standard and standard deviation from the initial calibration)? [ ] ___ ___

YES NO N/A

ACTION: If no, take action specified in section 3.2 above or recalculate RT windows using the procedure outlined in method 8081B-16, section 7.5.3.

9.16 Do all standard retention times for each mid concentration standard fall within the windows established during the initial calibration sequence? [ ] ___ ___

9.17 Do all standard retention times for each mid-concentration standard (analyzed after every 10 samples) fall within the daily RT windows (page 8081B-16, section 7.5.3)? [ ] ___ ___

ACTION: If the answer to either 9.15 or 9.16 above is no, check the chromatograms of all samples which followed the last in-control standard. All samples analyzed after the last in-control standard must be re-injected, if initial analysis indicated the presence of the specific analyte that exceeded the retention time criteria (page 8081B-18, section 7.5.7.). If samples were not re-analyzed, document under Contract Non-compliance in the Data Assessment.

Reviewer has two options to determine how to qualify questionable sample data. First option is to determine if possible peaks are present within daily retention time window. If no possible peaks are found, non-detects are valid. If possible peaks are found (or interference), qualify positive hits as presumptively present "NJ" and non-detects are rejected "R". Second option is to use the ratio of the retention time of the analyte over the retention time of either surrogate. The passing criteria is ± 0.06 RRT units of the RRT of the standard component. Reject "R" all questionable analytes exceeding criteria, and "NJ" all other positive hits.

For any multi-response analytes, retention time windows should be used but analyst and reviewer should rely primarily on pattern recognition or use option 2 specified in paragraph above.

YES NO N/A

See Table 10 below.

Table 10. CCV Criteria

Criteria	Action	
	Detected Associated Compounds	**Non-Detected Associated Compounds**
RT out of RT window	Use professional judgement	
%D not within +/- 20%	J	UJ
Time elapsed greater than section 9.12 criteria.	R	
%D, time elapsed, RT are all within acceptable limits.	No qualifications	

9.18 Are there any transcription/calculation errors between raw data and data summary forms? ___ [ ] ___

ACTION: If large errors exists, call lab for explanation/resubmittal, make any necessary corrections and document the effect in data assessments under "Conclusions".

10.0 Analytical Sequence Check (Form VIII-PEST/Equivalent)

10.1 Have all samples been listed on CLP Form VIII or equivalent, and are separate forms present for each column? [ ] ___ ___

ACTION: If no, take action specified in 3.2 above.

10.2 Was the proper analytical sequence followed for each initial calibration and subsequent analyses? [ ] ___ ___

ACTION: If no, use professional judgement to determine the severity of the effect on the data and qualify it

YES NO N/A

accordingly. Generally, the effect is negligible unless the sequence was grossly altered or the calibration was also out of limits.

11.0 Extraction Method Cleanup Efficiency Verification (Form IX/Equivalent)

11.1 Method 8081B permits a variety of extraction techniques to be used for sample preparation. Which extraction procedure was used?

1. Aqueous samples:

1. Separatory funnel (Method 3510)_____

2. Continuous liquid-liquid extraction (Method 3520)_____

3. Solid phase extraction (Method 3535)_____

4. Other _____

2. Solid samples:

1. Soxhlet (Method 3540) _____

2. Automated Soxhlet (Method 3541)_____

3. Pressurized fluid (Method 3545) _____

4. Microwave extraction (Method 3546)_____

5. Ultrasonic extraction (Method 3550)_____

6. Supercritical fluid (Method 3562) _____

7. Other _____

11.2 Is Form IX - Pest-1/Equivalent present and complete for each lot of Florisil/Cartridges used? (Florisil Cleanup, Method 3620A, is required for all organochlorine pesticide extracts.) [ ] ___ ___

YES NO N/A

ACTION: If no, take action specified in 3.2 above. If data suggests that florisil cleanup was not performed, make note in the reviewer narrative.

NOTE: Method 3620A uses Florisil, while the SOW/CLP allows for Florisil cartridges. Method 3620A does not list which pesticides and surrogate(s) to use to verify column efficiency. The reviewer must check project plan to verify method used as well as the correct pesticide list. If not stated or available, use the CLP listing or accept what the laboratory used.

11.3 Are all samples listed on modified CLP Pesticide Florisil/Cartridge Check Form? [ ] ___ ___

ACTION: If no, take action specified in 3.2 above.

11.4 If GPC Cleanup was performed, is Form IX - Pest-2/ Equivalent present? [ ] ___ ___

ACTION: If GPC was not performed and sample results indicate significant sulfur interference, make note in the data assessment.

NOTE: GPC cleanup is not required and is optional. The reviewer should check Project Plan to verify requirement.

11.5 Were the same compounds on Form IX used to check the efficiency of the cleanup procedures? [ ] ___ ___

11.6 Are percent recoveries (% R) of the pesticide and surrogate compounds used to check the efficiency of the cleanup procedures within QC limits listed on Form IX:

80-120% for florisil cartridge check? [ ] ___ ___

80-110% for GPC calibration? [ ] ___ ___

YES NO N/A

Qualify only the analyte(s) which fail the recovery criteria as follows:

ACTION: If % R are < 80%, qualify positive results "J" and quantitation limits "UJ". Non-detects should be qualified "R" if zero %R was obtained for pesticide compounds. Qualify positive results “J” (estimated).

NOTE: If 2,4,5-trichlorophenol was used to measure the efficiency of the Florisil cleanup and the recovery was > 5%, sample data should be evaluated for potential interferences.

12.0 Pesticide Identification

12.1 Has CLP Form X, showing retention time data for positive results on the two GC columns, been completed for every sample in which a pesticide was detected? [ ] ___ ___

ACTION: If no, take action specified in 3.2 above, or compile a list comparing the retention times for all sample hits on the two columns.

12.2 Are there any transcription/calculation errors between raw data and data summary forms (initial calibration summaries, calibration verification summaries, analytical sequence summaries, GPC and Florisil cleanup verification forms)? ___ [ ] ___

ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and note error in the data assessment.

12.3 Are retention times (RT) of sample compounds within the established RT windows for both analyses? [ ] ___ ___

Note: Confirmation can be supported by other qualitative techniques such as GC/MS (Method 8270), or GC/AED (Method 8085) if sensitivity permits.

YES NO N/A

ACTION: Qualify as unusable (R) all positive results which were not confirmed by second GC column analysis. Also qualify "R", unusable, all positive results not within RT windows unless associated standard compounds are similarly biased. The reviewer should use professional judgement to assign an appropriate quantitation limit.

12.4 Check chromatograms for false negatives, especially if RT windows on each column were established differently (see section 9.7 above). Also check for false negatives among the multiple peak compounds toxaphene and chlordane. Were there any false negatives? ___ [ ] ___

ACTION: Use professional judgement to decide if the compound should be reported. If there is reason to believe that peaks outside retention RT windows should be reported, make corrections to data summary forms (Form I) and note in data assessment.

12.5 Was GC/MS confirmation used as the second column Confirmation? (This is not required). [ ] ___ ___

12.6 Is the percent difference (%D) calculated for the positive sample results on the two GC columns <25.0%? [ ] ___ ___

NOTE: The method 8081B requires quantitation from one column. The second column is to confirm the presence of an analyte. Calibration for the Confirmation column is a one point calibration. It is the reviewer's responsibility to verify from the project plan what the lab was required to report. If the lab was required to report concentrations from both columns, continue with validation for % Difference. If required, but not reported, either contact the lab for results or calculate the concentrations from the calibration. If not required, skip this section. Document actions in Data Assessment.

YES NO N/A

ACTION: If the reviewer finds neither column shows interference for the positive hits, the data should be qualified as follows:

% Difference	Qualifier
0-25%	none
26-70%	"J"
71-100%	"NJ"
101-200% (No Interference)	"R"
101-200% (Interference detected) "NJ"	
>50% (Pesticide vale is <CRQL)	"U"
>201%	"R"

Note: The lower of the two values is reported on Form I. If using professional judgement,the reviewer determines that the higher result was more acceptable, the reviewer should replace the value and indicate the reason for the change in the data assessment.

13.0 Compound Quantitation and Reported Detection Limits

13.1 Are there any transcription/calculation errors in Form I results? Check at least two positive values. Were any errors found? ___ [ ] ___

NOTE: Single-peak pesticide results can be checked for rough agreement between quantitative results obtained on the two GC columns. The reviewer should use professional judgement to decide whether a much larger concentration obtained on one column versus the other indicates the presence of an interfering compound. If an interference is suspected, the lower of the two values should be reported and qualified according to section 12.6 above. This necessitates a determination of an estimated concentration on the confirmation column. The narrative should indicate that the presence of interferences has led to the quantitation of the second column confirmation results.

YES NO N/A

13.2 Are the EDLs (Estimated Detection Limits) adjusted to reflect sample dilutions and, for soils, % moisture? [ ] ___ ___

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and document effect in data assessments.

ACTION: When a sample is analyzed at more than one dilution, the lowest EDLs are used (unless a QC exceedance dictates the use of the higher EDL data from the diluted sample analysis). Replace concentrations that exceed the calibration range in the original analysis by crossing out the value on the original Form I and substituting it with data from the analysis of diluted sample. Specify which Form I is to be used, then draw a red "X" across the entire page of all Form I's that should not be used, including any in the summary package.

ACTION: EDLs affected by large, off-scale peaks should be qualified as unusable, "R". If the interference is on-scale, the reviewer can provide a modified EDL flagged "UJ" for each affected compound.

14.0 Chromatogram Quality

14.1 Were baselines stable? [ ] ___ ___

14.2 Were any electropositive displacement (negative peaks) or unusual peaks seen? ___ [ ] ___

ACTION: Note all system performance problems in the data assessment.

15.0 Field Duplicates

15.1 Were any field duplicates submitted for organochlorine pesticide analysis? [ ] ___ ___

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between field duplicate results must be addressed in the reviewer narrative. However, if large differences exist, the identity of the field duplicates is questionable. An attempt should be made to determine the proper identification of field duplicates.

INTRODUCTION

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to "SW846-Method 8082A" November 2000. Method 8082A is used to determine the concentration of PCB compounds in extracts prepared from many types of solid waste matrices, soils, and water samples. The validation methods and actions discussed in this document are based on the requirements set forth in SW846 Method 8082A, Method 8000C and the "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," January 2005. This document covers technical problems specific to each fraction and sample matrix; however, situations may arise where data limitations must be assessed based on the reviewer's professional judgement.

Summary of Method

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are defined on page 4.

The reviewer must prepare a detailed data assessment to be submitted along with the completed SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data and contract non-compliance.

Reviewer Qualifications

Data reviewers must possess a working knowledge of SW846 Analytical Methods and National Functional Guidelines mentioned above.

Yes NO N/A

DEFINITIONS

Acronyms

BNA - base neutral acid(another name for Semi Volatiles)
CLP - Contract Laboratory Program
CRQL - Contract Required Quantitation Limit
%D - percent difference
DCB -decachlorobiphenyl
DoC - Date of Collection
GC - gas chromatography
GC/ECD - gas chromatograph/electron capture detector
GC/MS - gas chromatograph/mass spectrometer
GPC - gel permeation chromatography
IS - internal standard
kg - kilogram
µg - microgram
MS - matrix spike
MSD - matrix spike duplicate
ℓ - liter
mℓ - milliliter
PCB - Polychlorinated biphenyl
PE - performance evaluation
PEM - Performance Evaluation Mixture
QC - quality control
RAS - Routine Analytical Services
RIC - reconstructed ion chromatogram
RPD - relative percent difference
RRF - relative response factor
RRF - average relative response factor (from initial calibration)
RRT - relative retention time
RSD - relative standard deviation
RT - retention time
RSCC - Regional Sample Control Center
SDG - sample delivery group
SMC - system monitoring compound
SOP - standard operating procedure
SOW - Statement of Work
SVOA - semivolatile organic acid
TCL - Target Compound List
TCLP - Toxicity Characteristics Leachate Procedure ___
TCMX -tetrachloro-m-xylene
TIC - tentatively identified compound
TOPO - Task Order Project Officer
TPO - Technical Project Officer
VOA - Volatile organic

Yes NO N/A

VTSR - Validated Time of Sample Receipt

Data Qualifiers

U- The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

J- The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.

– The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."

JN- The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

UJ- The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R- The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

LAB QUALIFIERS:

D- The positive value is the result of an analysis at a secondary dilution factor.

B- The analyte is present in the associated method blank as well as in the sample. This qualifier has a different meaning when validating inorganic data.

E- The concentration of this analyte exceeds the calibration range of the instrument.

A- Indicates a Tentatively Identified Compound (TIC) is a suspected adol-condensation product.

X,Y,Z- Laboratory defined flags. The data reviewer must change these qualifiers during validation so that the data user may understand their impact on the data.

Yes NO N/A

PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER:_____ SDG# _____

LAB:_____ SITE:_____

1.0 Data Completeness and Deliverables

1.1 Has all the data been submitted in CLP deliverable format? [ ] ___ ___

1.2 Have any missing deliverables been received and added to the data package? [ ] ___ ___

ACTION: Call lab for explanation/resubmittal of any missing deliverables. If lab cannot provide them, note the effect on review of the data in the reviewer narrative.

2.0 Cover Letter, SDG Narrative

2.1 Is a laboratory narrative or cover letter present? [ ] ___ ___

2.2 Are the case number and/or SDG number contained in the narrative or cover letter? [ ] ___ ___

3.0 Data Validation Checklist

3.1 Does this data package contain:

Water data? ____ ____

Waste data? ____ ____

Soil/solid data? ____ ____

POLYCHLORINATED BIPHENYLS

1.0 Traffic Reports and Laboratory Narrative

1.1 Are traffic report and chain-of-custody forms present for all samples? [ ] ___ ___

Yes NO N/A

ACTION: If no, contact lab for replacement of missing or illegible copies.

1.2 Do the traffic reports, chain-of-custody forms or SDG narrative indicate any problems with sample receipt, condition of the samples, analytical problems or special circumstances affecting the quality of the data? ___ [ ] ___

ACTION: If any sample analyzed as a soil, other than TCLP, contains 50%-90% water, all data should be qualified as estimated, "J." If a soil sample, other than TCLP, contains more than 90% water, non detects shall be qualified as unusable, "R."

ACTION: If samples were not iced or if the ice was melted upon arrival at the laboratory and the temperature of the cooler was elevated (> 10° C), flag all positive results "J" and all non-detects "UJ".

2.0 Holding Times

2.1 Have any PCB technical holding times, determined from date of collection to date of extraction, been exceeded? ___ [ ] ___

Water and waste samples for PCB analysis must be extracted within 7 days of the date of collection. Extracts must be analyzed within 40 days of the date of extraction. Soils and solid samples must be extracted within 14 days of collection and analyzed within 40 days of extraction.

ACTION: If technical holding times are exceeded, flag all positive results as estimated, "J," and sample quantitation limits "UJ" and document in the narrative that holding times were exceeded. If analyses were done more than 14 days beyond holding time, either on the first analysis or upon re-analysis, the reviewer must use professional judgement to determine the reliability of the data and the effects of additional storage on the sample results. At a minimum, all the data should at least be

Yes NO N/A

qualified "J", but the reviewer may determine that non-detects are unusable,"R." (Table 1)

Table 1. Holding Time Criteria

Matrix	Preserved	Criteria	Action	
			Detected compounds	**Non-detected compounds**
Aqueous	No	≤ 7 days(extraction) ≤ 40 days(analysis)	J*	UJ*
	No	> 7 days(extraction) > 40 days(analysis)	J	UJ
	Yes	≤ 7 days(extraction) ≤ 40 days(analysis)	No qualification	
	Yes	> 7 days(extraction) > 40 days(analysis)	J	UJ
	Yes/No	> 28 days (gross exceedance)	J	R
Non-aqueous	No	≤ 14days(extraction) ≤ 40 days (analysis)	J*	UJ*
	No	> 14days(extraction) >40 days(analysis)	J	UJ
	Yes	≤ 14days(extraction) ≤ 40 days(analysis)	No qualification	
	Yes	> 14days(extraction) > 40 days(analysis)	J	UJ
	Yes/No	> 28 days(gross exceedance)	J	R

* only if cooler temperature exceeds 10°C; no action required if cooler temperature < 10°C.

3.0 Surrogate Recovery (Form II/Equivalent)

3.1 Were the recoveries of tetrachloro-m-xylene (TCMX) and decachlorobiphenyl (DCB) presented on CLP Surrogate Recovery Summary forms (Form II), or equivalent, for each of the following matrices?

a. Water/Waste [ ] ___ ___

Yes NO N/A

b. Soil/Solid [ ] ___ ___

3.2 Are all the PCB samples listed on the appropriate surrogate recovery form for each of the following matrices?

a. Water [ ] ___ ___

b. Waste [ ] ___ ___

c. Soil/Solid [ ] ___ ___

ACTION: Call lab for explanation/resubmittals. If missing deliverables are unavailable, document the effect in the data assessment.

3.3 Are all recovery limits for the surrogates TCMX and DCB between 30-150% for all samples, including MS and MSDs, LCSs and all blanks? [ ] ___ ___

Note: Reviewer shall use lab in-house recovery limits, if available. In-house criteria should be examined for reasonableness.

ACTION: Circle all outliers in red. Follow surrogate criteria, Table 2.

Note: DCB is used when PCBs are determined as Aroclors. DCB is the internal standard when determining PCB congeners and TCMX the surrogate.

3.4 Were surrogate retention times (RT) within the windows established during the initial 5-point analysis? [ ] ___ ___

ACTION: Follow surrogate criteria, Table 2.

Table 2. Surrogate Recovery Criteria

Criteria	Action	
	Detected Target Compounds	**Non-detected Target Compounds**
%R > 200%	J	Use professional judgement

		Yes NO N/A
150% < %R ≤ 200%	J	No qualification
30% ≤ %R ≤ 150%	No qualification	
10% ≤ %R < 30%	J	UJ
%R < 10% (sample dilution not a factor)	J	R
%R < 10% (sample dilution is a factor)	Use professional judgement	
RT out of RT window	Use professional judgement	
RT within RT window	No qualification	

3.6 Are there any transcription/calculation errors between raw data and Form II? [ ] ___ ___

ACTION: If large errors exist, call lab for explanation/resubmittal. Make any necessary corrections and document the effect in data assessments.

4.0 Laboratory Control Sample (LCS)

4.1 Are raw data and percent recoveries present for all Laboratory Control samples as required by Method 8000B (section 8.5) and Method 8082A (section 8.4.2)? [ ] ___ ___

Verify that QC check samples were extracted and analyzed by the same procedures used for the actual samples.

ACTION: If any Laboratory Control Sample data are missing, call the lab for explanation/ resubmittals. Make note in the data assessment.

NOTE: For aqueous samples, an additional QC check sample must be prepared and analyzed when any analyte in a matrix spike fails the required acceptance criteria (see section 5.3 below).

Yes NO N/A

The additional QC check sample must contain each analyte that failed in the MS analysis.

Note: When the results for matrix spike analysis indicates a problem due to sample matrix effects, the LCS results are used to verify the laboratory can perform the analysis in a clean sample.

4.2 Were Laboratory Control Samples analyzed at the required concentration as specified in Method 8000B(sec 8.5) for all analytes as specified in Table 3. [ ] ___ ___

Note: Use lab in-house criteria, if available.

ACTION: If Laboratory Control Samples were not analyzed at the required concentration or the required frequency, make note in the data assessment and use professional judgement to determined the affect on the data.

4.3 Were the LCS recoveries within the percent recoveries as specified in Table 3. [ ] ___ ___

Table 3. LCS Criteria

Compound	% Recovery
Aroclor 1016	50-150
Aroclor 1260	50-150
Tetrachloro-m-xylene (surrogate)	30-150
decachlorobiphenyl (surrogate)	30-150

4.4 If no, were Laboratory Control Samples re-analyzed? [ ] ___ ___

ACTION: If QC check samples were not re-analyzed, or a general system problem is indicated by repeated failure to meet the QC acceptance criteria specified in the method, make note in the data assessment and use Table 4 recovery actions criteria.

Yes NO N/A

Table 4. LCS Recovery Actions

Criteria	Action	
	Detected Associated Compounds	**Non-Detected Compounds**
%R > Upper Acceptance Limit	J	No qualification
%R < Lower Acceptance Limit	J	R
Lower Acceptance Limit ≤ %R ≤ Upper Acceptance Limit	No qualifications	

5.0 Matrix Spikes (Form III/Equivalent)

5.1 Are all data for one matrix spike and matrix duplicate (unspiked) pair (MS/Dup) or matrix spike/matric spike duplicate (MS/MSD)present and complete for each matrix (Method 8082A Section 8.4.1)? [ ] ___ ___

NOTE: For soil and waste samples showing detectable amounts of target analytes, the lab may substitute replicate samples in place of the matrix spike (see Method 8000B-40, section 8.5.3).

5.2 Have MS/Dup or MS/MSD results been summarized on modified CLP Form III? [ ] ___ ___

ACTION: If any data are missing take action as specified in section 3.2 above.

5.3 Were matrix spikes analyzed at the required frequency for each of the following matrices? (One MS/Dup, MS/MSD must be performed for every 20 samples of similar matrix or concentration level. Laboratories analyzing one to ten samples per month are required to analyze at least one MS per month (Method 8000B-39 (section 8.5)).

a. Water [ ] ___ ___

Yes NO N/A

b. Waste [ ] ___ ___

c. Soil/Solid [ ] ___ ___

ACTION: If any MS/Dup or MS/MSD data are missing, take the action specified in 3.2 above.

5.4 Were Laboratory Control Samples analyzed for all analytes as specified in Table 5, or did the lab use the optional QC acceptance criteria i.e., in-house criteria? [ ] ___ ___

List the criteria used and make note in data assessment.

Criteria used _____

Table 5. MS/MSD Criteria

Compound	Percent Recovery QC Limits	RPD
Aroclor 1016	29-135	0-15
Aroclor 1260	29-135	0-20

5.5 Was the matrix spike prepared at the proper spike concentration? (Method 8000B, section 8.5.1-8.5.2) [ ] ___ ___

For aqueous organic extractable, the spike concentration should be prepared according options in: Method 8000B-40, (section 8.5.1 and 8.5.2).

5.6 Were the matrix spike and matrix spike duplicate recovery and RPD limits met as specified in Table 5. Note: No qualification of the data is necessary on MS and MSD data alone. Use professional judgement to use the MS and MSD results in conjunction with other QC criteria to determine the need for some qualification of the data. If any MS and MSD, percent recovery, or RPD results in the Arcolor fraction is out of specification (Table 5), qualify data to include the consideration of the existence interference in the raw data. In some instances it may be determined that only the replicate or spiked samples are affected. Alternatively, the data may suggest that the laboratory is having a systematic problem with one or more analytes, thereby affecting all associated samples. Use professional judgement to determine the need for qualifications of detects of non-spiked compounds.

Yes NO N/A

[ ] ___ ___

Table 6. MS/MSD Actions for Analysis

Criteria	Action	
	Detected Associated Compounds	**Non-Detected Compounds**
%R or RPD > Upper Acceptance Limit	J	No qualification
20% ≤ %R < Lower Acceptance Limit	J	UJ
%R < 20%	J	Use professional judgement
Lower Acceptance Limit ≤ %R ≤ Upper Acceptance Limit	No qualifications	

6.0 Blanks (Form IV/Equivalent)

6.1 Was reagent blank data reported on CLP equivalent Method Blank Summary form(s) (Form IV)? [ ] ___ ___

6.2 Frequency of Analysis: Has a reagent blank been analyzed for every 20 (or less) samples of similar matrix or concentration or each extraction batch? [ ] ___ ___

Note: Method blank should be analyzed, either after the calibration standard or at any time during the analytical shift.

ACTION: If any blank data are missing, take action as specified above (section 3.2) . If blank data is not available, reject (R) all associated positive data. However, using professional judgement, the data reviewer may substitute field blank data for missing method blank data.

6.3 Chromatography: review the blank raw data - chromatograms, quant reports or data system

Yes NO N/A

printouts.

Is the chromatographic performance (baseline stability) for each instrument acceptable for PCBs? [ ] ___ ___

7.0 Contamination

NOTE: "Water blanks", "distilled water blanks" and "drilling water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC blanks discussed below.

7.1 Do any method/instrument/reagent/cleanup blanks have positive results for PCBs? When applied as described below, the contaminant concentration in these blanks are multiplied by the sample Dilution Factor and corrected for % moisture when necessary. ___ [ ] ___

7.2 Do any field/rinse blanks have positive PCB results? ___ [ ] ___

ACTION: Prepare a list of the samples associated with each of the contaminated blanks. (Attach a separate sheet.)

NOTE: All field blank results associated to a particular group of samples (may exceed one per case or one per day) may be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field blanks must be qualified for surrogate, or calibration QC problems.

ACTION: Follow the directions in Table 7 below to qualify sample results due to contamination. Use the largest value from all the associated blanks.

Table 7. Blank Contamination Criteria

Blank Type	Blank Result	Sample Result	Action for Samples

Yes NO N/A

Method, Clean up, Instrument, Field	Detects	Not detected	No qualification
	< CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification
	> CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank contamination	Report the concentration for the sample with a U
		≥ CRQL and ≥ blank contamination	No qualification
	= CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification
	Gross contamination	Detects	Qualify results as unusable R

Note: Analytes qualified “U” for blank contamination are treated as “hits” when qualifying for calibration criteria.

Note: When applied as described in Table 7 above, the contaminant concentration in the blank is multiplied by the sample dilution factor.

NOTE: If gross blank contamination exists(e.g., saturated peaks, “hump-o-grams,” “junk” peaks), all affected positive compounds in the associated samples should be qualified as unusable “R”, due to interference. Non-detected pesticide target compounds do not require qualification unless the contamination is so high that it interferes with the analyses of non-detected compounds.

7.3 Are there field/rinse/equipment blanks associated with every sample? [ ] ___ ___

ACTION: For low level samples, note in data assessment that there is no associated field/rinse/equipment blank. Exception: samples taken from a drinking water tap do not have associated field blanks.

Yes NO N/A

8.0 Gas Chromatography with Electron Capture Detector (GC/ECD)Instrument Performance Check (CLP Form VI and Form VII Equivalent)

8.1 Was the proper gas chromatographic capillary column used for the analysis of PCBs? [ ] ___ ___

Action: Check raw data, instrument logs, or contact the lab to determine what type of columns were used. (Method 8082, section 4.2)

8.2 Indicate the specific type of narrow bore or wide bore (.53 mm ID, fused silica GC columns, such as DB-608 and DB-1701 or equivalent).

column 1: _____

column 2: _____

ACTION: Note any changes to the suggested materials in section 8.1 above in the data assessment. Also note the impact (positive or negative) such changes have on the analytical results.

9.0 Calibration and GC Performance

9.1 Are the following Gas Chromatograms and Data Systems Printouts for both columns present for all samples, blanks, MS, replicates?

a. Samples [ ] ___ ___

b. All blanks [ ] ___ ___

c. Matrix spike samples [ ] ___ ___

d. 5 pt. initial calibration standards [ ] ___ ___

e. calibration verification standards [ ] ___ ___

f. Laboratory Control samples (LCS) [ ] ___ ___

ACTION: If no, take action specified in 3.2 above.

9.2 Are data summary forms (containing calibration factors or response factors) for the initial 5

Yes NO N/A

pt. calibration and daily calibration verification standards present and complete for each column and each analytical sequence? [ ] ___ ___

Note: Calibration Aroclor mixtures other than 1016/1260 may be used (as per approved project QA plan)

NOTE: If internal standard calibration procedure is used (Method 8000B-15(section 7.4.2.2)), then response factors must be used for %RSD calculations and compound quantitation. If, external standard calibration procedures are used (Method 8000B-16 (section 7.4.2.1)), then calibration factors must be used. The internal standard approach is highly recommended for PCB congener analysis.

ACTION: If any data are missing or it cannot be determined how the laboratory calculated calibration factors or response factors, contact the lab for explanation/resubmittals. Make necessary corrections and note any problems in the data assessment.

9.3 Are there any transcription/calculation errors between raw data and data summary forms? ___ [ ] ___

ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and document the effect in data assessments.

9.4 Are standard retention time (RT) windows for each PCB peak of interest presented on modified CLP summary forms? [ ] ___ ___

ACTION: If any data are missing, or it cannot be determined how RT windows were calculated, call the lab for explanation/resubmittals. Note any problems in the data assessment.

NOTE: Retention time windows for all PCBs are established using retention times from three calibration standards analyzed during the entire analytical sequence (Method 8000B, section 7.6). Best results are obtained

Yes NO N/A

using retention times which span the entire sequence; i.e., using the calibration verification/continuing calibration standards analyzed every 12 hours.

9.5 Were RT windows on the confirmation column established using three standards as described above? [ ] ___ ___

NOTE: RT windows for the confirmation column should be established using a 3 pt. calibration, preferably spanning the entire analytical sequence as described in 9.4 above. If RT windows on one column are tighter than the other, this may result in false negatives when attempting to identify compounds in the samples.

ACTION: Note potential problems, if any, in the data assessment.

9.6 Do all standard retention times in each level of the initial 5 pt. calibrations for PCBs fall within the windows established during the initial calibration sequence? [ ] ___ ___

ACTION i: If no, all samples in the entire analytical sequence are potentially affected. Check to see if three standard spanning the entire sequence were used to obtained RT windows. If the lab used three standards from the 5 pt., RT windows may be too tight. If so, RT windows should be recalculated as per Method 8081B-15 (section 7.4.6).

ii. Alternatively, check to see if the chromatograms contain peaks within an expanded window surrounding the expected retention times.

If no peaks are found and the surrogates are visible, non-detects are valid. If peaks are present but cannot be discerned through pattern recognition or by using revised RT windows, qualify all positive results and non-detects as unusable, "R".

9.7 Has the linearity criteria for the initial calibration standards been satisfied for both

Yes NO N/A

columns? (% RSD for the calibration factors (CFs) for the three to five major peaks of each of the Aroclor compounds must be < 20.0%). [ ] ___ ___

ACTION: If no, follow Table 8 criteria.

Table 8. Initial Calibration CF Action for Aroclor Analysis

Criteria	Action	
	Detected Associated Compounds	**Non-Detected Associated Compounds**
% RSD > 20%	J	UJ
% RSD within allowable limits	No qualifications	

9.8 Does the calibration verification/continuing calibration standard contain the PCB peaks of interest, analyzed on each working day, prior to sample analyses (Method 8082, sections 7.6.2)? [ ] ___ ___

9.9 Has a calibration verification/continuing calibration standard been analyzed after every 10 samples and at the end of each analytical sequence (Method 8082A, section 7.6.2). [ ] ___ ___

ACTION: If no, take action as specified in section 3.2 above.

9.10 Has the percent difference (%D) between the Calibration Factor (CF) of each of the three to five peaks used to identify the Aroclor in the CCV and the CF from these peaks in the initial calibration exceeded ± 15%. ___ [ ] ___

9.11 Has a new 5 pt. initial calibration curve been generated for those PCB analytes which failed in the calibration verification/continuing calibration standard (8000B, section 7.7.3), and all samples which followed the out-of-control

Yes NO N/A

calibration verification/standard continuing calibration Standard? [ ] ___ ___

ACTION: If the %D for any analyte exceeded the ± 15% criterion and the instrument was not recalibrated for those analytes, qualify positive results for all associated samples (those which followed the out-of-control standard) "J" and sample quantitation limits "UJ". (see Table 9)

9.12 Have retention time (RT) windows been properly calculated for each analyte of interest (Method 8000B, section 7.6), using RTs from the associated calibration verification/continuing standard? [ ] ___ ___

ACTION: If no, take action specified in section 3.2 above

9.13 Do all standard retention times for each calibration verification/continuing calibration standard fall within the windows established during the initial calibration sequence? [ ] ___ ___

9.14 Do all standard retention times for each mid-concentration standard (analyzed after every 10 samples) fall within the daily RT windows. [ ] ___ ___

ACTION: For any multi-response analytes, retention time windows should be used but analyst and reviewer should rely primarily on pattern recognition or use paragraph B below. If the answer to either 9.13 or 9.14 above is no, check the chromatograms of all samples which followed the last in-control standard. If samples were not re-analyzed, all samples analyzed after the last in-control standard must be evaluated using professional judgement.

(A) For non-detected target compounds, check to see if the sample chromatograms contain any peaks that are close to the expected RT window of the Arcolor of interest. If no peaks are present, no qualification of data is necessary. If peaks are present close th RT window of the Aroclor of interest, qualify the non-detected values as presumptively present “N”.

Yes NO N/A

(B) For detected compounds in the affected samples, if peaks within the RT window, no qualification necessary. If peaks are close to the expected RT window of the Aroclor of interest, the reviewer can examine the data package for the presence of three or more standards the Aroclor of interest that were run within the analytical sequence during which the sample was analyzed. If three or more such standards are present, the RT window can be reevaluated using the Mean Retention Times of the standards. If the peaks in the affectd sample fall within the revised window, qualify the detected target compounds “NJ”. If the reviewer cannot do anything with the data to resolve the problem of concern, qualify all non-detects as unusable “R”. (Table 9)

9.15 Has no more than 12 hours elapsed from the injection of the opening CCV and the end of the analytical sequence sequence (closing CCV). (Table 9) [ ] ___ ___

Table 9. CCV Criteria

Criteria	Action	
	Detected Associated Compounds	**Non-Detected Associated Compounds**
RT out of RT window	Use professional judgement (Sec 9.14)	
%D not within +/- 15%	J	UJ
Time elapsed greater than section 9.15 criteria.	R	
%D, time elapsed, RT are all within acceptable limits.	No qualifications	

9.16 Are there any transcription/calculation errors between raw data and data summary forms? ___ [ ] ___

ACTION: If large errors exists, call lab for explanation/resubmittal, make any necessary corrections and document the effect in data assessments under "Conclusions".

10.0 Analytical Sequence Check (Form VIII-PEST/Equivalent)

10.1 Have all samples been listed on CLP Form VIII or equivalent, and are separate forms present for each column? [ ] ___ ___

Yes NO N/A

ACTION: If no, take action specified in 3.2 above.

10.2 Was the proper analytical sequence followed for each initial calibration and subsequent analyses? [ ] ___ ___

ACTION: If no, use professional judgement to determine the severity of the effect on the data and qualify it accordingly. Generally, the effect is negligible unless the sequence was grossly altered or the calibration was also out of limits.

10.3 Were the TCMX/DCB surrogate RTs for the samples within the mean surrogate RT from the initial calibration? [ ] ___ ___

Action: If no, see "Action" in section 9.14 above

11.0 Extraction Techniques for Sample Preparation

Method 8082A permits a variety of extraction techniques to be used for sample preparation. Check which extraction procedure was used?

1. Aqueous samples:

    1. Separatory funnel (Method 3510) [ ] ___ ___
    2. Continuous liquid-liquid extraction (Method 3520) [ ] ___ ___
    3. Solid phase extraction (Method 3535) [ ] ___ ___
    4. Other [ ] ___ ___

2. Solid samples:

    1. Soxhlet (Method 3540) [ ] ___ ___
    2. Automated Soxhlet (Method 3541) [ ] ___ ___
    3. Pressurized fluid (Method 3545) [ ] ___ ___
    4. Microwave extraction (Method 3546) [ ] ___ ___
    5. Ultrasonic extraction (Method 3550) [ ] ___ ___

Yes NO N/A

6. Supercritical fluid (Method 3562) [ ] ___ ___

7. Other [ ] ___ ___

11.1 Extract Cleanup - Efficiency Verification (Form IX/Equivalent)

11.1.1 Method 8082 (section 7.2) references method 3660 (sulfur) and 3665A (sulfuric acid) to use for cleaning extracts. Were one or both method used? [ ] ___ ___

ACTION: If no, take action specified in 3.2 above. If data suggests cleanup was not performed, make note in the data assessment.

NOTE: Method 3620A, Florisil, may be used per approved project QA plan. The method does not list which analytes and surrogate(s) to use to verify column efficiency. The reviewer must check project plan to verify method used as well as the correct PCB list. If not stated or available, use the CLP listing or accept what the laboratory used.

11.2 Are all samples listed on modified CLP PCBs Florisil/Cartridge Check Form? [ ] ___ ___

ACTION: If no, take action specified in 3.2 above.

11.3 Was GPC Cleanup (method 3640A) performed? [ ] ___ ___

NOTE: GPC cleanup is not required and is optional. The reviewer should check Project Plan to verify requirement.

11.4 Were the same PCB analytes used in calibration used to check the efficiency of the cleanup procedures? [ ] ____ ___

11.5 Are percent recoveries (% R) of the PCBs and surrogate compounds used to check the efficiency of the cleanup procedures within lab's in-house QC limits (use 70-130% if not available). [ ] ___ ___

Yes NO N/A

70-130% for GPC calibration? [ ] ___ ___

Qualify only the analyte(s) which fail the recovery criteria as follows:

ACTION: If % R are < 70%, qualify positive results "J" and quantitation limits "UJ". Non-detects should be qualified "R" if zero %R was obtained for PCBs. Use professional judgement to qualify positive results if recoveries are greater than the upper limit.

12.0 PCB Identification

12.1 Has CLP Form X or equivalent, showing retention time data for positive results on the two GC columns, been completed for every sample in which a PCB was detected? [ ] ___ ___

ACTION: If no, take action specified in 3.2 above, or compile a list comparing the retention times for all sample hits on the two columns.

12.2 Are there any transcription/calculation errors between raw data and data summary forms (initial calibration summaries, calibration verification summaries, analytical sequence summaries, GPC and cleanup verification forms)? ___ [ ] ___

ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and note error in the data assessment.

12.3 Are retention times (RT) of sample compounds within the established RT windows for both columns/analyses? [ ] ___ ___

ACTION: Qualify as unusable (R) all positive results which were not confirmed by second GC column analysis. Also qualify "R", unusable, all positive results not within RT windows unless associated standard compounds are similarly biased. The reviewer should use professional judgement to assign an appropriate quantitation limit.

Yes NO N/A

12.4 Check chromatograms for false negatives, especially if RT windows on each column were established differently.
Were there any false negatives? ___ [ ] ___

ACTION: Use professional judgement to decide if the compound should be reported. If there is reason to believe that peaks outside retention RT windows should be reported, make corrections to data summary forms (Form I) and note in data assessment.

12.5 Was GC/MS confirmation provided when sample concentration was sufficient (> 10 ug/ml) in the final extract? [ ] ___ ___

ACTION: Indicate with red pencil which Form I results were confirmed by GC/MS and also note in data assessment. GC/MS confirmation is an option, see section 7.10 of Method 8082A-20. If GC/MS confirmation is not available, follow action in section 3.2.

12.6 Is the percent difference (%D) calculated for the positive sample results on the two GC columns <25.0%? [ ] ___ ___

NOTE: The method requires quantitation from one column. The second column is to confirm the presence of an analyte. It is the reviewer's responsibility to verify from the project plan what the lab was required to report. If the lab was required to report concentrations from both columns, continue with validation for % Difference. If required, but not reported, either contact the lab for results or calculate the concentrations from the calibration. If not required, skip this section. Document actions in Data Assessment.

ACTION: If the reviewer finds neither column shows interference for the positive hits, the data should be qualified as follows:

% Difference	Qualifier

Yes NO N/A

0-25%	none
26-70%	"J"
71-100%	"NJ"
101-200% (No Interference)	"R"
101-200% (Interference detected)	"NJ"
>50% (PCBs value is <CRQL)	"U"
>200%	"R"

Note: The lower of the two values is reported on Form I. If using professional judgement,the reviewer determines that he higher result was more acceptable, the reviewer should replace the value and indicate the reason for the change in the data assessment.

13.0 Compound Quantitation and Reported Detection Limits

13.1 Are there any transcription/calculation errors in Form I results? Check at least two positive values. Were any errors found? ___ [ ] ___

NOTE: Single-peak PCBs results can be checked for rough agreement between quantitative results obtained on the two GC columns. The reviewer should use professional judgement to decide whether a much larger concentration obtained on one column versus the other indicates the presence of an interfering compound. If an interference is suspected, the lower of the two values should be reported and qualified according to section 12.6 above. This necessitates a determination of an estimated concentration on the confirmation column. The narrative should indicate that the presence of interferences has led to the quantitation of the second column confirmation results.

13.2 Are the EDLs (Estimated Detection Limits) adjusted to reflect sample dilutions and, for soils, % moisture? [ ] ___ ___

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and document effect in data assessments.

Yes NO N/A

ACTION: When a sample is analyzed at more than one dilution, the lowest EDLs are used (unless a QC exceedance dictates the use of the higher EDL data from the diluted sample analysis). Replace concentrations that exceed the calibration range in the original analysis by crossing out the value on the original Form I and substituting it with data from the analysis of diluted sample. Specify which Form I is to be used, then draw a red "X" across the entire page of all Form I's that should not be used, including any in the summary package.

ACTION: EDLs affected by large, off-scale peaks should be qualified as unusable, "R". If the interference is on-scale, the reviewer can provide a modified EDL flagged "UJ" for each affected compound.

14.0 Chromatogram Quality

14.1 Were baselines stable? [ ] ___ ___

14.2 Were any electropositive displacement (negative peaks) or unusual peaks seen? ___ [ ] ___

ACTION: Note all system performance problems in the data assessment.

15.0 Field Duplicates

15.1 Were any field duplicates submitted for PCB analysis? [ ] ___ ___

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between field duplicate results must be addressed in the reviewer narrative. However, if large differences exist, the identity of the field duplicates is questionable. An attempt should be made

Yes NO N/A

to determine the proper identification of field duplicates.

Validation of Metals for the Contract Laboratory Program (CLP) based on SOW ILMO5.3 (SOP Revision 13)

I.0 Scope

I.I This Standard Operating Procedure (SOP) applies to the evaluation of Routine Analytical Services (RAS) inorganic data generated in accordance with the EPA Contract Laboratory Program (CLP) protocols.

1.2 This Region 2 inorganic data validation SOP is used to determine the usability of analytical data generated from water and soil/sediment samples collected from Superfund sites in EPA Region 2.

1.3 Data should be generated and validated in accordance with the site specific Project Quality Objectives (PQOs) developed prior to the sample collection event. This SOP can be customized to validate the data according to the site specific PQOs. If the site specific DQOs are not available, this SOP must be used in its entirety.

1.4 This SOP is based, for the most part, upon analytical and quality assurance requirements specified in the Statement of Work SOW-ILM05.3, as well as in the final (October 2004) of the USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Data Review. The SOP Checklist, Appendix A.1, provides guidance in conducting the data validation. The result of the use of this SOP is a **Total Review** of the data: **Technical plus Contract - Compliance Review.**

2.0 Contract Compliance Review

This type of review is the first step in data validation which is carried out to ensure that the CLP laboratory has analyzed the environmental samples in accordance with the Statement of Work (SOW), and provided a data package which is both complete and compliant. This means that laboratory's procedures were performed exactly as specified in the CLP Statement of Works (SOW) and the data package contains all the deliverables including the information required under the contract.

2.1 Completeness

The data validator must check the entire data package to ensure that all deliverables required under the CLP contract are present and legible. In addition, copies of the Contract Compliance Screening (CCS) report, re-submittal from the laboratory, and Regional documentation should also be present in the data package. In Region 2, the data package completeness check is currently performed by the Regional Sample Control Coordinator (RSCC)for each Sample Delivery Group (SDG). The data package is not released to the data validator until all the required deliverables are received
from the laboratory.

2.2 Compliance

The data validator must check to ensure that all steps from sample receipt through sample preparation, analysis, data calculation and reporting are documented, and the information/data required under the contract is present in the appropriate reporting Forms and laboratory logs.

2.3 Contract Compliance Screening (CCS)

This screening step essentially checks the data package for the Completeness and Compliance requirements, and is performed by the Sample Management Office (SMO) currently operated by Computer Sciences Corporation (CSC), an EPA contractor. The CCS Report outlines the incomplete and non-compliant items as "Defects" in the data package, and is sent to the laboratory which is required to

provide additional or missing information/data required under the contract. The CCS Report for each SDG is transmitted electronically by the SMO to the Regional office. The CCS Report is intended to aid the data validator in locating any problems, both corrected and uncorrected. The incorrect original deliverable(s)of the data package must be replaced by the re-submittal(s)received from the laboratory in response to the CCS Report. The data validation should, however, be carried out even if the CCS Report is not available.

Web-based CCS is available for CLP laboratories to check their data prior to its delivery to EPA.

3.0 **Technical Review**

Technical review of the RAS data is carried out on the complete and compliant data to ensure its **validity** (i.e., data is of known quality and scientifically valid) and **usability** (i.e., data set is sufficiently complete and of sufficient quality to support a decision or an action described in the specific objectives of a data collection activity). The technical review process provides information on analytical limitations of data, if any, based on specific Quality Assurance/Quality Control (QA/QC) criteria. This is accomplished by performing an in-depth review of both the field deliverables which document the field sampling activities, and the laboratory analytical data deliverables which document the laboratory activities carried out to generate the reported data. Essentially, the validator shall first ensure that the data package is complete and compliant. The validator shall then evaluate data/information on all these deliverables (Final data sheets, Forms for QC analyses Chain-of-Custody/Traffic Report Forms, raw data, etc.) against the QA/QC acceptance criteria specified in the SOP “Checklist” (Appendix A.1). The validator must answer each question in the “ Checklist” and take an appropriate action as required under “Action” to qualify the data. As a result of the technical review, the data validator may qualify some of the data as **rejected** or as **estimated.** The data validator shall write a **Data Review Narrative** documenting the qualified data and the reason(s) for the qualification.

3.1 If the **raw data** necessary to support the reported results are not provided, the data validation must not be performed. The laboratory must be contacted to obtain missing raw data.

3.2 If batch quality control analyses are performed on samples other than **site specific samples**, data must not be validated
or at best be considered as estimated. The data user must be notified of this action.

3.3 **QA/QC Acceptance Criteria**

In order that reviews be consistent among reviewers, QA/QC protocol (stated in Appendix A.l) should be strictly adhered to. If a lab provides more than one set of QC analyses or more than one particular QC analysis for an SDG, the validator shall use the worst QC analysis to evaluate the SDG data. Professional judgement should only be used in the rare instances not addressed in the “Checklist”.

3.4 **Data Validation Flags**

Three types of data validation flags (J, R & U) are used in Region 2 to qualify the data.

3.4.1 **Flag "R" indicates Rejected Data**

Sample results determined to be unacceptable must preferably be lined over and flagged " R" with a red pencil only on the Inorganic Analysis Data Sheets (CLP Form I's). Data rejected on the basis of an unacceptable QC analysis should be excluded from further review or consideration. Data are rejected when associated QC analysis results exceed the expanded control limits of the QC criteria. The rejected data are known to contain significant errors based on documented information. The data user **must not** use the rejected data to make environmental decisions.

3.4.2 **Flag "J" indicates Estimated Data**

Sample results determined to be estimated must be flagged "J" with a red pencil only on the CLP Form I's. Data are flagged (J) when a QC analysis falls outside the primary acceptance limits. The qualified "J" data are not excluded from further review or consideration. However, only one flag (J) is applied to a sample result even though several associated QC analyses may fail. The "J" data may be biased high or low.

3.4.3 **Flg "U" indicates Non-Detects**

Sample results ≥ MDL associated with a contaminated blank are flagged "U" with a red pencil only on Form I's.

4.0 **Contractual Qualifiers**

The CLP laboratory applies contractual qualifiers on all Form I'S and the QC Forms when QC analyses are outside the control limits. These qualifiers are not applied on the Lotus or XLS spreadsheets with the exception of U and J. The contractual qualifiers and their meanings are as follows:

N : This qualifier indicates the lack of accuracy in the reported result, and is applied when matrix spiked sample recovery is outside the control limits.

E : This qualifier indicates the presence of interference, and is applied when the ICP serial dilution analysis is outside the control limits.

***** : This qualifier indicates the lack of precision, and is applied to sample results on Form I's and Form VI when the Lab Duplicate analysis is outside the control limits.

U : This is a concentration qualifier that laboratory applies to a non-detected result which is essentially less than the Method Detection Limit(MDL). A non-detected result of an analysis is indicated by the Contract Required Quantitation Limit (CRQL) of that analyze suffixed with "U".

J : This is a concentration qualifier that the laboratory applies to a positive result below the CRQL(i.e.,≥MDL but <CRQL).

NOTE: The laboratory qualifiers are crossed out and replaced with the appropriate data validation qualifiers (J, R or U) by the data validator.

4.0 Rounding Rule

The data reviewer must follow the standard practice to round off percent recoveries on the QC reporting forms.

5.0 Data Review Narrative (Appendix A.2)

The data review narrative should be written using the format of Appendix A.2. The narrative should indicate the QC analyses outside the acceptance limits and the actions taken to qualify the associated data. The narrative should be prepared on a Personal Computer or a typewriter. If hand-written, under no circumstances should a pencil be used to write the narrative. The Data Review Narrative should be written in four (4) Sections: (i)Data Case Description, (ii)Complete SDG File (CSF) Audit Section, (iii) Technical Review Section, and (iv) Contract-Problems/Non-Compliance Section.

5.1 Data Case Description Section

The data validator must briefly describe the data case in this Section, outlining important information such as the number of samples, their matrix, sampling date(s), analysis (TAL metals, mercury or cyanide), samples used for QC analyses, Field Blank(s), Field Duplicates, etc.

5.2 Complete SDG File (CSF) Audit Section

The data validator must perform an audit on each SDG in the data package to ensure that all SDG-specific documents (sampling, samples shipping and receiving, telephone contact logs, etc.) are present in the data case. The audit shall also discover any discrepancy in the deliverables. In Region 2, this audit is currently performed by the ESAT data validator and its findings reported under “Comments” on a CSF inventory checklist. The validator informs the CLP Project Officer (PO) of the missing or additional information/deliverable required for data validation. The PO then contacts the lab for the desired deliverable/information. The findings of the CSF audit are reported in the CSF Section of the Data Review Narrative (Appendix A.2).

5.3 Technical Review Section

The data validator shall report in this Section only the rejected (R) and estimated data (J) and the data rendered non-detects (U) as a result of technical review. It is imperative that the data reviewer highlights (i) QC analysis criteria applied to reject (R) or flag (J, U) the data, (ii) Samples rejected (R) or flagged (J, U), and (iii) the QC analysis out of control limits. The rest of the data that are not qualified (rejected or estimated) are not reported in this Section, and should be considered **fully useable.**

5.4 Contract-Problems/Non-Compliance Section

All the CLP non-compliant items detected during data review must be reported in this Section.

6.0 Computer-Aided Data Review and Evaluation (CADRE)

CADRE is a computer program that performs semi-automated Quality Assurance (QA) and Quality Control (QC) checks of results from the chemical analysis of soil and water samples according to the CLP protocols. After the CADRE data qualification is complete, a Lotus 1,2,3 spreadsheet or an XLS spreadsheet with data validation qualifiers (R,J,U) is generated for each SDG. Currently, Sample Management Office (SMO) performs this task using Data Assessment Tool (DAT), a software-driven process, and forwards to the Regions the customized electronic spreadsheets (Lotus 1,2,3 or XLS spreadsheet) and QC reports via the DART (Data Assessment Rapid Transmittal) system. Manual data validation is performed in conjunction with electronic data validation which can only be done by a trained and experienced data validator. The manual data review complements CADRE's findings to complete an assessment of data quality in a shorter time than by a solely manual process. The data validator must review the XLS or Lotus 1,2,3 spreadsheet against Form I's to ensure that the same results on Form I's and the Spreadsheet are qualified with the same data validation qualifiers. The spreadsheet for each SDG is provided with the Data Review Narrative.

7.0 Performance Evaluation Sample(PES)Based Data Validation Strategy

7.1 Scope and Summary

This strategy offers the use of Performance Evaluation Samples (PES) in the data validation process as a means of ensuring the quality of the CLP data while significantly reducing the validation time. The single blind PES provided by EPA (or any other reputable firm) is analyzed with samples of each matrix in a Sample Delivery Group (SDG). A software program (e.g.,PEAC TOOLS, SPS Web or equivalent)is used to determine whether or not the PES results fall within the previously statistically determined acceptance limits ("Action Low" and "Action High")for the Contaminants of Concern (**COC**). The PES results falling within the Action Limits are considered as acceptable results and may be designated as "Passed" analytes, and results of the analytes falling outside the Action Limits are considered as unacceptable and may be designated as "Failed" analytes. In either case ("Passed" Analytes or "Failed" analytes), the associated data is validated according to the Region 2 data validation SOP HW-2 in conjunction with the latest version of the WinCadre QC reports. The following strategy (procedure) is used:

7.2 "Passed" COC

If the COC in an SDG are within statistically generated Action Limits, the data validation is conducted according
to QC analyses indicated by check marks (√)in the "Review COC For" column of the Table I. The SDG samples are validated using the Region 2 data validation SOP in

conjunction with the latest version of the WinCADRE QC reports. The validation flags (J, R, U) are applied on Form I's as well on the CADRE Lotus 1,2,3 or XLS spreadsheet. Corrections, if needed, are
then made on the Lotus or XLS spreadsheet to ensure that all results on Form I's carry the same data validation and concentration flags as are on the Lotus or XLS Spreadsheet.

7.3 **"Failed" COC**

If the COC in an SDG are not within the statistically generated Action Limits, the data validation is conducted according to the data validation SOP QC Criteria indicated by check marks (√)in the "Review COC For" column of Table II. The SDG samples are validated using the Region 2 data validation SOP in conjunction with the latest version of the WinCADRE QC reports. The data validation flags (J,R,U) are applied on Form I's as well on the CADRE Lotus 1,2,3 or XLS Spreadsheet. Corrections, if needed, are then made on the Lotus or XLS spreadsheet to ensure that all results on Form I's carry the same data validation and concentration flags as are on the Lotus or XLS Spreadsheet.

7.4 **COC "Not Evaluated"**

Acceptance limits for the analytes not present/spiked in the PE sample are not provided on the PES Scoring Evaluation Report. Such analytes will be marked as "Not Evaluated" in the PES Evaluation Column. These analytes will be validated much the same way as the "Failed Analytes".

The failed analytes and the analytes not present/spiked in the PE sample require data validation according to the QC criteria specified in Table II, and are identified by the TOPO in the TDF for the Case/SDG.

Table I

Passed PES - All Contaminants of Concern are within the limits
(Action Low ≤ PES Result ≤ Action High)

QC Criteria	Review COC for
Holding Time & Preservation	√
Initial Calibration	
Initial Calibration Verification	
CRQL Standard	√
Blanks-Initial & Continuing	
Preparation Blank	
ICP Interference Check Sample	
Pre- Digestion/Distillation Matrix Spike	
Post Digestion Spike	
Laboratory Duplicate	
Field Duplicates Comparison	√
Lab Control Sample	
ICP Serial Dilution	
Field Blank Contamination	√
Percent Solids	√
Transcription/Computation Check	
Raw Data	
Total vs. Dissolved Concentrations Comparison	√

- The CSF (Complete SDG File) audit will be completed before the PES validation strategy is applied.
- Comparison of the Lotus or XLS Spreadsheet must be after the PES validation strategy is applied. The Contract
- Compliance can be checked after the PES validation strategy is applied.

Table II
Failed PES - Contaminants of Concern are not within the limits
(PES Result ≤ Action Low, PES Result ≥ Action High **OR** The Limits Not Established)

QC Criteria	Review COC for
Holding Time & Preservation	√
Initial Calibration	
Initial Calibration Verification	
CRQL Standard	√
Blanks-Initial & Continuing	
Preparation Blank	√
ICP Interference Check Sample	
Pre- Digestion/Distillation Matrix Spike	√
Post Digestion Spike	
Laboratory Duplicate	√
Field Duplicates Comparison	√
Lab Control Sample	√
ICP Serial Dilution	√
Field Blank Contamination	√
Percent Solids	√
Transcription/Computation Check	√
Raw Data	
Total vs. Dissolved Concentrations Comparison	√

- The CSF (Complete SDG File) audit will be completed before the PES validation strategy is applied.
- Comparison of the Lotus or XLS Spreadsheet must be after the PES validation strategy is applied.

- The Contract Compliance can be checked after the PES validation strategy is applied.

8.0 **Sampling Trip Report**

The sampler prepares a Sampling Trip Report for each sampling event and sends it to the RSCC. The report provides details of all activities performed for each sampling event on the Superfund site. It also lists the field QC samples such as Field Duplicates, Field/Rinse Blanks, sampling time and date for each sample, and samples associated with each field/rinse blank. The validator must use this information to evaluate the Field Duplicate pairs as well as the samples associated with contaminated Field/Rinse Blanks.

9.0 **Telephone Record Log (Appendix A.3)**

A Telephone Record Log (Appendix A.3) must be written by the data validator when a deliverable is missing or a clarification is needed about a lab procedure. The data validator should outline a basic profile of the Case on the Telephone Record Log Form, clearly indicating the reason(s) for inquiry and forward this Form to CLP PO/TOPO who will contact the lab to receive the missing document or information. The original Telephone Record Log is kept in the data package and a copy attached to the Data Review Narrative.

10.0 **Request for Re-Analysis (Appendix A.6)**

Data validator must note all items of contract non-compliance in the Data Review Narrative. If holding times and sample storage times have not been exceeded, the Project Officer (PO) may request re-analysis if items of non-compliance are critical to data assessment. Requests are to be made on "CLP Re-Analysis Request/Approval Record" form (Appendix A.4).

11.0 **CLP Data Assessment Summary Form (Appendix A.7)**

Fill in the total number of analytes performed by different methods and the number of analytes rejected (R) or flagged (J) as estimated due to corresponding quality control criteria. Place an "X" in boxes wherever analyses were not performed, or criteria do not apply.

12.0 **Data Review Log:**

It is recommended that the data validator maintain a log of the reviews completed to document:

a. Case number
b. SDG # (s)
c. number of samples
d. matrix of samples
e. contract laboratory
f. site name
g. start-date of the data case review
h. completion-date of the data case review
i. actual hours spent
j. reviewer's signature

13.0 **Record of Communication -**

This is a Regional document prepared and provided by the RSCC for each data package. The ROC indicates the Case #, site name, samples and sample matrix and the laboratory name. The presence of a ROC in a data package is an indication that the package has been reviewed by the RSCC for completeness and is ready for data validation.

14.0 **Forwarded Paperwork**

Upon completion of review, the following are to be forwarded to EPA for final review:

a. Data package
b. Completed data assessment checklist (Appendix A.1,original)
c. Original and a copy of completed data review narrative Appendix A.2)
d. CLASS Contract Compliance Screening (CCS) report
e. Telephone Record Log (Appendix A.3)
f. Field Duplicates Form (Appendix A.4)
g. Total/Dissolved Concentrations Form (Appendix A.5)
h. CLP Re-analysis Request/Approval Record Form (Appendix A.6)
i. Data Assessment Summary Form (Appendix A.7)
j. CADRE Spreadsheet on a computer diskette.

Signature of sample custodian present?	[___]	___	___
ACTION: If no, contact RSCC/WAM/PO.			
A.l.5 **Cover Page**			
Present?	[___]	___	___
Is the Cover Page properly filled in and the verbatim signed by the lab manager or the manager's designee?	[___]	___	___
Do the sample identification numbers on the Cover Page agree with sample Identification numbers on:			
(a) Traffic Report Sheet?	[___]	___	___

	YES	NO	N/A
(b) Form I's?	[___]	___	___
Is the number of samples on the Cover Page the same as the number of samples on the Traffic Report sheet and the Regional Record of Communication (ROC) for the data Case?	[___]	___	___

ACTION:
If no for any of the above, prepare Telephone Record Log and contact RSCC/PO for re-submittal of the corrected Cover Page from the laboratory.

A.1.6 **SDG Narrative, DC-1 & DC-2 Form**

Is the SDG Narrative present?	[___]	___	___
Is Sample Log-In Sheet(Form DC-1) present and complete?	[___]	___	___
Is Complete SDG Inventory Sheet(Form DC-2) present and complete?	[___]	___	___

ACTION:
If no, write in the Contract-Problems/ Non-Compliance Section of the Data Review Narrative.

A.1.7 **Form I to XV**

A.1.7.1 Are all the Form I through Form XV labeled with:

Laboratory Name?	[___]	___	___
Laboratory Code?	[___]	___	___
RAS/Non-RAS Case No.?	[___]	___	___
SDG No.?	[___]	___	___

		YES	NO	N/A
	Contract No.?	[___]	___	___

ACTION:
If no for any of the above, note under Contract Problem/Non-Compliance Section of the "Data Review Narrative" and contact PO for corrected Form(s) from the laboratory.

A.1.7.2	After comparing values on Forms I-IX against the raw data, do any computation/ transcription errors exceed 10% of the reported values on the Forms for:			
	(a) all analytes analyzed by ICP-AES?	___	[_]	___
	(b) all analytes analyzed by ICP-MS?	_	[___]	_
	(c) Mercury?	__	[_]	_____
	(d) Cyanide?	_	[_]	_

ACTION:
If yes, prepare Telephone Record Log and contact CLP PO/TOPO for the corrected data from the laboratory.

A.1.8 Raw Data

Data shall not be validated without the hard/electronic copies of the associated raw data for samples and QC samples.

A.1.8.1 Digestion/Distillation Log

Digestion Log for ICP-AES (Form XII)present?	[___]	___	___
Digestion Log for ICP-MS (Form XII) present?	[___]	___	___
Digestion Log for mercury (Form XII) present?	[___]	___	___
Distillation Log for cyanide (Form XII) present?	[___]	___	___
Are pH values for metals and			

	YES	NO	N/A
cyanide reported for each aqueous sample?	[___]	__	__
Are percent solids calculations present for soils/sediments?	[__]	___	___
Are preparation dates present on the sample preparation logs/bench sheets?	[___]	__	__

NOTE:
Digestion/Distillation log must include weights, volumes, and dilutions used to obtain the reported results.

A.1.8.2 Is the analytical instrument real-time printouts present for:

ICP-AES?	[___]	__	__
ICP-MS?	[___]	___	___
Mercury?	[__]	__	__
Cyanide?	[___]	___	___

Are all laboratory bench sheets and instrument raw data printouts necessary to support all sample analyses and QC operations:

Legible?	[__]	__	__
Properly labeled?	[__]	__	__

Are all field samples, QC samples and field QC samples present on:

Digestion/Distillation log?	[___]	___	___
Instrument Printouts?	[__]	__	__

ACTION:
If no for any of the above questions in Section A.1.8.1 and Section A.1.8.2, write Telephone Record Log and contact TOPO/PO for re-submittal from the laboratory.

		YES	NO	N/A

A.1.9 **Technical Holding Times**: (Aqueous and soil samples)

(Examine sample Traffic Reports and digestion/distillation logs to determine the holding time from the sample collection date to the sample preparation date.)

A.1.9.1	Cyanide distillation(14 days)exceeded?	__	[__]	__
	Mercury analysis(28 days) exceeded?	__	[___]	__
	Other Metals analysis(180 days)exceeded? ___	___	[__]	__

ACTION:
If yes, reject (R) and red-line non-detects and flag as estimated (J)results ≥ MDL even if sample(s) was preserved properly.

NOTE:
In addition to qualifying the data, a list of all samples and analytes which exceeded the holding times must be prepared. Report for each sample the number of days that were exceeded. (Subtract the sample collection date from the sample preparation date). Attach this list to the data review narrative.

A.1.9.2	Is pH of aqueous samples for:			
	Metals Analysis ≤ 2?	[___]	___	___
	Cyanide Analysis ≥ 12?	[__]	__	__

ACTION:
If no for any of the above, flag non-detects as “R” and detects as “J”.

A.1.9.3	Is the cooler temperature ≤ 10 C°?	[__]	__	__

ACTION:
If cooler temperature is >10 ^{0}C , flag non-detects as “UJ” and detects as “J”.

A.1.10 **Final Data Correctness - Form I**

A.1.10.1 Are Form I's for all samples

	YES	NO	N/A
present and complete?	[___]	___	___

ACTION:
If no, prepare Telephone Record Log and contact CLP PO/TOPO for submittal from the laboratory.

A.1.10.2 Verify there are no calculation and transcription errors in the results reported on Form I's. Circle on each Form I all results that are incorrect.

Is the calculation error less than 10% of the correct result?	[___]	__	__
Are results on Form I's reported in correct units (ug/L for aqueous and MG/KG for soils)?	[___]	___	___
Are results on Form I'S reported by correct significant figures?	[___]	___	__
Are soil sample results on Form I's corrected for percent solids?	[___]	___	___
Are all "less than MDL" values reported by the CRQLs and coded with "U"?	[___]	___	___
Are values less than the CRQLs but greater than or equal to the MDLs flagged with "J"?	[___]	___	___
Are appropriate contractual quality control and Method qualifiers used?	[___]	____	___

ACTION:
If no for any of the above questions, prepare Telephone Record Log, and contact CLP PO/TOPO for corrected data.

A.1.10.3 Do EPA sample identification numbers and the corresponding laboratory sample identification numbers match on the Cover Page, Form I's and in the raw data? [___] ___ ___

Was a brief physical description

		YES	NO	N/A
	of the samples before and after digestion given on the Form I's?	[___]	___	__
	Was any sample result outside the mercury/cyanide calibration range or the ICP-AES/ICP-MS linear range diluted and noted on the Form I?	[___]	___	___
	ACTION: If no for any of the above, note under the Contract-Problem/Non-Compliance Section of the Data Review Narrative.			

A.1.11 **Initial Calibration**

A.1.11.1	Is a record of at least 2 point (A blank and a standard)calibration present for ICP-AES analysis?	[___]	___	___
	Is a record of at least 2 point (a blank and a standard)calibration present for ICP-MS analysis?	[___]	___	___
	Is a record of at least 5 point calibration (a blank & 4 standards)present for Hg analysis?	[___]	___	___
	Is a record of at least 4 point calibration (a blank & 4 standards)present for cyanide?	[___]	___	___
	ACTION: If incomplete or no initial calibration was performed, reject (R) and red-line the associated data (detects & non-detects).			
	Is one initial calibration standard at the CRQL level for cyanide and mercury?	[___]	___	___
	ACTION: If no, write in the Contract Problem/ Non-Compliance Section of the Data Review Narrative.			
A.1.11.2	Is the curve correlation coefficient $\geq$ 0.995 for:			

		YES	NO	N/A
	Mercury Analysis?	[___]	___	___
	Cyanide Analysis?	[___]	___	___
	ICP-AES(more than 2 point Calib.)?	[___]	___	___
	ICP-MS (more than 2 point calib.)?	[___]	___	___

ACTION:
If no, qualify the associated sample results ≥ MDL as estimated "J" and non-detects as "UJ".

NOTE:
The correlation coefficient shall be calculated by the data validator using standard concentrations and the corresponding instrument response (e.g. absorbance, peak area, peak height, etc.).

A.1.12 **Initial and Continuing Calibration Verification- Form IIA**

A.1.12.1	Present and complete for every metal and cyanide?	[___]	___	___
	Present and complete for ICP-AES and ICP-MS when both these methods were used for the same analyte?	[___]	___	___

ACTION:
If no for any of the above, prepare a Telephone Record Log and contact PO/TOPO for re-submittal from the laboratory.

A.1.12.2	Was a Continuing Calibration Verification performed every 10 samples or every 2 hours whichever is more frequent?	[___]	___	___

ACTION:
If no for any of the above, write in the Contract-Problem/Non-Compliance Section of the Data Review Narrative.

A.1.12.3	Was an ICV or a mid-range standard distilled and analyzed with each batch of cyanide samples?	[___]	___	___

	YES	NO	N/A

ACTION:
If no for any of the above, write in the Contract-Problem/Non-Compliance Section of the Data Review Narrative and qualify results ≥ MDL as estimated (J).

A.1.12.2 Circle on each Form IIA all percent recoveries that are outside the contract windows.

Are ICV/CCVs within control limits for:

Metals - 90-110%R?	[___]	___	___
Hg - 80-120%R?	[___]	___	___
Cyanide - 85-115%R?	[___]	___	___

ACTION:
If no, qualify all samples between a previous technically acceptable CCV standard and a subsequent technically acceptable CCV standard as follows as follows:

Qualify as estimated (J) all detects and non-detects, if the ICV/CCV %R is between 75-89%(65-79% for Hg; 70-84% for CN). Qualify only positive results(≥ MDL) as "J" if the ICV/CCV %R is between 111-125%(121-135% for Hg;116-130% for CN). Reject (R) and red-line only
detects if the recovery is greater than 125% (135% for Hg; 130% for CN). Reject (R) and red-line all associated results (hits and non-detects)if the recovery is less than 75%(65% for Hg;70% for CN).

NOTE:
For ICV that does not fall within the acceptance limits, qualify all samples reported from the analytical run.

A.1.12.3 Was the distilled ICV or mid-range standard for cyanide within acceptance limits (85-115%)? [___] ___ ___

ACTION:
If no, Qualify all cyanide results ≥ MDL as "J".

A.1.13 **CRQL Standard Analysis - Form IIB**

A.1.13.1 For each ICP-AES run, was a CRI

	YES	NO	N/A
(CRQL or MDL when MDL > CRQL) standard analyzed? **(Note:CRI is not required for Al, Ba, Ca, Fe, Mg, Na and K.)**	[___]	___	___
For each ICP-MS run, was a CRI (CRQL or MDL when MDL > CRQL) standard analyzed for each mass/isotope used for the analysis?	[___]	___	___ ___
For each mercury run, was a CRQL standard analyzed?	[___]	___	___
For each cyanide run, was a CRQL standard analyzed?	[___]	___	___

ACTION:
If no for any of the above, write this deficiency in the Contract Problems/ Non-Compliance Section of the Data Review Narrative, inform CLP PO and flag results in the affected ranges (detects <2xCRQL)as J and non-detects UJ.

The affected ranges are:
ICP-AES Analysis - *True Value ± CRQL
ICP-MS Analysis - *True Value ± CRQL
Mercury Analysis - *True Value ± CRQL
Cyanide Analysis - *True Value ± CRQL
*** True value of the CRQL Standard**

A.1.13.2 Was a CRQL standard analyzed after the ICV/ICB, before the final CCV/CCB and once every 20 analytical samples in the analytical run for each analysis? [___] ___ ___

ACTION:
If no, write in the Contract Problem/ Non-Compliance Section of the "Data Review Narrative".

A.1.13.3 Circle on each Form IIB all percent recoveries that are outside the acceptance windows.

	YES	NO	N/A
Is the CRQL standard within control limits for:			
Metals(ICP-AES/ICP-MS)- 70 - 130%?	[___]	___	___
Mercury- 70 - 130%?	[___]	___	___
Cyanide - 70 - 130%?	[___]	___	___

ACTION:
If no, flag detects <2xCRQL as "J" and non-detects as "UJ" if the CRQL standard recovery is between 50-69%. Flag(J) only detects <2xCRQL if the recovery is between 131% and ≤180%. If the recovery is less than 150%, reject(R) and red-line non-detects and detects < 2xCRQL, and flag (J) detects between 2xCRQL and ICV/CCV. Reject and red-line only detects <2xCRQL and flag (J)detects ≥ 2xCRQL but < ICV/CCV if the recovery is > 180%.

NOTE:
1. Qualify all field samples analyzed between a previous technically acceptable analysis of the CRQL standard and a subsequent acceptable analysis of the CRQL standard
2. Flag (J) or reject (R) only the final sample results on Form I's when **Sample raw data** are within the affected ranges and the CRQL standard is outside the acceptance windows.
3. The samples and the CRQL standard must be analyzed in the same analytical run.

A.1.14 Initial and Continuing Calibration Blanks - Form III

		YES	NO	N/A
A.1.14.1	Present and complete for all the instruments used for the metals and cyanide analyses?	[___]	___	___
	Was an initial Calibration Blank analyzed after ICV?	[___]	___	___
	Was a continuing Calibration Blank analyzed after every CCV and every 10 samples or every 2 hours, whichever is more frequent?	[___]	___	___
	Were the ICB & CCB values ≥ MDL but < CRQL reported on Form III and flagged "J" by			

		YES	NO	N/A
	using MDLs from direct analysis(Preparation Method "NP1")? (Check Form III against the raw data)	[___]	___	___

ACTION:
If no, inform CLP PO/TOPO and make a note in the Contract-Problems/Non-Compliance Section of the "Data Review Narrative".

A.1.14.2 Circle with red pencil on each Form III all Calib. Blank values that are:

≥ MDL but ≤ CRQL

> CRQL

A.1.14.2.1	When MDL < CRQL, is any Calib. Blank value ≥ MDL but ≤ CRQL?	___	[___]	___

ACTION:
If yes, change sample results ≥ MDL but ≤ CRQL to the CRQL with a "U". Do not qualify non-detects.

A.1.14.2.2	When MDL < CRQL, is any Calib. Blank value > CRQL?	___	[___]	___

ACTION:
If yes, reject (R) and red line the associated sample results > CRQL but <ICB/CCB Blank Result. Flag as "J" detects > ICB/CCB blank value but < 10xICB/CCB value. Change the sample results ≥ MDL but ≤ the CRQL to CRQL with a "U".

A.1.14.2.3	Is any Calibration Blank value below the negative CRQL?	___	[___]	___

ACTION:
If yes, flag (J) as estimated all associated sample results ≥ CRQL but <10xCRQL.

NOTE:

1. For ICB that does not meet the technical QC Criteria, apply the action to all samples

	YES	NO	N/A

reported from the analytical run.

2. For CCBs that do not meet the technical QC criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.,

A.1.15 **Preparation Blank - FORM III**

NOTE:The Preparation Blank for mercury is the same as the calibration blank.

A.1.15.1 Was one Preparation Blank prepared with and analyzed for:

Each Sample Delivery Group (SDG)?	[___]	___	___
Each batch of the SDG samples digested/distilled?	[___]	___	___
Each matrix type?	[___]	___	___
All instruments used for metals and cyanide analyses?	[___]	___	___

ACTION:
If no for any of the above, flag as estimated (J) all the associated positive data <10xMDL for which the Preparation Blank was not analyzed.

NOTE:
If only one blank was analyzed for more than 20 samples, then the first 20 samples analyzed are not estimated(J),but all additional samples must be qualified (J).

A.1.15.2 Circle with red pencil on each Form III all Prep. Blank values that are:

$\geq$ MDL but $\leq$ CRQL, and

> CRQL

A.1.15.2.1 When MDL < CRQL, is any preparation blank value $\geq$ MDL but $\leq$ CRQL? ___ [___] ___

ACTION:
If yes, change sample result $\geq$ MDL

		YES	NO	N/A
	but ≤ CRQL to CRQL with a "U".			
A.1.15.2.2	When the MDL ≤ CRQL, is any Preparation Blank value greater than its CRQL?	___	[___]	___
	If yes, is the Prep. Blank value greater than the value of the associated Field Blank collected and analyzed with the SDG samples?	___	[___]	___
	If yes, is the lowest concentration of that analyte in the associated samples less than 10 times the Preparation Blank value?	___	[___]	___

ACTION:
If yes, reject (R) and red-line all associated sample results greater than the CRQL but less than the Prep.Blank value. Flag as "J" detects > Prep. Blank value but <10xPrep.Blank. If the sample result ≥ MDL but ≤ CRQL, replace it with CRQL-U.

If the Prep. Blank value is less than the same analyte value in the Field Blank, do not qualify the sample results due to the Prep. Blank criteria.

NOTE:
Convert soil sample result to mg/Kg on wet weight basis to compare with the soil Prep. Blank result on Form III.

A.1.15.2.3	Is the Prep. Blank concentration below the negative CRQL?	___	[___]	___

ACTION:
If yes, flag (J) all associated sample results less than 10xCRQL. Qualify non-detects as estimated (UJ).

A.1.15.2.4	When the MDL is greater than the CRQL, is the preparation blank concentration on Form III greater than two times the MDL?	___	[___]	___

ACTION:

		YES	NO	N/A
	If yes, reject (R) and red-line all positive sample results with sample raw data less than 10 times the Preparation Blank value.			

A.1.16 **ICP-AES/ICP-MS Interference Check Sample (ICS)- Form IV**

NOTE: Not required for CN, Hg, Al, Ca, Fe and Mg.

A.1.16.1	Present and complete?	[___]	___	___
	Was ICS analyzed at the beginning and end of each analytical run, and once for every 20 analytical samples?	[___]	___	___
	Was ICS analyzed at the beginning of the ICP-MS analytical run?	[___]	___	___

ACTION:
If no, flag as estimated (J) all sample results.

A.1.16.2 **ICP-AES Method**

A.1.16.2.1	**ICSA Solution:** For ICP-AES, are the ICSA "Found" analyte values within the control limits ± of CRQL of the true/established mean value?	[___]	___	___
	If no for any of the above, is the sample concentration of Al, Ca, Fe, or Mg in the same units (ug/L or MG/KG) greater than or equal to its respective concentration in the ICSA Solution on Form IV?	[___]	___	___

ACTION:
If yes, apply the following action to all samples analyzed between a previous technically acceptable analysis of the ICS and a subsequent technically acceptable analysis of the ICS in the analytical run:

Flag (J) as estimated only sample results ≥MDL

		YES	NO	N/A
	for which the ICSA "Found" value is greater than (True value+CRQL). Do not qualify non-detects. If the ICSA "Found" value is less than (True value-CRQL), flag non-detects as "UJ" and detects as "J".			
A.1.16.2.3	**ICSAB Solution** For ICP-AES, are all analyte results in ICSAB within the control limits of 80-120 of the true/established mean value?	[___]	___	___
	If no for any of the above, is the sample concentration of Al, Ca, Fe, or Mg in the same units (ug/L or MG/KG) greater than or equal to its respective concentration in the ICSAB Solution on Form IV?	[___]	___	___
	ACTION: If yes, apply the following action to all samples analyzed between a previous technically acceptable analysis of the ICS and a subsequent technically acceptable analysis of the ICS in the analytical run: Flag (J) as estimated those associated sample results ≥ MDL for which the ICSAB analyte recovery is greater than 120% but ≤ 150%. If the ICSAB recovery falls within 50-79%, qualify sample results ≥ MDL as "J" and non-detects as "UJ". Reject (R) and red-line all sample results (detects & non-detects) for which the ICSAB analyte recovery is less than 50%. If the recovery is above 150%, reject (R) and red-line only positive results.			
A.1.16.3	**ICP-MS Method**			
A.1.16.3.1	**ICSA Solution:** For ICP-MS, are the ICSA "Found" analyte values within the control limits of ±CRQL of the true/established mean value?	[___]	___	___
	ACTION: If no, apply the following action to all samples reported from the analytical run: Flag (J) as estimated only sample results ≥ MDL if the ICSA "Found" value is greater than (True value+CRQL). Do not qualify non-detects. If the ICSA "Found" value is less than (True value-CRQL), flag the associated sample detects as "J" and non-detects as "UJ".			

		YES	NO	N/A
A.1.16.3.3	**ICSAB Solution** For ICP-MS, are all analyte results in ICSAB within the control limits of 80-120% of the true/established mean value, whichever is greater?	[___]	___	___

ACTION:
If no, apply the following action to all samples reported from the analytical run:

Flag (J) as estimated those associated sample results ≥ MDL for which the ICSAB analyte recovery is greater than 120% but ≤ 150%. If the ICSAB recovery falls within 50-79% flag (J) as estimated the associated sample results ≥ MDL. Reject (R) and red-line those all sample detects and non-detects for which the ICSAB analyte recovery is less than 50%. If the recovery is above 150%,reject (R) and red-line only detects (≥ MDL).

A.1.17 **Spiked Sample Recovery: Pre-Digestion/Pre-Distillation)-Form V A**
Note:Not required for Ca,Mg,K,and Na(both matrices);Al and Fe (soil only)

A.1.17.1	Was Matrix Spike analysis performed:			
	For each matrix type?	[___]	___	___
	For each SDG?	[___]	___	___
	On one of the SDG samples?	[___]	___	___
	For each concentration range (i.e.,low, med., high)?	[___]	___	___
	For each analytical Method (ICP-AES,ICP-MS, Hg, CN)used?	[___]	___	___
	Was a spiked sample prepared and analyzed with the SDG samples?	[___]	___	___

ACTION:
If no for any of the above, flag as estimated(J)all the positive data for which a spiked sample was not analyzed.

NOTE:
If more than one spiked sample were analyzed for one SDG, then qualify the associated data based on the worst spiked sample analysis.

		YES	NO	N/A
A.1.17.2	Was a field blank or PE sample used for the spiked sample analysis?	___	[___]	___
	ACTION: If yes, flag (J) as estimated positive data of the associated SDG samples for which field blank or PE sample was used for the spiked sample analysis.			
A.1.17.3	Circle on each Form VA all spike recoveries that are outside the control limits (75-125%) that have sample concentrations less than four times the added spike concentrations.			
	Are all recoveries within the control limits when sample concentrations are less than or equal to four times the spike concentrations?	[___]	___	___
	NOTE: Disregard the out of control spike recoveries for analytes whose concentrations are greater than or equal to four times the spike added.			
	Are results outside the control limits (75-125%)flagged with Lab Qualifier "N" on Form I's and Form VA?	[___]	___	___
	ACTION: If no for any of the above, write in the Contract - Problems/Non-Compliance Section of the Data Review Narrative.			
A.1.17.4	**Aqueous**			
	Are any spike recoveries:			
	(a) less than 30%?	___	[___]	___
	(b) between 30-74%?	___	[___]	___
	(c) between 126-150%?	___	[___]	___
	(d) greater than 150%?	___	[___]	___
	ACTION: If the matrix spike recovery is less than 30%,reject (R) and red-line all associated aqueous data (detects & non-detects). If between 30-74%, qualify all associated aqueous data ≥ MDL as “J” and non-detects			

		YES	NO	N/A
	as "UJ". If between 126-150%, flag (J) all data ≥ MDL as "J". If greater than 150%, reject (R) and red-line all associated data ≥ MDL.			
	(**NOTE:**Replace "N" with "J", "R" as appropriate.)			
A.1.17.5	**Soil/Sediment**			
	Are any spike recoveries:			
	(a) less than 10%?	___	[___]	___
	(b) between 10-74%?	___	[___]	___
	(c) between 126-200%?	___	[___]	___
	(d) greater than 200%?	___	[___]	___
	ACTION: If yes for any of the above, proceed as follows:			
	If the matrix spike recovery is less than 10%,reject (R) and red-line all associated data (detects & non-detects); if between 10-74%,qualify all associated data ≥ MDL as "J" and non-detects as "UJ"; if between 126-200%, flag (J) all associated data ≥ MDL as "J" If greater than 200%, reject (R) and red-line all associated data ≥ MDL. (**NOTE:**Replace "N" with "J" or "R" as appropriate.)			
A.1.18	**Lab Duplicates) - Form VI**			
A.1.18.1	Was the lab duplicate analysis performed:			
	For each SDG?	[___]	___	___
	On one of the SDG samples?	[___]	___	___
	For each matrix type?	[___]	___	___
	For each concentration range (low or med.)?	[___]	___	___
	For each analytical Method (ICP-AES/ICP-MS,Hg,CN)Used?	[___]	___	___
	Was a lab duplicate prepared and analyzed with the SDG samples?	[___]	___	___

		YES	NO	N/A
	ACTION: If no for any of the above, flag (J) as estimated all the SDG sample results (detects & non-detects) for which the lab duplicate analysis was not performed.			
	NOTE: If more than one lab duplicate sample were analyzed for an SDG, then qualify the associated samples based on the worst lab duplicate analysis.			
A.1.18.2	Was a Field Blank or PE sample used for the Lab Duplicate analysis?	___	[___]	___
	ACTION: If yes, flag as estimated (J) all SDG sample results (hits & non-detects) for which Field Blank or PE sample was used for duplicate analysis.			
A.1.18.3	Circle on each Form VI all values that are:			
	RPD > 20%, or			
	Absolute Difference > CRQL			
	Are all values within control limits (RPD ≤ 20% or absolute difference ≤ ±CRQL)?	[___]	___	___
	If no, are all results outside the control limits flagged with an "*" (Lab Qualifier)on Form VI and on all Form I's?	[___]	___	___
	ACTION: If no, write in the Contract-Problems/ Non-Compliance Section of the Data Review Narrative.			
	NOTE: The laboratory is not required to report on Form VI the RPD when both values are non-detects.			
A.1.18.4	**Aqueous**			
A.1.18.4.1	When sample and duplicate values are both ≥ 5xCRQL (substitute MDL for CRQL when MDL > CRQL),			

	YES	NO	N/A
is any RPD > 20% but < 100%?	___	[___]	___
is any RPD ≥ 100%?	___	[___]	___

ACTION:
If the RPD is > 20% but < 100%, flag (J) as estimated the associated sample data ≥ CRQL. If the RPD is ≥ 100%, reject (R) and red-line the associated sample data ≥ CRQL.

(**NOTE:**Replace **"*"** with "J" or "R" as appropriate.)

A.1.18.4.2 When the sample and/or duplicate value <5xCRQL (substitute MDL for CRQL when MDL >CRQL), is the absolute difference between sample and duplicate values:

> ± CRQL?	___	[___]	___
> ± 2xCRQL?	___	[___]	___

ACTION:
If the absolute difference is > CRQL, flag as estimated all the associated sample results ≥ MDL but < 5xCRQL as "J" and non-detects as "UJ". If the absolute difference is > 2xCRQL, reject (R) and red-line all the associated non-detects and detects ≥ MDL but < 5xCRQL.
NOTE:
1. Replace "*" with "J", "UJ" or "R" as appropriate.)
2. If one value is >CRQL and the other value is non-detect, calculate the absolute difference between the value > CRQL and the MDL, and use this difference to qualify sample results.

A.1.18.5 **Soil/Sediment**

A.1.18.5.1 When sample and duplicate values are both ≥ 5xCRQL (substitute MDL for CRQL when MDL > CRQL),

is any RPD ≥ 35% but < 120%?	___	[___]	___
is any RPD ≥ 120%?	___	[___]	___

ACTION:
If the RPD is ≥ 35% and < 120%, flag (J) as estimated the associated sample

		YES	NO	N/A
	data ≥ CRQL. If the RPD is ≥ 120%, reject (R)and red-line the associated sample data ≥ CRQL.			
A.1.18.5.2	When the sample and/or duplicate value <5xCRQL(substitute MDL for CRQL when MDL > CRQL), is the absolute difference between sample and duplicate:			
	> ± 2 x CRQL?	___	[___]	___
	> ± 4 x CRQL	___	[___]	___

ACTION:
If the absolute difference is > 2 x CRQL, flag all the associated sample results ≥ MDL but < 5xCRQL as "J" and non-detects as "UJ". If the absolute difference is > 4xCRQL, reject (R) and red-line all the associated non-detects and detects ≥ MDL but <5xCRQL.

NOTE:
1. Replace "*" with "J", "UJ" or "R" as appropriate.)
2. If one value is >CRQL and the other value is non-detect, calculate the absolute difference between the value > CRQL and the MDL, and use this difference to qualify sample results.

A.1.19 Field Duplicates

Aqueous Field Duplicates

A.1.19.1	Was an aqueous Field Duplicate pair collected and analyzed? (Check Sampling Trip Report)	[___]	___	____

ACTION:
If yes, prepare a Form (Appendix A.4) for each aqueous Field Duplicate pair. Report the sample and Field Duplicate results on Appendix A.4 from their respective Form I's. Calculate and report RPD on Appendix A.4 when sample and its Field Duplicate values are both > 5xCRQL. Calculate and report the absolute difference on Appendix A.4 when at least one value (sample or duplicate) is <5xCRQL. Evaluate the aqueous Field Duplicate analysis in accordance with the

		YES	NO	N/A

QC criteria stated in Sections A.1.19.2 and A.1.19.3.

NOTE:
1. Do not transfer "*" from Form I's to Appendix A.4.
2. Do not calculate RPD when both values are non-detects.
3. Substitute MDL for CRQL when MDL > CRQL.
4. If one value is >CRQL and the other value is non-detect, calculate the absolute difference between the value > CRQL and the MDL, and use this the criteria to qualify the results.

A.1.19.2 Circle all values on the Form (Appendix A.4) for Field Duplicates that have:

RPD $\geq$ 20% or

Difference > $\pm$ CRQL

When sample and duplicate values are both $\geq$5xCRQL (substitute MDL for CRQL when MDL > CRQL),

is any RPD $\geq$ 20%?	___	[___]	___
is any RPD $\geq$ 100%?	___	[___]	___

ACTION:
If the RPD is >20% but < 100%, flag (J) only the associated sample and its Field Duplicate results $\geq$ CRQL. If the RPD is $\geq$ 100%, reject(R) and red-line only the associated sample and its Field Duplicate result $\geq$ CRQL.

A.1.19.3 When the sample and/or duplicate value(s) <5xCRQL (substitute MDL for CRQL when MDL >CRQL), is the absolute difference between sample and duplicate:

> $\pm$ CRQL?	___	[___]	___
> $\pm$ 2 x CRQL?	___	[___]	___

ACTION:
If the absolute difference is > CRQL, flag detects $\geq$ MDL but < 5xCRQL as "J" and non-detects as "UJ". If the difference is > 2xCRQL,reject (R) and red-line non-detects

		YES	NO	N/A
	and results ≥ MDL but <5xCRQL of the sample and its Field Duplicate.			

Soil/Sediment Field Duplicates

A.1.19.4	Was a soil field duplicate pair collected and analyzed? (Check Sampling Trip Report)	[___]	___	___

ACTION:
If yes, for each soil Field Duplicate pair proceed as follows:

Prepare Appendix A.4 for each Field Duplicate pair. Report on Appendix A.4 all sample and its Field Duplicate results in MG/KG from their respective Form I's. Calculate and report RPD when sample and its duplicate values are both greater than 5xCRQL. Calculate and report the absolute difference when at least one value (sample or duplicate)is < 5xCRQL. Evaluate the Field Duplicate analysis in accordance with the QC Criteria stated in Sections A.1.19.5 and A.1.19.6.

NOTE:
1. Do not transfer "*" from Form I's to Appendix A.4.
2. Do not calculate RPD when both values are non-detects.
3. Substitute MDL for CRQL when MDL > CRQL.
4. If one value is >CRQL and the other value is non-detect, calculate the absolute difference between the value > CRQL and the MDL, and apply the criteria to qualify the results.

A.1.19.5	Circle on each Appendix A.4 all values that have: RPD ≥ 35%, or Difference > ± 2xCRQL When sample and duplicate values are both ≥ 5xCRQL (substitute MDL for CRQL when MDL > CRQL),			
	is any RPD ≥ 35% but < 120%?	___	[___]	___
	is any RPD ≥ 120%?	___	[___]	___

ACTION:
If the RPD is ≥ 35% but < 120%,

		YES	NO	N/A
	flag only the associated sample and its Field Duplicate results ≥ CRQL as "J". If the RPD is ≥ 120%, reject (R) and red-line only the sample and its Field Duplicate results ≥ CRQL.			
A.1.19.6	When the sample and/or duplicate value(s) <5xCRQL (substitute MDL for CRQL when MDL > CRQL), is the absolute difference between sample and Field Duplicate:			
	> ± 2 x CRQL?	___	[___]	___
	> ± 4 x CRQL?	___	[___]	___
	ACTION: If the absolute difference is > 2xCRQL, flag Sample and its Field Duplicate resuts ≥ MDL but <5xCRQL as "J" and non-detects as "UJ". If the difference is >4xCRQL, reject(R) and red-line non-detects and detects ≥ MDL but <5xCRQL of the sample and its Field Duplicate.			
A.1.20	**Laboratory Control Sample (LCS)- Form VII**			
A.1.20.1	Was one LCS prepared and analyzed for:			
	Each SDG?	[___]	___	___
	Each matrix type?	[___]	___	___
	Each batch samples digested/distilled?	[___]	___	___
	For each Method(ICP-AES,ICP-MS,Hg,CN) used?	[___]	___	___
	Was an LCS prepared and analyzed with the samples?	[___]	___	___
	ACTION: If no for any of the above, prepare Telephone Record Log and contact CLP PO or TOPO for submittal of the LCS results. Flag (J) as estimated all the data for which an LCS was not analyzed.			
	NOTE: If only one LCS was analyzed for			

	YES	NO	N/A

more than 20 samples, then the first 20 samples analyzed are not flagged(J), but all additional samples must be qualified (J).

A.1.20.2 **Aqueous LCS**

Circle on each Form VII the LCS percent recoveries outside control limits 80-120%.

NOTE: 1.Use digested ICV as LCS for aqueous mercury
2.Use distilled ICV as LCS for aqueous cyanide

Is any LCS recovery:

Less than 50%?	___	[___]	___
Between 50% and 79%?	___	[___]	___
Between 121% and 150%?	___	[___]	___
Greater than 150%?	___	[___]	___

ACTION:
If the LCS recovery is less than 50%, reject (R) and red-line all associated sample data (detects & non-detects); for a recovery between 50-79%, flag detects as “J” all non-detects as “UJ”. if the LCS recovery is between 121-150%, flag only detects as “J”. if the recovery is greater than 150%, reject (R) and red-line all detects.

A.1.20.3 **Solid LCS**

If an analyte's MDL is equal to or greater than the true value of LCS, disregard the "Action" below for that analyte even though the LCS is out of control limits.

Is the LCS "Found" value greater than the Upper Control Limit reported on Form VII?	___	[___]	___

ACTION:

		YES	NO	N/A
	If yes, flag (J) all the associated detects ≥ MDL as estimated (J).			
	Is the LCS "Found" value lower than the Lower Control Limit reported on Form VII?	___	[___]	___
	ACTION: If yes, flag detects as "J" and non-dectes as "UJ".			
A.1.21	**ICP-AES/ICP-MS Serial Dilution - Form VIII** **NOTE**:Serial dilution analysis is required only when the initial concentration is equal to or greater than 50 x MDL.			
A.1.21.1	Was a Serial Dilution analysis performed:			
	For each SDG?	[___]	___	___
	On one of the SDG samples?	[___]	___	___
	For each matrix type?	[___]	___	___
	For each concentration range (low or med.)?	[___]	___	___
	Was a Serial Dilution sample analyzed with the SDG samples?	[___]	___	___
	ACTION: If no for any of the above, flag as estimated (J) detects ≥ MDL of all the SDG samples for which the ICP Serial Dilution Analysis was not performed.			
A.1.21.2	Was a Field Blank or PE sample used for the Serial Dilution Analysis?	___	[___]	___
	ACTION: If yes, flag as estimated (J) detects ≥ MDL of all the SDG samples			
A.1.21.3	Circle on Form VIII the Percent Differences (%D) between sample results and its dilution results that are outside the control limits ± 10%			

		YES	NO	N/A
	when initial concentrations ≥ 50 x MDLs.			
	Are results outside the control limits flagged with an "E"(Lab Qualifier) on Form VIII and all Form I's?	[___]	___	___
	ACTION: If no, write in the Contract-Problem/ Non-Compliance Section of the Data Review Narrative.			
A.1.21.4	Are any %D values:			
	> 10%?	___	[___]	___
	≥ 100%?	___	[___]	___
	ACTION: If the Percent Difference (%D) is greater than 10%, flag (J) as estimated all associated samples whose **raw data** ≥ MDL; if the %D is ≥ 100%, reject (R) and red-line all associated samples with **raw data** ≥ MDL.			
	(**NOTE:**Replace "E" with "J" or "R" as appropriate.)			
A.1.22	**Total/Dissolved or Inorganic/Total Analytes**			
A.1.22.1	Were any analyses performed for dissolved as well as total analytes on the same sample(s)?	___	[___]	___
	Were any analyses performed for inorganic as well as total analytes on the same sample(s)?	___	[___]	___
	ACTION: If yes, prepare a Form (Appendix A.5) to compare the differences between dissolved (or inorganic)and total analyte concentrations. Compute each difference on Appendix A.5 as a percent of the total analyte only when both of the following conditions are fulfilled:			
	(1) The dissolved(or inorganic)concentration is greater than total concentration, and (2) greater than or equal to 5xMDL.			
A.1.22.2	Is any dissolved (or inorganic) concentration greater than its total concentration by more than 20%?	___	[___]	___

		YES	NO	N/A
A.1.22.3	Is any dissolved(or inorganic) concentration greater than its total concentration by more than 50%?	___	[___]	___

ACTION:
If the percent difference is greater than 20%, flag (J) both dissolved/inorganic and total concentrations as estimated. If the difference is more than 50%, reject (R) and red-line both the values.

A.1.23 **Field Blank - Form I**
NOTE: **Designate "Field Blank" as such on Form I**

A.1.23.1	Was a Field/Rinsate Bank collected and analyzed with the SDG samples?	[___]	___	___
	If yes, is any Field/Rinsate Blank absolute value of an analyte on Form I greater than its CRQL(or 2xMDL when MDL>CRQL)?	___	[___]	___
	If yes, circle the Field Blank value on Form I that is greater than the CRQL,(or 2 x MDL when MDL > CRQL).			
	Is any Field Blank value greater than CRQL also greater than the Preparation Blank value?	___	[___]	___
	If yes, is the Field Blank value (> CRQL and > the prep. blank value) already rejected due to other QC criteria?	[___]	___	___

ACTION:
If the Field Blank value was not rejected, reject all associated sample data (except the Field Blank results)greater than the CRQL but less than the Field Blank value. Reject on Form I's the soil sample results whose raw values in ug/L in the instrument printout are greater than the CRQL but less than the Field Blank value in ug/L. Flag as "J" detects between the Field Blank value and 10xField Blank value. If the sample result $\geq$ MDL but $\leq$ CRQL, replace it with CRQL-U.

If the Field Blank value is less than the

		YES	NO	N/A
	Prep.Blank value, do not qualify the sample results due to the Field Blank criteria.			

NOTE:
1. Field Blank result previously rejected due to other criteria cannot be used to qualify field samples.
2. Do not use Rinsate Blank associated with soils to qualify water samples and vice versa.

A.1.24 **Verification of Instrumental Parameters - Form IX, XA, XB, XI**

A.1.24.1 Is verification report present for:

Method Detection Limits (Form IX-Annually)?	[___]	___	___
ICP-AES Interelement Correction Factors (Form XA & XB -Quarterly)?	[___]	___	___
ICP-AES & ICP-MS Linear Ranges (Form XI-Quarterly)?	[___]	___	___

ACTION:
If no, contact CLP PO/TOPO for submittal from the laboratory.

A.1.24.2 **Method Detection Limits - Form IX**

A.1.24.2.1 Are MDLs present on Form IX for:

All the analytes?	[___]	___	___
All the instruments used?	[___]	___	___
Digested and undigested samples and Calib.Blanks?	[___]	___	___
ICP-AES and ICP-MS when both instruments are used for the same analyte?	[___]	___	___

ACTION:
If no for any of the above, prepare Telephone Record Log and contact CLP PO/TOPO for submittal of the MDLs from the laboratory. Report to CLP PO and write in the Contract Problems/ Non-Compliance Section of the Data Review Narrative if the MDL concentration is not less than ½ CRQL.

		YES	NO	N/A
A.1.24.2.2	Is MDL greater than the CRQL for any analyte?	___	[___]	___
	If yes,is the analyte concentration on Form I greater than 5 x MDL for the sample analyzed on the instrument whose MDL exceeds CRQL?	[___]	___	___

ACTION:
If no, flag as estimated (J) all values less than five times MDL for the analyte whose MDL exceeds the CRQL.

A.1.24.3 **Linear Ranges - Form XI**

A.1.24.3.1	Was any sample result higher than the high linear range for ICP-AES or ICP-MS?	___	[___]	___
	Was any sample result higher than the highest calibration standard for mercury or cyanide?	___	[___]	___
	If yes for any of the above, was the sample diluted to obtain the result reported on Form I?	[___]	___	___

ACTION:
If no, flag (J) as estimated the affected detects ($\geq$ MDL) reported on Form I.

A.1.25 **ICP-MS Tune Analysis - Form XIV**

A.1.25.1	Was the ICP-MS instrument tuned prior to calibration?	[___]	___	___

ACTION:
If no, reject (R) and red-line all sample data for which tuning was not performed.

A.1.25.2	Was the tuning solution analyzed or scanned at least five times consecutively?	[___]	___	___
	Were all the required isotopes spanning the analytical range present in the tuning solution?	[___]	___	___
	Was the mass resolution within			

		YES	NO	N/A
0.1 amu for each isotope in the tuning solution?		[___]	___	___
	Was %RSD less than 5% for each isotope of each analyte in the tuning solution?	[___]	___	___
	ACTION: If no for any of the above, qualify all results ≥ MDL associated with that Tune as estimated "J", and all non-detects associated with that Tune as "UJ".			
A.1.26	**ICP-MS Internal Standards - Form XV**			
A.1.26.1	Were the Internal Standards added to all the samples and all QC samples and calibration standards (except the Tuning Solution)?	[___]	___	___
	Were all the target analyte masses bracketed by the masses of the five internal standards?	[___]	___	___
	ACTION: If none of the Internal Standards was added to the samples, reject (R) and red-line all the associated sample data (detects & non-detects). If internal standards were used but did not cover all the analyte masses, reject (R) and red-line only the analyte results not bracketed by the internal standard masses.			
A.1.26.2	Was the intensity of an Internal Standard in each sample within 60-125% of the intensity of the same Internal Standard in the calibration blank?	[___]	___	___
	If no, was the original sample diluted two fold, Internal Standard added and the sample re-analyzed?	[___]	___	___
	Was the %RI for the two fold diluted sample within the acceptance limits (60-125%)?	[___]	___	___
	ACTION: If no for any of the above, flag detects as "J" and non-detects "UJ" of all the analytes with atomic masses between the atomic mass of the internal standard lighter			

than the affected internal standard, and the atomic mass of the internal standard heavier than the affected internal standard.

A.1.27 **Percent Solids of Sediments**

A.1.27.1 Are percent solids in sediment(s):

< 50%? ___ [___] ___

ACTION:
If yes, qualify as estimated (J) all detects and non-detects of a sample that has percent solids less than 50%(i.e.,moisture content greater than 50%).

NOTE:
Flag(J) only the sample results that were not previously flagged due to other QC criteria.

Inorganic Data Review Narrative

Case# _____ **Site:** _____ **Matrix: Soil** ____

SDG# _____ **Lab:** _____ **Water** ____

Sampling Team: _____ **Reviewer:** _____ **Other** _____

A.2.1 **Data Validation Flags**:
The following flags may have been applied in red by the data validator and must be considered by the data user.

J - This flag indicates the result qualified as **estimated**

R and Red-Line - A red-line drawn through a sample result indicates **unusable** value. The red-lined data are known to contain significant errors based on documented information and must not be used by the data user.

U - This data validation qualifier is applied to sample results ≥ MDL when associated blank is contaminated

Fully Usable Data - The results that do not carry "J" or "red-line" are fully **usable**.

A.2.2 **Laboratory Qualifiers**:
The CLP laboratory applies a contractual qualifier on all

Form I'S and the QC Form when a QC analysis is outside the control limits. These qualifiers are not applied on the Lotus or XLS spreadsheets. These qualifiers and their meanings are as follows:

N: This qualifier indicates the lack of accuracy in the reported result, and is applied when matrix spiked sample recovery is outside the control limits.

E: This qualifier indicates the the presence of interference, and is applied when the ICP serial dilution is outside the control limits.

*****: This qualifier indicate the lack of precision , and is pplied on Fom I'S and Form VI when the Lab Duplicate analysis is outside the control limits.

U: This is a concentration qualifier that laboratory applies to a non-detected result which is essentially less than the Method Detection Limit(MDL). A non-detected result of an analyte is indicated by the Contract Required Quantitation Limit (CRQL) of that analyte suffixed with "U".

J: This is also a concentration qualifier that laboratory applies to a positive result below the CRQL.

NOTE: The laboratory qualifiers are crossed out and replaced with the appropriate data validation qualifiers (J, R or U) by the data validator.

APPENDIX E
OFF-SITE LABORATORY QUALITY CONTROL MEMORANDUM AND QUALITY ASSURANCE PLAN

This page intentionally left blank.

GUIDING PRINCIPLES

General

- The purpose of laboratory and field QC sampling and testing is to determine whether the sampling and testing process is prone to contamination, matrix effects, and/or laboratory performance problems.
- We must use the data provided to us along with reasonable assumptions as to how the data was generated.
- The quality control criteria discussed within; i.e., LCS, MS/MSD (or MS and laboratory duplicate), and surrogate spike compound recoveries must be considered in total when making a decision as to how to qualify or not qualify results.
- Organic MS/MSD samples will be spiked with the analytes listed in Table 3 of this Technical Scope of Work; LCS blank spikes must be spiked with the full analyte list.

LCS for all methods

If any LCS is outside control limits, the LCS and associated batch samples must be reprepared and reanalyzed. If the lab has a good reason to think that the exceedance is due to the measurement step only, then the LCS extract can be reanalyzed only possibly after some corrective action on the instrument. However, if the reanalysis results are not within QC acceptance criteria, then the LCS must be reprepared and reanalyzed along with all batch samples, and the results must be within QC acceptance criteria.

Surrogate Recoveries for Organic Methods

If surrogate recoveries are not within QC acceptance criteria for a field sample and QC sample surrogates are within criteria, the field sample must be reprepared and reanalyzed to confirm the exceedance. If a QC sample surrogate recovery is outside criteria, the QC sample must be reprepared and reanalyzed and the results must be acceptable.

Calibration – GC/MS

For the initial calibration, all average RRFs must be > 0.05, except for 1,4-dioxane in the 8260B analysis. If an average RRF< 0.05, corrective action (reanalysis) must be performed. If an analyte %RSD is > 90%, the initial calibration must be reanalyzed for that analyte.

For the continuing calibration, all RRFs must be > 0.05; otherwise, correction action (reanalysis) must be performed. If the %D value between the continuing calibration RRF and the initial calibration mean RRF is > 90%, the continuing calibration must be reanalyzed.

Calibration – GC Pesticides

The %RSD from the initial calibration must be less than the allowable limits provided in the Region II SOP HW-44 Validating Pesticide Compounds, Organochlorine Pesticides by 8081B. The %D for each analyte in the continuing calibration must be within ± 20%. If not, the instrument must be recalibrated (5 point initial calibration).

Breakdown Standard/Dual Column Confirmation
The DDT/endrin breakdown standard must be analyzed as per Region II SOP HW-44 Validating Pesticide Compounds, Organochlorine Pesticides by 8081B. Dual column confirmation analysis must also be conducted.

Elements
For elements, the lab must run either a MS/MSD or MS/lab replicate pair with each batch. For the elements calibration, if the correlation coefficient is not > 0.995, then the calibration standards must be reanalyzed. If the continuing calibration is not within the limits provided in Region II SOP HW-2, corrective action (reanalysis) must be taken.

Summary of 2008 LQAP Changes

- All amendments made since 2007 publishing were formally incorporated.
- Minor text additions/clarifications made throughout based on auditor corrective action response.
- Discussion of secondary containment policy augmented in Section 4.9, SOP 023 retired (reference removed).
- Since SOP 300 and SOP 798 were combined upon reissuance, reference to SOP 798 was corrected in Section 7.3.
- Base policy for corrective actions to be completed within 21 calendar days of notification by the QA Department added to Section 11.
- Section 11.2 NCR process updated to reflect LIMS electronic interface.
- Citation iterations updated in Bibliography.

TABLE OF CONTENTS

1. INTRODUCTION

Paragon Analytics (Paragon) is a full service environmental and radiochemistry laboratory located in Fort Collins, Colorado. Paragon is a division of DataChem Laboratories, Inc., and as such, has sister laboratories located in Salt Lake City, Utah; Cincinnati, Ohio; and Everett, Washington. Technical operations at each facility are conducted autonomously.

Paragon performs analyses for organic, inorganic, and radiological constituents in a variety of matrices. Paragon specializes in serving the Department of Energy (DOE), Department of Defense (DoD), and architect-engineering firms. Paragon routinely provides hardcopy data packages and electronic data deliverables that are easily validated by external validators.

The management team at Paragon applies an integrated approach to quality assurance, client service, and efficient operations, that enables Paragon to produce compliant data that meet or exceed all technical and service requirements as prescribed by our clients. This Laboratory Quality Assurance Plan (LQAP) defines Paragon's quality assurance (QA) program, and communicates Paragon's goals, values and policies regarding quality, ethical conduct, data integrity, and optimized operations.

1.1 MISSION STATEMENT

A mission statement is a broad statement that is intended to capture why an organization exists and how it is to serve its shareholders, customers and employees. The mission statement is the pinnacle of what an organization is ultimately striving to achieve. *Paragon's Mission is to provide high quality analytical chemistry and radiochemistry services on time, and to maintain a stimulating workplace that provides personal growth for employees.*

1.2 VISION STATEMENT

A vision statement is a statement intended to capture the one or two things that an organization wants to achieve over the mid- to long-term. It is the integration of an articulated set of longer-range goals. It is that which is just over the horizon. *Paragon's Vision is to be recognized by our peers and clients as the premier analytical chemistry and radiochemistry laboratory in the United States*.

1.3 QUALITY POLICY

Paragon's goal is to produce data of known, documented, and appropriate quality in accordance with applicable Federal or state regulations and requirements, National Environmental Laboratory Accreditation Conference (NELAC) standards, and client-prescribed criteria.

Within this framework, Paragon performs analyses in strict accordance with promulgated methodologies, including:

- USEPA, SW-846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods;

- USEPA, Methods for Chemical Analysis of Waters and Wastes (MCAWW);
- USEPA, Methods for Determination of Metals in Environmental Samples;
- American Public Health Association (APHA), Standard Methods for the Examination of Water and Wastewater (SM);
- USEPA, Methods for Determination of Organic Compounds in Drinking Water;
- American Society for Testing and Materials (ASTM), Annual Book of ASTM Standards, Volume 11 – Water and Environmental Technology;
- American Society for Testing and Materials (ASTM), Annual Book of ASTM Standards, Volume 12 – Nuclear Energy;
- USDOE, Environmental Measurements Laboratory (EML), Procedures Manual (HASL-300);
- USEPA, Eastern Environmental Radiation Facility (EERF), Radiochemistry Procedures Manual;
- USDOE, Radiological and Environmental Sciences (RESL), Procedures Manual;
- USEPA, Prescribed Procedures for Measurement of Radioactivity in Drinking Water; and
- US, Code of Federal Regulations (40 CFR).

1.4 STATEMENT ON WASTE, ABUSE AND FRAUD

Paragon is committed to achieving our goals in the most efficient and effective manner possible, thus avoiding wasteful use of resources. This is accomplished by assuring the proper utilization of Paragon's purchased materials and equipment, and time and ability of our personnel. *Any Paragon employee who has any suggestion or concern regarding Paragon's practices, is encouraged to discuss his/her idea or question with their Department Manager, the Quality Assurance Manager, and/or the Laboratory Director*. A means of confidentially reporting concerns anonymously is also available. Grievances and allegations of unethical conduct will be fully investigated, and appropriate actions taken.

Training regarding Paragon's Waste, Abuse and Fraud policies is provided to every new staff member, and to all employees lab-wide as an annual refresher. Paragon's policies regarding waste, abuse and fraud are included in **Appendix A**.

1.5 CODE OF ETHICS AND DATA INTEGRITY STATEMENTS

Paragon is responsible for creating a work environment that enables all employees to perform their duties in an ethical manner. *It is Paragon's expectation that all employees exhibit professionalism and respect for clients and each other in all interactions and tasks.* Paragon requires that each employee abide by the following guidelines:

- Every Paragon employee is responsible for the propriety and consequences of his or her actions. Each employee shall conduct him or herself in a professional manner towards all clients, regulators, auditors, vendors, and other employees. Professional conduct relates to honesty, integrity, respect, and tolerance for cultural diversity.

- Every Paragon employee shall perform all assigned duties in accordance with Paragon's established quality assurance policies and quality control procedures that have been developed to ensure conformance with contractual and regulatory requirements.

- Paragon expects all employees to use professional judgment and to document all situations thoroughly. It is the responsibility of each Paragon employee to consult the Department Manager or Quality Assurance Manager when atypical or unusual situations occur and to disclose and document the decision-making process. Every employee must disclose any instance of noncompliance. Paragon reports all noncompliance issues affecting data to the client.

- It is the responsibility of each Paragon employee to report any suspicion of unethical conduct to the Quality Assurance Manager or the Laboratory Director.

Data integrity procedures provide assurance that a highly ethical approach to testing is a key component of all laboratory planning, training and implementation of methods. The following list provides examples of improper, unethical, or illegal practices that Paragon ***does not*** tolerate:

- Falsification of records to meet method requirements (e.g., sample records, logbooks, sample results, electronic records). This includes intentional misrepresentation of the date or time of analysis (e.g., intentionally resetting a computer system's or instrument's date and/or time to make it appear that a date/time requirement has been achieved); and unwarranted manipulation of computer software (e.g., improper background subtraction to meet ion abundance criteria for GC/MS tuning compounds).

- Improper use of manual integrations performed to meet calibration or method quality control criteria (e.g., peak shaving or peak enhancement

performed solely to meet quality control requirements).

- Selective exclusion of data to meet quality control criteria (e.g., eliminating initial calibration points without technical justification).

- Misrepresentation of quality control samples (e.g., adding surrogates or tracers after sample extraction, omitting preparation steps for quality control samples; over- or under- spiking).

- Reporting results without analyses to support the results (i.e., dry-labbing).

- Notation of matrix interference as basis for exceeding acceptance limits in interference-free matrices.

- Intentional plagiarism or willful misrepresentation of another employee's work as one's own (e.g., Initial or Continuing Demonstration of Capability study (IDOC, CDOC) or Proficiency Testing (PT) study.

Strict adherence to Paragon's Code of Ethics and Data Integrity is essential to the reputation and continued health of our business. All Paragon employees are required to acknowledge their responsibility and intent to behave in an ethical manner by attesting to the requirements described above upon joining the Paragon staff, and annually thereafter. Included in **Appendix A** are the ethics documents that every employee is required to review and attest to.

1.6 REVIEW, REVISION, DISTRIBUTION AND HIERARCHY OF QA DOCUMENTS

Current copies of pertinent quality assurance guidance documents, such as Paragon's LQAP, the NELAC standards, the US DOE Quality Systems for Analytical Services (QSAS), the US DoD Quality Systems Manual (QSM) and others, are posted to the Paragon network so that they are accessible to every employee. Laboratory Standard Operating Procedures (SOPs) and other method references are also posted to the network for lab-wide employee access. Project-specific requirements are disseminated to the laboratory via Laboratory Information Management Systems (LIMS) program specifications (discussed further below).

Paragon recognizes a hierarchy of guidance that provides for comprehensive definition, yet flexible coverage, thus enabling both overall program and site-specific needs to be met. An overview explaining this hierarchy is given below. **SOP 926** provides detailed guidance on the review, revision, and distribution of laboratory-generated controlled documents.

1.6.1 LABORATORY QUALITY ASSURANCE PLAN

The LQAP is an encompassing controlled-document that describes

Paragon's quality assurance program and policies. All systems, policies, and procedures have been developed and implemented in accordance with applicable USEPA requirements, regulations, and guidance; the current NELAC standards; and requirements set forth in various client quality assurance documents and contractual specifications. This document has been prepared in accordance with these referenced documents, as well as others, cited in the attached **Bibliography**. The LQAP is intended to provide a 'quality requirements framework', including quality control (QC) procedures to be followed in the absence of project-specific requirements (note that project-specific requirements are communicated to laboratory staff via LIMS program specifications, which are discussed subsequently).

The Quality Assurance Manager (QAM) bears primary responsibility for ensuring that the LQAP meets industry standards. Proposed revisions to the LQAP are approved by key laboratory personnel (i.e., Laboratory Director, Quality Assurance Manager, and every Technical or Department Manager). Following approval, the QAM posts the revised LQAP to the Paragon network, and distributes attestation notifications to each laboratory Department, which are returned signed to the QA Department, to document implementation of the revised LQAP. Every employee must review the LQAP upon hire and annually thereafter. Archival records of all LQAP iterations are maintained by the Quality Assurance Department.

1.6.2 STANDARD OPERATING PROCEDURES

The second kind of controlled-document in the hierarchy of quality assurance guidance are the Standard Operating Procedures (SOPs). An SOP defines the QA/QC requirements for each method and describes in detail how personnel perform procedures and evaluate data. SOPs pertaining to general practices (e.g., standards, temperature monitoring, etc.), administrative procedures (e.g., procurement of supplies and materials, etc.) and health & safety requirements (e.g., calibration and use of the hand and foot monitor), are also maintained by Paragon. It is Paragon's intent that the information contained in our SOPs are both method-compliant, and accurately reflect actual practice. *Suggestions for SOP content clarification or revision are encouraged.* Although an overall biennial publication schedule is maintained, comments received are addressed as promptly as practicable. *Where SOP directives differ from concepts discussed in the LQAP, the requirements of the SOPs supersede the requirements of the LQAP.*

Every employee must review assigned SOPs upon hire and annually thereafter. Additionally, certain key staff (e.g., Technical and Department Managers), are designated as 'primary authors', whose function is to coordinate and approve updates to the SOPs for which

they have been assigned primary responsibility. The primary author, in conjunction with the QAM, determines if it is appropriate to re-release an SOP without revision (update due date), or to revise the SOP. The primary author and QAM determine the appropriateness of comments received, and revise accordingly. All processing notifications regarding SOPs, as well as plan documents (e.g., LQAP, etc.), are generated through Paragon's SOP and Training Records database. The appropriate Technical Manager, QAM and Laboratory Director perform a final review of the SOP and provide signatures prior to the document's publication. Following approval, the QAM publishes the document and posts it to the Paragon network, and distributes attestation notifications to each laboratory Department, which are returned signed to the QA Department to document implementation of the revised SOP. Dated copies of SOPs are removed from access as new revisions become available. *Laboratory personnel may only refer to current, controlled SOPs while performing procedures.* These practices ensure that the timeframe in which specific SOP iterations were in force is traceable.

Controlled documents that are printed out for reference or review are only valid for 30 calendar days from the date printed. An embedded document header identifies the document, and directs the person printing the document to write-in the date printed, and to discard the printout within 30 days. (3/9/09 DAS)

A list of current SOPs is provided in **Appendix H**. The Quality Assurance Department manages the review, revision and controlled distribution of documents and maintains associated records.

1.6.3 LABORATORY MANAGEMENT INFORMATION SYSTEMS (LIMS) PROGRAM SPECIFICATION

The last and most specific controlled-document in this hierarchy is the LIMS program specification. The LIMS program specification is a distillation of client Quality Assurance Project Plan (QAPjP) or contractual requirements, prepared electronically by the Paragon Project Manager (PM), in collaboration with the QAM and applicable Department Managers. This custom program specification, along with the associated LIMS test code nicknames, contain directives and controls that govern testing and reporting data. The program specification is often limited in scope and addresses only those QA/QC criteria required for a specific project. *When the client's requirements differ from those stated in the SOPs and/or LQAP, the project-specific LIMS program specification requirements supersede the others.* ***It is the responsibility of all personnel who work with samples or data to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of the samples or data.***

2. LABORATORY ORGANIZATION AND RESPONSIBILITIES

This section provides an overview of Paragon's organization and defines key personnel, their responsibilities, and the lines of communication between these employees. An organization chart that illustrates reporting relationships is provided in **Appendix B**.

2.1 GENERAL REQUIREMENTS FOR LABORATORY PERSONNEL

Paragon maintains sufficient personnel to perform analytical services for our clients. Each employee must have a combination of experience and education that enables him or her to demonstrate a specific knowledge of his or her job function, and a general knowledge of laboratory operations, test methods, QA/QC procedures, and records management. *All personnel are responsible for complying with the requirements that pertain to his/her assigned duties.*

2.2 KEY PERSONNEL

Education, experience and skill requirements for these positions are addressed in the **DataChem Career Ladder** document. Functional responsibilities are further discussed below.

In the event of a temporary absence, key personnel must notify other key staff of their absence and reassign their duties to another employee who is qualified to perform the assigned duties. For example, a PM may assign another PM to cover his or her duties; a Department Manager may assign a senior chemist to cover his or her duties within the Department; and the Laboratory Director may assign a Manager to cover his or her duties.

2.2.1 LABORATORY DIRECTOR

The Laboratory Director (and/or designee) is responsible for:

- All laboratory operations, including: business functions such as marketing, sales and financial issues; technical functions such as sample control, preparation, analysis, data management; and quality assurance;
- Providing input and support to proposal processes, including interacting with the Sales, Technical and Quality Assurance staff, to ensure that the laboratory is capable of complying with client and regulatory requirements;
- Supervising all personnel through Management staff, who ensure that QA/QC procedures are being performed and that any nonconformances or discrepancies are documented and remedied properly and promptly;
- Ensuring that corrective actions relating to Findings from internal and external audits are completed in a timely fashion;
- Ensuring that the laboratory has the appropriate resources and facilities to perform analytical services;
- Ensuring that sufficient numbers of qualified personnel are employed to supervise and perform the work of the laboratory;

- Defining the minimum level of education, experience, and skills necessary for all positions in the laboratory;

- Ensuring that only those vendors and supplies that are of adequate quality are used; and

- Directing the performance of the annual Managerial Review.

2.2.2 QUALITY ASSURANCE MANAGER

The Quality Assurance Manager reports to the Laboratory Director and is independent of daily operation and production requirements. Therefore, the QAM is able to evaluate data objectively and perform assessments without production influence. *The QAM has authority to stop work if systems are sufficiently out of control to compromise the integrity of the data generated.*

The QAM shall have documented training and/or experience in QA/QC procedures; knowledge of quality systems as defined by NELAC; and a general knowledge of the analytical test methods for which data review is performed.

The QAM (and/or designee) is responsible for:

- Defining and implementing the quality system;

- Developing and maintaining a pro-active program for prevention and detection of improper, unethical, or illegal practices (e.g., single- or double-blind proficiency testing studies, electronic data audits, maintaining documents that identify appropriate and inappropriate laboratory and data manipulation practices);

- Ensuring continuous improvement of laboratory procedures via training, control charts, proficiency testing studies, internal audits, and external audits;

- Coordinating the laboratory's participation in state and Federal certification programs;

- Scheduling the review and distribution and maintaining distribution records of controlled documents, including plans (e.g., LQAP, etc.) and SOPs;

- Reviewing Requests For Proposal (RFPs) to ensure compliance with required QA/QC practices;

- Facilitating external audits;
- Overseeing or conducting internal audits of the entire operation annually (technical, system, data, electronic);
- Coordinating, preparing and approving external and internal audit responses and corrective actions;
- Managing the laboratory's participation in proficiency testing (PT) studies;
- Reviewing nonconformances and approving corrective actions;
- Reviewing and updating control chart QC limits per established procedures;
- Ensuring that Method Detection Limit (MDL) studies are performed and documented per requirements;
- Managing the reference standards used in the calibration and/or verification of support equipment (e.g., weights, thermometers, balances);
- Revising the LQAP annually in accordance with industry standards;
- Maintaining an archival system for data records; and
- Maintaining technical and quality assurance training records, including employee demonstrations of capability (DOCs).

2.2.3 HEALTH & SAFETY MANAGER/RADIATION SAFTETY OFFICER (RSO)

The Health & Safety Manager/Radiation Safety Officer (RSO) reports to the Laboratory Director. This Manager is responsible for establishing and monitoring adequate systems, procedures and training to ensure that the laboratory staff, facilities and operational activities conducted, function in a manner that minimizes employee risk of illness and injury, is compliant with all applicable regulations pertaining to matters of safety and health, and that limits the financial liability of the corporation as it relates to these matters. As RSO, this Manager is also responsible for discharging the duties and requirements prescribed by Paragon's Radioactive Materials License.

Key responsibilities of the Health & Safety Manager/RSO (and/or

designee) include:

- Ensuring that all employees have sufficient training to perform their job without unnecessary risk of illness or injury, providing health and safety, including radiation safety, training for new employees, and maintaining health and safety-related training records;

- Providing procedural guidance in the form of the Chemical Hygiene Plan (CHP), Radiation Protection Plan (RPP), Respiratory Protection Plan (ResPP), Emergency and Contingency Plan (ECP) and Health and Safety SOPs, and ensuring that these guidances are reviewed annually by laboratory staff;

- Ensuring that the laboratory facilities are maintained and operated in a safe manner, including:

    (a) Performing routine safety inspections of all operational areas;

    (b) Performing routine radiation surveys and managing the radiation dosimetry program; and

    (c) Performing personal monitoring, as indicated, for chemical and other exposures.

- Maintaining the laboratory's Colorado Radioactive Materials License and ensuring compliance with the terms of the license. Included in this responsibility are:

    (a) Procuring and managing radioactive sources and standards;

    (b) Maintaining the laboratory's radioactive materials inventory, which also includes directing prescreen analyses that provide initial characterization of potential sample radioactivity;

    (c) Overseeing permitted low level radioactive materials releases to the sanitary sewer; and

    (d) Ensuring that radioactive materials waste are transported in accordance with all Federal and state regulations, and are transferred only to facilities that possess a radioactive materials license.

2.2.4 FACILITIES/WASTE COMPLIANCE MANAGER

The Facilities/Waste Compliance Manager, reports to the Laboratory Director. This Manager is responsible for day-to-day management of the building and serves as the primary point of contact for all matters related to waste collection and disposal.

The Facilities/Waste Compliance Manager (and/or designee) is responsible for:

- Coordinating heating, ventilation, and air-conditioning (HVAC) systems operation and maintenance;
- Maintaining the uninterruptible power supply (UPS) and coordinating maintenance and repairs to the electrical system;
- Maintaining the in-house vacuum system;
- Coordinating repairs to the building (e.g., doors, locks, windows, cabinetry);
- Maintaining the building's security and fire alarm system;
- Interfacing with fire inspectors; and responding to security and fire alarms on a 24-hour basis;
- Implementing waste reduction procedures;
- Managing the accumulation of radioactive waste in the laboratory;
- Developing and maintaining Satellite Accumulation Areas (SAAs) and 90-Day Storage Areas;
- Overseeing all waste disposal operations performed by Paragon, including (1) ensuring compliance with Federal, state, and local regulations for waste handling and disposal in accordance with RCRA, TSCA, and radioactive waste disposal regulations; (2) managing hazardous waste shipments to Temporary Storage and Disposal Facilities (TSDFs); (3) managing sanitary sewer releases; and (4) managing sample archives and the return of samples and sample residues to clients;
- Training personnel on proper techniques for sample handling and waste disposal, according to standards implemented by Federal, state, and local authorities and maintaining associated

training records; and

- Supervising the Sample Receiving Department.

2.2.5 INFORMATION SYSTEMS MANAGER

The Information Systems (IS) Manager reports to the Laboratory Director. This Manager is responsible for administering the network, maintaining data recovery systems, and for managing personal computing (PC) equipment and peripherals, thus supporting instrumentation and LIMS. The IS Manager (and/or designee) is responsible for:

- Managing and maintaining the laboratory computer system. This function includes determining and purchasing appropriate hardware and verifying that its function meets intended objectives, establishing network server structure, and developing and implementing proper maintenance and backup procedures;

- Procuring, configuring and maintaining all printers and copiers;

- Serving as a technical resource on computer-related issues;

- Documenting related operating procedures through SOPs, manuals or other proprietary documentation;

- Supervising recovery of all systems in the event of a disaster;

- Along with the Laboratory Information Systems Manager, analyzing information flow in the laboratory and suggesting the most effective hardware, applications software, and/or programming changes as solutions to meet long-term customer requirements; also, implementing those changes in data acquisition and management by purchasing hardware or software, where software is not developed internally; and

- Maintaining and implementing existing and future communications systems, including all internet and telephone systems.

2.2.6 LABORATORY INFORMATION MANAGEMENT SYSTEMS MANAGER

The Laboratory Information Management Systems (LIMS) Manager reports to the Laboratory Director, and bears the primary responsibility

for the LIMS, which serves the needs of the technical, business, and management functions of the laboratory.

Key responsibilities of the LIMS Manager (and/or designee) include:

- Designing and developing information systems that relate to data capture and reporting;
- Maintaining and supporting applications that access LIMS and maintaining and supporting database back-end applications used for LIMS;
- Documenting changes and procedures through SOPs, manuals or other proprietary documentation;
- Developing software, as needed, using the appropriate tools, and per industry standard methodologies and validations;
- Overseeing and assisting with the implementation, testing and verification of upgrades made to instrument software;
- Coordinating all efforts to automate and improve electronic systems and processes throughout the laboratory;
- Developing interfaces necessary to achieve the requirements for client-specified electronic data deliverables (EDDs), and managing all deliverable formats provided to clients (hardcopy, electronic); and
- Providing training, as applicable, for all LIMS-related applications.

2.2.7 PROJECT MANAGER

Project Managers report to the Laboratory Director. *The Project Manager serves as the primary point of contact between clients and Paragon.* Each PM (and/or designee) is responsible for:

- Managing and coordinating the laboratory's performance after contract award, by defining technical and service requirements for personnel via LIMS, and interacting with clients and laboratory personnel to ensure that technical criteria and client service needs are met, including monitoring holding times (if appropriate) and deliverable deadlines, for all project sample analyses;
- Reviewing and approving any nonconformances reported by

the laboratory and notifying the client, if appropriate, and communicating with clients pro-actively to ensure that all client service and technical concerns are resolved promptly;

- Reviewing all final reports for completeness, compliance with project requirements, clerical accuracy, and reasonableness;

- Generating, as directed by prompts provided in Paragon's proprietary EDD generator, and transmitting EDDs to their clients as required; and

- Communicating to the Laboratory Director any potential need for new or improved capabilities based on clients' feedback.

2.2.8 TECHNICAL OR DEPARTMENT MANAGER

Technical and Department Managers report to the Laboratory Director. These Managers exercise day-to-day supervision of laboratory personnel, procedures, and reporting of results. They maintain technical expertise in their area of specialization (e.g., organics, inorganics, radiochemistry).

Technical Managers and Department Managers (and/or their designee) are responsible for:

- Providing technical education and training to personnel, certifying that personnel with appropriate educational and/or technical background perform all tests for which the laboratory is accredited, and providing documentation of employee capability and training to the QA Department, and ensuring that training and documentation are up to date;

- Assigning job tasks and prioritizing analyses;

- Developing and implementing a preventive maintenance program for instrumentation in their laboratory, and ensuring that all equipment is maintained, serviced, and properly calibrated;

- Monitoring QA/QC standards of performance, including ensuring that corrective actions are developed, documented, and implemented for all external and internal audit Findings, PT study failures, and other corrective actions;

- Monitoring the validity of the analyses performed and data generated in the laboratory to ensure the production of

compliant data, including, contributing to and/or overseeing data review processes;

- Reviewing and revising (if appropriate) assigned SOPs, at minimum, annually, to ensure that SOPs are compliant with promulgated methodologies and reflect current practice;

- Maintaining current, compliant MDL studies for all methods, matrices, analytes, columns, and instruments;

- Coordinating and approving the purchase of reagents, standards, glassware, and equipment that meet requirements;

- Providing input to the Laboratory Director regarding methodologies, personnel resources, software, and instrumentation; and assisting in the evaluation and/or development of new methods and technologies that improve Paragon's ability to meet clients' needs;

- Reviewing RFPs and assisting in the preparation and submission of proposals; and

- Interacting with the Quality Assurance, Information Systems, and Health and Safety Departments to ensure that the laboratory is capable of complying with client and regulatory requirements.

2.3 GENERAL TECHNICAL PERSONNEL

A chemist (analyst) or technician reports to a Technical or Department Manager. This employee performs work in accordance with Paragon's controlled documents (e.g., SOPs, LQAP, etc.) and project-specific requirements as defined by the applicable LIMS specification. *Paragon believes that quality begins at the bench.* Accordingly, these employees are key contributors to Paragon's success.

A chemist or technician is responsible for:

- Demonstrating proficiency in the analyses for which they are responsible ***before*** analyzing samples (e.g., performing acceptable Initial Demonstration of Capability, IDOC studies), and documenting this demonstration of proficiency, as well as Continuing Demonstrations of Capability (CDOCs), with the QA Department;

- Performing analyses, recording all data accurately, directly, and promptly, and interpreting and reviewing data according to established procedures;

- Performing an annual review of assigned SOPs and plan documents;
- Complying with all QA/QC requirements that pertain to their job function;
- Complying with all health, safety, and waste disposal requirements, as applicable;
- Maintaining and repairing instrumentation;
- Demonstrating good house-keeping practices;
- Disclosing all instances of nonconformances promptly and in writing using the NCR process (**SOP 928**); and
- Participating in training sessions.

3. QUALITY ASSURANCE INDICATORS AND OTHER MEASUREMENT PARAMETERS

Paragon's objective is the development and implementation of policies and procedures that provide results of known, documented, and appropriate quality. This LQAP defines general policies for the analysis, documentation, evaluation, validation, and reporting of data. Specific, detailed procedures for chain-of-custody, calibration of instruments, analysis, reporting, quality control, audits, preventative maintenance, and corrective actions, are provided in SOPs as listed in **Appendix H**.

In order to produce data of known, documented, and appropriate quality, Paragon:

- maintains an effective quality assurance program that measures and verifies laboratory performance;
- provides for a Quality Assurance Department that is independent of the operational groups and that has stop-work authority, and that has the responsibility and authority to audit the laboratory and develop and enforce corrective actions;
- evaluates technical and service requirements of all analytical services requests before accepting samples from a client/project. This evaluation includes a review of facilities, instrumentation, staffing, turnaround times, and any project-specific quality control or reporting requirements;
- provides sufficient flexibility to allow controlled changes in routine methodology in order to achieve client-specific data requirements as prescribed in client documents and contracts;
- documents initial demonstration of capability (IDOC) and continuing demonstration of capability (CDOC) for all methods according to Appendix C of

the NELAC standards;

- performs all analyses according to promulgated methods or methods developed and validated by Paragon and documented in SOPs;

- recognizes as soon as possible and discloses and corrects any factors that adversely affect data quality; and

- maintains complete records of sample submittal, raw data, laboratory performance, and completed analyses to support reported data.

3.1 DATA QUALITY INDICATORS

Data Quality Indicators (DQIs) are qualitative and quantitative statements developed by data users that specify the quality of data from field and laboratory data collection activities in order to support specific decisions or regulatory actions. The DQIs describe *what* data are needed, *why* the data are needed, and *how* the data will be used to address the problem being investigated. DQIs also establish qualitative and quantitative goals that allow the data user to determine whether the data are of sufficient quality for the intended application.

The principal DQIs are **precision**, **accuracy** (bias), **representativeness**, **completeness**, and **comparability** (i.e., the PARCC parameters). The following sections define and describe the application of these parameters. The QA/QC protocols used for the majority of analyses are adopted from SW-846 and 40 CFR methodologies, the USEPA Organics and Inorganics CLP SOWs, and various radiochemistry guidances, which contain detailed descriptions of the quality control measures routinely employed.

3.1.1 PRECISION

Precision is an expression of the reproducibility or degree of mutual agreement among independent measurements as the result of repeated application of the same process under similar conditions. Precision refers to the distribution of a set of reported values about the mean, or the closeness of agreement between individual test results obtained under prescribed conditions. Precision reflects random error and may be affected by systematic error. Precision characterizes the natural variation of the matrix and the contamination that may vary within that matrix. For chemical parameters that do not allow homogenization prior to analysis (e.g., volatile organics analysis), one must review precision values carefully.

Analytical precision is a measurement of the variability associated with duplicate or replicate analyses of the same sample in the laboratory. Analytical precision is determined by the analysis of matrix spike/matrix spike duplicates (MS/MSD), laboratory control sample

pairs (LCS/LCSD), or by unspiked duplicate samples (DUPs). Total precision is a measurement of the variability associated with the entire sampling and analysis process, and is determined by analysis of duplicate or replicate *field* samples, thus incorporating the variability introduced by both the field and laboratory operations.

Precision is independent of bias or accuracy, and reflects only the degree to which the measurements agree *with one another*, not the degree to which they agree with the true or accepted value of the parameter measured. Precision for stable chemistry analyses is typically expressed as relative percent difference (RPD), as defined below:

$$RPD(\%) = \frac{X_1 - X_2}{(X_1 + X_2)/2} \quad (100)$$

where:

RPD = Relative Percent Difference

X_1, X_2 = analyte value of sample 1 and sample 2

Precision, for radiochemical analyses, is typically measured in terms of Duplicate Error Ratio (DER), calculated as follows:

$$DER = \frac{|S - D|}{2 * \sqrt{\sigma^2{}_S + \sigma^2{}_D}}$$

where:

DER = Duplicate Error Ratio

S, D = analyte values of (S)ample and (D)uplicate

σ = One Sigma error value associated with sample result

RPDs or DERs are compared to the control limits established for the analysis method, or other quality control criteria as prescribed in the applicable LIMS program specification. Precision objectives vary per analytical method. Sample homogeneity/non-homogeneity is an important factor that influences the precision of duplicate sample results.

3.1.2 ACCURACY

Accuracy is an expression of agreement between the measured and known or accepted reference values. Accuracy is the measure of the closeness of an observed value to the "true" value (e.g., theoretical or reference value or population mean). Accuracy is influenced by random error and systematic error (bias) that occur during sampling and analytical procedures; therefore, accuracy reflects the total error associated with a measurement. A measurement is accurate when the

value reported does not differ significantly from the known concentration of the spike or standard.

Accuracy is typically measured by determining the percent recovery of known target analytes (i.e., a surrogate or matrix spike) that are spiked into a field sample or reagent water or simulated solid matrix (laboratory control sample). Surrogate recovery is reported and is used to assess method performance for each sample analyzed for volatile and semivolatile organic compounds. For organic and inorganic parameters, the stated accuracy objectives apply to spiking levels at or near the midpoint of the calibration curve. For radiochemical analyses, the spiking levels for the control spikes may vary from five to fifty times the method reporting limit.

Percent recovery is calculated as:

$$R(\%) = \frac{(C_1 - C_2)(100)}{C_3}$$

where:

R% = Spike amount recovered
C_1 = Concentration of analyte in spiked sample
C_2 = Concentration of analyte in unspiked sample
C_3 = Concentration of spike added

Acceptance limits are usually based upon established laboratory performance for similar samples. Other quality control criteria may be prescribed in the applicable LIMS program specification. Recoveries outside the established limits may indicate some assignable cause other than normal measurement error, and the need for corrective action. This corrective action may include reanalysis of the quality control sample, recalibration of the instrument, reanalysis of the affected samples in the batch, re-preparation of samples in the batch, or flagging and qualifying the data as suspect if the problem cannot be resolved. For contaminated samples, recovery of matrix spikes may depend on homogeneity, matrix interference, and dilution requirements for quantitation.

Both accuracy and precision are calculated for each batch and the associated sample results must be interpreted by considering theses specific measures. The quality assurance objectives for precision and accuracy are to achieve the quality control acceptance criteria specified in the appropriate analytical procedure.

For organic analyses, precision and accuracy are determined by using matrix spike and matrix spike duplicate samples and/or surrogate spike compounds and laboratory control samples. For inorganic analyses,

precision and accuracy are determined by using duplicate samples or matrix spike duplicate samples (precision) and matrix spike and laboratory control samples (accuracy). For radiological analyses, precision and accuracy are determined from the results of duplicate samples or matrix spike duplicate samples (precision), laboratory control sample duplicates (precision) and laboratory control samples (accuracy).

Samples identified as field blanks cannot be used for duplicate or matrix spike sample analyses.

QC limits for accuracy and precision may be developed from intra-laboratory historical data or adopted from prescribed limits required by the client. If quality control acceptance criteria do not exist for a given method, then the laboratory may establish advisory control limits derived from a minimum of four data points. Until verified by a statistically significant data population, the control limits will be considered as advisory limits only, and the laboratory will not automatically initiate reanalysis if these limits are not achieved. See Section 9.3 for further discussion of control limits and control charts.

Bias describes the systematic error of a measurement process that causes errors in one direction from the true value. Sources of bias include incomplete homogenization before subsampling and incomplete extraction of target analytes. Calibration drift, which is the nonrandom change in a measurement system over time, is another example of systematic error, and is detectable by the periodic measurement of calibration check standards. *Bias is **not** equivalent to accuracy.*

3.1.3 REPRESENTATIVENESS

Representativeness is a qualitative element. It expresses the degree to which data accurately and precisely represent a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition within a defined spatial and/or temporal boundary.

Sample handling protocols (e.g., holding times, storage, preservation and transportation) have been developed to preserve the representativeness of the samples. Proper documentation establishes that quality control protocols have been followed, and sample identification and integrity are ensured. *Paragon makes every attempt to ensure that the aliquots taken for analysis are homogenous and representative of the samples received.*

3.1.4 COMPARABILITY

Comparability is a qualitative expression of the confidence with which one data set can be compared to another. Comparability is achieved by:

- following established, standardized, and approved sample collection techniques and analytical methods;
- achieving holding times;
- reporting results in common units;
- using consistent detection levels; and
- reporting data according to consistent rules.

See Chapter 10 of this LQAP for further discussion of standard units typically used to report various analytical parameters.

3.1.5 COMPLETENESS

Completeness is an expression of the amount of valid data obtained from a measurement system compared to the amount that was expected to be obtained under normal conditions. Completeness is the percentage of measurements that are judged to be usable (i.e., that meet project-specific requirements). Completeness goals are defined in the site sampling and analysis plan, QAPjP or contract, and vary with the size and complexity of the project. Completeness goals of 80-95% are traditionally accepted as realistic. Paragon's objective is 100% completeness for samples unaffected by matrix interferences.

It is recognized that some samples are highly contaminated with target and/or non-target compounds, which necessitate cleanups, multiple analyses, and/or extensive dilutions. In these instances, the internal QC results for a sample help to demonstrate the impact upon recoveries and detection limits due to these atypical situations.

Factors that adversely affect completeness include:

- receipt of samples in which chain-of-custody or sample integrity is compromised in some manner (e.g., broken containers, improperly preserved);
- receipt of insufficient volume to perform initial analyses or repeat analysis if initial efforts do not meet QC acceptance criteria;
- receipt of samples for which more than 50% of the holding time

has expired; and

- receipt of samples that contain high levels of contamination that can cause persistent effects on instrumentation designed for trace-level analyses.

The equation used to calculate completeness is:

$$C\% = \frac{S}{R} (100)$$

where:

C = completeness
S = number of successful analyses
R = number of requested analyses

The USEPA has established that there is a 5% probability that the results obtained for any one analyte will exceed the control limits established for the test as a result of random error, assuming the confidence interval is established at 95% (preamble to 40 CFR Part 136, Vol. 49, No. 209, October 26, 1984). As the number of compounds measured increases in a given sample, the probability for realizing statistical error also increases. The number of compounds present in various methods (e.g., GC/MS Methods SW8260B and SW8270C, ICAP Method SW6010B and Gamma Spectroscopy Method EPA 901.1), increases the probability that one or more analytes will not meet acceptance criteria, to significantly more than the 5% per analyte frequency. The number of target analytes included in these methods can be used to show that a minimum of four to seven target analytes will exceed the control limits established for these methods as a result of the statistical probability for random error. *Establishing quality control criteria that are not consistent with the measurement of the quality objectives for which they are intended is discouraged.*

3.2 TRACEABILITY

Traceability is the extent to which results can be substantiated by hard-copy documentation, electronic or computer-generated data calculations, computer software, and data generation. Traceability documentation exists in two forms: (1) that which links final numerical results to authoritative measurement standards, and (2) that which explicitly describes the history of each sample from collection to analysis. Measurement traceability is further discussed in Chapter 7 of this LQAP.

3.3 SENSITIVITY

The term sensitivity is used in a broad sense to describe the various limits that enable a laboratory to meet project-specific data quality objectives (DQOs).

These limit types include: instrument detection limit (IDL), method detection limit (MDL), method quantitation limit (MQL) or method reporting limit (RL), contract-required detection limit (CRDL), and contract-required quantitation limit (CRQL).

3.3.1 IDL AND MDL

The IDL is a minimum value that addresses the detection capability of the instrument *only*, hence IDL studies are performed on a per analyte per instrument basis. IDL studies are particularly important to metals analyses. These IDL studies must be conducted on a quarterly basis, per method requirements, or whenever there is a significant change in instrument components or reagents.

The MDL is a minimum value that addresses the detection capability for the sample preparation procedures and the instrument. Hence, Paragon performs MDL studies for each preparatory and determinative method combination, matrix, instrument, and analytical column. MDL studies are performed with a frequency that's prescribed by the method, at minimum, annually. Some Wet Chemistry methods require MDL studies to be performed every 6 months. MDL studies are also required for method validation, and whenever the basic chemistry of a procedure changes.

MDL is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. MDLs are determined from replicate analysis (minimum of seven) of a sample in a given matrix containing the analyte(s). 40 CFR Part 136 Appendix B defines the MDL is defined as:

$$MDL = t(n-1, 1-\alpha, = 0.99) \times \sigma$$

where:

σ = Standard deviation of the replicate analyses

$t(n-1, 1-\alpha, = 0.99)$ = Student's t-value appropriate to a 99% confidence level

An MDL check sample, at a concentration about half that spiked for the MDL study and approximately twice the calculated MDL, is also analyzed with the MDL study (immediately following), to demonstrate that the MDL is valid. Performance criteria is that the MDL check is acceptable if it yields a confident positive detection (i.e., all analytes in the check sample can be identified by method-specified criteria). If MDL check sample results do not support the determined MDL, appropriate corrective actions must be taken (e.g., repeat MDL check sample analysis, repeat MDL study, raise MDL).

An MDL study is not performed for radiological analyses, or any components for which spiking solutions are not available or relevant (e.g., pH, ignitability, etc.). Reporting limits for these kinds of parameters, where applicable, are established based on the laboratory's knowledge of extraction efficiency, instrument sensitivity, and experience with the procedure. **SOP 329** provides additional information about MDL studies.

Although the QA Department provides oversight, each Department Manager is responsible for ensuring that all IDL and MDL studies are conducted and documented as needed.

Results calculated between the MDL and the MQL (RL), see section following, contain a significant amount of error (approximately ±100%). Therefore, values reported between the MDL and MQL (RL) are qualified as estimated – 'J' flagged for organic parameters, 'B' flagged for inorganic parameters. Also, IDL and MDL values are based on an interference-free matrix, and cannot evaluate the effects of sample matrix on the calculated IDL or MDL. Therefore, established IDLs and MDLs may not be achievable in environmental matrices.

3.3.2 MQL, RL

Paragon defines MQL (RL) as the analyte concentration at or above which the laboratory's precision and accuracy requirements can be routinely demonstrated and achieved. The statistical error associated with this region of a calibration curve is significantly smaller than that associated with the region near the MDL. The MQL (RL) values for most analytes reported by Paragon are numbers that are approximately 3 to 5 times the values of the MDL for those analytes. It is Paragon's policy to analyze a calibration standard at or below the MQL (RL) when performing an initial calibration.

The MQL or RL is the lowest level that can be reliably measured by a laboratory with defined limits of precision and accuracy. The USEPA CLP SOW uses the terms CRDL and CRQL to describe *contractually-required* levels of reporting. These reporting terms do not describe instrument sensitivity.

3.4 MINIMUM DETECTABLE CONCENTRATION

The minimum detectable concentration (MDC) is used for radiochemical procedures and is defined as the concentration at which there is a 95% confidence that an analyte signal will be distinguishable from an analyte-free sample.

The general formula for calculating the MDC is based on calculations derived by Curie (Curie, L.A., "Limits for Qualitative Detection and Quantitative

Determination," Analytical Chemistry 40(3); pp. 586-693; 1968) and is calculated as follows:

$$MDC = \frac{(4.65\ X\ \sigma_b) + 2.71}{T * K}$$

where:

MDC = Minimum Detectable Concentration

σb = Standard deviation of the measurement background

T = Sample count time

K = Factor for incorporating efficiency, abundance, aliquot yield, ingrowth and decay, and activity conversion factors

3.5 TOTAL PROPAGATED UNCERTAINTY

Total propagated uncertainty (TPU), is a summation of the various uncertainties present in a measurement process, and is an integral part of every reported radiochemical value. TPU, reported as ±TPU, is the expressed estimated measure of the total uncertainty inherent in that reported radiochemical result.

The components of the TPU are classified as either random or systematic. Random uncertainties, also called counting uncertainties (CU), derive from the statistically random (normally distributed) nature of radioactive decay, and are estimated as the square root of the total number of counts acquired during analysis. In cases where the chemical yield is determined by the analysis of a radioactive tracer, the yield uncertainty (YU) is also a random uncertainty, and is estimated as the square root of the total number of tracer counts acquired. CU and YU are calculated in activity units to afford comparability to the sample result.

Systematic uncertainties are attributable to actual errors in the measurement of a physical quantity. For example, if a balance has an accuracy of $\pm$0.1%, the results of those gravimetric measurements are not normally distributed, but rather are assumed to be biased by that amount. Estimates of systematic uncertainties in laboratory processes are somewhat subjective, but should be supported by empirical data whenever possible. Systematic uncertainties associated with the preparation of a sample are called preparation uncertainties (PU), and are defined based on the number of volumetric and gravimetric measurements, quantitative transfers, etc. Systematic uncertainties associated with the analysis, called instrument uncertainties (IU), include biases associated with sample positioning, standard values, calibration coefficients, etc. PU and IU are typically provided as a percentage of the final result. To afford comparability to sample results, PU and IU are expressed in activity units by multiplying the percentage by the sample activity (A).

All contributions to TPU are considered to be independent of each other, and the individual contributions are combined as the square root of the sum of the squares (see equation below). The final TPU result is expressed in activity units, such as

pCi/g or pCi/L.

$$TPU = \sqrt{CU^2 + YU^2 + (A * PU)^2 + (A * IU)^2}$$

TPU is expressed as a value at a specific confidence interval. The default convention at Paragon is to provide the TPU at the 2-sigma confidence interval. This asserts approximately a 96% confidence level that the actual sample value is within the reported uncertainty range of the calculated result. **SOP 708** provides more information about the calculation and use of TPU.

3.6 QUALITY ASSURANCE PROJECT PLAN (QAPjP) EXCEPTIONS

As a result of the unknown nature of environmental samples prior to analysis, Paragon has minimal control over analytical and quality control complications that result from sample matrix conditions. These conditions may include highly concentrated samples that contain target compounds of interest and/or non-target components; high organic content (both natural and synthetic); and extremes in pH, viscosity, solubility, etc. Each of these conditions may require a different approach.

Analysis for some samples may be achieved through the use of reduced aliquot sizes. Some sample matrices may require the laboratory to use cleanup and/or dilution techniques in order to analyze the sample by the desired protocol. Unfortunately, reduction of analysis aliquot or diluting a sample necessitates raising reporting limits (RLs) or MDCs, and often adversely impacts the calculation of surrogate, tracer, and matrix spike compound recoveries.

Paragon has the responsibility to identify matrix interferences that preclude the generation of 'compliant' data. This determination may be made by demonstrating reproducibility (i.e., reanalysis of the affected sample) to show that the quality control measurement failure resulted from sample matrix conditions beyond the laboratory's control and not as a result of analytical error. For example, if the surrogate or tracer recoveries are outside of control limits, then samples may be re-extracted and/or reanalyzed. Repeated non-compliant results indicate that sample matrix probably prevented the laboratory from reporting results deemed compliant.

Analytical projects containing particularly "dirty" samples (i.e., highly contaminated with target compounds and/or matrix co-extractives) will often fail to meet pre-established completeness goals (set forth in the QAPjP), when prior site history does not reveal the matrix constituents issues. Although the laboratory performs all analytical testing and cleanup procedures by the prescribed protocols, the results obtained may not meet validation criteria as a result of elevated reporting limits or the frequency at which surrogate, internal, tracer, or matrix spike recoveries fail to meet acceptance limits. In cases where the laboratory is unable to meet quality control criteria as a result of sample

matrix complications, results that are qualified by data validation guidelines may still be useful to the end user of the data.

Paragon is committed to adhering to the method requirements and quality control procedures prescribed by our clients. Paragon strives to produce compliant data, however, uncertainties associated with environmental samples may preclude the laboratory's ability to generate fully compliant data. Paragon will not assume responsibility for conditions beyond our reasonable control, that directly impact the "validity" versus the usability of the associated analytical data generated by the laboratory.

4. SAMPLE CONTAINERS, PRESERVATION, HANDLING, HOLDING TIMES

Defining the magnitude and nature of an environmental problem, and developing an appropriate solution, requires the collection of representative samples for laboratory analysis and data evaluation. The objective of field sampling is to remove a small portion of an environment that is representative of the entire body. *Analytical methods have been standardized, but the results of analyses are only as good as the sampling protocol and the sample preservation and handling methods.* Defining sampling procedures and the quality elements applicable to environmental testing is beyond the scope of this document, and beyond the responsibility of the laboratory.

Although the laboratory is not responsible for sample collection, it is responsible for maintaining the integrity of the sample after receipt. After the sample has been collected, the constituents of the sample must remain as close as possible to the field condition (i.e., degradation must be prevented). The length of time that these constituents will remain stable is related to their character and the preservation method used. Preservation is accomplished by the addition of chemical preservatives and/or storage at a controlled temperature, and by the strict observation of prescribed maximum holding time allowances. **Appendix C** lists sample container types, preservation requirements, and holding times.

4.1 FIELD SUPPORT

Unless not required by the client, sample kits are prepared at the laboratory to provide the client with all of the sample containers, preservatives and documentation needed for the analyses needed for a project. Paragon provides shipping containers, custody documents, custody seals, clean sample bottles, labels, applicable high-purity chemical preservatives for water samples, trip blanks, and, upon request, "blue ice" packs to support field-sampling events. Hard-sided, insulated, "picnic" coolers are typically used to transport samples from the field to the laboratory. These coolers meet or exceed all protocol requirements (i.e., USDOT, USEPA, ASTM) for shipping. Paragon **SOP 205** provides further information on sample kits.

4.2 SAMPLE CONTAINERS

Paragon provides certified clean (I-Chem 300™, Eagle Pitcher Level 1, or equivalent) sample bottles for sample collection. Used sample bottles are never used by the laboratory. The Sample Receiving Department maintains certificates

of cleanliness that are provided by the vendor for all sample bottles. These certificates are provided to the client upon request. Containers are stored in clean areas, away from laboratory processes, to prevent exposure to fuels, solvents, and other contaminants.

4.3 SAMPLE PRESERVATION AND HOLDING TIMES

Paragon provides the required chemical preservatives for water samples and, upon request, "blue ice" packs, for thermal preservation during transport. Typically, high quality reagent grade chemical preservatives (i.e., acids, solutions, etc.) are added to individual sample bottles, as appropriate per method and US Department of Transportation (DOT) requirements. Only trace metals grade nitric acid is used for preservation of metals or radiochemical samples, as applicable. It is the responsibility of those collecting the samples to properly use these materials (e.g., don't rinse or overfill container such that the preservative is washed out), and to ensure that chemical preservation requirements are met, and proper preservation techniques (chilling) are performed. Holding times begin with the collection of samples and continue until analysis is complete. See **Appendix C** for a summary of container, preservation and holding time requirements specific to various analyses and matrices.

4.4 SAMPLE RECEIPT SCHEDULE

Paragon receives samples six days of the week, Monday through Saturday. Paragon requests that clients ship samples for delivery within one day of collection, and give advance notice to the laboratory regarding shipment of RUSH samples or samples with short hold time requirements. Shipping containers received at the laboratory on holidays or after business hours are placed in a walk-in refrigerator and opened on the next business day, unless other arrangements are made in advance.

4.5 CHAIN-OF-CUSTODY

Chain-of-custody (COC) documentation begins with field sampling and continues through laboratory analysis and disposal. A chain-of-custody record that identifies all individuals who handle the sample is used to establish an intact, continuous record of the physical possession, storage, and disposal of collected samples, including their aliquots, extracts or digestates. The chain-of-custody record is initiated in the field by field personnel who complete a COC form listing all samples. This form contains the following information and remains with the samples during transport:

- client project name and project location;
- field sample number/identification;
- date and time of sample collection;
- matrix;
- container type and number of containers for each sample;

- preservative;
- analysis requested;
- sampler's remarks and signature;
- signature of person relinquishing samples and date and time relinquished;
- custody seal number (if applicable); and
- designation of matrix spike/matrix spike duplicate (MS/MSD) samples (optional).

  Note that contingent upon the sample matrix and analysis to be performed, additional sample volume may need to be submitted to accommodate MS/MSD analyses.

All transfers of samples, except directly between commercial couriers, must be recorded on the chain-of-custody form via the "relinquished" and "received by" sections. All information, except signatures, should be clearly printed.

The USEPA National Enforcement Investigations Center (NEIC) defines evidence of custody as:

- in one's actual possession, or
- in one's view, after being in one's physical possession, or
- having been in one's possession and then locked or sealed to prevent tampering, or
- kept in a secure area, restricted to authorized personnel only.

To ensure that sample custody objectives of traceability are achieved for every project, the chain-of-custody initiated in the field, is continued and maintained internally throughout the laboratory per the requirements specified in **SOP 318.** Internal chain-of-custody begins with sample acceptance and login (**SOP 202**), is maintained as samples are distributed for use throughout the laboratory (further discussed in LQAP Section 4.10), and concludes with final sample disposition (i.e., return to the client or disposal). Paragon applies a unique barcode to each sample bottle received, and maintains several scanners and PCs throughout the laboratory to document and assist with sample, aliquot, extract and digestate movement throughout the facility. This electronic process is accomplished through LIMS, which retains records of all sample and fraction transactions made.

4.6 SAMPLE ACCEPTANCE POLICY

Paragon's sample acceptance policy requires that a sample meet the following conditions:

- The sample shall be completely documented (sample identification,

location, date and time of collection, collector's name, preservation type, sample type, any special remarks concerning the sample);

- The sample shall be identified by a unique identifier using durable labels completed in indelible ink;
- The sample shall be collected in adequate volume;
- The sample shall be collected in an appropriate container;
- The sample shall be delivered to the laboratory with at least one-half the holding time remaining;
- The sample shall not exceed allowed radioactivity levels; and
- The sample shall not show signs of contamination, breakage, or leakage.

Sample receipt discrepancies are documented by Sample Receiving Department personnel on the Condition of Sample Upon Receipt, Form 201 (**Appendix D**), which is forwarded to the Project Manager as part of the workorder folder. Where samples do not meet the criteria stated above, the Project Manager requests information from the client before proceeding. If the client can provide the information and, in cases of compromised sample integrity, directs the laboratory to proceed, then data acquired from the sample(s) analysis is reported and the problems noted during sample receipt are disclosed in the narrative of the final data report.

In support of the protection of employee health and of Paragon's radioactive materials license, Paragon observes prescreening protocols that designate or determine samples with radioactive content. Detailed procedures for conducting radiological survey of incoming sample packages are given in **SOP 008**, further details regarding prescreening protocols are given in **SOP 703**.

4.7 SAMPLE RECEIPT PROTOCOLS

Upon receipt of the field samples at the laboratory, personnel ensure that sample bottles are maintained according to storage requirements, and in a manner that does not contaminate the samples (see section 4.9 for further details).

Ascension numbers that increment serially each month of the year are applied as workorder number assignments. Following sample arrival and initial screen for USDOT compliance and removable radioactivity, sample receiving personnel inspect the sample and record any discrepancies using Form 201 (**Appendix D**). The following information is documented:

- client and project name, as applicable;
- presence/absence and condition of (i.e., intact, broken) custody seals on the shipping containers;
- presence/absence of chain-of-custody and completeness;

- sample condition (intact, broken, leaking);
- presence/absence of removable sample tags;
- agreement/non-agreement between the sample labels, tags, chain-of-custody, and any other client documentation;
- receipt of adequate sample volume;
- sample temperature, where applicable;
- presence/absence of headspace in VOA and ^{222}Radon vials; and
- chemical preservation, where applicable.

Sample temperature is verified upon receipt by measuring the temperature of the temperature blank (if available) or by measuring the temperature of a representative samples(s) with an infrared (IR) temperature device. See **SOP 210** for instructions and procedures related to IR temperature guns. Samples that require thermal preservation are considered acceptable if the temperature upon arrival is between just above freezing to 6ºC. Samples that require thermal preservation but are hand-delivered to the laboratory immediately after collection, may not meet the temperature requirement. If the hand-delivered sample is packed in ice, then Sample Receiving personnel record its temperature and note that the chilling process was initiated.

4.8 SAMPLE LOGIN POLICIES AND PROCEDURES

After completing sample receipt procedures, the following sample information and analytical requests are entered into LIMS under the unique workorder number assigned:

- client name, contact, address, phone number;
- Paragon Project Manager;
- date and time of sample receipt;
- unique laboratory identifier for each sample;
- sample description, including date/time of collection;
- analyses requested (LIMS calculates holding times for each analysis);
- program specification or other special instructions, if applicable; and
- due date.

In general, a group of received samples is assigned one workorder number in LIMS. Each sample container is assigned a unique Paragon identifier (barcode) that is placed on each container. This unique identification includes all samples, subsamples, and subsequent extracts and/or digestates.

See **SOPs 201 and 202** for additional information about sample login and

distribution.

4.9 SAMPLE STORAGE

Samples requiring thermal preservation are stored in designated refrigerated storage areas that are maintained just above freezing to 6ºC, centered at 4±2ºC. Freezer storage areas are maintained at freezing to ⁻20ºC, centered at ⁻15±5ºC. The temperature of refrigeration units is monitored continuously using electronic min/max thermometers and recorded each business day, near to the beginning of the work shift. If the temperature exceeds the prescribed range, then corrective action is taken and documented immediately, and the client notified, if appropriate; see **SOP 326** for further details. Directives for corrective action pertaining to catastrophic failure of cooling units (as well as laboratory ovens, etc.) are included in Paragon's Emergency and Contingency Plan (ECP).

Samples are stored away from all standards, reagents, food and other sources of contamination. Samples are stored in such a manner as to prevent cross-contamination. For example, pure product or potentially contaminated samples are tagged as "hazardous" and stored within a secured area, separate from other samples. Paragon provides designated sample storage areas according to the following parameter groups: metals, inorganics (WetChem), semivolatile organics, volatile organics, fuels, and radiochemical analyses.

Samples having suspected radioactive activity and scheduled also for stable chemical analyses are refrigerated. Samples to receive tritium analyses are refrigerated. Samples designated for radiochemistry analyses *only*, with the exception of tritium, are segregated and maintained at ambient temperature.

To effectively monitor the storage and potential contamination of volatile organic samples, Paragon observes a refrigerator blank program (detailed in **SOPs 511, 512**).

To provide for the safe containment of sample material that could be released as a result of sample container failure, all samples are stored in secondary containment bins. These secondary containment bins are of a sturdy and inert nature, and are sufficient in size to fully contain the sample(s) in the event of a spill, leak or breakage. The bin(s) may be uniquely identified (labeled) to assist in locating samples via the chain-of-custody system. The bins are thoroughly cleaned between uses.

4.10 SAMPLE ACCESS

It is Paragon's policy that neither samples nor data may be released to unauthorized personnel. In order to ensure that this policy is maintained, the laboratory facilities are maintained under controlled access and are restricted to authorized personnel only (see **SOP 132** for further details pertaining to building security).

As discussed previously in this section, Paragon personnel follow strict sample handling and internal chain-of-custody procedures to ensure the integrity of all data generated. Limited access electronic controls in LIMS further protect the validity of the data results. Samples are scanned and transacted in LIMS when they are removed from a storage area for preparation or analysis. The sample ID, analyst, date, time, and location are recorded with each transaction. Likewise, the samples are scanned and transacted in LIMS upon their return to the storage unit. Barcode scanning and LIMS transaction is also observed for the return of sample remainders to the client, and for disposal (see LQAP Section 4.13). Paragon **SOP 318** contains internal chain-of-custody details; procedures for sample return to the client are described in **SOP 027**.

4.11 SAMPLE HOMOGENIZATION AND SUBSAMPLING

Obtaining a representative aliquot of sample for testing is critical to the representativeness of the analytical results obtained. Proper subsampling techniques, particularly for solid matrices, are a component of each bench employee's technical instruction. Sample homogenization procedures prior to radiochemical analysis are prescribed in **SOP 721**. Representative subsampling procedures for stable chemistry analyses, may be discussed in individual preparatory SOPs, and additional guidance, "Subsampling Soils and Sediments", is also posted to the Paragon network for ready reference. Client-specified procedures for homogenization or aliquotting may also be defined in the applicable LIMS program specification.

4.12 SUBCONTRACTING ANALYTICAL SERVICES

Paragon strives to identify the need to subcontract specific analytical procedures during the bid response process. Analyses may also need to be subcontracted, however, in cases of emergency where the ability to meet sample holding time criteria is endangered. In these instances, Paragon compiles a list of qualified subcontract laboratories that are suitable to perform the needed analyses, then submits the list to the client for selection and approval. If NELAC certified analyses are to be subcontracted, the subcontract laboratory must also hold NELAC certification for the analyses that are to be conducted. The same concept regarding subcontract laboratory qualifications may apply for other program samples (e.g., DOD laboratory approval status is required for the analyses to be conducted in the case of DOD samples that must be subcontracted for analysis). Note that for subcontracted DOD sample analyses, the subcontract laboratory must receive project-specific approval from the DOD client before any samples are analyzed.

Paragon's Project Manager must receive permission from the client, in writing, before the subcontract laboratory can be procured and samples forwarded to the laboratory. At a minimum, the specific terms of the subcontract laboratory agreement must include:

- analytical method required (e.g., SW-846, 40 CFR, etc.);

- number and type of samples expected;
- project-specific quality control requirements;
- deliverables required (hardcopy, electronic);
- laboratory certifications required;
- price per analysis; and
- turnaround time requirements.

See **SOP 103** for guidance on evaluating a subcontract laboratory's qualifications. Detailed procedures pertaining to submitting samples to a subcontract laboratory are provided in **SOP 207**.

4.13 SAMPLE DISPOSAL

After completion of sample analysis and submission of the project report, unused portions of samples are retained by the laboratory for a minimum of 90 days from date of invoice. Samples are disposed or returned to the client according to the nature of the samples and the client's specifications. Paragon documents and retains all conditions of disposal and correspondence between all parties concerning the final disposition of the sample.

Samples, digestates, leachates, extracts, and process waste that are characterized as hazardous, radioactive, or mixed waste are disposed in accordance with Federal and state laws and regulations. Paragon maintains records to demonstrate that all disposal efforts were conducted in compliance with these laws and regulations. This documentation includes the unique sample identity, date of disposal, nature of disposal (e.g., sample depleted, sample disposed in hazardous waste facility, sample disposed in mixed waste facility, sample returned to client); and name of the individual responsible for disposal.

5. LABORATORY FACILITIES

Appendix E contains a diagram of the Paragon laboratory facility. Paragon maintains constant and consistent test conditions throughout the facility (e.g., temperature, air purification, lighting). All entrances and exits are wired to a laboratory-wide security system that is monitored continuously. Access to the laboratory area from the front offices is restricted by means of keypad locks requiring numeric security code entry. Visitors must sign in at the front desk and must be escorted at all times (some vendors are allowed access without continuous escort, in order to facilitate repairs or deliveries). Further details pertaining to building security are provided in **SOP 132**.

The following sections highlight areas of the laboratory that are involved with sample receipt, handling, preparation, and analysis of samples.

5.1 SAMPLE RECEIPT AREAS

Paragon's sample receiving area consists of a large dedicated room of more than

500 ft^2. It contains two fume hoods and radiation survey equipment to safely handle incoming radioactive and mixed waste samples. There is an outside access door to facilitate sample delivery and shipping of sample kits. Adjacent to the sample receiving area is the bottle storage room and the radioactivity prescreening lab.

5.2 SAMPLE STORAGE AREAS

Paragon's sample receiving area has a walk-in cooler and a freezer that are used for temporary storage of samples that require thermal preservation. In addition, there are several designated sample storage locations throughout the laboratory that are used to store samples scheduled for specific analyses (see section 4.9 for further details).

5.3 SAMPLE PREPARATION AREAS

The laboratory has nine sample preparation/extraction/digestion areas. These areas are divided as follows: six radiochemistry preparation laboratories; two organics extraction laboratories; and one metals digestion laboratory. The total floor space of these six laboratories is approximately 4500 ft^2.

Laboratory preparation procedures are segregated as much as possible to minimize the potential for contamination, maximize processing efficiency, and maintain analytical integrity. Rigorous cleaning of glassware (**SOPs 334** and **720**) and apparatus ensures that cross-contamination is minimized. Each laboratory area has a dedicated or locally shared HVAC system that continuously exchanges the laboratory air with filtered and conditioned outside air. There are 34 laboratory hoods in the six sample preparation areas, and each sample preparation area has at least one hood that is capable of maintaining an average face velocity of 100 feet per minute.

5.4 STANDARDS PREPARATION AREAS

A dedicated radiochemical standards preparations room, and an organics standards preparation area are maintained. Metals and inorganic standards are stored independently from sample storage areas and are prepared in their respective laboratory areas.

5.5 ANALYTICAL LABORATORIES

The Paragon facility houses a volatile organics analysis (VOAs) laboratory that is on an upper level of the building, away from all other laboratory operations. The Paragon facility also houses one general chemistry (WetChem) laboratory, two radiochemical counting rooms, a total organic carbon (TOC) laboratory area, two gas chromatograph (GC)/high performance liquid chromatography (HPLC) labs, a semivolatile organic compounds (SVOCs) laboratory, and a metals laboratory that contains separate inductively coupled plasma (ICP), mercury, and inductively coupled plasma/mass spectrometry (ICP/MS) rooms.

5.6 OTHER LABORATORY AREAS

Other areas of the Paragon facility include a tank room for compressed gasses, several waste management areas, telephone and computer storage rooms, staff offices, Reporting Group and Reports Management data processing rooms, and various scanning/reproduction and supply storage areas.

5.7 DEIONIZED WATER SYSTEM

Within the laboratory, there are two main deionized (DI) water distribution systems available for glassware cleaning, bulk reagent preparation, and general use. One system is located in the janitor's area and serves the radiochemistry side of the facility (ASTM Type II water generated). The other system is located adjacent to the metals laboratory area and serves the stable chemistry side of the facility (ASTM Type I water generated). These DI water systems are capable of continuously delivering water that meets the requirements specified for the ASTM water type, and are monitored and documented each business day to ensure that the water meets these criteria. Paragon also maintains a third treated water system that is used to support washing of stable chemistry laboratory glassware.

DI water is defined as municipal tap water that has been treated by passing it through a particulate filter, activated carbon unit, cation exchange resin, anion exchange resin, mixed bed resin, and a final "polishing" cartridge. This water contains no detectable heavy metals or inorganic compounds of interest, and is free of organic compounds of analytical interest above Paragon's routine reporting limits. Additionally, a benchtop Millipore Synergy 185™ unit is available for laboratory use should further finishing be desired.

SOP 319 provides detailed information pertaining to Paragon's DI water systems, including discussions of independent monthly testing to verify that electronic readouts of water quality are accurate, maintenance by a vendor contractor, and corrective measures to be taken should water quality degrade to below acceptable limits.

6. ANALYTICAL PROCEDURES

Paragon is capable of analyzing various matrices, including surface and groundwater, drinking water, soil, sediment, vegetation, tissue, filter and aqueous and solid wastes. Paragon does not routinely perform analyses on air (non-particulate), however, analysis of these matrices may be available through our sister laboratories. Analyses are performed using promulgated methodologies as requested by the client and their regulators, and as required by Paragon's certifying authorities. *New iterations of established methodologies are evaluated on an ongoing basis and implemented as client needs dictate.* Analytical procedures are conducted in strict adherence with SOPs that describe the preparation, analysis, review and reporting of samples. In some cases, these SOPs may also describe proprietary methods developed by Paragon and used per the client's request. A list of Paragon's analytical capabilities is presented in **Appendix C.** A list of Paragon's SOPs is provided in **Appendix H**. References for analytical procedures used are presented in the

attached **Bibliography**. Paragon also, upon request, develops and validates procedures that are more applicable to a specific client objective.

6.1 ANALYTICAL METHODS

Selection of the appropriate method is dependent upon data usage and regulatory requirements. Paragon may modify existing methods in order to:

- achieve project-specific objectives;
- incorporate modifications or improvements in analytical technology;
- address unusual matrices not covered in available methods; and
- provide analytical capabilities for an analyte for which there are no promulgated methodologies.

Paragon discloses method modifications to our clients by providing the appropriate SOP for review.

6.2 METHOD COMPLIANCE

Compliance is the proper execution of recognized, documented procedures that are either approved or required. Strict adherence to these procedures is necessary to provide data acceptable to a regulatory body of competent jurisdiction in a specific regulatory context.

Compliance is, however, separate from, but not inconsistent with, technical scientific quality. Paragon understands that the expectations of our clients commonly include the assumption that data and reports will satisfy a regulatory purpose and will be found acceptable and compliant with regulatory requirements.

6.2.1 UNDERSTANDING THE REGULATORY FRAMEWORK

Compliance is not likely to be achieved in the absence of an understanding of the regulatory framework. Upon receipt of a statement of work (SOW), Paragon attempts to ascertain, prior to accepting samples:

- what regulatory jurisdiction pertains to a project (USEPA, State Department of Health, etc.)
- within the regulatory jurisdiction, what body of regulations has primacy (RCRA, SDWA, CWA, etc.); and
- within this context, what QA/QC protocols are required (DOE, DoD -- AFCEE, NFESC, etc.).

Paragon works with our clients to achieve a mutual understanding of all

requirements and makes the following commitments:

- Paragon will proactively attempt to identify and understand the regulatory context of client's needs.
- Paragon will strive to be expert in understanding and executing the regulatory requirements for compliance.
- Paragon will ensure that we have the capabilities, resources and facilities to perform the requested analyses.
- Paragon will identify and disclose to clients instances of non-compliance in a forthright and timely fashion.

6.2.2 RESOLVING COMPLIANCE CONTRADICTIONS

Multiple regulatory jurisdictions may overlap for a specific project, which may cause uncertainty or contradictions to arise. Similarly, methods and protocols may be prescribed in a scope of work or QAPjP that either will not achieve stated or implied DQOs, or that conflict with the regulatory requirements. Paragon will attempt to detect these inconsistencies and contradictions and will disclose them to clients in a timely fashion. Paragon voluntarily accepts a responsibility to provide information to our clients; however, the primary responsibility for resolving inconsistencies with regulators remains with the client.

6.2.3 DISCLOSURE OF NON-COMPLIANCE

As previously stated, it is Paragon's policy to disclose in a forthright manner any detected non-compliance that may affect the usability of data produced by Paragon. It is not within our expertise to predict the manner in which a specific regulator or regulatory body will interpret the rules governing analysis; therefore, Paragon is unable to guarantee compliance. It is Paragon's policy that our responsibility begins with a bona-fide and competent attempt to evaluate potential compliance issues, and ends with disclosure of any findings that may enable our clients to make an informed decision.

Procedures for documenting non-compliances and applying corrective actions are given in **SOP 928**. A copy of Paragon's Nonconformance Report (NCR) is provided in **Appendix F**.

6.3 NON-STANDARD METHOD VALIDATION

When a non-promulgated method (i.e., methods other than EPA, ASTM, etc.) is required for specific projects or analytes of interest, or when the laboratory develops a procedure, the laboratory must establish the validity of the method prior to extracting or analyzing a client's samples. *Validity is established by*

meeting criteria for precision and accuracy. Method development and validation must include the following:

- Initial Demonstration of Capability (IDOC) for each analyst performing the method;
- MDL studies or MDC determination, as applicable, for every analyte, matrix, instrument, and column (if applicable);
- validated extraction and analytical criteria; and
- SOP generation and approval per established processes.

7. MEASUREMENT TRACEABILITY AND CALIBRATION

Paragon follows a well-defined calibration routine for all instruments and equipment. Calibration may be performed by laboratory personnel using certified reference materials traceable to NIST or equivalent certified materials, or by external calibration agencies or equipment manufacturers. The discussion in this section of the LQAP is general in nature because the requirements for calibration are instrument or equipment and method specific. Details of calibration procedures and requirements can be found in Paragon's standard operating procedures (SOPs), analytical methods and operations manuals.

A list of all major instrumentation available at Paragon is provided in **Appendix G**. The Quality Assurance Department maintains this list.

7.1 TRACEABILITY OF CALIBRATION

Paragon's program of calibration and/or verification and validation of equipment must ensure that, wherever possible, measurements performed by the laboratory are traceable to national standards of measurement. Paragon requests and maintains calibration certificates (e.g., weights, thermometers, balances) that demonstrate traceability to national standards of measurement. If traceability to national standards of measurement is not available or applicable, then Paragon provides evidence of correlation of results (e.g., verifying an in-line resistivity meter by reading the system's output with a conductivity meter; participating in a PT studies).

7.2 REFERENCE STANDARDS OF MEASUREMENT

Paragon uses reference standards of measurement (such as Class S weights or NIST-traceable thermometers) for calibration verification purposes only (i.e., these reference standards are not available to laboratory staff for general use). Reference standards of measurement are calibrated or verified by a qualified vendor that must provide, where possible, traceability to a national standard of measurement. Thermometer Masters are independently recertified annually, weight masters are independently recertified every five years. Certificates of vendor calibration/verification for the reference standards recertifications are maintained by the Quality Assurance Department.

The certified reference standards are then used to annually verify other measurement devices (e.g., laboratory thermometers, laboratory weight sets) in-house. The in-house verification efforts are managed by the Quality Assurance Department. All items so verified are tagged with a sticker indicating the unique identity of the device, the date of verification and the initials of the technician who performed the verification, and the date the verification is valid through. Procedures for the in-house verification of thermometers are given in **SOP 923**. Procedures for the verification of weight sets are given in **SOP 901**.

7.3 TRACEABILITY OF STANDARDS, SOLVENTS AND REAGENTS

Paragon purchases the highest quality standards, solvents, and reagents appropriate to the analytical methodologies employed. The vendor must supply a Certificate of Analysis, Certificate of Purity, or equivalent. These certificates are maintained by the Department who uses the materials.

With the exception of extraction solvents, each Department documents the date of receipt, date opened and an expiration date for all standards and reagents by labeling the original container, or certificate and/or by entering this information into Paragon's Standards and Reagents database. Because of the quantity of solvents consumed in a short time frame, solvents are labeled only with the date received.

Each Department is responsible for the preparation, documentation, storage and disposal of its chemicals. Standards preparation information is documented by entry in a Paragon's Standards and Reagents database. The following information, needed to maintain traceability of the standard, is recorded for each standard:

- date of receipt of reference standard;
- unique internal identification number and traceability to purchased stock or neat compounds, as applicable (i.e., vendor/lot numbers; unique Paragon identifier);
- date of preparation;
- name of preparer;
- amount of reference material used;
- volume/identity of reagents and solvents used;
- final volume;
- concentration;
- expiration date of the stock and prepared standards.

See **SOP 300** for additional information about standards preparation, storage, and expiration. Verification (re-verification) of radiochemical standards is also

addressed in SOP 300.

7.4 GENERAL REQUIREMENTS FOR CALIBRATION

Each calibration is dated and documented to ensure that it is traceable to the method, instrument, date of analysis, analyte, concentration, and response. Sufficient information must be documented to permit reconstruction of the calibration. Acceptance criteria for calibrations must comply with method requirements.

7.5 INSTRUMENT CALIBRATION

This section defines the essential elements of initial instrument calibration (ICAL) and continuing instrument calibration verification (CCV). These procedures ensure that the data will be of known, documented, and appropriate quality for a given application. *Samples yielding concentrations that exceed the upper limit of the calibration curve shall be diluted and reanalyzed, if possible, to bring the results within the calibrated range. Results of samples outside the known calibration range, above or below, must be reported as qualified values and discussed in the case narrative.*

Initial instrument calibration is used for quantitation and continuing instrument calibration verification is used to confirm the validity of the initial calibration. The following items are required of both initial and continuing instrument calibrations:

- The details of the instrument calibration procedures, including evaluation and acceptance criteria, and corrective measures to be taken in the event that these acceptance criteria are not met, must be included or referenced in the test method SOP.

- Sufficient raw data records must be retained to allow reconstruction of the instrument calibration (e.g., calibration date, test method, instrument, date of analysis, name of analyst, concentration of standard(s), response, response factor).

Additional essential elements of initial as well as continuing instrument calibrations are discussed below.

7.5.1 INITIAL INSTRUMENT CALIBRATION

The following items are essential elements of initial instrument calibration:

- Samples must be quantitated from the ICAL, unless the reference method states otherwise.

- The initial calibration range must consist of at least the minimum number of calibration points specified by the

reference method. If the reference method does not specify the number of calibration standards, then the minimum number is two, not including blanks or a zero standard. Exception: multi-component analytes, such as chlordane, toxaphene or Aroclors, may be analyzed using a one-point calibration, per SW-846 guidance, if so requested by the client.

- The lowest calibration standard must be above the detection limit (MDL) and at or below the RL (i.e., the method reporting limit must be within the calibrated range of the method).

- Calibration standards must include concentrations at or below the regulatory limits, if these limits are known to the laboratory.

- Criteria for the acceptance of an initial instrument calibration must be established (e.g., RSD, correlation coefficient, etc.).

- If ICAL results are outside acceptance criteria, then corrective action must be performed, and the instrument recalibrated before analyzing samples.

- Exclusion of initial calibration points without technical justification is not allowed (poor injection or power failure are valid reasons to exclude a calibration point).

- All reported target analytes and surrogates must be included in the initial calibration.

- The ICAL must be verified (see section 7.5.3) before samples can be analyzed.

7.5.2 CONTINUING INSTRUMENT CALIBRATION

A continuing calibration verification (CCV) standard must be analyzed with the frequency prescribed in the reference method, or as dictated by the applicable LIMS program specification (typically within every 12hr time period). For example:

- When an ICAL is not performed on the day of analysis, then validity of the initial calibration must be verified with an acceptable CCV prior to sample analysis.

- A CCV must be repeated at the beginning and end of each analytical sequence. (For GC/MS methods that use an internal standard, only one CCV must be analyzed before each

analytical sequence). Some methods additionally prescribe that a CCV must be analyzed after every 10 (or 20) samples analyzed.

The following items are essential elements of continuing instrument calibration:

- With the exception of multi-component analytes, all reported target analytes must be included in the continuing instrument calibration standard.
- Criteria for the acceptance of a CCV must be established (e.g., %D, %Drift, from the initial calibration).
- If the CCV results exceed acceptance criteria, then corrective actions must be performed. If routine corrective action procedures do not produce a second consecutive CCV within acceptance criteria, then a new calibration must be performed and successfully verified.

Additional aspects of calibration verification are discussed below.

7.5.3 CALIBRATION VERIFICATIONS

All ICALs must be verified with a ***second source*** standard obtained from a different manufacturer/vendor and traceable to a national standard, when available. If a different manufacturer/vendor is not available, the laboratory must request a different lot number of the standard.

In most cases, a second-source initial calibration verification (ICV) standard is analyzed immediately after the ICAL and before any samples are analyzed. However, analysis of an ICV is not required, if the continuing calibration verification (CCV) standard is from a second source.

The concentrations of the calibration verification standards must be varied within the established calibration range. At least one of the standards must fall below the middle of the calibration range. Paragon usually accomplishes this criterion by analyzing the ICV at a different and lower concentration than the CCV. Acceptance criteria for an ICV are usually the same as those for a CCV.

Sample data associated with an unacceptable calibration verification standard may be reported as qualified data in the following cases:

- When the acceptance criteria for the CCV is exceeded high (i.e., high bias), and only non-detects were determined for the

affected analyte(s) in associated samples, then those non-detects may be reported.

- When the acceptance criteria for the CCV is exceeded low (i.e., low bias), then these sample results may be reported if they exceed a maximum regulatory limit.

- When the acceptance criteria for the CCV are exceeded (high or low), and the effect on the system from previous sample analysis is substantiated (e.g., by reanalysis or sample response characteristics on a different detector), then the sample results may be reported.

Other levels of concentrations and frequencies of analysis for calibration checks (ICVs, CCVs) may be required by specific client programs. These requirements, which supercede method, SOP or LQAP requirements otherwise stated, are communicated to the laboratory staff via LIMS program specifications.

8. PREVENTIVE MAINTENANCE AND REPAIR OF EQUIPMENT

Paragon maintains an organized maintenance program that is broader than the particular instruments or devices a specific employee may operate or is familiar with. The objective of Paragon's equipment maintenance program is to provide a structure of care that prevents quality control failures and minimizes lost productivity that results from equipment malfunction or failure. Within this program are provisions for corrective actions, maintaining spare parts, and a contingency plan in the event of catastrophic failure (e.g., loss of power for a significant period of time).

See Appendix G for a comprehensive list of Paragon's equipment.

Paragon's maintenance program is based on equipment manufacturer's recommendations, operator training guidance, and other considerations (e.g., sample throughput). The established maintenance program applies to all laboratory primary instrumentation, as well as support equipment (see Section 8.6 for a definition of what constitutes support equipment). Provisions for documenting all routine and non-routine instrument equipment maintenance and repairs is also established within the maintenance program.

Responsibilities for applying Paragon's maintenance program rests with the Department that utilizes the equipment, the Quality Assurance Department bears responsibility for certain support equipment such as balances, ovens, refrigerators, freezers, and temperature measurement devices. Only authorized personnel are permitted to perform maintenance.

Culturally, Paragon makes a distinction between 'operational' and 'routine' maintenance, that external parties generally do not. Paragon considers the normal/typical things that operators do to keep the equipment functioning properly (e.g., septum replacement, reagent refill, etc.), as 'operational' maintenance, and does not generally view these tasks as routine

maintenance events that require specific documentation in a dedicated maintenance log. Paragon's view is that the fact that the equipment is performing properly and yielding acceptable QC results, evidences that these maintenance tasks were performed as needed. Paragon's maintenance system does, however, provide for attestations that this maintenance was performed, where applicable. In contrast, Paragon defines routine maintenance as those things done in-house only periodically (i.e., that are beyond what is performed as usual 'operational' maintenance), that are short of vendor repair (e.g., annual GFPC drawer evaluation).

Documentation requirements are discussed further in Section 8.4 below.

Note that Paragon does not consider 'priming', or analysis of solvent blanks, which generally get recorded in the instrument run log, as maintenance.

8.1 MAINTENANCE SCHEDULES

With the exception of certain support equipment that is maintained by the QA Department, each Department Manager is responsible for developing procedures and schedules for maintaining the equipment utilized within their Department, and for delegating specific maintenance responsibilities to employees.

In general, Paragon performs maintenance as needed (including preventive considerations). Certain aspects of routine maintenance are considered to be 'operational', and are performed each time the instrument is run. Other maintenance is performed 'periodically' (e.g., roughly monthly, contingent upon sample throughput). Each instrument operator is responsible for the performance of their own instrument, and may perform maintenance duties at their discretion. For these reasons, Paragon's culture is not one of 'scheduled' maintenance, in the traditional (calendar) sense. Consequently, although the Department Manager provides oversight, it is not necessary or practicable to create formal maintenance schedules, or to have maintenance performance synchronized within the Department.

Paragon maintains service contracts for most major analytical equipment, including gas and high-performance liquid chromatographs, mass spectrometers, liquid scintillation counters, and cold vapor atomic absorption and inductively coupled plasma spectrophotometers. Preventive maintenance is included in most of these service contracts. Service contracts that include preventive maintenance are also retained for Paragon balances and the DI water system.

8.2 SETTINGS

Paragon's equipment list (Appendix G) depicts the following information: a) the identity and type (i.e., manufacturer and model number) of equipment (including its configuration) and its software; b) the equipment's serial number or other unique identification; c) the current location; d) the date received and date placed in service (if available); and e) the condition when it was received (e.g., new, used, reconditioned).

While it is true that some settings (e.g., detector wavelength) may be stipulated in reference methods, most instrument settings are not specifically prescribed, as they are instead, dictated by acceptable outcome (e.g., peak resolution, etc.). In a similar vein, Paragon provides typical instrument settings in the associated determinative SOP, but actual settings may vary contingent upon instrument performance and contributing factors, such as ambient conditions and operator subjectivity.

For the most part (i.e., not applicable to some types of equipment), instrument configuration and settings information is captured electronically by the instrument's 'method' files. Typically there is an 'acquisition' method file and a 'quantitation' method file that together, control the manner in which the data are obtained and subsequently calculated. These instrument files are archived via established laboratory electronic backup protocols (Form 159 – IS / LIMS Policy Statement), and are retrievable, thus providing for the reconstruction of data. The utilization of proper settings is evidenced by analytical data and QC results that meet performance criteria.

8.3 TRENDS

The dominant focus of trending contained in pertinent guidance documents relates to the generation of acceptable 'at on-set' and 'continuing' method QC checks. Concurrent with these requirements, Paragon's culture for trending observation labwide consists of ensuring that acceptable instrument checks are generated, and that the system is not producing any artifacts at levels of concern, prior to analyzing sample sets.

The expertise of the operator is a major component in effective equipment operation. Experienced operators develop an intuitive sense as to how their instrument is performing. Generally this sense is not based on a specific indicator, as there may be many contributing factors to that particular indicator, but rather on an accumulation of ques (similar to those factors that would be considered during the troubleshooting process). Because this type of expertise does not lend itself well to documentation, Paragon emphasizes cross-training to ensure consistent data generation, and the retention of 'corporate knowledge'.

8.4 EQUIPMENT DOCUMENTATION REQUIREMENTS

Analysts are responsible for maintaining calibration/verification and maintenance records of all instruments and equipment involved in the creation of the analytical data they generate. Considerations of maintenance, settings and trends, and their documentation, vary widely contingent upon the type of equipment, how automated it is, and the degree of sample throughput. Documentation can be accomplished by various means, electronically and via hardcopy. For example, ICP, ICP/MS and CVAA routine maintenance is entered into the instrument's PC and printed out in the raw data header, while service contract maintenance and repair are documented in hardcover logbooks. Labwide, dedicated hardcover maintenance logbooks are assigned to each piece of major Paragon

instrumentation, however, the manner is which equipment documentation is recorded, is at the discretion of the Department Manager. It is not Paragon's intent to unify or centralize maintenance information.

Although the manner of record keeping varies, in order to provide a clear and complete history of repairs and maintenance associated with the instrument, each entry must include the following elements:

- the date of the maintenance or repair:
- the reason for the maintenance or repair (e.g., was this action taken to correct a problem or was this action routine instrument maintenance);
- a full description of the maintenance or repair conducted;
- the name of the analyst or vendor who performed the maintenance or repair;
- reference that it was verified that the equipment is operating properly before being placed back in service (SOP 317), and where this information can be found; and
- the initials of the analyst making the entry and date of entry.

Where applicable, the identity of the reference material used as an instrument check must also be recorded, and where applicable, a statement as to the calibration's expiration must also be made.

Details regarding equipment documentation are also provided in SOP 303. Note that maintenance logs are included in monthly logbook review.

Table 8.1 (Maintenance Snapshot) following provides a brief summary of laboratory equipment, an overview of associated maintenance performed, and comments regarding how associated maintenance documentation is accomplished.

8.5 CORRECTIVE ACTIONS, SPARE PARTS, CONTINGENCY PLAN

8.5.1 CORRECTIVE ACTIONS

Corrective measures for failed QC checks are given in the associated determinative SOP. General procedures for removing equipment from service and placing new or repaired equipment into service, are provided in SOP 317. Detail regarding corrective measures and repair for support equipment failures (e.g., ovens, cooling units, pipets, DI water system), are discussed in SOPs 320, 326, 321 and 319, respectively. Actions to be taken in the event of catastrophic failure are discussed in Section 8.5.3 below.

Paragon maintains service contracts (preventive maintenance, repair) for most major analytical equipment. Some equipment (particularly some support equipment) does not lend itself to repair and would likely be replaced instead, per requirements given in SOP 127.

8.5.2 SPARE PARTS

An adequate inventory of spare parts is required to minimize equipment downtime. This inventory should include those parts and supplies that:

- are subject to frequent failure;
- have limited useful lifetimes, or
- cannot be obtained in a timely manner should failure occur.

Department Managers are responsible for maintaining an adequate inventory of necessary spare parts for all major instruments and equipment items. Examples of spare parts maintained for major instrumentation include: septa, inserts, columns, tube fittings, filaments, source parts, and traps.

8.5.3 CONTINGENCY PLAN

In the event of a catastrophic instrument failure, Paragon will make every effort to analyze samples within holding times by alternate means. If the redundancy in instrumentation is insufficient to handle the affected samples, then the Department Manager will notify the Project Manager immediately. In turn, the PM will notify the client to discuss options that will ensure successful completion of the project.

Paragon will also take appropriate mitigating steps and notify the client should significant power, cooling unit, etc. failures occur that create circumstances which could adversely impact the client's sample results. An automated system is in place to notify the IS Manager and Laboratory Director should a power outage of significant duration occur. However, any employee who notes an outage or unit failure is responsible for contacting the Department Manager or Laboratory Director, who will in turn direct the necessary actions. The specific course of action taken is dependent upon the nature and extent of the failure. General procedures to be followed in the event of catastrophic failure are provided as an appendix to Paragon's Emergency and Contingency Plan (ECP).

8.6 SUPPORT EQUIPMENT

Paragon defines support equipment as all those devices which are not the primary determinative instrument defined by the analytical method, which support laboratory operations. Support equipment includes balances, ovens, refrigerators,

freezers, water baths, temperature measurement devices, and mechanical (e.g., Eppendorf ™ pipets. Per Paragon's definition, support equipment also includes: desiccators; centrifuges; vortex mixers; sonicators; homogenizers (including ball mills, riffle splitters and shatter boxes); pressure filters; vacuum pumps; zero headspace (ZHE) extractors; tumbling devices; platform shakers; water baths; chillers; heating blocks, mantles, hot and stir plates; evaporators; muffle furnaces; kilns and cleanup apparati.

Additionally, Paragon's deionized (DI) water systems (SOP 319) and health physics equipment (Appendix G) and are also considered to be support equipment.

Requirements pertaining to glassware are given in SOPs 334 and 720. Procedures for maintaining computers and other electronic devices (e.g., printers, backup devices, etc.) are developed, implemented and maintained by the IS Department (Form 159, et. al.)

Support equipment must be calibrated or verified, typically annually, within the applied range of use. NIST-traceable references must be used when available, and the results of the calibration/verification must be documented and within the specifications required of the application for which the equipment is intended.

All support equipment must be maintained in proper working order, and records must be retained to document the equipment's performance, maintenance, and repair. *Each business day, near to the beginning of the work shift, the proper functioning and calibration of the following equipment must be verified: balances, ovens, refrigerators, freezers*. Water bath temperatures must be verified each day of use. Additional monitoring must also be performed and documented, if so prescribed by a test method (e.g., recording the temperature of a water bath during digestion).

Per **SOP 321**, the volumes dispensed from mechanical pipets are verified prior to each use, as these volumes are critical measurements. Because automatic dispensing devices used to deliver solvents or reagents (e.g., for sample preservation and extractions) are not used to deliver critical volumes, these devices are exempt from daily verification.

Where necessary, in-house verifications are performed to document the capability of graduated laboratory glassware (e.g., records are on file in the Quality Assurance Department that document the capacity of the cyanide Midi-Dist sample tube glassware).

Certificates of Accuracy are acquired from the manufacturer and are retained on file within each Department for glass microliter syringes.

The following SOPs provide additional information about calibration and

Table 8.1 Maintenance Snapshot

Extractions - GPC (Gel Permeation Cleanup) Apparatus Column flow 5.0 (+/-0.1)mL/min (stipulated in SOP) SOP 641. Maintenance discussed sufficiently in SOP (adequate MeCl2 supply; proper flow rate; no leaks, all connections tight). Maintaining hardcover log.	**Extractions - Ignitability Apparatus** SOP 629. Operation and checks discussed sufficiently in SOP (Procedures). If not functioning properly, most likely replace. No maintenance log required.
Extractions Support - Kilns Desired setting given in SOP. Unit either works or doesn't. Vendor repair possible contingent upon problem, most likely replaced. No maintenance log required.	**Extractions Support - Recirculating Chillers** Setting = sufficient water flow, stated in SOP. Either works or doesn't. Vendor repair possible contingent upon problem, most likely replaced. No maintenance log required.
'Extractions Support - Lunar Lander Pressure Filter SOP 608, 609, 666. No special considerations, either works or doesn't. Most likely replace rather than repair. No maintenance log required.	**Extractions Support - Rotary Tumbler** SOPs 603, 608, 609, 666, 668. Desired setting given in SOP. Device either works or doesn't. Vendor repair contingent upon problem (replaced). No maintenance log required.
'Extractions Support - Mixer, Homogenizer No special considerations, either works or doesn't. Most likely replace rather than repair. No maintenance log required.	**Extractions Support - Sonicators** (handheld) (bath, hand-held) - SOPs 665, 673. Temperature requirement and recording directives given in SOPs, as applicable. Specific setting does not need documented (aside from temperature which is evidenced by acceptable reading, setting not critical). Maintenance log not required, unit either works or doesn't (replaced).
'Extractions Support - Nitrogen Evaporator SOPs 637, 665. Desired setting given in SOP. Unit either works or doesn't. Vendor repair not likely, replaced. No maintenance log required.	**Extractions Support - Steam Generator & Evaporator** SOPs 607, 672. Desired setting given in SOP (i.e., value open & flowing). Unit either works or doesn't. Vendor repair not likely, replaced. No maintenance log required.
Extractions Suppot - RapidVap Concentrator Various SOPs. Unit either works or doesn't. Vendor repair not likely, replaced. No maintenance log required.	**Extractions Support - Zero Headspace Extractors** SOPs 608, 669. Detailed operation/maintenance contained in SOP. Benchsheet attestation.
Metals - ICP Analyzer, Autosampler, includes ICP/MS SOPs 807, 827, 834. Maintenance tasks are discussed sufficiently in the SOPs (check gas pressures and supply; for ICP/MS, verify that cooling water for instrument is flowing; check filters on rear of instrument and vacuum monthly; check pump tubing (replace when necessary); check drainage bottle (empty if necessary). Routine maintenance is documented via run data headers, which are e-files maintained on the instrument PC. Settings are included in calibration report printout. Hardcover maintenance logs are being kept for repair documentation.	**Metals - Mercury Analyzer (CVAA)** SOP 812; does not presently contain maintenance text in Procedures Section, SOP will be revised accordingly per established publication schedule (make sure lamp life is adequate; clean window; replace Nafion cartridge as necessary; check adequate reagent supply; replace tubing, tighten fittings as necessary). Routine maintenance is documented via run data header, which is an e-file maintained on the instrument PC. Settings are included in calibration report printout. Hardcover maintenance log is being kept for repair documentation.
Organics - Gas Chromatograph, (Autosampler), Purge & Trap (includes sample heators); all detectors (including MS) GC SOPs: 402, 406, 407, 409, 424, 425, 434, 438, 444 GC/MS SOPs: 506, 525. ECDs (SOP 016 for leak/wipe tests), FPD (detector considerations), FIDs (periodic cleaning, jet replacement - indicated by instrument performance), PIDs (adequate lamp, clean window), others?. Instrument injection port and seal maintenance (liner cleaning/replacement, septum replacement, etc.); front portion of column clipped off; splitter cleaned, where applicable; check adequate gas flow and reserves (columns & detectors); replace traps (including Vocarb) as needed; use of column and trap bake cycles; tubing clean; fittings tight. Autosampler maintenance essentially means operate with adequate flushes. Maintaining maintenance logs/headers.	**Organics - TOC Analyzer, Autosampler** SOP 670. Routine maintenance discussed as Section 8.1 (check adequate gas pressure and supply; make sure 8-port valve connections are tight; check adequate reagent supply; check halogen scrubber and gas/liquid separator; check mist trap and drain if necessary). Maintaining hardcover log.

Table 8.1 Maintenance Snapshot

Organics - HPLC & Components, includes LC/MS-MS SOPs 404, 408, 439, 446, 447, 336 Maintenance discussed sufficiently in SOPs (check that eluent supply and pressure are adequate; replace column frits/guard columns/columns as necessary; all fittings tight; empty and refill HPLC water supply; replace detector lamp as necessary). Maintaining hardcover log.	
RAD - Alpha Spectrometer (towers & octetes) Operationally discussed sufficiently in SOP. Certain practices, like detector segregation (U/Th vs Am/Pu) could be considered preventive maintenance; also, use of the 'thin film' method for Polonium. Daily vacuum pressure check; weekly cleaning. Periodic maintenance provided for in established instrument training modules. Detectors are placed 'off-line' rather than repaired (either cleaned or changed out). Some repair can be done in-house (replace octet tubing, check connections), otherwise via vendor. Hardcover maintenance log is being kept. Detectors are tracked so that trend information can be ferreted out if needed.	**RAD - Liquid Scintillation Counters** SOP 704. Operationally discussed sufficiently in SOP. LSC operation is more about being optically clean. Instrument is checked annually (alignment, etc.) under service contract. In-house repair is really not applicable. Hardcover maintenance log is being kept.
RAD - Gamma Spectrometers SOP 713. Operationally discussed sufficiently in SOP. Check N2 tank and fill as necessary; hose and fittings checks; clean detectors, shields weekly. Periodic maintenance provided for in established instrument training modules. Some repair can be done in-house, otherwise maintenance is provided under contract. Hardcover log being maintained.	**RAD - Scaler w/ Lucas Cell Counter** Operationally discussed sufficiently in SOP, although a lot of expertise is involved and that expertise/knowledge is primarily obtained by demonstration, not via an operator's manual (each use, make sure cell and tubing are clean and that fittings are tight). Cells are good for 20 runs, then CCV checked. If not acceptable, run CCV again. If still not acceptable, take cell out-of-service per SOP 317. Photomultiplier is cleaned monthly. Plateau is verified annually. Periodic maintenance provided for in established instrument training modules. Hardcover log is being maintained.
RAD - Gas Flow Proportional Counter (Counting Room, PreScreen) SOP 724. Operationally discussed sufficiently in SOP (daily tank pressure check and flow to instrument). Periodic puck maintenance; planchet holder and slides cleaning also performed; provided for in established instrument training modules. Detectors are put 'off-line' rather than repaired. A drawer evaluation is conducted annually. Paragon is considering putting the GFPCs under a maintenance contract. A hardcover log is being maintained.	
RAD Support - Ball Mill SOP 336. Operation/maintenance defined sufficiently in SOP. Device either works or doesn't. Since performance doesn't vary, no maintenance log required.	**RAD Support - Riffle Splitter** SOP 336. Operation/maintenance defined sufficiently in SOP. Device either works or doesn't. Since performance doesn't vary, no maintenance log required.
RAD Support - Platform Shakers SOP 336. Operation/maintenance defined sufficiently in SOP. Device either works or doesn't. Since performance doesn't vary, no maintenance log required.	**RAD Support - Shatterbox** SOP 336. Operation/maintenance defined sufficiently in SOP. Device either works or doesn't. Since performance doesn't vary, no maintenance log required.
Support - Balances SOP 305. Vendor serviced (cleaned, certified) annually (records maintained by QA Dept.). Daily use checks (e.g., level, pan/chamber clean, etc.) and calibration verification defined in SOP (performed by Department). Logbooks (Form 301) that contain acceptance limits and corrective action directives are kept & subject to monthly review.	**Support - Ovens & Muffle Furnaces** SOP 320. Assigned verified thermometers (muffle furnaces rough-checked with thermistor). Daily performance check defined in SOP, performed by Department. Logbooks (Form 312) that contain acceptance limits and corrective action directives kept & subject to monthly review. Problems usually thermometer-related (managed by QA Dept.), when necessary, appliance vendor contacted for servicing (records maintained by Facilities or QA). Departmental staff make minor setting adjustments when necessary (documentation of setting not required, proper setting evidenced by acceptable readings). 'Return to Service' actions defined in SOP, recorded in logbook.

Table 8.1 Maintenance Snapshot

Support - Centrifuges Desired setting given in SOP, but performance not critical. Unit either works or doesn't (vendor repaired if possible, replaced).	**Support - Thermometers** (glass, electronic, IR) - SOP 923. Annual verification and records managed by QA Dept. Directives to notify QA if malfunction given in SOPs 320, 326, 210. Corrective measures, return to service discussed in SOP 923.
Support - Cooling Units (Refrigerators, Freezers) SOP 326. Assigned verified thermometers. Continuous electronic monitoring discussed in SOP. Logbooks (Form 347) that contain acceptance limits and corrective action directives kept Departmentally & subject to monthly review. Problems usually thermometer-related (managed by QA Dept.), or defrost needed (managed by Dept.). When necessary, appliance vendor contacted for servicing (records maintained by Facilities or QA). Departmental staff make minor setting adjustments when necessary (documentation of setting not required, proper setting evidenced by acceptable readings). 'Return to Service' actions defined in SOP, recorded in logbook	**Support - Vacuum Pumps** (instrument, independent) - Organic, Inorganic, RAD. Those affiliated with instruments are included in instrument maintenance practices/documentation. Potential oil change for stand-alones. Managed by Facilities. Not capital equipment. No maintenance log required.
Support - Dessicators Tight seals on unit, for indicating DrieriteTM, replace when pink (can be 'recharged'). SOP directives are sufficient.	**Support - Vortex Mixers** No real setting, technique driven (training). Device either works or doesn't. Vendor repair not likely, replaced. No maintenance log required.
Support - Heating Mantles / Hot Plates / Stir Plates Desired setting given in SOP, not critical, so long as monitored temperature can be sustained. Unit either works or doesn't. Vendor repair unlikely, replaced. No maintenance log required.	**Support - Water/Sonic Baths** Complete unit, or device on top of hot plates. Temperature requirement and recording directives given in SOPs. Specific setting does not need documented (evidenced by acceptable temperature). Should not leak. Maintenance log not required, unit either works or doesn't (vendor repaired if possible, replaced).
Support - Millipore Water System SOP 319. Monitoring (Departmental), acceptance criteria, corrective actions discussed in SOP. Context with larger resin units also discussed. Logbooks (Form 712) subject to monthly review maintained. Independent monthly check also discussed. If needed, unit repair may be attempted in-house, most likely unit would be replaced (discussed in SOP); SOP 127 requirements. Documentation of setting not required, proper setting evidenced by acceptable readings. 'Return to Service' criteria = acceptable readings must be maintained.	
WetChem / Metals - pH Meter / ISEs / Conductivity Meter SOP 1126, 1128, several others. Care & feeding of probes is adequately addressed as Procedures in SOPs. Probe/instrument manuals are listed in the SOPs Reference Section.	**WetChem - Ion Chromatograph, Autosampler** SOPs 1113, 1125. Maintenance considerations need to be added to the beginning of SOP Section 9 (check that eluent supply and pressure are adequate; replace column frits/guard columns/columns as necessary; check that gas supply and pressure are adequate; all fittings tight; empty waste container as necessary). Consider adding detector maintenance detail as well. Settings are included in calibration report printout. Instrument is not networked, still subject to IS backup protocols. Hardcover repair log is being maintained.
WetChem - Cyanide Distillation Apparatus SOP 1110. Necessary detail already in SOP.	**WetChem - UV Spectrophotometer** Various SOPs. Performance mostly involves optically clean and matched cuvettes. Sufficient operational maintenance detail is given in the SOPs. Hardcover maintenance log kept.
WetChem - Flow Injection Analyzer SOPs 1127, 1129, 1123. Sufficient operational detail in Sections 11-14 of SOP)adequate reagent supply; clean, unclogged tubing; fittings tight). Software methods stored in instrument PC, subject to IS back-up protocols (no printout). Hardcover repair log is maintained.	

verification of support equipment:

- **SOP 305** -- balance calibration and verification
- **SOP 320** -- monitoring and recording of oven temperatures
- **SOP 326 --** monitoring refrigerator and freezer temperatures.

9. QUALITY CONTROL PROCEDURES

Paragon's quality control program provides a systematic process that enables the laboratory to evaluate and control the validity of analytical results, by measuring and monitoring accuracy and precision by method and matrix; by developing control limits and using these limits to detect errors or out-of-control events; and by requiring corrective actions to prevent or minimize the recurrence of these events. Paragon observes QC procedures to ensure that sample data meet laboratory and client quality objectives.

The purpose of preparing and analyzing QC samples is to demonstrate accuracy and precision of the sample data and efficacy of the method for the target analytes being investigated. Acceptance criteria may be dictated by reference methods or by project requirements. All assessments of QC data are performed after all rounding and significant figure truncations have been performed.

For all analyses performed by Paragon, the QC concepts and samples described in the following sections are mandatory. Determinative SOPs contain a Table that summarizes the types and frequency of QC samples, acceptance criteria, and corrective actions required. Observation of maximum holding time allowance is discussed in LQAP Chapter 4.

9.1 DEFINITION OF BATCH

9.1.1 PREPARATION BATCH

A preparation batch consists of as many as 20 field samples of the same or similar matrix, that are prepared together by the same analyst(s) within a limited or continuous time period, following the same method, and using the same kind of equipment and same lots of reagents. Each batch must contain the appropriate number and kind of method control samples (e.g., MB, LCS) and matrix-specific QC samples (e.g., MS/MSD, DUP). Cleanup procedures may be included as part of the preparation batch. All field and QC samples in the batch should be subjected to the same preparation and cleanup procedures.

9.1.2 ANALYSIS BATCH

The analysis batch (or sequence) consists of samples that are analyzed together within the same or continuous time period, on the same instrument, and processed using the same calibration. Each analysis sequence must contain the appropriate number and kind of standards and samples as defined by the method. If samples from a preparation

batch are analyzed in multiple analysis batches, extended method control and matrix-specific QC samples need not be analyzed with every analysis batch.

Where no sample pre-treatment (such as extraction or digestion) is required prior to analysis (e.g., analysis of volatile organic compounds, anions analysis by ion chromatography, etc.), the preparation batch and analysis sequence are equivalent.

9.2 PREPARATION BATCH QC SAMPLES AND STANDARDS – DEFINITION AND USE

The results of quality control samples provide an estimate of accuracy and precision for the preparation and analysis steps of sample handling. The following sections describe the QC information provided by each of these analytical measurements.

9.2.1 METHOD BLANK

A method blank (MB) consists of an aliquot of well-characterized, controlled, or certified matrix (e.g., reagent water, Ottawa sand, solid reference material, boiling chips) that is processed through the entire sample preparation, cleanup, and analysis procedure. For radiochemical analyses, a suitable blank solid matrix has not been identified; therefore, reagent water is routinely used for the blank for most solid matrices. The volume or weight of the blank must be approximately equal to the sample volume or weight processed for sample analyses.

The purpose of the MB is to demonstrate that interferences caused by contaminants in solvents, reagents, glassware, and other sample processing hardware, are known and minimized. A method blank should not contain target analytes at or above the reporting limit, unless otherwise permitted in the method. Other maximum blank contamination control criteria may apply, as indicated in the associated LIMS program specification.

While some methods may require background correction, sample results are typically not corrected for blank contamination.

9.2.2 LABORATORY CONTROL SAMPLE

A Laboratory Control Sample (LCS) consists of an aliquot of well-characterized, controlled, certified matrix (e.g., reagent water, sand, solid reference material, Teflon^{TM} chips) that is spiked with analytes of interest and processed through the sample preparation, cleanup, and analysis procedure.

The purpose of the LCS is to provide an estimate of bias based on recovery of the compounds from the clean, controlled matrix, and to demonstrate that the laboratory is performing the method within accepted guidelines without potential non-matrix interferences.

Where sample pretreatment is not required, such as with ion chromatography or gamma spectroscopy analysis, or the analysis of volatile organic compounds, the ICV standard or other appropriate control standard may be employed as the LCS.

An LCS for methods with extensive lists of analytes that may interfere with one another may include a limited number of analytes, but the analytes included must be representative of as many analytes as is practical.

Other client-specific QC requirements may be prescribed in the applicable LIMS program specification. The requirements set forth in the LIMS program specification supercede those stated in the method, SOP or LQAP.

9.2.3 MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A matrix spike (MS) or matrix spike duplicate (MSD) is a field sample to which known concentrations of target analytes are added before the sample is processed. The purpose of MS/MSD samples is to assess the performance of the method for a particular matrix and to provide information about the sample's homogeneity. Results of the MS/MSD samples are evaluated in relation to the method QC samples to determine the effect of the matrix in regards to accuracy and precision. Sample results are not corrected for MS/MSD excursions.

To generate MS/MSD pairs for any analysis, there must be an adequate volume/weight of field sample available. Inadequate sample volumes preclude the possibility of generating this pair of QC samples. Paragon asks clients to designate the sample to be used for MS/MSD analysis to ensure that adequate sample volumes are collected.

For some analyses, changing the composition of the sample in any way invalidates the analysis to be performed (e.g., hardness, alkalinity, pH). Therefore, an MS/MSD pair cannot be generated for these analyses. Normally, duplicate sample aliquots are analyzed in order to generate an estimate of the method's precision.

Other client-specific quality control requirements may be prescribed in the applicable LIMS program specification. The requirements set forth in the LIMS program specification supercede those stated in the method, SOP or LQAP.

9.2.4 SAMPLE DUPLICATE

A sample duplicate (DUP) is a second representative portion of sample that is carried through the preparation, cleanup and analysis process. Results for the duplicate sample are compared to the initial sample analysis results as a means of evaluating precision. For organic analyses, the MS/MSDs fulfill this function. The degree of sample homogeneity directly impacts the integrity of the sample duplicate analysis.

Precision criteria for sample duplicate analyses are those prescribed in the reference method and/or SOP, unless otherwise superceded by client-specific requirements contained in the applicable LIMS program specification.

9.2.5 SURROGATES

Surrogates are organic compounds that are similar to the target analytes, but are unlikely to be present in actual field samples. They are introduced into all field and QC samples in a batch prior to sample preparation, and provide an estimate of bias based on recovery of similar compounds, for a given extraction technique and analysis method combination. Sample results are not corrected for surrogate recoveries.

Acceptance criteria for surrogates are those prescribed in the reference method and/or SOP, unless otherwise superceded by client-specific requirements contained in the applicable LIMS program specification.

9.2.6 CHEMICAL YIELD MONITORS OR ISOTOPIC TRACERS

Chemical yield monitors are used in radiochemical analyses and provide information similar to the surrogate spikes discussed above. The primary difference between a chemical yield monitor and a surrogate is that sample results are corrected for chemical yield recoveries and not corrected for surrogate recoveries. A chemical yield monitor is a substance that has similar chemical characteristics as the parameter being measured. It is introduced into all field and QC samples in a batch during the preparation procedure. Chemical yield monitors provide information regarding the performance of a method on a sample-by-sample basis.

Chemical yield monitors are evaluated against established laboratory control limits. These Paragon default control limits may be superceded by other quality control criteria specified in the applicable LIMS program specification.

9.3 CONTROL CHARTS

Control charts are a tool that can assist the laboratory in evaluating method control and assessing trends. Control charts can clarify the routine performance expectations for a method, and can give warning before a measurement system drifts into an out-of-control situation. Information such as radiochemical calibration parameters, results of daily efficiency checks, etc. can be documented in control charts. Accuracy control charts, discussed further below, that contain method LCS (and surrogate, as applicable) performance information, are managed through LIMS. Although the QAM is responsible for periodically (at minimum, semi-annually), reviewing the control-charted LCS information, and adjusting established QC limits as appropriate or necessary, this control-charted LCS information is accessible to *all* bench personnel through LIMS.

Further discussions of control charts and control limits and other considerations such as outlier rejection and trend evaluation follow below.

9.3.1 ACCURACY CONTROL CHARTS

Accuracy (recovery) for a batch can be evaluated by plotting the individual percent recovery points for analytes on a control chart and comparing the values against the current control limits. If the spike recovery values for the current analytical batch meets the acceptance criteria for that method, then the data point (and batch) are accepted.

Accuracy control charts are generally maintained for each method that utilizes an LCS. For methods that cannot use LCS samples (e.g., pH, flashpoint, conductivity), other tools are used to assess method control. If fewer than 20 data points for a method, matrix, and analyte combination are acquired, then control charts yield scant information.

9.3.2 CONTROL LIMITS

Control limits for each controlled analyte are calculated, and can be updated, using Paragon's LIMS. The recovery values from all data processed within a specified date range, are used to calculate the control limits and compile the control chart.

The upper and lower control limits of the control chart are designated as the value equal to the average recovery plus or minus three times the standard deviation (i.e., 99% confidence interval).

The upper and lower warning limits for the control chart are designated as the value equal to the average recovery plus or minus two times the standard deviation (i.e., 95% confidence interval).

The average recovery, standard deviation, minimum value, maximum value, and population are displayed on each control chart.

Control limits are updated as needed (e.g., acquisition of a sufficient number of data points to establish meaningful control limits for a newly implemented method; if deemed appropriate as a result of a corrective action investigation; etc.). The frequency with which control limits are updated may vary for different methods. Generally, intra-laboratory historical control limits are not updated more than once per year.

9.3.3 OUTLIER REJECTION

For the generation of control charts, and other quality control data that monitor the laboratory's performance, it is essential to prevent spurious or erroneous data from being incorporated. It may be necessary to reject data as an outlier to prevent an adverse effect on the values being calculated. In every case, the cause of the outlier rejection must be clearly understood before any data point is manually rejected.

For the purposes of statistically determining whether a data point is an outlier or not, Paragon may use the procedures discussed in the Dixon Rank Sum Test or the Grubbs Test. If a data point is determined to be an outlier, it will not be incorporated into the dataset when updating QC limits.

9.3.4 TREND EVALUATION

Trend analysis techniques can be applied to control charts as a preventive tool to help indicate conditions that could cause an analysis to become out of control. In evaluating control charts, a trend is recognized if one or more of the following situations exist:

- A series of seven successive points occur on the same side of the mean;
- A series of five successive points occur going in the same direction;
- Two consecutive points occur between the warning and control limits;
- A single value occurs outside of control limits.

Corrective action investigation should be employed for every trend identified. Items to be considered upon investigation may include, but are not limited to, the following:

- Has there been a change in instrumentation or personnel?
- Has instrument maintenance been properly performed?

- What conditions have changed since the trend began?
- Have standard or spike solutions changed?

9.4 SECOND COLUMN OR SECOND DETECTOR CONFIRMATION

Second column or detector confirmation is performed for several GC and HPLC methods. Whenever two dissimilar chromatography columns or two detectors of a different nature are available for a given method, the laboratory performs second column or second detector confirmation analysis to confirm the identity of target analytes in field samples. When second column analysis is performed for any chromatography technique, the following policies apply:

- Every attempt will be made to calibrate the second (confirmatory) column in the same manner as the quantitative (primary) column. The same initial and continuing calibration standards will be analyzed on the confirmation column in the same manner as the quantitation column. The purpose of this dual calibration requirement is to allow the possibility of reporting quantitative results from the confirmation column if interferences on the primary column prevent accurate target analyte quantitation.

- For chromatographic techniques, the determination of target analytes in a sample depends solely on peak retention times observed in both primary and secondary column chromatograms. If target analyte peaks are present at the proper retention times in both confirmation and quantitation column chromatograms at levels above the MDL, then Paragon considers this analyte to be confirmed.

- In general, Paragon reports the higher value of the two columns per SW8000 guidance (e.g., 8011, 8081, 8082, 8141, 8151, 8021). It is also Paragon's policy to report the higher value of the two columns for other EPA methods (e.g., 608, 615).

  If no interferences are present, and an analyte's value from either the primary or secondary column is greater than the reporting limit but between the MDL and the reporting limit on the other column, then Paragon reports the higher value that is greater than the reporting limit for that analyte.

- Paragon customarily reports the value from the primary column for methods SW8330 and SW8332. Co-elutions or interferences are frequently observed on the secondary column for these HPLC methods.

- Other reporting rules may apply as dictated in the applicable LIMS program specification. The rules of the LIMS program specification

supercede standard Paragon policy.

9.5 MANUAL RE-INTEGRATION POLICIES AND PROCEDURES

Many data collection systems allow the analyst to reprocess data, thereby allowing for the manual re-integration of analyte peaks. Paragon makes every attempt to optimize peak integration parameters; however, manual reprocessing of data must be performed to correct a data system's integration error (e.g., incorrect or missed peak assignment, over- or under-integration of area). Manual re-integrations may not be performed solely to meet initial or continuing calibration criteria or any QC criteria (e.g., tuning, or surrogate or spiking compound recovery).

Whenever a manual integration is performed, the analyst performing this process must include a hardcopy of the original and re-integrated peak in the final data report. In addition, the analyst must initial and date the re-integrated page and document the reason for re-integration on the printout. The re-integration must be documented in the case narrative.

Further details regarding manual integration procedures are given in **SOP 939**.

10. DATA REDUCTION, VALIDATION AND REPORTING

Data transfer and reduction are essential functions in summarizing information to support conclusions. It is essential that these processes are performed accurately and are followed by multiple reviews before data are submitted to the client. All analytical data generated by Paragon are extensively reviewed for accuracy and completeness. The data validation process consists of data generation, reduction, and multiple levels of review, as described below.

10.1 DOCUMENTATION OF RAW DATA

Where possible, raw data are captured and processed electronically using verified software programs (see **SOPs 709 and 1400** for further information regarding software verification).

To facilitate manual documentation of raw data (where suitable LIMS benchsheet interfaces do not yet exist), Paragon creates custom logbooks comprised of forms or benchsheets that are tailored to contain the information required to adequately document the process being performed, and the associated data. The Quality Assurance Department controls these forms and benchsheets, and issues bound and paginated logbooks to the laboratory as needed via controlled distribution.

As applicable, hardcover, bound laboratory notebooks (most frequently used for instrument maintenance logs or Project Manager notebooks) are also issued via controlled distribution to laboratory staff as needed.

The manually recorded raw data are entered into the laboratory logbook directly, promptly, and legibly in indelible ink. All raw data entries must, at a minimum, contain the following information:

- the initials of the individual who performed the process;
- the date the process was performed;
- the methodology used; and
- the identity of all samples or standard solutions that were employed in carrying out the process.

Raw data must be maintained as part of the laboratory's records. Raw data not only includes instrument outputs, but sample preparation, standard materials documentation, and equipment maintenance information as well. Raw data may be archived electronically or as hardcopy.

10.2 CORRECTION OF ERRORS IN DOCUMENTS

During the course of processing and reviewing sample preparations and analysis results, it may be necessary to correct documentation errors. Detailed requirements for the correction of manual documentation errors are prescribed in **SOP 303**; the correction of electronic information is governed by LIMS controls and audit trails. In summary, manual entries may not be obliterated by erasure, use of correction fluid, or other means. In order to maintain the integrity of the documentation generated by the laboratory, changes to hardcopy documentation must be made in the following manner:

- A single line must be struck through the error so that the original text remains legible;
- As applicable, a corrected entry must be made adjacent to the error; and
- The person making the change must initial and date the corrective entry.

If not clearly evident, the reason for the data change must be indicated.

10.3 DATA REDUCTION

Paragon's analysts perform data reduction. This process consists of interpreting instrument results and verifying calculated concentrations in samples from the raw data. The complexity of the data reduction is dependent on the specific analytical method and the number of discrete operations involved in obtaining a measurement (e.g., digestions, dilutions, cleanups, concentrations). The analyst calculates the final reportable values from raw data or enters all necessary raw data into the LIMS so that the LIMS can calculate the final reportable values.

Data are reduced according to protocols described in SOPs and method-specific review checklists. Computer software used for data reduction is validated before use and verified regularly by manual calculations. All information used in calculation is recorded in order to facilitate reconstruction of the final results (e.g., raw data, calibration files, tuning records, results of standard additions, interference check results, sample response, and blank or background-correction protocols). Information about the preparation of the samples is maintained in order to facilitate reconstruction of the final results (e.g., weight or volume, percent moisture for solids, extract volume, dilution factor).

Copies of all raw data and the calculations used to generate the final results, as recorded in hardbound laboratory notebooks, spreadsheets, electronic data files and LIMS record files, are retained in the project file to allow reconstruction of the data reduction process.

10.4 REPORTING OF SAMPLE RESULTS

Sample results are reported either on an "as-received" basis, or in units of dry-weight measure. The number of significant figures reported is consistent with the limits of uncertainty inherent to the analytical method. In most cases, results are reported to no more than two or three significant figures. Analytical problems, and/or any modifications of referenced methods are noted in the data package case narrative.

Standard units appropriate to the analytical method are used to report all sample results. Measurements for radiochemical analyses are reported in units of activity such as:

- picocuries per liter (pCi/L), aqueous; or picocuries per gram (pCi/g), solid matrix samples.
- disintegrations per minute per liter (dpm/L) or disintegrations per minute per gram (dpm/g).
- Becquerels per liter (Bq/L) or Becquerels per gram (Bq/g).

It should be noted that one (1) Curie is equal to 2.22×10^{12} dpm; and is also equal to 3.7×10^{10} Bq.

Standard units for inorganic and organic analyses are units of mass per volume (aqueous samples), or mass per weight (solid matrix samples). For example, Wet Chemistry parameters such as hardness, total organic carbon (TOC), etc., are typically reported in milligrams per liter (mg/L) or milligrams per kilogram (mg/kg). Metals results for liquid samples may be reported as mg/L or as micrograms per liter (µg/L). Some methods have specific reporting units mandated by their analysis technique. For example, pH is reported as pH units, and specific conductance is reported as milli-Siemens (mmho/cm) or micro-Siemens (µmho/cm).

10.5 DATA REVIEW

Paragon employs multiple levels of data review. All data generated and reduced follow review protocols specified in laboratory SOPs (such as **SOPs 052** and **715**), and method-specific checklists. The preparatory technician and analyst who generates the analytical data perform a **Level 1** review of the data for correctness and completeness. This data review verifies that:

- the appropriate SOPs have been followed;
- any special sample preparation or analytical requirements that were communicated to the laboratory via the LIMS program specification have been met;
- all sample preparation information is correct and complete;
- all analysis information is correct and complete;
- QC samples meet criteria for frequency, accuracy and precision;
- all calculations, conversions, and data transfers are accurate;
- all documentation is present and complete, including benchsheets and/or run logs, any applicable NCRs, and documentation and presentation of manual integrations per SOP 939, as applicable.

Procedures for handling unacceptable data are discussed subsequently (LQAP Section 10.6).

Following completion of the Level 1 Review, the analyst then forwards the data to the Department Manager or another qualified reviewer whose function is to provide an independent **Level 2** review of the data. In addition to the elements evaluated in the Level 1 review described above, the Level 2 reviewer verifies that:

- the calibration data are scientifically sound, appropriate to the method, and completely documented;
- qualitative identification of target analytes is correct;
- quantitative results are correct.

The Level 2 reviewer selects a sample and verifies it to the benchsheet. If no errors are found, then the review is considered complete. If any problems are discovered, then additional samples are verified to the benchsheet with the process continuing until no additional errors are found or until the data package has been reviewed in its entirety. The Level 2 review is documented by recording

the date and initials of the reviewer on the checklist employed. This sign-off signifies that the data are approved for release and a final report is prepared.

Once the final report is prepared, an additional overall technical review is performed before it is routed to the Project Manager for a **Level 3** review. The intent of this review is to verify that the report is complete and that the data meet the overall objectives of the project.

Each step of the review process involves evaluation of data quality based on both the results of the QC data and the professional judgment of those conducting the analysis and/or review. This application of technical knowledge and experience to the evaluation of the data is essential in ensuring that data produced are consistently of known, documented, and appropriate quality.

10.6 PROCEDURES FOR HANDLING UNACCEPTABLE DATA

All QC information is recorded in the same format, with the same units, as that of the associated sample results. It is the analyst's responsibility to evaluate QC data against applicable prescribed limits. When an analysis of a QC sample (e.g., MB, LCS, CCV, etc.), indicates that the associated samples do not meet requirements, the analyst must immediately notify the Department Manager. The Department Manager then consults with the PM (and QAM, as applicable) to determine whether or not the affected samples must be re-prepped and/or re-analyzed, and/or if specific corrective action needs to be taken before additional analysis may proceed. A Nonconformance Report (NCR) as discussed in Chapter 11 of this LQAP, is initiated per **SOP 928**, as applicable. If the non-compliant data cannot be corrected, then the affected results must be flagged as discussed below, and the discrepancy disclosed in the data package case narrative. The completed NCR Form is included in the data report.

10.7 DATA REPORTING

Data reports contain final sample results, the methods of analysis used and limits of detection, and QC data. The extent of supportive data included (e.g., benchsheets, run logs, calibration data, instrument raw data printouts, etc.), is contingent upon the type of report contracted by the client.

Results of subcontracted data are clearly indicated as subcontract laboratory results when incorporated into the final data package report.

10.7.1 FACSIMILE OR IMAGED REPORTS

For projects that require rapid turnaround of sample analysis results, the laboratory may provide a facsimile or imaged e-mail attachment to the client, followed by the full data report at a later date. If the analysis results provided by facsimile or imaged e-mail attachment have undergone the same review processes followed for final data packages, then this forwarded report indicates that the sample analysis results are

final. However, if the accelerated turnaround time requirements preclude a full review/validation of the sample data, then the report is marked as "PRELIMINARY" to indicate that results may change as the review process is completed.

10.7.2 HARDCOPY DATA PACKAGES

The format and content of a data report is dependent upon project specifications, and it is beyond the scope of this document to describe project-specific report requirements. In the absence of client-specified data package deliverables, the following sections describe the items that must be included in all data reports.

10.7.2.1 COVER LETTER

Items contained in the cover letter include:

- the client's name and address;
- Paragon's name and address, name of contact and telephone number;
- a tabular presentation of field/client sample ID, Paragon Sample ID, date received, matrix, and date collected. This item is typically presented as an attachment, the Sample Cross Reference Table;
- a list of each analysis performed and total number of pages for each analytical report;
- identification of all test data provided by a subcontract laboratory;
- a discussion of previously submitted or partial reports that pertain to the samples discussed in the current report; and
- the signature of Paragon's Project Manager or designee.

10.7.2.2 REPORT FORMAT

Analysis reports are presented in tabular format, and consistent significant figures and units of measurement are used. The following information is included in each report:

- laboratory name, client name, project name and/or number;
- client/field sample ID and Paragon sample ID;

- date of sample receipt, date and time of sample collection, and date/time of sample preparation and/or analysis;
- sample matrix;
- reporting units and identification of whether the sample results are reported on an "as-received" or dry weight basis;
- method reference for the parameter analyzed and method reporting limits;
- identification of numerical results with values below the method reporting limit;
- case narrative that identifies test methods, describes any deviation from the method or contractual requirements, additions or exceptions to the SOP, and discloses any conditions that may affect the quality of the results;
- identification of sample results that did not meet sample acceptance criteria;
- footnotes or qualifiers referenced to specific data (as applicable) and explanations or keys to flags and abbreviations used;
- surrogate and tracer recoveries, where applicable;
- where applicable, a statement of the estimated uncertainty of the test result; and
- a signature and title, or equivalent electronic identification, of the personnel who accepts responsibility for the content of the report, and the date of issue.

If a report is reissued, the amendments must clearly state that the report is reissued. The cover letter and case narrative must describe why the report has been reissued and which sample results have been reissued.

10.7.2.3 QC REPORTS

Each final report includes QC reports that summarize results from the associated LCS, MB, and matrix QC samples. Additional QC samples may be prepared and reported to comply with project-specific requirements.

10.7.2.4 DATA QUALIFIERS – FLAGGING CODES

Whenever the data quality objectives of the LQAP are not met, the associated sample results must be flagged with the appropriate flagging codes. These codes are applied only in the event that the laboratory cannot generate (through reanalysis) fully compliant data. If sample values are reported outside the calibration range of the method or unreliable interferences exist in the sample, then descriptive codes are applied to the result.

Data qualifiers are added by the laboratory prior to reporting the analysis results. The laboratory appends data qualifiers to each environmental field sample based on an evaluation of all available QC information (e.g., MS/MSD samples, laboratory blanks, LCSs, calibration verification standards, etc.). Analytical batch comments are added to the narrative section of each data report to explain any nonconformance or other issues.

Other flagging practices may be observed if so dictated by the applicable LIMS program specification.

10.7.3 ELECTRONIC DATA DELIVERABLES (EDDS)

The electronic data deliverables generated by the laboratory are project-specific and are produced in a format specified by the client. *Information presented in corresponding fields of the hardcopy report and EDD are identical as both are generated from LIMS.* Before submitting the EDD file, the Project Manager or designee verifies that the EDD is complete and meets the client's format requirements. All EDDs are submitted to the client on computer disks or are transmitted electronically.

10.8 RECORDS AND DATA STORAGE

Records provide the direct evidence and support for the necessary technical interpretations, judgments, and discussion concerning laboratory results. These records, particularly those that are anticipated to be used as evidentiary data, provide the historical evidence needed for later review and evaluation. Records must be legible, identifiable, and retrievable. They must be protected against damage, deterioration, fire, theft, vermin, and loss. Though only 5-year retention is required by NELAC, Paragon retains all records for a minimum of seven (7) years, or as otherwise specified per the client's contract.

Laboratory records include the following kinds of documentation:

- personnel qualifications, experience, and training;

- correspondence between Paragon and clients;
- quality assurance records (e.g., retired SOPs and LQAPs, PT study results, internal and external audit reports and responses);
- contents of laboratory logbooks;
- equipment maintenance records;
- traceability of standards, solvents and reagents;
- instrument checks and calibrations;
- raw data;
- final data reports; and
- sample management records (e.g., sample login, field and internal chain-of-custody, storage, disposal).

10.8.1 ELECTRONIC RECORDS

Paragon employs a multi-level system that addresses both the frequent backup of sample results (in LIMS) and the periodic backup of raw data (from both networked and non-networked instruments). Additionally, the software that Paragon uses for these backups, contains a disaster recovery module that allows for the complete recovery of the backup database, in its entirety. In short, Paragon's LIMS is backed up hourly, and, along with all network servers, is additionally backed up to tape each business day. As indicated in the IS and LIMS Policy Statement (**Appendix A**), instrument backups are performed approximately monthly. Contingent upon the volume of analysis, the frequency of backup might vary.

Backup of the instrument computers is done centrally by the IS Manager if the instrument computer is on the network. It is the responsibility of the operator\user to coordinate a convenient time for both the IS Manager and the user for non-network instrument backup. The instruments that are not on the network are backed up using portable devices. These devices, as well as media, are checked out from the IS Manager, then are returned to the IS Manager for safe storage.

An electronic archive for maintaining final project reports was implemented in 2001. Upon completion of a workorder, all data reports are scanned to create image files that are catalogued and saved to a dedicated server that is backed up daily as described above. The scanned images remain available on the network for review should any questions regarding the data arise. Retention of hardcopy data reports prior to 2001 is discussed below.

10.8.2 HARDCOPY RECORDS

Prior to electronic compilation and storage, Paragon created paper copies of project reports. These hardcopy data archives are retained off-site by a records storage contractor. The QAM maintains a database inventory of all records that are stored at the contractor's facility. The contractor is responsible for the maintenance and protection of these records. Access to the records is limited to only designated individuals. If any records need to be retrieved from the storage site, the requestor must fill out an archive request form (Form 136) and submit it to the Quality Assurance Department. E-mail requests directed to the QAM are also acceptable. The QA Department then requests the records from the contractor, who retrieves the records and delivers them to the laboratory on the next business day.

Hardcopy originals of records that have been imaged and verified may be destroyed confidentially (i.e., shredded). Detailed procedures for archiving records and submitting archive requests are provided in **SOP 069**.

As of this writing, no provisions have been made to permanently destroy any records generated by Paragon. Should Paragon permanently destroy any records, written notification will be provided to all clients affected.

In the event that the laboratory changes ownership, the responsibility for the retention of records in accordance with the guidelines established in this LQAP, is conferred to the new owner. Should Paragon go out of business, Paragon will inform our clients in writing of this business decision, and will transfer records at the client's request.

10.9 CLIENT INQUIRIES/COMPLAINTS

The focal point of contact with the client is the Paragon Project Manager. If a complaint or any circumstance raises doubt concerning Paragon's compliance with its policies or procedures, or with the requirement of a method or quality system, it is the Project Manager who initiates investigation and follows through to resolution. The QAM, Department Managers, and Laboratory Director are made aware of, and involved in, the resolution process as needed. Documentation of the complaint and its resolution are maintained as part of the project records. Where resubmission of data is required and/or implementation of preventive measures is necessary, an NCR Form (**Appendix F**) is used and processed (**SOP 928**), through the QAM. Paragon will respond to all complaints in a timely fashion.

10.10 CONFIDENTIALITY

All laboratory results and associated raw data are confidential and may not be released to or discussed with any party other than the client who requested the analytical services. Access to laboratory records and LIMS is limited to laboratory personnel, on a restricted basis, based on need (i.e., job function). Records are available for an accrediting authority's on-site review, and records specific to the client (as well as quality system records) are available to the client for client audits. Paragon expects that auditors will honor our clients' and Paragon's confidentiality requirements, and will not discuss any results, documents, or records viewed during the course of an audit.

Confidentiality is included as a component of Paragon's ethics training, which is provided to each person as they join the Paragon staff, and annually, as a refresher training, thereafter.

11. CORRECTIVE ACTIONS

Corrective action is necessary when any measurement system fails to meet the requirements of this LQAP, the appropriate SOP or project-specific instructions, or whenever an error is detected. Items that may need corrective action range from a minor problem such as an analyst failing to initial a form, to a major problem such as a chemist preparing a sample using the wrong reference method.

Corrective actions fall into two general categories: short-term and long-term. Short-term corrective actions are those that can be applied immediately. Examples include: having an analyst initial a form where the initial was missed, or correcting an error in a logbook entry per procedures described in SOP 303. Long-term corrective actions are those that require a clarification of practice or a change in policy in order to effectively resolve the problem. Corrective actions must be completed by the date designated by the QA Department (i.e., within 21 calendar days or less, unless otherwise provided for). Associated SOPs may need to be revised and republished for long-term corrective actions, laboratory staff must be re-trained in accordance with the updated procedures.

11.1 RESPONSIBILITIES FOR CORRECTIVE ACTION INITIATION

The type of corrective action taken is coordinated by the Department, Quality Assurance and applicable Project Managers. A controlled Nonconformance Report (**Appendix F**) is used to document the corrective action. *Any* individual who notes a problem or deviation is responsible for initiating the NCR in a timely manner.

It is the responsibility all personnel who work with samples to note any discrepancies or nonconformances that occur with sample handling. It is the responsibility of the chemists who prepare samples for analysis to document any problems that are noted during sample preparation. It is the analyst's responsibility to monitor the proper functioning of the analytical system prior to, during and following sample analysis. To accomplish this, various DQIs as

discussed in Chapter 3 of this LQAP are monitored and evaluated against laboratory established or project-specific QA/QC requirements. If the evaluation reveals that any of the QC acceptance criteria are not met, then the analyst must immediately correct the problem. When an acceptable resolution cannot be achieved and/or data quality is negatively impacted, the analyst must notify the Department and Project Managers and must initiate an NCR (**SOP 928**) immediately. Per the guidance contained in SOP 928, the laboratory shall notify all affected clients of potential data quality issues in a timely manner, and corrective actions taken to resolve the issue shall be completed in a reasonable timeframe, with documentation submitted to the client.

11.2 PARAGON'S CORRECTIVE ACTION PROCESS

Non-conformances are reported (documented) electronically through a LIMS interface that is available to all staff. The individual who discovered the problem or deviation is responsible for initiating the next sequential NCR in LIMS. Note that in addition to documenting laboratory sample or test issues, NCRs are also used to address client inquiries, and to investigate Performance Test (PT) sample failures.

Documented on the NCR are the initials of the initiator and descriptions of the method, workorder(s) and samples affected; the type, content and extent of the problem noted; the probable cause and the root of the problem (if known); measures taken to prevent recurrence; the specific corrective actions taken and their outcome; and the final disposition/resolution of the data.

As described in **SOP 928**, the processing of the NCR flows from the initiator, to their immediate Supervisor and/or Department Manager and the relevant Project Manager(s), and finally to the Quality Assurance Manager. In this manner, a consensus is achieved as to what specific corrective actions are to be taken. The Project Manager, at his or her discretion, may or may not contact the client to discuss options based on the nature of the nonconformance. Whether or not the client is contacted is noted on the NCR, if the client is contacted, the Project Manager documents who was contacted and when. The Project, Department and Quality Assurance Managers electronically sign and date the NCR, documenting their final approval and verification of the disposition of the data. The LIMS provides for delegation of signature authority as needed to cover key staff outages.

The LIMS, which is subject to Paragon's frequent backup protocols, maintains an archive of all NCRs generated. In this manner, NCRs are retained as part of the laboratory's electronic records. Also, contingent upon the level of data deliverable specified by the client, a copy of the associated NCR report is included in the analytical data package. Corrective actions that require follow-up, including those initiated by internal or external auditors, are catalogued in a separate LIMS Table that tracks audit findings. This LIMS Audit Findings Table

is managed by the QA Department but is available to all staff on a read-only basis.

12. AUDITS

12.1 INTERNAL AUDITS

Periodic evaluations conducted by the Quality Assurance Department and the analysis of Proficiency Test (PT) samples are two types of internal audits used to assess and document the performance of laboratory staff and processes. Audit documentation constitutes a permanent record of the conformance of Paragon's measurement systems to quality system requirements.

Internal audits include both technical and systems audits, and are performed periodically per an annual schedule developed and maintained by the Quality Assurance Department. Considerations taken into account in developing the internal audit schedule include, but are not limited to, requests made by the Laboratory Director; the scheduled occurrence of external audits; as needed to support a specific project's requirements; to verify the continued effectiveness of corrective actions previously taken; or in response to an identified need to evaluate compliance in any area of laboratory operations. The intention of the internal audit schedule is to provide for the evaluation of each laboratory area or system at least once annually, thereby providing an overview of laboratory operations. Form 168 or other audit questionnaire may be used as a guide to conduct and document internal audits. Each year, the internal audits conducted are compiled into the annual Quality Systems Audit (QSA), which is discussed subsequently (LQAP Section 12.1.3).

All internal audits are conducted by QA staff or designees who, by experience, are deemed to be knowledgeable in the area assessed. The assigned auditor identifies the scope, time frame and expected duration of the audit, and communicates this information to the applicable Department Manager. The auditor reviews relevant information such as regulations, contract requirements, published procedures, SOPs, etc., prior to the audit. The criteria set forth in these applicable guidances establish the basis of the audit. These reference materials may also be used as auditor's aids.

The audit is conducted in an efficient and professional manner. Findings, Observations and comments are communicated to the Department Manager.

Short-term corrective actions may be taken at the time an item is noted, or an appropriate long-term corrective action plan may be developed. An audit is considered to be closed-out when deficiencies have been satisfactorily corrected.

An audit report summarizing the Determinations made and the corrective actions taken or planned is compiled; the original auditor's notes are customarily included

as an attachment of the audit report. The outcome of the audit is communicated to the Laboratory Director. Internal audit corrective actions requiring follow up are tracked in a LIMS Table that is available for viewing to all laboratory personnel. The QAM oversees satisfactory completion of corrective measures taken. Internal audit records are maintained by the Quality Assurance Department.

See **SOP 937** for additional information pertaining to internal audit procedures.

12.1.1 INTERNAL TECHNICAL AUDITS

Departmental functions that may be reviewed during a technical audit may include, but are not limited to:

- Adherence to SOPs and compliance with promulgated method requirements during sample preparation and analysis;
- Maintenance of internal chain-of-custody;
- Proper preparation, storage, use and documentation of standards;
- Performance and documentation of instrument maintenance;
- Performance and documentation of data review;
- Evaluation of documentation practices pertaining to benchsheet and logbook entries, Nonconformance Report (NCR) generation and analyst demonstration of capability.

12.1.2 INTERNAL SYSTEM AUDITS

Examples of elements that may be reviewed as a system audit may include, but are not limited to:

- An assessment of the SOP process, including procedures for submitting and approving revisions, update and distribution of SOPs, tracking of employee SOP assignments and sign-offs, SOP electronic file management, and archiving of older SOP iterations and records.
- LIMS data capture and reporting processes.
- Sample handling, storage and disposal practices, including maintenance of sample storage areas, sample tracking and internal chain-of-custody documentation, duration of retention, and disposal designation and documentation.
- Use of Paragon's Standards and Reagents database.

- Performance and documentation of laboratory logbook review.

12.1.3 ANNUAL QUALITY SYSTEMS AUDIT

A lab-wide review of conformance to Paragon's quality system is conducted annually by the QA Manager or designee(s) as required by Section 5.5.3.1 of the NELAC Standard. The annual Quality Systems Audit (QSA) shall be managed, conducted and reported according to the audit procedures described above. Inputs to the QSA may include, but are not limited to, summaries of the following: Nonconformance Reports (NCRs), Proficiency Testing (PT) study results, deficiencies noted during data review, internal audit Determinations, and Determinations made via external audits.

12.1.4 PROFICIENCY TESTING STUDIES

Paragon participates in agency studies and/or contracts approved vendors to provide PT samples in accordance with a schedule developed and maintained by the Quality Assurance Department. Participation in PT studies enables Paragon to demonstrate capability for continued accreditation, competency in a newly developed method, or the effectiveness of corrective actions taken.

Paragon participates in the following inter-laboratory proficiency testing studies:

- Water Supply (WS) -- twice annually
- Water Pollution (WP) -- twice annually
- Soil/Hazardous Waste and UST -- twice annually
- Radiochemistry -- twice annually
- US Department of Energy (USDOE) Mixed Analyte Performance Evaluation Program (MAPEP) -- twice annually

These PT studies support various regulatory programs (SDWA, CWA, RCRA) and require that the laboratory perform analyses per various methodologies (e.g., EPA 600 series, MCAWW, ASTM, SW-846), matrices and analytes. Analyte lists include: volatile organics, semivolatile organics, organochlorine pesticides, polychlorinated biphenyls, organophosphorous pesticides, phenoxyacid herbicides, high explosives, petroleum hydrocarbons, metals, minerals, nutrients and radionuclides. The analyses of PT samples are conducted in-house, in the manner prescribed by the provider, and within the turnaround time stipulated. The PT samples are distributed to the laboratory and are

processed by qualified analysts who routinely perform the analytical method.

PT study results are evaluated by the Quality Assurance Department and the applicable Department Manager as they become available. The NCR and corrective action process as described in Chapter 11 of this LQAP, is used to address any deficiencies that are noted. An archive of PT study reports, maintained by the QA Department, is posted to the network for lab-wide access.

12.1.5 ANNUAL MANAGERIAL REVIEW

A lab-wide Managerial Review is performed annually as required by Section 5.5.3.2 of the NELAC Standard. The Managerial Review assesses operational effectiveness in terms of meeting Paragon's business goals. It is a tool used to document and facilitate the consideration and introduction of needed operational changes and improvements.

The Managerial Review is performed by a designee under the direction of the Laboratory Director. The general techniques of scoping, assessment interview, reporting and follow-up as described in the internal audit procedures discussed above and outlined in SOP 937, are used to conduct the annual Managerial Review. The contents of the annual Managerial Review are considered to be confidential. A confidential footer must, therefore, appear as a component of the annual Managerial Review report.

Inputs to the Managerial Review may include, but are not limited to the following: a snapshot summary of product generated (i.e., number of samples analyzed and the types of analyses performed), various business assessment reports (e.g., TAT, on- time delivery), output from the annual QSA (i.e., problem areas identified), interview of laboratory staff, and presentation of items discussed during strategic planning sessions and/or Manager's meetings.

12.2 EXTERNAL AUDITS

External audits may be performed by a state or Federal agency or a client as part of an ongoing certification process. Items evaluated by external assessors may include, but are not limited to, reviews of the following: analytical capabilities and procedures; COC procedures; document control; quality systems; and QC procedures. Blind PT samples may be submitted to the laboratory as a form of external audit.

See **Appendix I** for a list of Paragon's state and Federal certifications. Should Paragon drop or lose an accreditation, the PMs must notify all clients that may be affected in a timely manner.

13. PERSONNEL TRAINING

The selection of well-qualified personnel is a factor that contributes to Paragon's success. Therefore, qualifications of personnel are based upon education and experience. In order to maintain qualified staff, provide personnel advancement within the laboratory, and to provide for personnel's ongoing awareness of potential hazards and protective measures, Paragon follows a formal documented program of orientation and training. Records of Health & Safety and waste training are maintained by the Health & Safety Manager/RSO and Facilities/Waste Compliance Manager. Technical training records are forwarded to the Quality Assurance Department for retention.

13.1 ORIENTATION

Before working in the laboratory, new employees receive a four-part orientation as described below:

- Human resources -- involves matters of immediate personal concern, such as benefits and company policies

- Quality assurance -- addresses topics related to ethical conduct, good laboratory practices and ongoing documentation of employee capability demonstrations. Required readings (SOPs, LQAP) are assigned at this time.

- Health & safety -- provides for a review of Paragon's various safety program documents (Chemical Hygiene Plan, CHP; Radiation Protection Plan, RPP; Emergency and Contingency Plan, ECP; Respiratory Protection Plan, ResPP; Waste Management Plan, WMP); as well as other safety and security training.

- Department functional orientation -- focuses on the new employee's basic understanding of their role within the Department and the overall role of Operations within the structure of Paragon. The Departmental training expands upon the employee's scientific background and work experience to provide the employee with a level of competence that enables the individual to successfully function within the defined responsibilities of his/her position.

Temporary employees receive the same orientation as regular staff, with the exception of the human resources orientation.

SOP 143 details information regarding quality assurance orientation and training for new employees.

13.2 TECHNICAL TRAINING

Chemists (analysts) and technicians are qualified to perform specific analytical procedures and methods. The qualification process, at a minimum, consists of

background/theory training, on-the-job training, and demonstration of proficiency. Additional training may include further individualized instruction, programmed learning, conferences and seminars, and specialized training by instrument manufacturers.

Department Managers are responsible for providing documentation of analytical training and proficiency for each employee in their group(s) to the Quality Assurance Department for retention.

13.2.1 INITIAL DEMONSTRATION OF CAPABILITY (IDOC)

New analysts and technicians are trained by Department Managers according to the following guidelines:

- The new employee reads the SOP(s) pertinent to the analytical method being learned, and receives background/theory instruction, as applicable.

- The new employee observes the procedure in which the analytical method and required process documentation is demonstrated by trained personnel. Job requirements are outlined and quality control measurements are defined. For most methods, the trainee performs an Initial Demonstration of Capability (IDOC) by preparing and/or analyzing four (4) blank spike samples under the supervision of the Technical or Department Manager, or an analyst proficient in that method.

- The results of the new employee's preparation and/or analysis are evaluated and problems and corrective actions are discussed. If the blank spike recovery and precision data meet quality control criteria for that method, the employee is deemed to have demonstrated proficiency and is allowed to work on client samples. If the values generated are outside acceptance limits, then training continues until the trainee can consistently meet the acceptance criteria for the method.

- After the certification process has been successfully completed, the Department Manager forwards the documentation to the Quality Assurance Department for retention.

13.2.2 CONTINUING DEMONSTRATION OF CAPABILITY (CDOC)

Paragon's personnel are required to demonstrate their proficiency upon hire and annually thereafter for the methods they perform. Results from four (4) laboratory control sample (LCS) spikes performed by the chemist (analyst) or technician may be compiled to serve as the employee's Continuing Demonstration of Capability (CDOC).

Alternately, MDL studies and reports from PT sample analysis may be used to demonstrate an employee's CDOC.

13.2.2.1 METHOD DETECTION LIMIT (MDL) STUDIES

Most of the analytical methods employed at Paragon require the periodic generation of MDL data. The generation of acceptable MDL values requires a thorough understanding of the total analytical process and is a rigorous test of the proficiency of the analytical staff that performs the analysis. An analyst's or technician's performance in an MDL study that generates values that are consistent with past performance may be used to demonstrate initial and/or continuing proficiency in a method. This MDL information may be used in lieu of other demonstrations of proficiency, except where a regulatory promulgated method explicitly requires specific procedures to be followed for the initial demonstration of proficiency.

13.2.2.2 PROFICIENCY TEST (PT) SAMPLES

As discussed in Chapter 12 of this LQAP, Paragon participates in several proficiency testing programs. These programs typically submit single-blind standards to the laboratory and return a performance summary after results have been evaluated by the sponsoring agency or qualified vendor. Successful participation in these PT study programs by personnel is a rigorous demonstration of the staff's ability to perform routine analytical procedures. Records of successful participation in these programs may be used to demonstrate that an employee has been adequately trained in the methods that he/she performs. This IDOC/CDOC information may be used in lieu of other demonstrations of proficiency, except where a regulatory promulgated method explicitly requires specific procedures to be followed for the initial demonstration of capability.

13.3 TRAINING RECORDS

Technical and quality assurance training records are maintained by the Quality Assurance Department. Health & Safety training records are managed and retained by the Health & Safety Manager/RSO. Waste management training records are managed and maintained by the Facilities/Waste Compliance Manager. Employee training record files may contain, but are not limited to, the following:

- signed annual Ethics training documents
- resume or personnel qualifications form
- transcript or diploma
- QA training and signature/initial on file
- documentation of annual assigned SOP readings
- documentation of annual LQAP reading
- IDOC/CDOC documentation
- PT study results
- MDL study results
- off-site training certificate

14. GLOSSARY, ACRONYMS AND SYMBOLS

14.1 GLOSSARY

TERM	DEFINITION
Acceptance Criteria:	Specified limits placed on characteristics of an item, process, or service defined in requirement documents. (ASQ)
Accreditation:	The process by which an agency or organization evaluates and recognizes a laboratory as meeting certain predetermined qualifications or standards, thereby accrediting the laboratory. In the context of the National Environmental Laboratory Accreditation Program (NELAP), this process is a voluntary one. (NELAC)
Accrediting Authority, Primary:	The agency or department designated at the Territory, State, or Federal level as the recognized authority with responsibility and accountability for granting NELAC accreditation for a specified field of testing. (NELAC) [1.5.2.3]
Accuracy:	The degree of agreement between a observed value and the accepted reference value. Accuracy includes a combination of random error (precision) and systematic error (bias) components that are due to sampling and analytical operations. (QAMS)
Aliquot:	A discrete, measured, representative portion of a sample taken for analysis. (EPA QAD)
Ambient:	Usual or natural surrounding conditions, e.g. ambient temperature – the natural, uninfluenced temperature of the surroundings. (NIRP Glossary)

TERM	**DEFINITION**
Analyte:	The specific chemicals or components for which a sample is analyzed; may be a group of chemicals that belong to the same chemical family and that are analyzed together. (DoD QSM)
Audit:	A systematic evaluation to determine the conformance to quantitative and qualitative specifications of some operational function or activity. (EPA-QAD)
Background:	Ambient signal response recorded by measuring instruments that is independent of radioactivity contributed by the radionuclides being measured in the sample. (DOE QSM)
Batch:	Environmental samples that are prepared and/or analyzed together with the same process and personnel, using the same lot(s) of reagents. A **preparation batch** is composed of one to twenty environmental samples of the same NELAC-defined matrix, meeting the above-mentioned criteria and with a maximum time between the start of processing of the first and last sample in the batch to be 24 hours. An analytical batch is composed of prepared environmental samples (extracts, digestates, or concentrates) which are analyzed together as a group. An **analytical batch** can include prepared samples originating from various environmental matrices and can exceed 20 samples. (NELAC Quality Systems Committee)
Bias:	The deviation of a single measured value of a random variable from a corresponding expected value, or a fixed mean deviation from the expected value that remains constant over replicated measurements within the statistical precision of the measurement (Synonyms: deterministic error, fixed error, systematic error). (DOE QSM)
Blank:	A sample that has not been exposed to the analyzed sample stream in order to monitor contamination during sampling, transport, or analysis. The blank is subjected to the same analytical and measurement process as the associated samples. Blanks include: Equipment blank: a sample of analyte free media which has been used to rinse common sampling equipment to check effectiveness of decontamination procedures. (NELAC) Field blank: a blank prepared in the field by filling a clean container with pure deionized water and appropriate preservative, if any, for the specific sampling activity being undertaken. (EPA OSWER) Trip blank: Contaminant free water, or appropriate matrix, which accompanies bottles and samples during shipment to assess the potential for sample contamination during shipment. Trip blanks are

TERM	**DEFINITION**
	not opened in the field, and are required for Volatile Organic Analysis only. (NIRP) Instrument Blank: A clean sample (e.g., distilled water) processed through the instrumental steps of the measurement process; used to determine instrument contamination. (EPA-QAD) Method blank: a sample of a matrix similar to the batch of associated samples (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all the steps of the analytical procedures. (NELAC) Reagent blank: a sample consisting of reagent(s), without the target analyte(s) or sample matrix, introduced into the analytical procedure at the appropriate point and carried through all subsequent steps to determine the contribution of the reagents and of the involved analytical steps. (QAMS)
Blind Sample:	A sub-sample for analysis with a composition known to the submitter. The analyst/laboratory may know the identity of the sample, but not the composition. It is used to test the analyst's or laboratory's proficiency in the execution of the measurement process. (NELAC)
Calibration:	To determine, by measurement or comparison with a standard, the correct value of each scale reading on a meter, instrument, or other device. The levels of the applied calibration standard should bracket the range of planned or expected sample measurements. See Initial Calibration. (NELAC)
Calibration, Continuing:	The process of analyzing standards periodically to verify the maintenance of calibration of the analytical system.
Calibration Curve:	The graphical relationship between the known values, such as concentrations, of a series of calibration standards and their instrument response. (NELAC)
Calibration, Initial:	The process of analyzing standards, prepared at specified concentrations, to define the quantitative response, linearity and dynamic range of the instrument to the analytes of interest. Initial calibration is performed whenever the results of a continuing calibration do not conform to the requirements of the method in use or at a frequency specified in the method. See Calibration.
Calibration, Initial Check/Verification	Verification of the ratio of instrument response to analyte amount, a calibration check is done by analyzing for analyte standards in an appropriate solvent. Calibration check solutions are made from a

TERM	**DEFINITION**
(ICV):	stock solution which is different from the stock used to prepare calibration standards. (NIRP Glossary)
Carrier:	Carriers are typically non-radioactive (e.g. natural strontium, barium, yttrium) elements. They follow similar chemical reactions as the analyte during processing and are added to samples to determine the overall chemical yield for the analytical preparation steps. The yield of the carrier is typically determined gravimetrically or by ICP and is used to correct radiochemical results for acceptable losses occurring during the preparation process. (DOE QSM)
Chain-of-Custody (COC) Form:	Record that documents the possession of the samples from the time of collection to receipt in the laboratory. This record generally includes: the number and types of containers, the mode of collection, preservation, and requested samples. (NELAC)
Confidential Business Information (CBI):	Information that an organization designates as having the potential of providing a competitor with inappropriate insight into its management, operation or products. NELAC and its representatives agree to safeguarding identified CBI and to maintain information identified as such in full confidentiality. (NELAC)
Confirmation:	Verification of the identity of a component through the use of an approach with a different scientific principle from the original method. These may include, but are not limited to: second column calibration, alternate wavelength, derivatization, mass spectral interpretation, alternative detectors, or additional cleanup procedures. (NELAC)
Conformance:	An affirmative indication or judgment that a product or service has met the requirements of the relevant specifications, contract, or regulation; also the state of meeting the requirements. (ANSI/ASQC E4-1994)
Control Chart:	A graphical plot of test results with respect to time or sequence of measurement, together with limits within which they are expected to lie when the system is in a state of statistical control.
Control Limit:	A range within which specified measurement results must fall to signify compliance. Control limits may be mandatory, requiring corrective action if exceeded, or advisory, requiring that nonconforming data be investigated and flagged.
Corrective Action:	The action taken to eliminate the causes of an existing

TERM	DEFINITION
	nonconformity, defect, or other undesirable situation in order to prevent recurrence. (ISO 8402)
Counting Efficiency:	The ratio of the net count rate of a radionuclide standard source to its corresponding known activity. (DOE QSM)
Counting Uncertainty (Poissonian):	A statistical estimate of uncertainty in a radiochemical measurement due to the random nature of decay. Every radiochemical result is reported with an associated counting uncertainty, usually at the 95% confidence interval.
Data Quality Indicators:	The qualitative or quantitative statements that specify the quality of data required to support decision for any process requiring chemical or physical analysis.
Data Reduction:	The process of transforming raw data by arithmetic or statistical calculations, standard curves, concentration factors, etc., and collation into a more useable form. (EPA-QAD)
Daughter:	A nuclide formed by radioactive decay of a parent radionuclide.
Deficiency:	An unauthorized deviation from acceptable procedures or practices, or a defect in an item. (ASQC)
Demonstration of Capability (DOC):	A procedure to establish the ability of the analyst to generate acceptable accuracy. (NELAC)
Detection Limit, Analyte:	The lowest concentration or amount of the target analyte that can be identified, measured, and reported with confidence that the analyte concentration is not a false positive value. See Method Detection Limit. (NELAC)
Detection Limit, Instrument (IDL):	The concentration of an analyte that produces an output signal twice the root mean square of the background noise, or the parameter determined by multiplying by three the standard deviation obtained of three to five times the desired IDL on three nonconsecutive days with seven consecutive measurements per day. IDL is only required for the metals and analysis. (DOE QSM)
Detection Limit, Method (MDL):	The Method Detection Limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. It may be determined using replicate spike samples prepared by the lab and taken through all steps of the method. The detection limit is calculated using the appropriate student's t-parameter times the standard deviation of a series of spiked samples. (Ref. 40 CFR Part

TERM	**DEFINITION**
	136, Appx. B)
Digestion:	A process in which a sample is treated (usually in conjunction with heat) to convert the sample into a more easily measured form. (DoD QSM)
Dilution Factor:	The factor by which the dilution level of the sample differs from that of a predefined method blank. The method blank is prepared within the prescribed parameters of the method, and has a dilution factor of one. The dilution factor does not include a dryness factor. (DOE QSM)
Document Control:	The act of ensuring that documents (and revisions thereto) are proposed, reviewed for accuracy, approved for release by authorized personnel, distributed properly, and controlled to ensure use of the correct version at the location where the prescribed activity is performed. (ASQC)
Dry Weight:	The weight of a sample based on percent solids. The weight after drying in an oven at $105 \pm 5^{o}C$.
Duplicate, Replicate Analysis:	The analyses or measurements of the variable of interest performed identically on two sub samples of the same sample. The results from duplicate analyses are used to evaluate analytical or measurement precision but not the precision of sampling, preservation, or storage internal to the laboratory. (EPA-QAD)
	The measurements of the variable of interest performed identically on two or more sub-samples of the same samples within a short time interval. (NELAC)
Duplicate (Replicate) Error Ratio (DER/RER):	A measure of precision used to assess agreement between radiochemical duplicates (replicates) that compares the discrepancy between two measurements to the associated uncertainties.
Duplicate, Replicate Sample:	A second aliquot of the same sample that is treated the same as the original sample in order to determine the precision of the method.
	A second, separate sample collected at the same time, from the same place, for the same analysis, as the original sample in order to determine overall precision.
Eluent:	A solvent used to carry the components of a mixture through a stationary phase. (DoD QSM)
Elution:	A process in which solutes are washed through a stationary phase by

TERM	DEFINITION
	the movement of a mobile phase. (DoD QSM)
Energy Calibration:	The correlation of the multi-channel analyzer (MCA) channel number to decay energy, obtained from the location of peaks from known radioactive standards. (DOE QSM)
False Negative:	An analyte incorrectly reported as absent from the sample, resulting in potential risks from their presence. (DoD QSM)
False Positive:	An item incorrectly identified as present in the sample, resulting in a high reporting value for the analyte of concern. (DoD QSM)
Finding:	An assessment conclusion that identifies a condition having a significant effect on an item or activity. An assessment finding is normally a deficiency and is normally accompanied by specific examples of the observed condition. (NELAC)
Half Life ($T_{½}$):	The time required for 50% of a radioactive isotope to decay. (DOE QSM)
Holding Time (Maximum Allowable):	The maximum times that samples may be held prior to analysis and still be considered valid or not compromised. (40 CFR Part 136)
Homogeneity:	The degree to which a property or substance is evenly distributed throughout a material.
Interference, Spectral:	Occurs when particulate matter from the atomization scatters the incident radiation from the source or when the absorption or emission of an interfering species either overlaps or is so close to the analyte wavelength that resolution becomes impossible. (DoD QSM)
Interference, Chemical:	Results from the various chemical processes that occur during atomization and later the absorption characteristics of the analyte. (DoD QSM)
Internal Standards:	A known amount of standard added to a test portion of a sample as a reference for evaluating and controlling the precision and bias of the applied analytical method. (NELAC)
Isomer:	Generally, any two chemicals with the same chemical formula but with a different structure. (DoD QSM)
Isotope:	A variation of an element that has the same atomic number of protons but a different weight because of the number of neutrons. Various isotopes of the same elements may have different radioactive behaviors, some are highly unstable. (NIRP Glossary)

TERM	**DEFINITION**
Lot:	A quantity of bulk material of similar composition processed or manufactured at the same time.
Matrix:	The substrate of a test sample. **Field of Accreditation Matrix:** these matrix definitions shall be used when accrediting a laboratory: Drinking Water: any aqueous sample that has been designated a potable or potential potable water source. Non-Potable Water: any aqueous sample excluded from the definition of Drinking Water matrix. Includes surface water, groundwater, effluents, water treatment chemicals, and TCLP or other extracts. Solid and Chemical Materials: includes soils, sediments, sludges, products, and by-products of an industrial process that results in a matrix not previously defined. Biological Tissue: any sample of a biological origin such as fish tissue, shellfish, or plant material. Such samples shall be grouped according to origin. Air and Emissions: whole gas or vapor samples including those contained in flexible or rigid wall containers and the extracted concentrated analytes of interest from a gas or vapor that are collected with a sorbent tube, impinger solution, filter, or other device. (NELAC) Non-aqueous Liquid: any organic liquid with <15% settleable solids.
Minimum Detectable Activity (MDA, Lower Limit of Detection):	The minimum detectable activity is the smallest amount (activity or mass) of an analyte in a sample that will be detected with a probability beta of nondetection (Type II error) while accepting the probability alpha of erroneously deciding that a positive (non-zero) quantity of analyte is present in an appropriate blank sample (Type I error). For the purposes of this standard, the alpha and beta probabilities are both set at 0.05 unless otherwise specified. (ANSI N 13.30 and ANSI N42.23)
Minimum Detectable Concentration (MDC):	The Minimum Detectable Activity expressed in concentration units.
National Voluntary Laboratory Accreditation Program (NVLAP):	A program administered by NIST that is used by providers of proficiency testing to gain accreditation for all compounds/matrices for which NVLAP accreditation is available, and for which the provider intends to provide NELAP PT samples. (NELAC)

TERM	DEFINITION
Negative Control:	Measures taken to ensure that a test, its components, or the environment do not cause undesired effects, or produce incorrect test results. (NELAC)
Nonconformance:	An indication or judgment that a product or service has not met the requirements of the relevant specifications, contract or regulation, also the state of failing to meet the requirements. (DoD QSM)
Performance Based Measurement System (PBMS):	A set of processes wherein the data quality needs, mandates, or limitations of a program or project are specified and serve as criteria for selecting measurement processes which will meet those needs in a cost effective manner. (NELAC)
Positive Control:	Measures taken to ensure that a test and/or its components are working properly and producing correct or expected results from positive test subjects. (NELAC)
Precision:	The degree to which a set of observations or measurements of the same property, obtained under similar conditions, conform to themselves; a data quality indicator. Precision is usually expressed as standard deviation, variance, or range, in either absolute or relative terms. (NELAC)
Proficiency Test Sample:	A sample, the composition of which is unknown to the analyst and is provided to test whether the analyst/laboratory can produce analytical results within specified acceptance criteria. (QAMS)
Qualitative:	Analysis without regard to quantity or specific numeric values. (NIRP Glossary)
Quality Assurance:	An integrated system of activities involving planning, quality control, quality assessment, reporting, and quality improvement to ensure that a product or service meets defined standards of quality with a stated level of confidence. (QAMS)
Quality Control (QC):	The overall system of technical activities whose purpose is to measure and control the quality of a product or service so that it meets the needs of the users. (QAMS)
Quality Control Sample:	An uncontaminated matrix spiked with known amounts of analytes. It is generally used to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system. (EPA-QAD) Laboratory Control Sample (LCS): (However named, also Laboratory Fortified Blank, Blank Spike, or QC Check Sample): A

TERM	DEFINITION
	sample matrix, free from the analytes of interest, spiked with verified known amounts of analytes or a material containing known and verified amounts of analytes. It is generally used to establish intra-laboratory or analyst specific precision and bias, or to assess the performance of all or a portion of the measurement system. (NELAC)
	Laboratory Duplicate (DUP): Aliquots of a sample taken from the same container under laboratory conditions and processed and analyzed independently. (NELAC)
	Matrix Spike (spiked sample or fortified sample): A sample prepared by adding a known mass of target analyte to a specified amount of matrix sample for which an independent estimate of target analyte concentration is available. Matrix spikes are used, for example, to determine the effect of the matrix on a method's recovery efficiency. (QAMS)
Quantitation Limits, Practical (PQL):	Levels, concentrations, or quantities of a target variable (e.g. target analyte) that can be reported at a specified degree of confidence. (NELAC) The value at which an instrument can accurately measure an analyte at a specific concentration (i.e. a specific numeric concentration can be quantified). These points are established by the upper and lower limits of the calibration range. (DoD clarification)
	The lowest concentration where the 95% confidence interval is within 20% of the true concentration of the sample. The percent uncertainty at the 95% confidence level shall not exceed 20% of the results for concentrations greater than the practical quantitation limit. (DOE QSM)
Quantitative:	Analysis with regard to quantities or specific numeric values. (NIRP Glossary)
Radioactive Decay:	The process by which a spontaneous change in nuclear state takes place. This process is accompanied by the emission of energy and subatomic particles. (DOE QSM)
Radiation Yield:	The amount of radiation of the type being measured that is produced per each disintegration, which occurs. For gamma spectrometry, this is commonly called gamma abundance. (DOE QSM)
Raw Data:	Any original factual information from a measurement activity or study recorded in a laboratory notebook, worksheets records, memoranda, notes, or exact copies thereof that are necessary for the reconstruction and evaluation of the report of the activity or study.

TERM	DEFINITION
	Raw data may include photography, microfilm, or microfiche copies, computer printouts, magnetic media, including dictated observations, and recorded data from automated instruments. If exact copies of raw data have been prepared (e.g. tapes which have been transcribed verbatim, data and verified accurate by signature), the exact copy or exact transcript may be submitted. (EPA-QAD)
Reagent Water:	Shall be water (defined by national or international standard) in which no target analytes or interferences are detected as required by the analytical method. (NELAC)
Region of Interest (ROI):	In radiochemical analysis, the Multi-channel Analyzer region defining the isotope of interest displayed in terms of energy or channels. (DOE QSM)
Relative Percent Difference (RPD):	A measure of precision between two duplicate (replicate) results expressed as the percent difference between the results relative to the average of the results.
Reliability Check (Daily):	A periodic check of the Continuing Calibration of an instrument used for radiochemical measurements.
Reporting Limit:	The level at which method, permit, regulatory and client specific objectives are met. The reporting limit may never be lower than the statistically determined MDL, but may be higher based on any of the above considerations. Reporting limits are corrected for sample amounts, including the dry weight of solids, unless otherwise specified.
Retention Time:	The time between sample injection and the appearance of a solute peak at the detector. (DoD QSM)
Rounding Rules:	If the figure following those to be retained is less than 5, the figure is dropped, and the retained figures are kept unchanged. As an example, 11.443 is rounded to 11.44. If the figure following those to be retained is greater than 5, the figure is dropped, and the last retained figure is raised by 1. As an example, 11.446 is rounded to 11.45. If the figure following those to be retained is 5, and if there are no figures other than zeros beyond the five, the figure 5 is dropped, and the last-place figure retained is increased by one if it is an odd number or it is kept unchanged if an even number. As an example, 11.435 is rounded to 11.44, while 11.425 is rounded to 11.42. If a series of multiple operations is to be performed (add, subtract, divide, multiply), all figures are carried through the calculations. Then the final answer is rounded to the proper number of significant figures.

TERM	DEFINITION
Sample:	A single container or series of containers identified by a unique number comprised of material drawn from a single location or a composite of locations during a fixed period representative of that location (s) and time period(s) for the purpose of analytical testing or physical evaluation. (DOE QSM)
Selectivity:	(Analytical chemistry) The capability of a test method or instrument to respond to a target substance in the presence of non-target substances. (EPA-QAD)
Sensitivity:	Capability of method or instrument to discriminate between measurement responses representing different levels (e.g. concentrations) of a variable of interest. (NELAC)
Signal-to-Noise Ratio:	The signal carries information about the analyte, while noise is made up of extraneous information that is unwanted because it degrades the accuracy and precision of an analysis and also places a lower limit on the amount of analyte that can be detected. In most measurements, the average strength of the noise is constant and independent of the magnitude of the signal. Thus, the effect of noise on the relative error of a measurement becomes greater and greater as the quantity being measured (producing the signal) decreases in amplitude. (DoD QSM)
Split Sample:	A portion or subsample of a total sample obtained in such a manner that is not believed to differ significantly from other portions of the same sample.
Standard Operating Procedure (SOP):	A written document which details the method of an operation, analysis, or action whose techniques and procedures are thoroughly prescribed and which is accepted as the method for performing routine and repetitive tasks. (QAMS)
Reference Material:	A certified reference material produced by the U.S. National Institute of Standards and Technology or other equivalent organization and characterized for absolute content, independent of analytical method. (EPA-QAD) A reference material one or more of whose property values are certified by a technically valid procedure, accompanied by or traceable to a certificate or other documentation which is issued by a certifying body. (ISO Guide 30 – 2.2)
Standard (Spike) Addition:	In radiochemistry, the addition of a known quantity of a radiotracer to a sample and to a split or splits of a sample. Both the sample and split(s) are then processed through the method and the difference in response between the samples used to correct for overall bias

TERM	**DEFINITION**
	resulting measurement bias and from losses during preparation. This method of internal calibration is used in radiochemical determinations where isotopic differentiation between target analyte and tracer is not possible.
Statistical Minimum Significant Difference (SMSD):	The minimum difference between the control and a test concentration that is statistically significant, a measure of test sensitivity or power. The power of a test depends in part on the number of replicates per concentration, the significance level selected, and the type of statistical analysis. If the viability remains constant, the sensitivity of the test increases as the number of replicates is increased. (NELAC)
Surrogate:	A substance with properties that mimic the analyte of interest. It is unlikely to be found in environmental samples and is added to them for quality control purposes. (QAMS)
Target Analytes:	Identified on a list of project-specific analytes for which laboratory analysis is required.
Tolerance Chart:	A chart in which the plotted quality control data is assessed via a tolerance level (e.g. +/-10% of a mean) based on the precision level judged to be acceptable to meet overall quality/data use requirements instead of a statistical acceptance criteria (e.g. +/- 3 sigma) (applies to radio bioassay laboratories). (ANSI)
Total Propagated Uncertainty (TPU):	An estimate or approximation of the total error associated with a measured value by propagation of individual (preparation, determination) uncertainties.
Traceability:	The property of a result of a measurement whereby it can be related to appropriate standards, generally international or national standards, through an unbroken chain of comparisons. (VIM-6.12)
Tracer:	A traceable internal standard, usually a unique isotope of the element being determined, added to each sample in known amount which enables quantitation of analytes of interest independent of external means of calibration.
Tracer Chemical Recovery:	The percent yield of the recovered radioisotope after the sample/tracer aliquot has undergone preparation and instrument analysis. (DOE QSM)
Tune:	An injected standard required by the method as a check on instrument performance for mass spectrometry. (DoD QSM)
Validation:	Confirmation by examination and provision of evidence that specified

TERM	DEFINITION
	requirements have been met. (EPA-QAD)
Verification:	Confirmation by examination and provision of evidence that specified requirements have been met. (NELAC) NOTE: In connection with the management of measuring equipment, verification provides a means for checking that the deviations between values indicated by a measuring instrument and corresponding known values of a measured quantity are consistently smaller than the maximum allowable error defined in a standard, regulation or specification peculiar to the management of the measuring equipment. The result of verification leads to a decision either to restore in service, to perform adjustment, to repair or downgrade, or declare obsolete. In all cases, it is required that a written trace of the verification performed shall be kept on the measuring instrument's individual record.
Warning Limits:	The limits (typically 2 standard deviations either side of the mean) shown on a control chart within which most results are expected to lie (within a 95% probability) while the system remains in a state of statistical control.

14.2 ACRONYMS

TERM	DEFINITION
AA	Atomic Absorption
AFCEE	Air Force Center for Environmental Excellence
ANSI/ASQ	American National Standards Institute/American Society for Quality
APHIS	USDA Animal and Plant Health Inspection Service
API	American Petroleum Institute
ARAR	Applicable or Relevant and Appropriate Requirement
ASCII	American Standard Code Information Interchange
ASTM	American Society for Testing and Materials
BFB	Bromofluorobenzene
BNA	Base-Neutral and Acid Extractable Organic Compounds

TERM	DEFINITION
BS	Blank Spike
BTEX	Benzene, Toluene, Ethylbenzene, Xylene
°C	Degrees Celsius
CAS	Chemical Abstract Service
CCC	Calibration Check Compound
CCB	Continuing Calibration Blank
CCV	Continuing Calibration Verification
CDPHE	Colorado State Department of Public Health and the Environment
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CF	Calibration Factor
CFR	Code of Federal Regulation
CLLE, CLE	Continuous Liquid-Liquid Extractor
CLP	Contract Laboratory Program
COC	Chain of Custody
CVAA	Cold Vapor Atomic Absorption Spectroscopy.
CWA	Clean Water Act
D	Drift or Difference
DBCP	1,2-Dibromo-3-chloropropane
DCM	Dichloromethane
DENIX	Defense Environmental Management Information Exchange
DER	Duplicate Error Ratio
DFTPP	Decafluorotriphenylphosphine
DI	Deionized
DOC	Demonstration of Capability
DoD	Department of Defense
DOE	Department of Energy

TERM	DEFINITION
DOT	Department of Transportation
DPM	Disintegrations per Minute
DQI	Data Quality Indicator
DRO	Diesel Range Organics
ECD	Electron Capture Detector
EDB	Ethylene Dibromide
EDD	Electronic Data Deliverable
EERF	Eastern Environmental Radiation Facility
EMSL	Environmental Monitoring Systems Laboratory
EPA	Environmental Protection Agency
FID	Flame Ionization Detector
FPD	Flame Photometric Detector
GALP	Good Automated Lab Practice
GC	Gas Chromatography
GC/MS	Gas Chromatography/Mass Spectrometry
GFAA	Graphite Furnace Atomic Absorption
GFPC	Gas Flow Proportional Counting
GPC	Gel Permeation Chromatography
GRO	Gasoline range organics
HECD	(Hall) Electrolytic Conductivity Detector
HEM	Hexane Extractable Material
HDPE	High-Density Polyethylene
HPGe	High Purity Germanium Gamma Spectrometer
HPLC	High-Performance Liquid Chromatography
IC	Ion Chromatography
ICAP-AES	Inductively Coupled Argon Plasma -Atomic Emission Spectroscopy

TERM	DEFINITION
ICB	Initial Calibration Blank
ICP	Inductively Coupled Plasma
ICP-MS	Inductively Coupled Plasma - Mass Spectrometry
ICS	Interference Check Standard
ICV	Initial Calibration Verification
IDL	Instrument Detection Limit
IPC	Instrument Performance Check
IPN	Incoming Project Notice
IRPIMS	Installation Restoration Program Information Management System
IS	Internal Standard
ISO/IEC	International Standards Organization/International Electrotechnical Commission
KD	Kuderna Danish
LCS	Laboratory Control Sample
LD	Laboratory Duplicate
LFB	Laboratory Fortified Blank
LFM	Laboratory Fortified Matrix
LIMS	Laboratory Information Management System
LLRW	Low Level Radioactive Waste
LQAP	Laboratory Quality Assurance Plan
LRB	Laboratory Reagent Blank
LSC	Liquid Scintillation Counting
LUFT	Leaking Underground Fuel Tank
LUST	Leaking Underground Storage Tank
MAPEP	Mixed Analyte Performance Evaluation Program
MCAWW	Methods for Chemical Analysis of Waters and Wastes

TERM	DEFINITION
MDA	Minimum Detectable Activity
MDC	Minimum Detectable Concentration
MDL	Method Detection Limit
MEK	Methyl Ethyl Ketone (2-Butanone)
MIBK	Methyl Isobutyl Ketone
MSA	Method of Standard Additions
MSD	Matrix Spike Duplicate
MSDS	Material Safety Data Sheet
MTBE	Methyl tert-butyl ether
N/A	Not applicable
NIST	National Institute of Standards
NCR	Nonconformance Report
ND	Non Detect
NEIC	National Enforcement and Investigations Center
NELAC	National Environmental Laboratory Accreditation Conference
NELAP	National Environmental Laboratory Accreditation Program
NEPA	National Environmental Policy Act
NFESC	Naval Facilities Engineering Service Center
NIRP	Navy Installation Restoration Program
NIST	National Institute of Standards and Technology
NPDES	National Pollutant Discharge Elimination System
NVLAP	National Voluntary Laboratory Accreditation Program
OSHA	Occupational Safety and Health Administration
PAH	Polynuclear Aromatic Hydrocarbon
PARCC	Precision, Accuracy, Representativeness, Completeness, Comparability
PBMS	Performance Based Measurement System

TERM	**DEFINITION**
PCB	Polychlorinated biphenyl
PCDD	Polychlorinated dibenzo-p-dioxin
PCDF	Polychlorinated dibenzofuran
PEG	Polyethylene Glycol
PEL	Permissible Exposure Limit
PETN	Pentaerthrite tetranitrate
PID	Photoionization Detector
PM	Project Manager
PNA	Polynuclear Aromatic Hydrocarbon
PQL	Practical Quantitation Limit
psi	pounds per square inch
PT	Proficiency Testing
PTFE	Polytetrafluoroethylene
QA	Quality Assurance
QAPjP	Quality assurance project plan
QASS	Quality Assurance Summary Sheet
QC	Quality Control
QIP	Quench Indicating Parameter
r^2	Correlation Coefficient
RCRA	Resource Conservation and Recovery Act
RDX	Hexahydro-1,3,5-trinitro-1,3,5-triazine
RFP	Request for Proposal
RI	Remedial Investigation
RI/FS	Remedial Investigation/Feasibility Study
RL	Reporting Limit
ROI	Region of Interest

TERM	DEFINITION
RPD	Relative Percent Difference
RPM	Revolutions Per Minute
RRT	Relative Retention Time
RSD	Relative Standard Deviation
RSO	Radiation Safety Officer
RT	Retention Time
RTW	Retention Time Window
SARA	Superfund Amendments and Reauthorization Act
SDWA	Safe Drinking Water Act
SMSD	Statistical Minimum Significant Difference
SOP	Standard Operating Procedure
SOW	Statement of Work
SPCC	System Performance Check Compound
SPLP, SLP	Synthetic Precipitation Leaching Procedure
SVOC	Semivolatile Organic Compound
TAL	Target Analyte List
TCLP	Toxicity Characteristic Leaching Procedure
TCMX	Tetrachlorometaxylene
TCL	Target Compound List
TDS	Total Dissolved Solids
TIC	Tentatively Identified Compound
TLV	Threshold Limit Value
TOC	Total Organic Carbon
TPH	Total petroleum hydrocarbon
TPU	Total Propagated Uncertainty
TRPH	Total Recoverable Petroleum Hydrocarbons

TERM	DEFINITION
TSCA	Toxic Substances Control Act
TSDF	Treatment, Storage, and Disposal Facility
TSS	Total Suspended Solids
TVPH	Total Volatile Petroleum Hydrocarbons
USACE	United Stated Army Corp of Engineers
USDA	United States Department of Agriculture
USEPA	United States Environmental Protection Agency
USGS	United States Geological Survey
UST	Underground Storage Tank
VOA	Volatile Organic Analysis
VOC	Volatile Organic Compound
WET	Waste Extraction Test
ZHE	Zero Headspace Extraction

ALS - Fort Collins

Information Systems (IS) Policies

All employees of Paragon Analytics are expected to comply with each of the following policies and/or procedures. Attempts to circumvent these policies and controls are subject to disciplinary action, including immediate termination.

Local Area Network Policies

1. Users of the Paragon network are given a password that is *not* to be shared with anyone else, other than the IS Department, for *any* reason. All work performed is to be done using your own unique account and password identification. Your password shall be changed every 90 days, and the same password cannot be used more than once in a 2-year period. You will be prompted by the system when your password is about to expire. Contact the IS Manager as soon as possible to arrange a new password. Do not attempt to change your password yourself.
2. Training is provided and access is granted to users dependant on their job function.
3. Each user has a drive mapping to H: which is their own secure area. Storage of more than 10 megabytes should be approved by the IS Manager as there are space restrictions.
4. Creation of directories in the existing network structure should be done by IS Department personnel only. Please send requests via e-mail or contact the IS Manager or staff directly. This prevents multiple entries as well as maintenance problems.
5. Any malicious deletion of files or directories can result in termination.
6. There is an external e-mail system that should be checked *daily* as that is how company information is most often conveyed. You can check your mail from any computer as it is web based. All current employees have been trained in its use. If you have questions please contact the IS manager. E-mail is property of Paragon Analytics and no expectation of privacy exists.
7. When you leave your computer or any computer you are logged in to for an extended period of time (like lunch), you are expected to log out from the network. When you leave the building, you are expected to log out from the network. There are only a few exceptions, like some of the instrument computers.

Hardware Policies and Software Policies

1. There is not to be *any* hardware or software brought into Paragon for installation on company computers. This includes screensavers. If, as a part of your job function, you require either hardware or software, please request it via e-mail or in person from the IS Manager.

   Screensavers should be used sparingly. They have been known to cause computer problems especially on instrument computers. The best ones to use are either the 'Blank Screen' or the 'Starfield Simulation'.
2. Paragon computers are not to be used for games.

ALS - Fort Collins

Virus Protection Procedures

1. In the event of a virus detection, contact the IS Manager immediately. **Do not do anything further. Do not reboot the computer under any circumstance.**
2. All floppies or CDs brought in from outside that you may have been using to do company work at home, must scanned by IS staff prior to inserting them into any computer. Failure to do so could result in termination. Virus signatures are updated daily in most cases, but new viruses are launched at any time.
3. Do not open any mail from anyone you do not know. Especially be wary of e-mails with attachments. Best practice is to keep your preview pane closed at all times to limit the possibility of self-extracting viruses.

Computer Failures Procedures

1. You are to contact the IS Department if you have hardware or network failures. You are not to try and 'fix' them yourselves without first calling IS staff.
2. Please report consistent failures like computer lockups to the IS Manager either by e-mail, voice mail, or in person.

Backup Procedures

1. The entire network is backed up daily between 1 AM and 5:30 AM. Users are not allowed on the network during these hours.
2. Backup of the instrument computers is done centrally by the IS Manager if the instrument computer is on the network. It is the responsibility of the operator\user to coordinate a convenient time for both the IS Manager and the user for backup. The instruments that are not on the network are to be backed up using portable devices. Those devices as well as media are to be checked out from the IS Manager at a convenient time for the operator\user and then returned to the IS Manager for safe storage. Backups should be done on the average of once a month. In some instances, depending on the volume of analysis, the frequency of backup might vary.

Telephone Systems

1. For those people with personal extensions, please contact the IS Manager for instructions on configuring the greetings and voice mail.
2. Each extension is password protected for voice mail. In the case of a Department phone where everyone needs access to messages, the password may be shared. In all other cases, the password should be kept confidential.
3. Please contact either the Office Manager or the IS Manager for instructions on all other operations concerning the phone system.

In the case of an emergency, the IS Manager can be contacted 24 hours/day by cell phone. The number is listed on the computer laboratory door.

ALS - Fort Collins

Laboratory Information Management System (LIMS) Policies

Paragon's Laboratory Information Management System (LIMS) is a data management system, which is used to track, manage, and report data to our clients. Throughout this process, it is the responsibility of Paragon Analytics and its employees to maintain *strict client confidentiality* regarding the handling of client's data and their samples. Consequently, because the LIMS is used as a tool to handle and process all data through the laboratory, it is imperative that all employees follow the basic LIMS operating guidelines listed below. **Note that these policy statements are not intended as a substitute for proper LIMS training - LIMS training is conducted by authorized personnel on topics that are related to the job function of each employee.**

1. Prior to using LIMS, employees must have received proper training in all LIMS processes that are required to help them perform their job. The training schedule will be coordinated between individual Department Managers and the LIMS Manager.
2. Employees must have a user account assigned to them by the LIMS Manager (Mark Roche') before they are allowed to use the LIMS. 'Sharing' or using another person's account is *strictly prohibited.* Similarly, employees are prohibited from performing any work in LIMS while another user is logged on. Additionally, to prevent unauthorized access to restricted areas in LIMS, all employees are required to log off the system before they leave their PC for any extended period of time.
3. All changes to any validated data contained within LIMS must have prior approval by the Department Manager—**unauthorized changes are a serious violation of employee conduct and may result in disciplinary action, including immediate dismissal**. Accidental changes or errors in data entry should immediately be reported to the Department and LIMS Managers.
4. Because of the sensitive nature of our business, LIMS has been equipped with a full set of security and auditing features. Employees are assigned to groups and they are given specific permissions to access menus and operations in LIMS, which are pertinent to the tasks they are required to perform. **Any employee who attempts to circumvent these features in any way will be subject to disciplinary action, including immediate dismissal**.
5. Invariably, in the course of LIMS operations, errors may occur in the application. Some of these errors can lead to extensive data loss, system downtime and, therefore, rework. **When these errors occur, it is the employee's responsibility to immediately notify the LIMS Manager so that data loss may be avoided or minimized**.

Some processes in LIMS may require the system to access thousands or, even hundreds of thousands of records at a time. Therefore, some operations in LIMS may take several minutes to complete. During this processing time, it may appear as if your computer is locked up or not responding. Although there are times when it may be appropriate to forcibly shutdown LIMS when this occurs, employees should seek assistance from the LIMS Manager prior to attempting this shutdown process if they are unsure of the consequences. Improper shutdown of LIMS may result in *extensive data loss, system downtime, and rework*.

Please contact the IS and/or LIMS Managers if you have any questions regarding the policies set forth in this document.

Ethics and Data Integrity Policies

The intent of this policy statement is to highlight and clarify Paragon's requirements and expectations for behavior in the work place. Paragon requires that all employees conduct themselves with honesty and integrity at all times. It is Paragon's expectation that all employees exhibit professionalism and respect for clients and each other in all interactions and tasks. To this end, Paragon requires that every employee abide by the following guidelines:

- Every Paragon employee is responsible for the propriety and consequences of his or her actions.
- Every Paragon employee is required to conduct him or herself in a professional manner toward all clients, regulators, auditors, vendors, and other employees. Professional conduct relates to honesty, integrity, respect, and tolerance for cultural diversity.
- Every Paragon employee must perform all assigned duties in accordance with Paragon's established quality assurance policies and quality control procedures, which have been developed in substantial conformity with contractual and regulatory requirements.
- Every employee must disclose any instance of noncompliance. Employees are expected to use professional judgment, and to document all situations thoroughly. It is the responsibility of each Paragon employee to consult the Department Manager or Quality Assurance Manager when atypical situations occur, and to fully disclose and document the decision-making process utilized. Paragon reports all noncompliance issues to the client, if data are affected by the noncompliance.
- It is the responsibility of each Paragon employee to report any suspicion of unethical conduct or fraudulent activities to the Department and/or Quality Assurance Manager, or the Laboratory Director.

Following are examples of improper, unethical, or illegal practices that will <u>not</u> be tolerated by Paragon:

- Improper use of manual integrations performed to meet calibration or method quality control criteria (e.g., peak shaving or peak enhancement performed solely to meet quality control requirements).
- Intentional misrepresentation of the date or time of analysis (e.g., intentionally resetting a computer system's or instrument's date and/or time to make it appear that a date/time requirement has been achieved).
- Falsification of records to meet method requirements (e.g., sample records, logbooks, sample results, LIMS records).
- Reporting results without analyses to support the results (i.e., dry labbing).
- Selective exclusion of data to meet quality control criteria (e.g., eliminating initial calibration points without technical justification).

ALS - Fort Collins

- Misrepresentation of laboratory performance by presenting calibration data or quality control limits within data reports that are not relevant to the results being reported.
- Notation of matrix interference as basis for exceeding acceptance limits in interference-free matrices.
- Unwarranted manipulation of computer software (e.g., improper background subtraction to meet ion abundance criteria for GC/MS tuning compounds; chromatographic baseline manipulations).
- Improper alteration of analytical conditions from standard analysis to sample analysis (e.g., modifying EM voltage, changing temperature or eluent profiles to shorten analytical run time).
- Misrepresentation of quality control samples (e.g., adding surrogates or tracers after sample extraction, omitting preparation steps for quality control samples; over- or under-spiking).
- Reporting results from the analysis of one sample for another (file substitution).
- Intentional plagiarism or willful misrepresentation of another employee's work as one's own (e.g., DOC or PT study).

Any unethical conduct, such as willful falsification, concealment, or alteration of a material fact or the false, fraudulent or fictitious statement or representation made by any person performing work may subject that person to prosecution and punishment in accordance with applicable Federal statutes. Any breach of ethics will result in disciplinary action, up to and including termination, according to Paragon's disciplinary guidelines.

Waste, Abuse and Fraud Notification

The DataChem/Paragon quality policy states that we are committed to 'generating accurate and reliable data in accordance with contractual and regulatory requirements; and to performing work in the most efficient manner possible, thus avoiding waste of resources.' Hence, it is against corporate policy to improperly manipulate or falsify data, to engage in unethical conduct, or to tolerate wasteful practices that abuse resources.

Additionally, as a Federal contractor, per DOE Order 221.1a, all DataChem/Paragon employees are instructed that 'whosoever is aware of any case of fraud, data manipulation/ falsification, waste or misuse/abuse of resources, corruption, mismanagement or other unethical practice or misconduct, is obligated to inform the appropriate Department Manger.' Alternately, the Quality Assurance Manager or Laboratory Director may be contacted.

Furthermore, a Confidential Reporting Procedure page is posted on the DCL intranet. This page explains that in the event of an allegation, the facility Laboratory Director and QA Manager will conduct a confidential investigation using qualified technical and management personnel. The investigation may include interviews, data audits, internal method audits, and surveillance to determine inappropriate practices. All records of the investigation are kept strictly confidential. Client contact and data recall is initiated as applicable.

Note that an anonymous electronic reporting form that may be used by any employee who wishes to report improper laboratory practices is available on the Confidential Reporting Procedure web page. This electronic form goes to the corporate QA office and is then sent to the facility Laboratory Director and QA Manager so that a confidential investigation as previously described can be conducted.

Per the USDOE General Provision DEAR 952.203.70 "Whistleblower Protection for Contractor Employees" policy, to which Paragon also adheres, the Office of the Inspector General (OIG) of the USDOE or USEPA may be contacted where the allegation pertains to DOE or EPA programs, operations, facilities, contracts, or information technology systems. Contact information for these offices are provided below.

Detailed training pertaining to electronic and behavioral ethics, and confidential reporting and investigation of improper practices, is provided to all DataChem/Paragon employees annually.

ALS - Fort Collins

Employees may report waste, abuse and fraud allegations to the Paragon Analytics representatives listed below, and/or to the Inspector General's Offices of the USDOE or USEPA, using the contact information given below. Employees reporting such allegations pertaining to DOE or EPA programs are afforded "Whistleblower Protection" per DEAR 952.203.70.

Contact Information:

Paragon Analytics: Ken Campbell, Lab Director	(970) 490-1511, ext.217
Paragon Analytics: Deb Scheib, QA Manager	(970) 490-1511, ext.227
USDOE OIG Hotline:	(800) 541-1625
USEPA OIG Hotline:	(888) 546-8740

Further information regarding the USDOE and USEPA policies discussed herein are provided in the following 7 attachments.

ADDITIONAL SERVICES

Rush Turn-Around Times
Typical Sample Kits are included at no additional charges: Bottles, coolers, preservatives, labels, and coolant.
Electronic Data Deliverables
Analysis of Hazardous and Mixed Waste Samples
Analysis of Sediments and Tissues
Analysis of Air Filters
On-Site Laboratory Services
Subcontracting of Specialty Analyses: Dioxins, Asbestos, Microscopy, & tests not listed above
Special Methods or Detection Limits
Specialty Method Development
Sample and Waste Disposal
Open for Saturday Sample Receipt

GENERAL NOTES

Typical Rush Turnaround Time (TAT) Surcharges **:
2.5X for Minimum TAT.
2X for Minimum TAT + 1 Business Day
1.75X for Minimum TAT + 2-3 Business Days
1.5X for Minimum TAT + 5 Business Days
1.25X for Minimum TAT + 10 Business Days

**** TATs are based on faxed sample results-within times determined as business days from sample receipt. (Sat. Delivery = Mon Rcpt.)**
Rush TATs should be requested at least 1 week before sample delivery and need Laboratory approval before sample receipt.

Volume Discounts are available upon request. Typical Discounts are: 20% for >10 sample SDGs or more for large projects
Payments are due within 30 days of invoice receipt, with 1.5% per month charges on late balances. Prompt payment discounts are 2%10 Net 30.
Samples received with short sample hold times, (3 business days or less), will accrue a 50% rush surcharge. Short hold time tests (<3 d) are exempt.
Subcontract analysis surcharges: "Invoicing Only" for 10% surcharge; Shipping & handling to sub-lab for 20%; PAI Reports for 30%-50%.
Typical Sample Kits must be requested at least 3 bus. days before Delivery Date, or rush shipping charges will apply. Un-returned supplies are available & billable at: materials cost + shipping costs + 20% handling.

ALS - Fort Collins

Note: Request 3X - 5X Minimum Quantities for Re-Runs & MS/ MSD

PARAMETER	MATRIX	Min TAT	METHOD	Min. Quant.	Standard Quantity	Container Type	Preserv.	Req'd pH	Holding Time	Additional Sample Receiving Concerns

Small Batches, < 5 samples, incur the greater of a $250 minimum or 5 sample charge, due to Method QC Reqmts. (Blanks, MS/MSDs, & LCS/LCSDs).
(Small Batch surcharges may be waived for large projects.)
Special Reporting Limits are available for additional costs.
Special Requirements raised after project initiation will typically incur additional surcharges of 5% - 30%:
Ex: TICs, special Detection Limits, extra report copies, EDDs, special reporting forms, multiple re-runs for dilutions, etc.

Radioactive Samples will typically incur a 25% Health and Safety Surcharge for:
Alpha > 1 nCi/L or 0.5 nCi/g;
Beta > 2 nCi/L or 1 nCi/g;
H-3 > 100 nCi/L or 1 nCi/g;
Gamma > 2 nCi/L or 1 nCi/g;

Note: *Radioactive samples require lab approval before receipt.*
Note: *Mixed waste or hazardous samples require special disposal costs or return costs and prior lab approval.*

Appendix D

Condition of Sample Upon Receipt (Form 201)

CONDITION OF SAMPLE UPON RECEIPT FORM **ALS - Fort Collins**

Client: _____ Workorder No: _____

Project Manager: _____ Initials: _____ Date: _____

1. Does this project require any **special handling** in addition to standard Paragon procedures?		YES	**NO**
2. Are custody **seals** on **shipping containers** intact?	NONE	**YES**	NO
3. Are Custody seals on **sample containers** intact?	**NONE**	YES	NO
4. Is there a **COC (Chain-of-Custody) present** or other representative documents?		**YES**	NO
5. Are the **COC and bottle labels complete and legible**?		**YES**	NO
6. Is the **COC in agreement** with samples received? (IDs, dates, times, no. of samples, no. of containers, matrix, requested analyses, etc.)		**YES**	NO
7. Were **airbills / shipping documents** present and/or removable?	DROP OFF	**YES**	NO
8. Are all aqueous **samples requiring preservation preserved correctly?** (excluding volatiles)	N/A	**YES**	NO
9. Are all aqueous **non-preserved samples pH 4-9**?	N/A	**YES**	NO
10. Is there **sufficient sample** for the requested analyses?		**YES**	NO
11. Were all samples placed in the **proper containers** for the requested analyses?		**YES**	NO
12. Are all samples within **holding times** for the requested analyses?		**YES**	NO
13. Were all sample containers received **intact**? (not broken or leaking, etc.)		**YES**	NO
14. Are all samples requiring no headspace (VOC, GRO, Rx CN/S, radon), headspace free? **Size of bubble**: ____ < green pea ____> green pea	N/A	**YES**	NO
15. Were samples checked for and free from the presence of **residual chlorine?** (Applicable when PM has indicated samples are from a chlorinated water source; note if field preservation with sodium thiosulfate was not observed.)	**N/A**	YES	NO
16. Were the samples **shipped on ice**?		**YES**	NO
17. Were cooler temperatures measured at 0.1-6.0°C? **IR gun used*: #2 #4**	RAD ONLY	YES	NO

Cooler #:								
Temperature (°C):								
No. of custody seals on cooler:								
DOT Survey/ Acceptance Information — External µR/hr reading:								
Background µR/hr reading:								

Were external µR/hr readings ≤ two times background and within DOT acceptance criteria? **YES / NO / NA** (If no, see Form 008.)

Additional Information: PROVIDE DETAILS BELOW FOR A NO RESPONSE TO ANY QUESTION ABOVE, EXCEPT #1 AND #16

If applicable, was the client contacted? **YES / NO / NA** Contact: _____ Date/Time: _____

Project Manager Signature / Date: _____

*IR Gun #2: Oakton, SN 29922500201-0066 *IR Gun #4: Oakton, SN 2372220101-0002

CONDITION OF SAMPLE UPON RECEIPT FORM **ALS - Fort Collins**

Client: _____ Workorder No: _____

Project Manager: _____ Initials: _____ Date: _____

Additional Information:

Was the laboratory directed to proceed with the analysis of any samples yielding the presence of residual chlorine? **YES / NO / NA**

NOTE:

No pH adjustments shall be made without prior consent of Project Manager. After pH adjustments, hold metals and radchem samples ≥ 24 hrs. before analysis.

Was the pH of any sample adjusted by the laboratory? **YES** (See Table below) / **NO**

pH Excursion:

Paragon Sample ID	Client Sample ID	Initial pH	Final pH	Reagent Used	Volume Added (mL)	Lot No. of Reagent	Requested Analysis	Initials / Date / Time

If applicable, was the client contacted? **YES / NO / NA** Contact: _____ Date/Time: _____

Nonconformance Report
(Example)

ALS Laboratory Group
ANALYTICAL CHEMISTRY & TESTING SERVICES

NCR #: 10463

PARAGON ANALYTICS
225 Commerce Drive ◆ Fort Collins, CO 80524 ◆ (800) 443-1511 ◆ (970) 490-1511 ◆ FAX (970) 490-1522

CONTROLLED
NON-CONFORMANCE REPORT

Non-Conformance

Initiated By: Lance R. Steere on 2/28/2008

Event Type: Method Requirements Not Met -- HTV

Event Explanation: Samples in these 5 WO's generally received with only 1-2 hours of hold time remaining. By the time they are delivered to the Wetchem lab, most of the hold times have expired. The lab was notified in all cases that samples were expected, and analysis commenced very soon after samples deleivered to the analysts. Morning sampling certainly challenges our ability to meet 24 hr hold times.

Action To Prevent Reccurence: N/A - see comments in explanation

Corrective Action

Corrective Action: Document in Narrative
Department Manager Approval: Deb Scheib
Approval Date: 2/29/2008
Corrective Action Comments:

KENNETH D. CAMPBELL
PARAGON ANALYTICS, A division of DataChem Laboratories, Inc.
225 COMMERCE DRIVE
FORT COLLINS, CO 80524

Dear KENNETH D. CAMPBELL: Certificate No. 06251CA

This is to advise you that the laboratory named above has been accredited under National Environmental Laboratory Accreditation Program (NELAP) as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, et seq.

The Fields of Accreditation for which this laboratory has been accredited are enclosed. Recognition of accreditation is subject to maintaining accreditation with the primary Accrediting Authority. In addition, the laboratory shall comply with the National Environmental Laboratory Accreditation Conference (NELAC) Standards and all associated California Environmental Laboratory Accreditation Program Branch (ELAP) regulations and statutes.

Please note that your laboratory is required to notify California ELAP of any major changes in key accreditation criteria within 30 calendar days of the change. This written notification includes, but is not limited to, changes in ownership, location, key personnel, and major instrumentation (HSC 100845(b) and (d), and NELAC Standard Section 4.3.2). The certificate must be returned to California ELAP upon loss of accredited status.

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories accredited by the State of California.

If you have any questions, please contact Mandy Mok at (510) 620-3155.

Sincerely,

George C. Kulasingam, Ph.D., Chief
Environmental Laboratory Accreditation Program Branch

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

PARAGON ANALYTICS, A division of DataChem Laboratories, Inc.

FORT COLLINS

225 COMMERCE DRIVE

FORT COLLINS, CO 80524

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **06251CA**

Expiration Date: **08/31/2009**

Effective Date: **08/31/2008**

Richmond, California
subject to forfeiture or revocation

formerly, Paragon Analytics (a Division of Data-Chem Laboratories, Inc.)
225 Commerce Drive
Fort Collins, CO 80524

RE: Radiochemistry Certification

Dear Ms. Scheib:

On October 22 & November 6, 2008 an on-site assessment was performed at ALS Laboratory Group (formerly, Paragon Analytics) in Fort Collins to evaluate the laboratory's adherence to certification protocol outlined in the EPA Manual for the Certification of Laboratories Analyzing Drinking Water (5th Edition, 2005), and to quality control and procedural requirements in the individual methods under review. During the visit, I interviewed key personnel in the Radiochemistry department, including Renee Gallegos (Manager) and Steve Workman (Technical Manager), along with other personnel involved with sample receiving, sample prep, instrumentation, etc. I found all items in compliance with method requirements. My overall impression was that the Radiochemistry staff is technically competent and well managed.

Enclosed is your new Colorado Department of Public Health and Environment Safe Drinking Water (SDW) Radiochemistry Certificate and status report dated November1, 2008, which is effective through October 31, 2009, unless suspended or revoked prior to that date, and is based on your laboratory's successful completion of the on-site assessment and successful participation in recent PT Studies (ERA RAD-72/74 & MRAD-8).

This certification must be renewed by October 2009. Routine on-site inspections are conducted every two years (biennial), unless the certification is modified. In all probability there will not be an assessment at the time of renewal, but it is the laboratory's responsibility to submit a renewal application and annual certification fee. If you have any questions, or if there are changes that may affect your certification status, you can reach me at (303) 692-3045.

Sincerely,

Ken Johnson, Certification Officer
Laboratory Services Division

Dear Ms. Scheib:

Enclosed are Paragon Analytics' new Connecticut Certificate of Approval and Approved Analytes List. Please review the documents carefully and notify the program of any errors or omissions. Note that Connecticut certifies out of state laboratories by reciprocity. Certification could only be granted for those analytes for which documentation of certification was provided.

Sincerely yours,

Jeffrey C. Curran

REPORT PROFILE

Report Printed on: 07/16/2008 9:08:01 AM
Report Name: APPROVED TESTS_ALT_NEW
Printed by: jeff
Report published from: CERTIFICATION REPORTS screen #3

lab code = ID1242P
test code = *
matrix code = *
matrix selection = ALL OR SOME MATRICES SELECTED
certifications approved or provisional on 07/16/2008

THIS IS THE LAST PAGE OF THE REPORT

State of Connecticut, Department of Public Health

Approved Environmental Laboratory

THIS IS TO CERTIFY THAT THE LABORATORY DESCRIBED BELOW HAS BEEN APPROVED BY THE STATE DEPARTMENT OF PUBLIC HEALTH PURSUANT TO APPLICABLE PROVISIONS OF THE PUBLIC HEALTH CODE AND GENERAL STATUTES OF CONNECTICUT, FOR MAKING THE EXAMINATIONS, DETERMINATIONS OR TESTS SPECIFIED BELOW WHICH HAVE BEEN AUTHORIZED IN WRITING BY THAT DEPARTMENT.

PARAGON ANALYTICS – DIVISION OF DATACHEM LABORATORIES

LOCATED AT 225 Commerce Drive IN Fort Collins, Colorado 80524

AND REGISTERED IN THE NAME OF Ken Campbell

THIS CERTIFICATE IS ISSUED IN THE NAME OF Ken Campbell WHO HAS BEEN DESIGNATED BY THE REGISTERED OWNER\AUTHORIZED AGENT TO BE IN CHARGE OF THE LABORATORY WORK COVERED BY THIS CERTIFICATE OF APPROVAL AS FOLLOWS:

DRINKING WATER, NON-POTABLE WATER/WASTEWATER, SOLID WASTE/SOIL

Examination For:

INORGANIC CHEMICALS

ORGANIC CHEMICALS

RADIOCHEMICALS

SEE COMPUTER PRINT-OUT FOR SPECIFIC TESTS APPROVED

THIS CERTIFICATE EXPIRES June 30, 2010 AND IS REVOCABLE FOR CAUSE BY THE STATE DEPARTMENT OF PUBLIC HEALTH

DATED AT HARTFORD, CONNECTICUT, THIS 16th DAY OF July 2008

Registration No.

PH - 0232

SUZANNE BLANCAFLOR, MS
CHIEF, ENVIRONMENTAL HEALTH SECTION

Laboratory Scope of Accreditation

Attachment to Certificate #: E87914-06, expiration date June 30, 2009. This listing of accredited analytes should be used only when associated with a valid certificate.

Re: Idaho Certification

Ms. Scheib,

We have reviewed the information you submitted in support of renewing your radiology certification for testing drinking water in the State of Idaho. The attached certificate itemizes the specific analytes and methods for which Paragon Analytics, Inc. has been approved which does not go beyond the certification from the Colorado Department of Public Health and Environment.

The radiological certificate expires October 31, 2008. For continuation of future drinking water certification with the state of Idaho please request a renewal application.

If you have any questions, please feel free to contact me.

Sincerely,

Richard Hudson, PhD
Chief, Bureau of Laboratories
Drinking Water Laboratory Certification Authority

NELAP-RECOGNIZED

MEMORANDUM

TO: DEB SCHEIB
PARAGON ANALYTICS, A DIVISION OF DATACHEM LABORATORIES, INC.
225 COMMERCE DRIVE
FORT COLLINS, CO 80524

FROM: Jack McKenzie and Aurora Shields
Laboratory Improvement Specialists

Enclosed please find your NELAP certificate of accreditation. Also, note the effective and expiration dates of your new accreditation and be sure to review the parameters listed. It is possible your laboratory applied for parameters not listed on the enclosed accreditation. Those parameters have been denied. If there are any questions concerning the parameters listed, contact this office at (785) 296-1639-Jack or (785) 296-6198-Aurora.

It is essential the laboratory accreditation officer be notified within 30 days of any changes in laboratory director, methods which involve a change in technology, change in ownership, or change in location.

An application packet for re-accreditation will be mailed to you approximately five (5) months prior to the expiration date of your current accreditation.

RE: Laboratory Certification 2008

Dear Ms. Scheib,

Please find enclosed your laboratory's Drinking Water Certificate for 2008. Please review the certificate and associated analytes/methods that your laboratory is certified for the analysis of drinking water samples in Kentucky. The certificate is valid until December 31, 2008. Also enclosed is a receipt for your certification fee for 2008.

If you have any comments or questions regarding the enclosed documents please contact Patrick Garrity at (502) 564-3410 extension 574 or by email at patrick.garrity@ky.gov.

PARAGON ANALYTICS A Division Of Data Chem Laboratories Inc. 285

Dear Mr. Campbell:

Your laboratory was originally due to be re-certified for Microbiology and /or Chemistry by September 30, 2008. However, it is not possible to meet that scheduled deadline. It is necessary for us to extend your certification with a new expiration date of December 30, 2008.

We have received your laboratory certification and payment. The documents are currently under review. Thank you for your cooperation.

If you have any questions, please contact me at lames@mde.state.md.us or 410-537-3712.

Lab #175

Dear Ms Scheib:

Based upon an evaluation of laboratory data by staff of the Missouri Department of Natural Resources' Environmental Services Program and the on-site evaluation performed by the Utah Department of Health, Division of Epidemiology and Laboratory Services, Paragon Analytics, Inc, is certified under the provisions of the Missouri Public Drinking Water Regulations to perform chemical analysis for public water systems in the State of Missouri.

Enclosed is a certificate of approval and a certified parameter list for your laboratory. Please reference the certified parameter list for parameters and methods of analysis that have been approved by the State of Missouri to complete chemical testing for public water systems. **Your certification will expire at the same time your certification from the State of Utah expires and is contingent upon no changes being made with the approved methods or equipment.** Please notify this office within 30 days of changes, which occur in these specified areas before the June 30, 2008 expiration date.

Sincerely,

has been approved to perform the indicated procedures on drinking water under the Missouri Public Drinking Water Regulations (10 CSR 60-5.020). Specific method numbers or references are included in parenthesis when appropriate.

RADIOACTIVITY

Gross Alpha (EPA 900.0), Gross Beta (EPA 900.0), Gross Alpha & Beta Radioactivity in Drinking Water Evaporation Technique (EPA 900.0), Cesium 134 (EPA 901.1), Gamma Emitters (EPA 901.1), Alpha Emitting Radium Isotopes (EPA 903.0), Radium 226 (EPA 903.0), Total Radium (EPA 903.0), Radium 226 in Drinking Water Radon Emanation Technique (EPA 903.1), Radium 228 in Drinking Water Radiochemical Technique (EPA 904.0), Tritium in Drinking Water Liquid Scintillation Technique (EPA 906.0), Strontium-90 (ASTM D5811-95), Strontium-89/90 Radiochemical Technique (DOE-Sr-01), Strontium-89/90 Radiochemical Technique (DOE-Sr-02), Uranium Alpha Spectrometry Technique (ASTM D-3972-90), Uranium Alpha Spectrometry Technique (DOE-U-02)

Expiration Date: June 30, 2008
Certificate No.: 175
Original Certifying State: Utah

State of Missouri
Department of Natural Resources

Certificate of Approval
for Chemical Laboratory Service

This is to certify that

Paragon Analytics, Inc

is hereby approved to perform the analysis of drinking water as specified on the Certified Parameter List, which must accompany this certificate to be valid.

Certification No. 175

Date Issued July 20, 2007

Expiration Date June 30, 2008

Chief, Public Drinking Water Branch
Water Protection Program
Department of Natural Resources

Director, Environmental Services Program
Department of Natural Resources

Evaluation Officer, Environmental Services Program

September 10, 2008

Debra Scheib
Paragon Analytics, Inc.
225 Commerce Drive
Fort Collins, CO 80524

Dear Ms. Scheib:

Paragon Analytics' State of Utah Department of Health certification for the Clean Water Act, Resource Conservation and Recovery Act and Safe Drinking Water Act parameters by the methods on the enclosed list of certified parameters for the laboratory is being recognized by the North Dakota Environmental Laboratory Certification Program (NDELCP) for the period July 01, 2008 through June 30, 2009. The main requirements for maintaining this recognition of certification are (1) that I be notified, in writing, within thirty days of any changes in the status of Paragon Analytics' Utah certification for the parameters by the methods on the enclosed list during the effective period of this recognition of certification; and (2) that I be sent copies of the reports of Paragon Analytics' participation in water pollution, RCRA, water supply and radiochemistry proficiency test studies for the parameters by the methods on the enclosed list during the effective period of this recognition of certification.

If Paragon Analytics desires to renew certification with North Dakota when this recognition of certification expires, an authorized representative will need to contact me to initiate the renewal process. Anyone having questions about this recognition of Paragon Analytics Utah certification by the NDELCP should call me at 701-328-6172.

Sincerely,

Errol Erickson

Errol Erickson
Laboratory Certification Officer for Chemical Parameters

NORTH DAKOTA STATE DEPARTMENT OF HEALTH
RECOGNITION OF CERTIFICATION OR ACCREDITATION

The North Dakota State Department of Health recognizes the certification or accreditation of

Paragon Analytics, Inc. - 225 Commerce Drive - Fort Collins, CO

by

State of Utah Department of Health

for

All Clean Water Act, Resource Conservation and Recovery Act and Safe Drinking Water Act chemical parameters by the methods on the accompanying list of certified parameters for this laboratory

Certification Number: R-057

Date of Issue: September 10, 2008 Expiration Date: June 30, 2009 Covers: 7/1/2008 - 6/30/2009

This certificate remains the property of the North Dakota State Department of Health and may be recalled, for cause, at any time, by the Department. Recognition of a laboratory's certification or accreditation from another state's certification or accreditation program by the North Dakota State Department of Health is neither an endorsement of the results reported by the laboratory nor a guarantee of the validity or accuracy of the results reported by the laboratory.

Myra Kosse

JON S. CORZINE
Governor

LISA P. JACKSON
Commissioner

July 30, 2008

Deb Scheib
Paragon Analytics
225 Commerce Drive
Fort Collins, CO 80524

Dear Ms. Scheib:

Re: Application Modification Request
Laboratory Certification ID# CO003

Based on your request for certification for the parameter(s) listed below and a review of your supporting documentation, enclosed is an up-dated annual certified parameter list (ACPL). This will replace the current ACPL your laboratory holds. Please review it carefully and notify this office immediately if any discrepancies are noted.

Parameter Code	Parameter	Method	Status
SHW04.47300	Uranium	SW-846 6020	Certified

If this office can be of any further assistance, please call Vas Komanduri at (609) 292-3950.

Sincerely,

Joseph F. Aiello, Chief

RE: Nevada Environmental Laboratory Certification Extension.

Dear Paragon Analytics:

Your 2006-2007 Nevada scope (including any approved additions) has been **extended** until July 31, 2009.

This will serve as notice to you and your clients.

We are still processing 2007-2008 applications. We will be processing your 2007-2008 and 2008-2009 applications simultaneously. Your patience is appreciated.

If you or your clients have any questions please contact Donald LaFara at 775-687-9491.

Sincerely,

Don LaFara

PARAGON ANALYTICS
225 COMMERCE DR
FORT COLLINS CO 80524

RE: Environmental Laboratory Certification Extension.

Dear PARAGON ANALYTICS:

Your laboratory is paid in full for the FY07 (August 1, 2006-July 31, 2007) and your certification has been **extended**.

Either your FY06 (August 1, 2005-July 31, 2006) scope or your FY07 (August 1, 2006-July 31, 2007) scope is in effect until receipt of your FY08 (August 1, 2007-July 31, 2008) scope and certificate from the State of Nevada; Department of Conservation and Natural Resources; Division of Environmental Protection.. However, your continued certification is dependent on receipt of your FY08 application.

This will serve as notice to you and your clients.

If you or your clients have any questions please contact Donald LaFara at 775-687-9491.

Sincerely,

Don LaFara

Re: Lab ID No. 68-03116

Dear Laboratory Director:

Enclosed is your new Certificate of Accreditation to operate as a Pennsylvania Accredited Laboratory. This Certificate of Accreditation expires 3/31/2009 unless suspended or revoked earlier.

Your Laboratory identification number is 68-03116. Please use this number on all correspondence with the PA Department of Environmental Protection (Department).

Your laboratory is accredited to perform only the analyses by the methods listed on the Scope of Accreditation that accompanies the Certificate of Accreditation. The Certificate of Accreditation remains the property of the Department and must be displayed in the laboratory.

Please note this certification must be renewed annually. Renewal applications must be submitted to the Department *no later than 60 days prior to the expiration of the certification.* Failure to submit a renewal application within this time period may result in a lapse of the laboratory's accreditation. Should this occur, the laboratory may not conduct any further analyses for which accreditation is required and, if the laboratory is accredited to perform analyses on drinking water, the laboratory must notify the public water suppliers served by the laboratory of the laboratory's failure to renew its certificate of accreditation. Copies of the renewal application may be found on the Department's web site (www.dep.state.pa.us/dep/deputate/mts/bol).

If you have any questions concerning your certificate, you may contact the Laboratory Accreditation Program at the address, phone number or fax number listed above.

Sincerely,

Aaren S. Alger, Chief
Laboratory Accreditation Program

November 27, 2007

Ms. Debra Scheib
Paragon Analytics, Inc.
225 Commerce Drive
Fort Collins, CO 80524

Dear Ms. Scheib,

This is to confirm that the State of Tennessee Drinking Water Laboratory Certification Program has approved Paragon Analytics, Inc. (TN02976) for Drinking Water Laboratory Certification in Radiochemistry by reciprocity with the State of Colorado under the Safe Drinking Water Act.

The certification is through October 31, 2008 unless withdrawn earlier.

Results of future evaluations made by the State of Colorado and/or USEPA such as performance evaluation reports, on-site audits, certifications, or changes in personnel, etc., must be forwarded to this office. Should the State of Colorado withdraw certification of your laboratory, certification by the State of Tennessee shall likewise be revoked.

Please use the identification number TN02976 when submitting analytical data or other correspondence to this office.

If you have any question, please contact Craig LaFever at (615) 532-0181.

Sincerely,

Craig LaFever

Subject: Notification of Paragon Acquisition / Name Change
Attachments: Acquisition Announcement.pdf

Frank -

Please accept this e-mail as official notification that effective 11/1/08, DataChem (of which Paragon is a part of) was purchased by ALS Laboratory Group (owned overall by Campbell Brothers, Ltd., Australia). Please see the acquisition announcement on letterhead attached. Paragon was able to bring extensive environmental and radiochemistry capabilities to ALS; in addition to the Environmental Division, ALS has Mineral, Coal, Tribology, Food/Pharma, and Electronics/Consumer Divisions. I am confident that ALS Paragon will be able to accomplish great things together.

Please note that Datachem was purchased as an intact entity - there have been no changes to equipment or staffing, including key personnel.

We'll be known as ALS Paragon for awhile, transitioning fully to ALS Environmental Division (Fort Collins, CO) by March 31st. To that end, please re-issue our current certification as ALS Laboratory Group, Environmental Division (Fort Collins, CO), at your convenience. Additionally, I would appreciate your referencing us as 'formerly Paragon Analytics, a Division of DataChem Laboratories, Inc.' in the cover letter.

Please don't hesitate to let me know if you have any questions or concerns.

Best Regards,

Deb

PARAGON ANALYTICS
A Division of DataChem Laboratories, Inc.

ALS Laboratory Group
ANALYTICAL CHEMISTRY & TESTING SERVICES

November 1, 2008

We are pleased and excited to announce that Paragon (a division of DataChem Laboratories, Inc.) has been acquired by the ALS Laboratory Group, North America, based in Houston, Texas. Paragon is now part of the global ALS Laboratory Group, offering a greater range of analytical chemistry all around the world.

Paragon is a recognized quality leader and is one of the largest providers of environmental, industrial hygiene, and radiochemistry testing services in the U.S. Paragon has clients throughout the U.S. and enjoys a nationwide reputation for producing quality and legally defensible data.

We want to assure Paragon's clients that senior management, technical managers, project managers, and our highly trained chemists and scientists will remain with the company. We are committed to the continued success and geographic expansion of our business; which has developed into one of the most successful environmental, industrial hygiene, and radiochemistry laboratories consistently delivering the highest level of performance. We will continue to honor all pricing and service arrangements you have with Paragon. As a group, we will be going forward with ALS Laboratory Group to combine the best aspects of both companies into a stronger network of laboratories that will continue to excel as your preferred laboratory partner. We will continue to provide you a high level of service and legally defensible data.

With this union, Paragon joins a most impressive global network of environmental laboratories which now includes 51 locations spread around the globe. These countries include Canada, Mexico, Chile, Peru, Australia, China, Indonesia, Malaysia, Singapore, Taiwan, Sweden, Czech Republic, Denmark, Norway, and the U.S.; all providing clients with superior analytical and technical support for local and international projects. The ALS Laboratory Group is a diverse, global company with 117 laboratories operating in 35 countries staffed by over 6,000 employees. In addition to environmental services, the ALS Laboratory Group offers a broad range of sophisticated state-of-the-art services to four main market segments including: mining and mineral exploration, equipment maintenance through used lubricant analysis, commodity analysis and certification, and environmental monitoring. The ALS Laboratory Group is part of a long established Australian public company, Campbell Brothers Limited which has operated service-oriented businesses for over 130 years.

If you have any questions, please do not hesitate to contact the following:

Texas Commission on Environmental Quality

NELAP-Recognized Laboratory Accreditation is hereby awarded to

ALS LABORATORY GROUP, ENVIRONMENTAL DIVISION (FORT COLLINS, CO)
225 COMMERCE DRIVE
FORT COLLINS, CO 80524

in accordance with Texas Water Code Chapter 5, Subchapter R, Title 30 Texas Administrative Code Chapter 25, and the National Environmental Laboratory Accreditation Program.

The laboratory's scope of accreditation includes the fields of accreditation that accompany this certificate. Continued accreditation depends upon successful ongoing participation in the program. The Texas Commission on Environmental Quality urges customers to verify the laboratory's current accreditation status for particular methods and analyses.

Director,

On the basis of your most recent assessment, Proficiency Testing results and continuing compliance with the ELCP requirements, the laboratory listed is certified for environmental monitoring under the Safe Drinking Water Act and authorized to perform the following methods, for the analytes and matrix listed:

Drinking Water

Inorganics and Metals

120.1 [1982]	Conductivity
150.1 [1982]	pH
160.1 [1971]	Residue, Filterable
200.7 [1994]	Aluminum
200.7 [1994]	Antimony
200.7 [1994]	Arsenic
200.7 [1994]	Barium
200.7 [1994]	Beryllium
200.7 [1994]	Boron
200.7 [1994]	Cadmium
200.7 [1994]	Calcium
200.7 [1994]	Chromium
200.7 [1994]	Cobalt
200.7 [1994]	Iron
200.7 [1994]	Lithium
200.7 [1994]	Magnesium
200.7 [1994]	Manganese
200.7 [1994]	Molybdenum
200.7 [1994]	Nickel
200.7 [1994]	Potassium
200.7 [1994]	Selenium
200.7 [1994]	Silica
200.7 [1994]	Silver
200.7 [1994]	Sodium
200.7 [1994]	Strontium
200.7 [1994]	Thallium
200.7 [1994]	Tin
200.7 [1994]	Titanium
200.7 [1994]	Vanadium

The expiration for the laboratory's certification is 6/30/2009. The Utah Environmental Laboratory Certification Program (ELCP) encourages clients and data users to verify the most current certification letter for the authorized method. For further assistance please call 801-584-8469.

The effective date of this certificate letter is: 7/1/2008.

The analytes by method which a laboratory is authorized to perform at any given time will be those indicated in the most recent certificate letter. The most recent certification letter supersedes all previous certification or authorization letters. It is the certified laboratory's responsibility to review this letter for discrepancies. The certified laboratory must document any discrepancies in this letter and send notice to this bureau within 15 days of receipt. This certificate letter will be recalled in the event your laboratory's certification is revoked.

Respectfully,

Barbara R. Jepson for Luedtke

The effective date of this certificate letter is: 7/1/2008.

The analytes by method which a laboratory is authorized to perform at any given time will be those indicated in the most recent certificate letter. The most recent certification letter supersedes all previous certification or authorization letters. It is the certified laboratory's responsibility to review this letter for discrepancies. The certified laboratory must document any discrepancies in this letter and send notice to this bureau within 15 days of receipt. This certificate letter will be recalled in the event your laboratory's certification is revoked.

Respectfully,

Barbara R. Jepson for Dr. Luedtke

Director,

On the basis of your most recent assessment, Proficiency Testing results and continuing compliance with the ELCP requirements, the laboratory listed is certified for environmental monitoring under the Resource Conservation and Recovery Act and authorized to perform the following methods, for the analytes and matrix listed:

Characteristics

	Solid	Non-Potable Water	
1010 A	☐	☑	Ignitability
1311	☑	☐	Toxicity Characteristic Leaching Procedure Metals
1311	☑	☐	Toxicity Characteristic Leaching Procedure Semi-Volatiles
1311	☑	☐	Toxicity Characteristic Leaching Procedure Volatiles
1312	☑	☐	Synthetic Precipitation Leaching Procedure (TCLP Approval)
Sec 7.3.3	☑	☐	Reactive Cyanide
Sec 7.3.4	☑	☐	Reactive Sulfide
Sec 8.3	☑	☐	Reactivity

Inorganics

	Solid	Non-Potable Water	
1664 A [199	☐	☑	Oil & Grease

The effective date of this certificate letter is: 7/1/2008.

The analytes by method which a laboratory is authorized to perform at any given time will be those indicated in the most recent certificate letter. The most recent certification letter supersedes all previous certification or authorization letters. It is the certified laboratory's responsibility to review this letter for discrepancies. The certified laboratory must document any discrepancies in this letter and send notice to this bureau within 15 days of receipt. This certificate letter will be recalled in the event your laboratory's certification is revoked.

Respectfully,

Barbara R. Jepson for Dr. Luedtke

Ms. Debra Scheib
ALS Lab Group, Environmental Division (Fort Collins)
225 Commerce Drive
Fort Collins, CO80524-1416

Dear Ms. Scheib:

Per your request a new Certificate and Scope of Accreditation have been issued and are enclosed to reflect the ownership change for your laboratory, formerly Paragon Analytics, a Division of DataChem Laboratories, Inc. We wish you success in your new situation.

If you have any further comments or questions please feel free to contact Lee Fearon in our office at (360) 895-6146 or at his e-mail address of lfea461@ecy.wa.gov.

Sincerely,

Stewart M. Lombard
Lab Accreditation Unit Supervisor

Enclosures: 1. Certificate
2. Scope of Accreditation

Scope of Accreditation

ALS Lab Group, Environmental Division (Fort Collins)

Fort Collins, CO

is accredited by the State of Washington Department of Ecology to perform analyses for the parameters listed below using the analytical methods indicated. This Scope of Accreditation may apply to any of the following matrix types: non-potable water, drinking water, solid and chemical materials, and air and emissions. Accreditation for all parameters is final unless indicated otherwise in a note. Accreditation is for the latest version of a method unless otherwise specified in a note. EPA refers to the U.S. Environmental Protection Agency. SM refers to American Public Health Association's publication, Standard Methods for the Examination of Water and Wastewater, 18th, 19th or 20th Edition, unless otherwise noted. ASTM stands for the American Society for Testing and Materials. PSEP stands for Puget Sound Estuary Program. Other references are detailed in the notes section.

Matrix Type/Parameter Name	Reference	Method Number	Notes
Non-potable Water			
Alpha, Gross	EPA	900.0	1
Beta, Gross	EPA	900.0	1
Gamma Emitting Isotopes	EPA	901.1	1
Radium 226	EPA	903.0	1

Volatile Organic Compounds	EPA	8260	1
Alpha, Gross	EPA	9310	1
Beta, Gross	EPA	9310	1
Radium 228	EPA	9320	1
Radium Alpha Emiting Isotopes	EPA	9315	1

Accredited Parameter Note Detail

(1) Accreditation based in part on recognition of Utah NELAP accreditation. (2) Method has been modified to use lower concentrations of surrogate compounds than specified in the method. (3) Only Sr 90 is determined.

S M Lombard — November 20, 2008

Authentication Signature — Date

Stewart M. Lombard, Lab Accreditation Unit Supervisor

The State of Washington Department of Ecology

This is to certify that

ALS Lab Group, Environmental Division (Fort Collins)
Fort Collins, CO

has complied with provisions set forth in Chapter 173-50 WAC and is hereby recognized by the Department of Ecology as an ACCREDITED LABORATORY for the analytical parameters listed on the accompanying Scope of Accreditation. This certificate is effective February 3, 2008, and shall expire February 2, 2009.

Witnessed under my hand on November 20, 2008.

RADIOACTIVE MATERIALS LICENSE

Pursuant to the *Colorado Radiation Control Act*, Title 25, Article 11, *Colorado Revised Statutes*, and the State of Colorado *Rules and Regulations Pertaining to Radiation Control* (the Regulations) and in reliance on statements and representations heretofore made by the licensee designated below; a license is hereby issued authorizing such licensee to transfer, receive, possess and use the radioactive material(s) designated below; and to use such radioactive material(s) for the purpose(s) and at the place(s) designated below. This license is subject to all applicable rules, regulations, and orders now or hereafter in effect of the Colorado Department of Public Health and Environment and to any conditions specified below.

---

1. **Licensee: Paragon Analytics a Division of DataChem Laboratories**
   dba: Paragon Analytics

2. Address: 225 Commerce Drive, Fort Collins, Colorado 80524

3. Colorado License Number 847-02, Amendment Number: 12

4. Expiration date: June 30, 2012

5. Reference Number: Fee Category: 3.M

---

6. Radioactive materials (element and mass no.)	7. Chemical and/or physical form	8. Maximum quantity licensee may possess at any one time
A. Hydrogen-3	A. Any	A. 1.85 GBq (50 mCi)
B. Any radioactive material with atomic numbers 3-83	B. Any	B. 370 MBq (10 mCi)
C. Any radioactive material with atomic number 84-100	C. Any	C. 370 MBq (10 mCi)
D. Source Material	D. Any	D. 37 MBq (1 mCi)
E. Any radioactive material with atomic numbers 3-98	E Sealed Sources	E. 187 MBq (5 mCi) total, no single source to exceed 1.48 MBq (40 μCi)

RADIOACTIVE MATERIALS LICENSE

CONDITIONS

9. Radioactive material authorized in Items 6.A. through 6.D. may be received in the form of environmental samples (such as soil, water, vegetation, milk, and building debris, etc.) for radiochemical analysis. Radioactive material authorized in Items 6.A. through 6.D. may also be received and used as reference standards in the analytical procedures.

10. Radioactive materials authorized in Item 6.E. is limited to commercially distributed radioactive standards and/or calibration sources to be used for the calibration and checks of analytical equipment.

11. Radioactive material may be used and stored only at 225 Commerce Drive, Fort Collins, Colorado, 80524.

12. The licensee shall comply with the provisions of the State of Colorado *Rules and Regulations Pertaining to Radiation Control*, Part 4, "Standards for Protection Against Radiation", and Part 10, "Notices, Instructions and Reports to Workers: Inspections".

13. Radioactive material shall be used by, or under the supervision of Steven Workman, Lance Steere, Charles Orchard, Renee Gallegos, or Rebecca Schwab.

14. The designated Radiation Safety Officer is Charles Orchard.

15. Radioactive material authorized by Item 6 of this license shall be stored and used in a manner that will preclude possession or use by unauthorized personnel.

16. Each sealed source containing radioactive material authorized in Item 6 shall be tested for leakage and/or contamination in accordance with RH 4.16 of the State of Colorado *Rules and Regulations Pertaining to Radiation Control* at intervals not to exceed six months.

17. The licensee shall not transfer possession and/or control of radioactive material or products containing radioactive material as a contaminant except by transfer of waste to an authorized recipient; by transfer to a specifically licensed recipient; or as provided otherwise by specific condition of this license pursuant to the requirements of Section 3.22 of the Regulations.

18. Wipe tests for contamination must be completed weekly when radioactive materials are used.

19. The analysis of the wipes must be capable of detecting 20 disintegrations per minute (DPM) of alpha emitting radioactive material and 200 DPM of beta/gamma emitting radioactive material on the test sample.

RADIOACTIVE MATERIALS LICENSE

20. If an area survey or wipe test detects the presence of radioactive materials in excess of the limits specified below, then the area and/or affected equipment shall be decontaminated until:

    A. the removable contamination is not greater than: 20 DPM (alpha) per 100 cm2 and 200 DPM (beta/gamma) per 100 cm2.

    B. the average fixed contamination is not greater than: 100 DPM (alpha) per 100 cm2 and 1000 DPM (beta/gamma) per 100 cm2.

    C. the maximum fixed contamination is not greater than 300 DPM (alpha) per 100 cm2 and 3000 DPM (beta/gamma) per 100 cm2.

21. The licensee shall maintain records of surveys and wipe tests for contamination, waste disposal, and the analysis of liquid process wastes disposed of via the sewer.

22. The licensee shall maintain in effect a decommissioning financial warranty acceptable to the Department in accordance with the requirements of Part 3, Section 3.9.5 of the Regulations.

23. The State of Colorado *Rules and Regulations Pertaining to Radiation Control* shall govern the licensee's statements in applications or letters, unless the licensee's statements are more restrictive than the regulations. Except as specifically provided otherwise by this license, the licensee shall possess and use radioactive material described in Item 6 of this license in accordance with statements, representations, and procedures contained in:

    A. the application and attachments dated May 21, 2007; and

    B. the license correspondence and attachments received June 7, 2007; August 23, 2007; and

    C. the Irrevocable Standby Letter of Credit Number NZS535426, dated January 14, 2005, in the amount of $250,000.00, issued by Wells Fargo Bank, N.A., Trade Services Division, Northern California, One Front Street 21st Floor, San Francisco, California 94111.

FOR THE COLORADO DEPARTMENT OF PUBLIC HEALTH AND ENVIRONMENT

Comments:

- Paragon Analytics is also a listed radiochemistry laboratory with the State of Indiana (Phillip Zillinger 317-921-5571)

- The certifications and licenses depicted herein represent the suite of certifications that Paragon maintains. In some cases, expired certificates are shown to indicate that re-application has been submitted, and receipt of updated certification is pending.

STANDARD OPERATING PROCEDURE 001 REVISION 7

TITLE: TREATMENT OF QUARANTINED SOILS, AQUEOUS EXTRACTS, AND SOLID RESIDUES AND CLEANING CONTAINERS USED TO STORE QUARANTINED SAMPLE MATERIALS

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2/2/07

QUALITY ASSURANCE MANAGER _____ DATE 2/2/07

LABORATORY MANAGER _____ DATE 2-2-07

HISTORY: Rev0, 4/15/92; Rev1, PCN #218, 4/13/94; Rev2, PCN #476, 5/26/95; Rev3, 3/15/99; Rev4, 2/11/02; Rev5, 4/7/03; Rev6, 2/13/04 and 11/10/05 (re-released w/o revision); Rev7, 2/2/07.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedures used to destroy possible biological infestation (e.g., fire ants, nematodes, etc.), in soils obtained from geographic areas, domestic or foreign, designated as 'Quarantined', by the United States Department of Agriculture (USDA) Animal and Plant Health Inspection Service (APHIS). The treatment protocols described herein apply also to the aqueous extracts, including TCLP extracts, and solid residues derived from 'APHIS QUARANTINE' soils. Procedures for cleaning the containers in which these potentially contaminated materials are stored are also discussed. **Note that APHIS QUARANTINE does NOT apply to solvent extracts or acid digestates because the solvent or acid treatment of the sample aliquot is sufficient to kill any biological infestation that may be present.**

2. SUMMARY

Disposal of APHIS QUARANTINE soils and derivatives, without treatment, is permitted so long as the APHIS QUARANTINE materials are disposed in a waste stream that is incinerated at an approved facility at temperatures above 110°C. However, it is best to treat prior to disposal.

Adding bleach to the APHIS QUARANTINE materials is one means by which potential biological infestation may be destroyed. APHIS QUARANTINE soils or solid sample residues may also be treated by heating at a specified minimum temperature for a prescribed period of time. Aqueous (including TCLP) extracts of APHIS QUARANTINE soils may also be treated by boiling rapidly for one full minute.

The specific means used to treat APHIS QUARANTINE materials is at the discretion of Paragon's Waste Manager. After suitable treatment, the materials are handled as non-

quarantined laboratory waste, and are disposed in accordance with Paragon SOPs 003 and 015.

3. RESPONSIBILITIES

3.1 Information about APHIS QUARANTINE soil samples is disseminated to laboratory staff via project special handling instructions created by the Sample Control Manager. APHIS QUARANTINE soils, and the aqueous extracts (including TCLP) and solid residues derived from them, are distinguished by an 'APHIS QUARANTINE' label. The Sample Control Manager is responsible for creating 'APHIS QUARANTINE' labels so that they are available to laboratory staff.

3.2 The Paragon Project Manager is responsible for working with the Sample Control Manager to identify samples that are APHIS QUARANTINE, and for assuring that appropriate information and labeling materials are provided to laboratory staff.

3.3 As discussed in SOP 202, upon receipt, Sample Receiving personnel apply an 'APHIS QUARANTINE' label to all APHIS QUARANTINE soil sample containers received. Additional 'APHIS QUARANTINE' labels are distributed to laboratory staff along with the samples, when they are delivered to the individual laboratory areas.

Laboratory staff are responsible for applying the APHIS QUARANTINE labels to applicable aqueous (including TCLP) extracts, and solid residues.

3.4 Paragon's Waste Manager is responsible for adequately training staff per the treatment procedures described in this SOP.

3.5 It is the responsibility of the Technician to perform these procedures according to this SOP and to inform the Health & Safety Manager and Waste Compliance Officer of any problems that may occur during the performance of these procedures.

4. APPARATUS AND MATERIALS

4.1 beakers, Pyrex™, 1L or sufficient size

4.2 spatula or disposable "tongue depressors"

4.3 squirt bottle

4.4 hot plate(s)

4.5 oven, capable of maintaining 110-130°C or greater

4.6 baking containers (e.g., large aluminum pan)

4.7 scrub brush

5. REAGENTS

5.1 tap water

5.2 laboratory soap

5.3 bleach, common household

6. PROCEDURES

6.1 BOILING AQUEOUS EXTRACTS OF APHIS QUARANTINE SOILS

6.1.1 Shake the container to loosen any solids that may be present, and dump the container's contents into a Pyrex™ beaker large enough to contain the materials and sufficient tap water to allow a full boil without boiling over. Use a spatula or other suitable implement to loosen any solids that remain in the container and add them to the Pyrex™ beaker.

6.1.2 Use a squirt bottle filled with tap water to rinse the container, its lid, and the spatula. Collect the rinsate in the same Pyrex™ beaker.

6.1.3 Fill the beaker to approximately three-quarters full with tap water, and place it on a hot plate located in a fume hood. Bring the contents to a full boil.

6.1.4 Allow the contents to boil rapidly for at least one full minute.

6.1.5 Carefully remove the beaker from the hotplate. Allow the contents to cool to nearly room temperature.

6.1.6 Discard the liquid contents of the beaker as aqueous laboratory waste. Transfer any residual solid material to a baking container, and treat as described in Section 6.2.

6.1.7 Clean the beaker in a normal manner (SOP 334).

6.2 HEAT TREATMENT FOR APHIS QUARANTINE SOILS AND SOLID RESIDUES

6.2.1 Use a spatula or other suitable implement to spread the quarantined soil or solid residues on the bottom of a suitable baking container (e.g., aluminum pan). Do not allow the thickness of the solid materials to exceed approximately two inches. Use the spatula to scrape away as much solid material as possible that is clinging to the inside of the container, add the scraped-off material to the baking container. Use the edge of the baking container to scrape off any solid material remaining on the spatula.

NOTE: Solid samples in heat resistant containers may be heat-treated in the original sample container.

6.2.2 Place the baking container(s) in an oven set to maintain 110-120°C. Allow sufficient time for the solid materials to equilibrate to oven temperature and continue to bake for at least 16 hours.

Alternately, the solid materials may be equilibrated to 130°C or greater and baked for two hours.

6.2.3 Carefully remove the baking containers from the oven and allow them to cool to nearly room temperature.

6.2.4 Discard the solids and aluminum baking containers as contaminated soils and solids waste.

6.3 BLEACH TREATMENT OF APHIS QUARANTINE SOILS AND SOLID RESIDUES

6.3.1 Place solid materials in a bath of bleach solution. Make sure that the materials are totally submerged, let them soak for at least 1 hour.

6.3.2 Remove the solid materials from the bleach bath, and dispose of them in the appropriate waste stream.

6.3.3 Dispose of the bleach bath solution via an appropriate waste stream.

6.4 TREATMENT OF APHIS QUARANTINED MATERIALS CONTAINERS

6.4.1 Fill empty containers with bleach solution. Let soak for a period of at least 1hour. Empty and wash as described below.

6.4.2 Fill the sink to about three-quarters full with hot, soapy water.

6.4.3 Place the APHIS QUARANTINE materials containers in the sink and allow them to soak. Remove the APHIS QUARANTINE and any other labels from the containers and discard them as sanitary waste.

6.4.4 Thoroughly scrub the containers with a brush.

6.4.5 After scrubbing and cleaning with hot soapy water, rinse thoroughly with tap water.

6.4.6 Dispose of the cleaned containers as sanitary waste.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

7.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel are trained in the use and location of these items.

7.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), and when handling materials or equipment potentially contaminated with chemicals, or within a laboratory area.

7.1.3 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) are labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

7.1.4 Food and drink are prohibited in all lab areas.

7.2 WASTE DISPOSAL

7.2.1 Dispose of treated APHIS QUARANTINE soils, solid residues, and aqueous extracts per the standard waste handling procedures found in SOPs 003 and 015.

7.2.2 Containers used to store quarantined materials, and cleaned as described in this SOP, shall be disposed of as sanitary waste.

Re-released w/o revision 10/2/07 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the procedures used to verify that the face velocity of laboratory exhaust fume hoods is within normal and acceptable operating parameters.

2. SUMMARY

The face velocity of the laboratory exhaust hoods shall be checked on a monthly basis to ensure that the face velocity for each hood is within the operating range specified for that hood. The face velocity will be checked using an air velocity-measuring device. The results of the measurement shall be indicated on a label affixed to the hood indicating the date checked, rated face velocity, sash position to give the rated face velocity, and due date for the next face velocity check.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician performing this procedure to:

- follow the SOP explicitly.
- complete the associated Test Log and return it to the Health and Safety Manager.
- tag-out (SOP 317) any hood that fails to meet the minimum acceptance criteria.
- notify the Health & Safety Manager when a fume hood fails to meet the minimum acceptance criteria.

3.2 It is the responsibility of the Health and Safety Manager to investigate any hood that fails to meet the minimum acceptance criteria and effect any repairs necessary before returning the fume hood to normal service.

3.3 In the event that professional services, such as plumbers or HVAC technicians, are required to effect the repairs, the Health and Safety Manager is responsible for

requesting those services from the Facilities Manager. The Facilities Manager is responsible for procuring professional services.

4. APPARATUS AND MATERIALS

4.1 Alnor Model RVA Anemometer or equivalent.

4.2 Avery® #5160 labels or equivalent.

5. PROCEDURE

5.1 FACE VELOCITY MEASUREMENTS

The face velocity shall be determined by taking a face velocity measurement in feet per minute averaged over the entire surface area of the hood's opening.

5.1.1 During the measurement the technician should always stand to the side of the anemometer, with the instrument at arm's length, so that the measured airflow is not blocked by the person performing the measurement.

5.1.2 The sash shall be positioned at the level indicating the rated face velocity.

5.1.3 The Alnor model RVA is placed at the top left corner of the hood opening, with the center of the instrument six inches away from the top and left side of the opening (see Figure 1).

5.1.4 The Alnor Model RVA's anemometer is allowed to spool up until a constant readout is achieved prior to measurement.

5.1.5 After the Alnor Model RVA has spooled up, depress and hold the test button.

5.1.6 Slowly (approx. 3-4 inches per second) move the anemometer to the right until the center of the instrument is approximately six inches from the right side of the hood opening. Slowly move the anemometer down six inches and move to the left, as shown in Figure 1.

5.1.7 Continue to move the anemometer along the path shown in Figure 1 until the center of the instrument is within six inches of the bottom of the hood opening.

5.1.8 Complete the last pass of the hood opening.

5.1.9 Release the test button and record the reading. This reading is the average face velocity over the entire hood surface.

5.2 ANALYSIS OF FACE VELOCITY MEASUREMENTS

5.2.1 The average face velocities and date of test for each hood shall be recorded in the Monthly Fume Hood Face Velocity Test Log (see attached example).

5.2.2 If the minimum target velocity is not achieved, corrective action must be taken, as described in the next Section.

5.2.3 The sash location that meets the face velocity requirement must be marked with an approved label, such as the one shown in Figure 2. These labels may be printed on Avery 5160® labels from the template located at i:\oprnts\safety\hoodlbl.doc. Any equivalent label with the same information is acceptable.

5.3 CORRECTIVE ACTION FOR NONCONFORMING MEASUREMENTS

5.3.1 If the fume hood velocity check fails to meet the minimum acceptance criteria, the hood sash height may be adjusted to achieve the target velocity.

5.3.1.1 Measure the sash height, in any units.

5.3.1.2 Multiply this number by the measured face velocity, determined in Step 5.1.9.

5.3.1.3 Divide the result by the desired face velocity. The result is the desired sash height, in the same units used to measure the sash height in Step 5.3.1.1.

5.3.1.4 Move the hood sash to the desired height.

5.3.1.5 IN NO CASE WILL THE APPROVED SASH HEIGHT BE LESS THAN TWELVE INCHES FROM THE BOTTOM OF THE HOOD OPENING.

5.3.1.6 Go to Step 5.1.3 and repeat the velocity measurement.

5.3.1.7 If the new measurement is acceptable, record it in the Test Log and note in the comments field that the sash height was adjusted.

5.3.1.8 If the new measurement is still unacceptable, the hood must be tagged out of service (SOP 317) and the Health and Safety Manager must be notified as described in the next Step.

5.3.2 Any exhaust fume hood exhibiting an average face velocity measurement that is below the minimum face velocity required for that hood shall be taken out of service and tagged (SOP 317). The Health and Safety Manager must be notified immediately.

5.3.3 After corrective action is taken (i.e., repairs), the face velocity of the hood shall be measured and shall meet the minimum acceptance criteria before being placed back into service. A notation describing the corrective action will be made in the Test Log of the month the hood is returned to service.

6. SAFETY AND HAZARDS

6.1 The technician performing this procedure must be observant of any hazardous operations that are being undertaken in the hood at the time of the measurement. If the hood is currently in use for a task that may pose any undue risk to the technician, the test should be delayed until it is safe to perform the test. In no case shall the test be delayed past the expiration date of the current calibration without taking the hood out of service.

6.2 As the technician may be working in non-routine or unfamiliar locations to perform this task, he or she must be familiar with the location of the nearest safety shower and eyewash station before beginning measurements in any hood being used for hazardous operations.

6.3 Gloves, safety glasses, and a lab coat shall be worn during fume hood face velocity measurements.

CONTROL CRITERIA
Lower Limit = Minimum Target Velocity listed below.
Upper Limit = 125 fpm, or as approved by H&S Manager

CORRECTIVE ACTION:
1) If a simple sash adjustment is required to meet acceptance criteria, adjust the sash, re-measure the face velocity, place the calibration mark at the new sash height location, and make a note in the comment section below.
2) Otherwise, tag the hood "OUT OF SERVICE", per SOP 317, and note in the comment section below.
3) Report "OUT OF SERVICE" hood to the Health and Safety Manager.
4) After corrective action, and before returning the hood to service, make note in the comment section below describing repairs.

STANDARD OPERATING PROCEDURE 003 REVISION 5

TITLE: MANAGEMENT OF NONRADIOACTIVE HAZARDOUS WASTE

FORMS: 783 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11/7/07

QUALITY ASSURANCE MANAGER _____ DATE 11/7/07

LABORATORY MANAGER _____ DATE 11-7-07

HISTORY: New, 7/14/94;; Rev1, PCN #241, 2/3/00; Rev2, 4/3/02; Rev3, 8/9/02; Rev4, 9/22/03, 7/20/05 (re-released without revision); Rev5, 11/7/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the management of hazardous waste throughout the analytical chemistry laboratories. This SOP shall be used to provide the laboratory staff with guidelines for managing the hazardous waste aspects of all waste generated in the laboratory, including hazardous waste, mixed hazardous/radioactive wastes, and polychlorinated biphenyl (PCB) wastes, which are regulated under the Toxic Substances Control Act (TSCA).

Procedures for dealing with the radioactive aspects of wastes are dealt with in SOP 015 – Disposal of Radioactive Waste. The hazardous waste management requirements for mixed wastes are identical to nonradioactive hazardous wastes, although disposal options may be limited. TSCA PCB wastes may be a TSCA only waste, with no RCRA hazardous components, or the TSCA PCB waste may have RCRA hazardous components.

Paragon is a large quantity generator of hazardous waste and must comply with Environmental Protection Agency (EPA) regulations found in the Resource, Conservation and Recovery Act (RCRA). Paragon must also comply with Colorado State Department of Public Health and the Environment (CDPHE) waste regulations.

It should be noted that not all aspects of the regulations are discussed in this SOP. The State and Federal regulations are the basis for the information contained herein. The State and Federal regulations will be adhered to during all waste handling and disposal operations.

2. SUMMARY

This SOP covers hazardous waste characterization, waste accumulation containers, Satellite Accumulation Area (SAA) management, 90-Day Accumulation Area management, waste streams unique to Paragon, waste disposal requirements, and safety and training requirements for personnel who dispose of hazardous waste. Special

requirements for mixed hazardous/radioactive waste and TSCA PCB waste management are also discussed.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who perform this procedure to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. HAZARDOUS WASTE CHARACTERIZATION

4.1 REFERENCE INFORMATION
40 CFR 261.3, 6CCR 1007-3, Section 261, Subpart C and Section 268.7
40 CFR 262.11, 6CCR 1007-3, Section 262.11 and Section 262.40(c)

4.2 GENERAL INFORMATION
Paragon is a large quantity generator and must identify all hazardous waste generated at the facility by one or all of the following methods: analysis, process knowledge, or other determinations.

A hazardous waste is a solid, liquid, or contained gaseous material that is no longer used or serves the purpose for which it was produced, and could pose a danger to human health or the environment.

Laboratory materials and sample remainders to be discarded are considered solid wastes. Most of these solid wastes are classified as hazardous waste based upon the presence of characteristic, or listed hazards as defined by RCRA. These RCRA hazards are determined by chemical analyses or process knowledge. Their presence will make the material being discarded a hazardous waste that requires special handling and disposal.

A waste determination is performed by gathering information about each process and the chemicals involved. It is then determined if the chemicals and/or the process classifies the waste as hazardous and subject to RCRA requirements.

NOTE: Additional tests may be needed to completely characterize the waste.

4.3 CHARACTERISTIC HAZARDOUS WASTE
40 CFR 261.10, 6CCR 1007-3, Section 261, Subpart C

Characteristic hazardous wastes are solid wastes that are hazardous to human health and/or the environment because of their physical or chemical character. The EPA identifies four physical/chemical properties or hazardous characteristics that determine a solid waste as a “Characteristic Hazardous Waste”: :ignitability,

corrosivity, reactivity, and toxicity. The presence of any one of these hazards is sufficient to make the material a hazardous waste. The characteristic hazards may be determined via analytical tests. Knowledge about the material itself, or the process that created the material may also provide sufficient information to classify a waste as hazardous.

NOTE: Additional tests may be needed to completely characterize the waste.

4.3.1 Ignitability Hazards (D001)
40 CFR 261.21(a)

A solid waste is hazardous due to ignitability if a representative sample of the waste falls into any of the following categories:

- A liquid (other than an aqueous solution containing <24% alcohol by volume) with a flash point <140°F (60°C). The lower the flash point, the more dangerous the material. 40 CFR 261.21(a)(1).
- A nonliquid that can burn under standard temperature (68°F) and pressure (1 atm) through friction, moisture absorption, or spontaneous chemical changes, and burns vigorously and persistently once ignited. 40 CFR 261.21(a)(2).
- An ignitable compressed gas as defined in 49 CFR 173.300.
- An oxidizer as defined by the United States Department of Transportation (DOT) 49 CFR 173.151. 40 CFR 261.21 (a)(4).

4.3.2 Corrosivity Hazards (D002)
40 CFR 261.22

A solid waste is hazardous due to corrosivity if it has either of the following properties:

- Any aqueous waste with a pH ≤2.0 or ≥12.5.
- A liquid waste that corrodes steel at a rate of 6.35mm (0.25 inches) per year.

4.3.3 Reactivity Hazards (D003)
40 CFR 261.23

A solid waste is hazardous due to reactivity if it exhibits any of the following properties:

- Unstable and readily undergoes violent change without detonating.

- Reacts violently with water.
- Forms potential explosive mixtures with water.
- Produces toxic gases, vapors, or fumes in sufficient quantities to present a danger to human health or the environment when mixed with water.
- It is a cyanide or sulfide bearing waste which when exposed to pH conditions between 2 and 12.5, generates toxic gases, vapors, or fumes in sufficient quantities to present a danger to human health or the environment.

  Waste material that contains cyanides or sulfides in concentrations greater than 50ppm is considered a hazardous waste. CDPHE states a waste meets the definition of reactive if it contains a releasable sulfide concentration of 500 mg H_2S/Kg or a releasable cyanide concentration of 250mg HCN/Kg.
- Is readily capable of detonation or explosive decomposition or reaction at standard temperature and pressure.
- Is a forbidden explosive or a Class A or Class B explosive as defined in 49 CFR 173.51, 173.53 and 173.88.

4.3.4 Toxicity Hazards (D004 through D043)
40 CFR 261.24

A solid waste exhibits toxicity characteristics if the extract from a representative sample of the waste contains any of the contaminants at a concentration greater than or equal to the applicable regulatory level during a leaching test called the Toxic Characteristic Leaching Procedure (TCLP).

4.4 LISTED WASTES
40 CFR 261.11(a)(3), 261.30 - 261.33, 6CCR 1007-3, Section 261, Subpart D

Listed Wastes are those waste streams or chemicals that EPA knows from experience present a threat to human health or the environment regardless of their concentration when disposed. A waste is considered a Listed Waste if it meets the description in one of the four lists of waste contained in 40 CFR Section 261 Subpart D. The four lists of hazardous waste are F-, K-, P-, and U. Paragon will generally only produce F, U and sometimes P listed waste. General definitions for the listed wastes are as follows:

- F listed hazardous wastes are from non-specific sources.
- K listed hazardous wastes are from specific sources.

- P listed wastes posses "extremely hazardous properties" that make them lethal in very small quantities and are identified as acutely hazardous waste.
- U listed wastes meet the criteria of 40 CFR 261.11(a)(3), which identifies various factors that could render a waste toxic.

P and U listed wastes are any commercial chemical product, or manufacturing chemical intermediate, having the generic name listed in paragraph (e) or (f) in 40 CFR 261.33. Commercial chemical product or manufacturing chemical intimidates refer to a chemical substance which is manufactured or formulated for commercial or manufacturing use. The chemical in question must also be the sole active ingredient in the product to qualify as a U or P listed waste. Mixtures of Chemicals contained on the P or U list in items such as standards for volatile analysis, may not be considered a P or U listed waste. This is because these chemicals are in small amounts and are not the sole active ingredient. The main ingredient is the solvent. Questions regarding waste classifications should be referred to the Waste Disposal Coordinator.

Also, P and U listed waste are off-specification or discarded commercial chemical products, any residue remaining in a container that held commercial chemical products, or any residue or contaminated media resulting from the cleanup of a spill of a commercial chemical product in the P or U listing.

5. WASTE HANDLING REQUIREMENTS

After a waste has been classified as a Hazardous Waste, EPA requires these wastes to be handled according to RCRA and CDPHE regulations. Included in these regulations are requirements for Satellite Accumulation Areas (SAA) and 90-Day Accumulation Areas used for waste collection. The regulations have requirements for the waste container types, labeling of containers, waste quantities, and inspections of these areas.

5.1 SATELLITE ACCUMULATION AREA (SAA) MANAGEMENT
40 CFR 262.34 (c), 6CCR 1007-3, Section 262.34(c)

A Satellite Accumulation Area (SAA) as defined by EPA is a small accumulation site where Hazardous Wastes are accumulated in close proximity to the point of generation prior to transfer to the 90-Day Accumulation Area. RCRA and the CDPHE have specific requirements for the management of Satellite Accumulation Areas. The requirements include designated areas as Satellite Accumulation Areas, container type, container labeling, container maintenance, limitations on waste quantities in the SAA, and weekly inspections.

5.1.1 Defining Satellite Accumulation Areas
6CCR 1007-3, Section 262.34(c)

The SAAs at Paragon are unique to each lab's function. An SAA must be at or near the location where the waste is generated. Each lab generating waste will have an area or areas designated as an SAA(s) defined by a sign and/or an area marked with tape. The locations of all SAAs shall be designated in the Emergency & Contingency Plan.

The satellite accumulation waste containers are stored only in designated SAAs. The waste containers cannot be left outside the SAA such as on a bench, in another SAA, or in another lab. The only location to which waste from an SAA may be moved is to a 90-Day Accumulation Area.

All SAAs must be accessible at all times and must be free and clear of debris.

5.1.2 Satellite Accumulation Container Types
40 CFR 265.172, 6CCR 1007-3, Section 265, Subpart I

Specific types of containers are required for use as Satellite Accumulation Containers. UN Specification Hazardous Materials containers fulfill all the requirements for Satellite Accumulation Containers. Other types of containers may be used in SAAs if the container is compatible with the waste stream. The Waste Management Staff must approve all SAA containers used in the lab.

Containers holding ignitable or reactive waste must be located at least 50 feet (15 meters) from the facility's property line and away from any source of possible ignition.

5.1.3 Labeling Requirements For Satellite Accumulation Area Containers
40 CFR 262.34(a)(3), 6CCR 1007-3, Sections 262.34(d)(4), 262.34(a)(3), & 262.34(c)

Regulations require that all Satellite Waste Accumulation Containers be labeled at a minimum with the phrase "Hazardous Waste" and the identity of the waste (e.g., Hazardous Waste, Aqueous Laboratory Waste). A preprinted Uniform Hazardous Waste label may be used.

Start dates are not required for containers in SAAs until the 55-gallon limit is obtained. Once the 55-gallon limit is reached the container must be dated immediately (within a few minutes).

5.1.4 Satellite Accumulation Container Maintenance
40 CFR 265.171 and 265.173

All containers must be kept in a clean condition. Any spills of waste materials onto the container are required to be cleaned up immediately. If waste containers are in secondary containment, the secondary containment must be free and clear of all liquids and debris.

The condition of the containers is required to be managed such that the containers are in good condition at all times. The container must be replaced if it becomes damaged (e.g., distended, cracked, or dented). If a container has been damaged, request a new container from waste management staff immediately. Transfer the material from the damaged container into the new container and apply the proper labels.

PAR laboratory staff are required to ensure that all containers of hazardous waste are closed at all times when not in use. The definition for "in use" is when a staff member is in direct control and in the presence of the container during waste transfer operations.

Container labels must be visible during storage. Replace any worn, mutilated, or defaced labeling on the containers. Contact the waste management staff if labels or assistance is needed.

There are "In Process Waste" containers used throughout some of the labs. These containers are not regulated as SAA containers until they leave the process from which they were generated. "In Process Waste" containers that are not attached to and instrument shall be emptied into the appropriate SAA container at the end of work every day.

Instrument effluent "In Process Waste" containers that are attached to an instrument are not required to be emptied until the container is full. Once the container is full and removed from the instrument, it must then be placed in an assigned SAA or disposed into a drum in the 90-Day Accumulation Area as appropriate.

NOTE: Instrument effluent may not be a RCRA hazardous waste. Waste determinations should be performed to verify if RCRA hazardous waste regulations are applicable to the effluent.

5.1.5 Quantity of Wastes Allowed in Satellite Accumulation Area
40 CFR 262.34(c), 6CCR 1007-3, Section 262.34(c)

Wastes may be accumulated in an SAA in total quantities of no more than 55 gallons. A SAA may have more than one waste stream but the total of all waste streams cannot exceed 55 gallons. Each laboratory has a limited number of containers for waste. Paragon's policy is to

limit the number of containers so that the total volume is less than 55 gallons per SAA. The procurement of more carboys for the purpose of storing waste is not allowed without consent of the waste management staff.

Any waste streams that have accumulated 55 gallons or more must be dated within a few minutes of becoming full as stated in Section 1. The full container must be removed from the SAA to the 90-Day Accumulation Area as required in Section 1. PAR laboratory staff are responsible to ensure that no more than 55 gallons is accumulated in any Satellite Accumulation Area.

Once a process has been discontinued, the waste generated from that process must be removed from the SAA and disposed into a 90-Day Accumulation Area. If the waste from the discontinued process is the only waste accumulated in the SAA, then the SAA must be closed.

5.1.6 Waste Accumulation Time Limits
40 CFR 262.34(c)(2), 6CCR 1007-3, Section 262.34(c)

When the 55-gallon limit has been reached in the SAA, the container(s) must be removed from the SAA immediately. CDPHE interprets "immediately" to mean within 24 hours. PAR staff must notify waste management personnel immediately when their SAA has reached the 55-gallon limit.

NOTE: Colorado has adopted the 24-hour regulation that is more stringent than the EPA RCRA regulations.

5.1.7 Weekly Inspections of the Satellite Accumulation Area
40 CFR 265.174

Weekly inspections of the SAA are required by the State of Colorado Hazardous waste regulations and by RCRA. This inspection must cover container condition, container labeling, and container closure condition. Waste management staff shall use the lab specific SAA Weekly Inspection forms to document the weekly inspections. The Weekly Inspection forms (Form 783) are bound into logbooks located near the SAAs.

5.2 90-DAY ACCUMULATION AREA MANAGEMENT
40 CFR 262.34(b)

The 90-Day Accumulation Area is the designated area where wastes are stored in drums upon leaving the Satellite Accumulation Area. Also, waste can be directly

disposed into assigned drums in the 90-Day Accumulation Area, instead of in an SAA, with permission from the waste management staff.

The 90-Day Accumulation Area must be clean and easily accessible. RCRA requires there to be adequate space between containers and aisles for the movement of emergency equipment to easily access any one container to make repairs or remove the container.

5.2.1 Waste Accumulation Time Limits
6 CCR 1007-3, Section 262.34(a), 262.34(a)(2)

Waste materials accumulated in the 90-Day Accumulation Area may be stored in the area for a maximum of 90 days prior to transfer to a Treatment, Storage and Disposal Facility (TSDF) for final disposition. This time clock begins the moment waste accumulation begins in the 90-Day Accumulation Area.

Full 55-gallon drums from the SAAs brought to the 90-Day Accumulation Area must have been marked with an accumulation start date as required in Section 1. The time clock starts from the date on the drum, not the date when the drum is placed in the 90-Day Accumulation Area.

5.2.2 90-Day Accumulation Container Types
40 CFR 265.171, 265.172, 265.176, & 265.177, 6 CCR 1007-3, Section 262.34(a)(1)

All containers used in the 90-Day Accumulation Areas must be United Nations Specification (UN Spec) transportation containers and must be compatible with the waste.

TSDFs may have their own requirements for containers used for shipment of waste, such as over packs.

5.2.3 90-Day Accumulation Containers Labeling Requirements
40 CFR 262.31, 262.32(a)&(b), 6 CCR 1007-3, Section 262.34(a)(2)&(3)

The waste container must at all times be labeled with the phrase "Hazardous Waste" that is clearly visible on the container. Before transporting hazardous waste off-site, the generator must label each container in accordance with DOT regulations on hazardous materials per 49 CFR Part 172.

Before transporting hazardous waste off-site, the waste must be packaged in accordance with the applicable DOT regulations under 49 CFR Parts 173, 178, and 179.

The side of the container is labeled with a preprinted Uniform Hazardous Waste label, specific for the waste stream. The Accumulation Start Date is marked in the Accumulation Start Date section of the Hazardous Waste Label.

The appropriate DOT Hazard Warning Label must be placed on the container next to the Hazardous Waste Label. A double arrow up label must be placed on each side of the container.

The waste container must be marked with the date when the first aliquot of waste was placed into the drum. The start date is entered in the appropriate box on the preprinted Uniform Hazardous Waste label and on the top of the drum.

The top of the container (e.g., drum) must be marked with the waste name (e.g., Aqueous Lab Waste) and container number. The container number is unique for each container, and consists of the waste stream, month and year of generation, and number of the barrel for that particular waste stream started in a given month (xx-mmyyyy-nn). For example, the third barrel of Aqueous Lab Waste generated in December, 2001 is labeled AW-122001-03.

5.2.4 Container Management
6 CCR 1007-3, Sections 262.34(a)(1) and 265.77

Containers holding ignitable or reactive waste must be located at least 50 feet (15 meters) from the facility's property line.

A container holding hazardous waste that is incompatible with waste in containers nearby must be separated from the other wastes.

All containers must be kept in a clean condition. Any spills of waste materials onto the container are required to be cleaned up as soon as possible. All labels must be intact and in good condition. Replace any worn, mutilated, or defaced labeling on the containers.

The containers must be in good condition at all times. The container must be replaced if it becomes damaged (e.g., distended, cracked, or dented). If a container has been damaged, arrange for a replacement container and transfer the material. The new container must be properly labeled.

PAR laboratory staff are required to ensure that all containers of hazardous waste are closed at all times when not in use. The definition for "in use" is when a staff member is in direct control and in the presence of the container during waste transfer operations.

5.2.5 Container Spill Management Requirements
40 CFR 262.34 and Subparts I, AA, BB, CC of 40 CFR 265

Containers that contain liquids must be stored in such a way to contain a leak. This may be accomplished by use of a spill pad or drip pad that is capable of containing the entire contents of the largest container. Additionally, it is acceptable to use an over pack container to contain any spillage.

All spill pads are to be cleaned regularly. Any spilled material is collected and placed in the proper waste containers.

5.2.6 Inspections of the 90-Day Accumulation Area
40 CFR 265.174

Weekly inspections of the 90-Day Accumulation Area are required by RCRA. The inspection must cover container condition; container labeling, container closure condition, and accumulation start time. The waste management staff shall use the 90-Day Accumulation Area inspections logs to document the weekly inspections.

6. PAR WASTE STREAMS
40 CFR 262.11

Paragon generates various hazardous waste streams including analytical process wastes, unaltered sample waste, unused chemicals, empty containers, planchet waste, universal waste, mixed waste, radioactive waste, PCB waste, and nonhazardous waste.

NOTE: All process waste streams have a written waste determination.

6.1 ANALYTICAL PROCESS WASTES
Individual laboratories generate different waste streams and may have multiple waste streams based on the analyses performed. The analytical process materials generated at Paragon must be evaluated to determine if they qualify as a hazardous waste under RCRA. On an ongoing case-by-case basis, the analytical data plus process knowledge about the waste stream will be used to write a waste determination. Once the waste determination is completed, the waste will be disposed of appropriately. Sample digestates and extracts are identified as process waste.

Waste characterization analysis is performed for radioactive satellite containers and drums of process waste. Copies of all analyses are retained on file and a waste determination form is completed.

Waste reduction is a requirement of RCRA. To meet this requirement, the process wastes that are multi-phased and potentially radioactive are divided by phases. Each phase is analyzed and a detailed written waste determination is completed. The waste is disposed of per the determination in the appropriate waste stream.

6.2 UNALTERED SAMPLES AS WASTES
40 CFR 261.4(d)

Some samples upon completion of analysis are returned to the client. The samples are packaged for return shipment per SOP 027 directives. Permission to return the samples is obtained from the client prior to sample shipment. Unaltered samples that are not designated for client return are held for 90 days after invoicing, unless otherwise specified by the client.

After a work order is invoiced, the samples may be moved from the various sample storage areas to the sample archive storage area to be held until disposal. The appropriate waste stream is assigned to all samples based on analyses reported in Paragon's Laboratory Information Management System (LIMS). The samples are segregated in the sample archive storage area by waste streams and by the month the samples are available for disposal. Once the specified archival time has ended, the samples are disposed of in the appropriate waste stream. Samples are disposed of on a monthly basis. Sample disposal is tracked per sample container to ultimate disposal through LIMS. Records of disposal are maintained by the Waste Compliance Officer.

6.3 UNUSED CHEMICALS AS WASTE
Chemicals that are not completely used prior to their expiration date or are not needed shall be brought to the waste characterization area. A waste determination (see Section 4) will then be made as to whether the chemical classifies as a Hazardous Waste or not. If the chemical is a Hazardous Waste, it will be stored in an SAA (see Section 5) until disposal can be accomplished (see Section 7). The chemicals that are not Hazardous Waste will be disposed of according to all applicable State and Federal regulations.

Unused Chemicals that are classified as a hazardous waste will be classified as a P, U and/or characteristic waste according to applicable State and Federal regulation (see Section 4)

6.4 EMPTY CONTAINERS AS WASTE
40 CFR Part 261.7, 6 CCR 1007-3, Sections 262.7

Empty containers may come from the analysis of samples (i.e., pipet tips, digestion cups), from the disposal of samples, or from chemicals that have been disposed of or completely used. Any container that contained a RCRA defined Hazardous Waste may be considered RCRA Empty and exempt from RCRA disposal requirements if the container meets the definitions contained in 40 CFR Part 261.7.

6.5 PLANCHETS AS WASTE

Various analyses involve sample material to be placed on planchets. After analysis, these planchets are disposed into a drum designated for planchet waste only with the assumption the planchets may possibly be radioactive. A representative sample of the drum is analyzed for radioactivity and other possible hazards. The drum is then shipped for appropriate disposal.

Prescreen planchet waste is segregated as radioactive or nonradioactive. Radioactive planchets are disposed into the planchet waste drum. Nonradioactive planchets are nonhazardous based upon analytical knowledge, and are disposed of as sanitary waste.

Planchets used for swipes are determined to be radioactive or nonradioactive. Radioactive swipes are disposed in the planchet waste drum. Nonradioactive swipes are nonhazardous waste based on the analytical process. Nonradioactive swipes are disposed of in the sanitary waste.

6.6 UNIVERSAL WASTE

40 CFR 261.9, and Part 273, 6CCR 1007-3, Section 273.6, 273.11, 273.13-273.19

Universal wastes are widely generated wastes including fluorescent lamps and batteries. Some fluorescent lamps fail the TCLP test for mercury, lead, or other heavy metals, and are considered hazardous waste. The universal waste regulations reduce the management requirements for universal wastes to increase proper recycling or disposal, but still require the management of the waste to be conducted in a manner that protects human health and the environment. Paragon accumulates less than 5,000 kilograms (11,000 pounds) of universal waste and is considered a Small Quantity Handler of Universal Waste.

The universal waste must be handled and collected in a way that prevents releases of any waste or components to the environment. Paragon has fluorescent lamps that are both hazardous and nonhazardous. All used lamps are collected and stored in their original box or specially purchased cardboard boxes. The boxes are labeled with a Universal Label identifying the contents. The nonhazardous lamps are segregated from the hazardous lamps and labeled with a nonhazardous waste label.

On site disposal of universal waste is prohibited. The local landfill does not accept any type of fluorescent lamps. All hazardous and nonhazardous lamps are sent to a permitted TSDF.

All used batteries shall be given to waste management staff. The batteries are collected and recycled.

6.7 MIXED WASTE

Mixed waste is waste that is determined to be both hazardous and radioactive. Unaltered samples and process waste can be mixed waste. Storage and handling of mixed waste must meet the requirements for RCRA waste and radioactive waste. Storage requirements for mixed waste are the same as for RCRA waste except that mixed aqueous waste drums must be contained in over pack drums. The requirements for handling radioactive aspects of the waste are detailed in SOP 15 - Disposal of Radioactive Waste.

6.8 RADIOACTIVE WASTE

All of Paragon's waste streams have the potential to be radioactive. The handling of wastes determined to be radioactive are addressed in SOP 15 - Disposal of Radioactive Waste.

6.9 PCB WASTE

40 CFR 761.50 and 761.64

PCBs or Aroclors are regulated under TSCA. A TSCA PCB waste is a material that has PCBs at a concentration of 50 ppm or greater. There are additional and unique requirements for management of PCB wastes as opposed to RCRA. Most PCB wastes dealt with at Paragon fall under 40 CFR 761.64. This Section of the regulation provides unique handling and disposal requirements for PCB waste generated as a result of chemical analysis of PCBs. The requirements for PCB wastes include container labeling, container types, temporary storage, and final storage prior to disposal. Some PCB wastes may be TSCA only; however, some PCB wastes may contain TSCA PCB and RCRA wastes. In this case, both TSCA and RCRA requirements apply. This will be most noticeable in storage and accumulation times.

Occasionally Paragon will receive samples that are radioactive and contain PCBs ≥50ppm. Paragon policy is to return these samples to the client after analysis. The samples are returned per DOT and EPA regulations.

6.9.1 <u>PCB Container Types For Long Term Storage</u>

40 CFR 761.40

The containers used to contain PCB wastes must be labeled with an EPA approved "Caution Contains PCBs" label. Paragon has available

both the large PCB Mark ML and the small PCB Mark MS labels. One of these labels must be used on all containers used to contain PCB Wastes.

If the waste is also a RCRA Waste, the appropriate Hazardous Waste Label must be placed on the container and all other RCRA labeling requirements apply.

All PCB waste containers in SAAs and Long Term Storage must be dated with the date the waste was added to the containers.

If there is an inner and outer containment system being used, both containers must be labeled with the appropriate labels.

6.9.2 Storage of PCB Waste
40 CFR 761.65

The Long Term Storage area must meet the construction requirements for the walls, roof, flooring, and curbing as detailed in the regulations. Rain and moisture must be kept from reaching the containers of PCB waste and the floor and curbing must provide the required containment volume. There must not be any types of openings to allow liquids to leak from the containment area. The storage area must not be located in the 100-year flood plain.

PCB wastes must be shipped within 9 months of the start date on the container. If the material is a RCRA waste, the maximum storage time will be 90 days.

All entries to the Long Term Storage area must be marked with the EPA-approved "Caution Contains PCBs", large PCB Mark ML label.

6.9.3 PCB Storage Area Inspections
Monthly inspections are required for PCB waste. Paragon's policy is to conduct weekly inspections on Short Term and Long Term Storage areas. The criterion for inspection is the same as for RCRA as described in Sections 1 and 1. PCB RCRA waste is inspected per the regulations for both TSCA and RCRA.

6.10 NON RCRA HAZARDOUS WASTE
Waste from the above waste streams that is determined to not be a RCRA Hazardous waste is classified as a non hazardous waste. Included in the nonhazardous waste description is floor sweepings from routine cleaning and sanitary trash. These wastes must have a written waste determination, including sanitary waste that is sent to the local landfill. Many of the waste streams

generated at Paragon are nonhazardous based on process and analytical knowledge.

7. WASTE DISPOSAL REQUIREMENTS

7.1 GENERAL

Paragon utilizes the services of several TSDFs for disposal of wastes. TSCA PCB wastes will be incinerated at an approved TSCA incineration facility. The facility will also be capable of handling destruction of RCRA components.

A staff member that has completed the US DOT Hazardous Materials Shipper Training must conduct the final manifesting and shipping operations.

Waste determinations are completed for some process wastes. The data are then sent to the local Publicly Operated Treatment Works (POTW) for permission to discharge through the sanitary sewer system. After written notification to dispose is received from the POTW, the waste is discharged through Paragon's holding tanks into the sanitary sewer system.

Sample containers (e.g., bottles and jars) that have been emptied into SAA containers or 90-Day Accumulation Area containers must be RCRA Empty and defaced before disposal in the sanitary solid waste. Empty sample containers that held radioactive materials must be washed, rinsed, defaced, and scanned for radioactivity before disposal as sanitary waste.

7.2 WASTE DISPOSAL OPERATIONS

All waste will be disposed of according to the waste determination specific to the waste. Waste determinations for all waste streams except unaltered samples will be hand written and kept on file. The unaltered sample waste determination is performed by LIMS electronically from data input from client information and process knowledge.

Laboratory personnel will dispose of unaltered sample wastes according to waste packs created in LIMS. The waste pack will list the waste stream for the samples. The sample will be placed into an SAA or waste container in a 90-Day Accumulation Area, that is appropriate for the LIMS characterized waste.

Laboratory personnel will dispose of all other types of waste according to the waste determination kept on file by the waste management staff. These wastes will be disposed into an SAA or 90-Day container designated for that specific waste stream.

Waste that is determined to be Non RCRA Hazardous will be disposed of properly. Non RCRA Hazardous waste may or may not be able to be disposed of in a sanitary waste stream or the sanitary sewer system. The waste management staff will give disposal instructions for these types of waste. The exception to this

statement is routine floor sweeping material, mop residue from non-spill cleaning activities and sanitary trash. These wastes can be disposed of in sanitary waste streams.

8. SAFETY AND TRAINING FOR PERSONNEL PERFORMING WASTE DISPOSAL

40 CFR 262.34(a)(4) & 265.16(a), 6 CCR 1007-3, Section 262.34(a)(4) & 265.16(a)

The safety hazards associated with waste disposal involve potential spread of hazardous and radioactive material contamination, and loading and moving the waste containers. All personnel shall utilize the appropriate personal protective equipment for the task at hand. This will include, at a minimum, gloves, lab coat, and safety glasses. At other times, respirators and Tyvek coveralls may be required. All operations involving moving containers (e.g., full 55 gallon drums) shall utilize suitable moving devices such as barrel dollies and use of steel-toed shoes. Waste disposal procedures are addressed Section 7.

Personnel handling hazardous waste must be trained with classroom and on-the-job training that teaches them to perform their jobs to maintain compliance with the hazardous waste regulations.

A staff member that has completed the US DOT Hazardous Materials Shippers Training must conduct the final manifesting and shipping operations.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the procedures for conducting (1) the radioactive external exposure rate survey of all sample shipping containers received by the laboratory; and (2) the DOT radioactive survey of all incoming radioactive material packages for external radiation exposure rate and removable radioactive contamination. Radiation exposure rate guidelines, which determine acceptance or rejection of samples or materials and the manner in which they are processed, are described in this SOP. Directions for calibration of the radiation survey equipment used are presented in SOP 013. Detailed sample receipt and login processes are discussed in SOP 202.

2. OVERVIEW

2.1 Upon receipt, sample receiving personnel survey all sample shipping containers and incoming radioactive material packages for external radiation exposure rate. A DOT Survey form (Form 008) is completed. Additional steps taken are contingent upon the radiation rate levels determined by the external radiation exposure rate survey results. The steps taken are based on whether the surveyed items are samples or DOT-classified radioactive materials.

2.2 In general, sample shipments are accepted so long as external radiation exposure rates do not exceed 0.5mR/hr. If the radiation survey results are below 0.5mR/hr but are higher than two times the laboratory background levels, then the samples are only "provisionally" logged in (see SOP 202). The samples are then routed through a formal prescreening process (see SOP 703). The Radiation Safety Officer (RSO) may designate some client's samples as "always prescreen." The RSO, based on the prescreening results, determines acceptance or rejection of the samples. If the client's samples are not designated as "always prescreen" and the initial receipt survey results are less than two times laboratory background levels,

then the samples are accepted and processed for login (sample prescreening is not required).

2.3 Radioactive material packages are those labeled as (1) Excepted Radioactive Material, (2) Low Specific Activity (LSA) Radioactive Material, or (3) Radioactive Material I, II, or III, per 49 CFR 173 or IATA Dangerous Goods Regulations. The Colorado Rules and Regulations Pertaining to Radiation Control also apply.

In addition to the external radiation rate exposure survey, shipping containers for incoming radioactive material packages are also subjected to an external wipe test. The resultant wipe is counted and the results are recorded by the instrument printout (see SOP 010). Further wipe testing is conducted on all primary radioactive material containers (results recorded on Form 009). The wipe tests constitute the removable radioactive material contamination survey.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. APPARATUS AND MATERIALS

4.1 Ludlum Model 19 MicroRoentgen (Micro R) meter or equivalent

4.2 Ludlum Model 1000 Scaler with Model 43-10 Alpha Scintillation Detector or equivalent

4.3 Ludlum Model 1000 Scaler with Model 44-7 End Window Geiger-Mueller Detector or equivalent

4.4 Oxford LB5100 Gas Flow Proportional Counter

4.5 filter papers, 47mm, Whatman #42 or Rad-Wipe Smears, or other equivalent

4.6 planchets, steel, 46mm

5. PROCEDURE

5.1 Where possible, the Project Manager (PM) will inform Sample Control staff of deliveries from clients whose samples may be radioactive. An Incoming Project Notice (IPN) form (Form 214) or a COC faxed from the field may be used for this purpose.

5.2 Calibrate all radiation survey equipment per SOP 013.

5.3 EXTERNAL RADIATION SURVEY OF SHIPPING CONTAINERS

5.3.1 This step applies to all incoming sample and radioactive materials containers. Ideally, shipping containers (i.e., coolers, ice chests, etc.) from radiological contractors are identified and segregated in the receiving area upon receipt. Coolers from radiological contractors may be identified via the return address information indicated externally on the cooler, or by the Chain-of-Custody (COC) paperwork contained inside.

NOTE: Per SOP 202, intactness of the chain-of-custody seals must be noted prior to opening.

5.3.2 Visually inspect the shipping container for damage that compromises the container's integrity. ***Notify the RSO immediately if any DOT classified radioactive material containers are damaged.***

5.3.3 Check the exposure rate at the container's surface using the Ludlum Model 19 Micro R survey meter. ***Notify the RSO immediately if any package exceeds the external radiation exposure rate limitations presented in Table 1 below:***

Table 1: RADIATION EXPOSURE RATE LIMITATIONS FOR SHIPPING CONTAINERS

		Incoming Radioactive Material Packages
Non-Exclusive Use Radioactive Material Shipment Type	***Maximum Allowable Surface Dose Rate at Surface (mR/hour)***	***Transport Index (TI) Maximum at One Meter (mR/hour)***
Excepted Radioactive Material (e.g., environmental samples)	0.5	N/A
Low Specific Activity (LSA)	0.5 *	N/A
Radioactive I	0.5	0.0
Radioactive II	50	1.0
Radioactive III	200	10

* In-house Paragon Limitation

Note that sample shipping containers must yield incoming radioactive survey results of less than 0.5 mR/hour.

NOTE: Due to radioactive material license limitations, Paragon will not accept Radioactive Material - LSA, N.O.S. packages yielding a greater than 0.5 mR/hour external surface radiation exposure rate, without prior approval by the RSO.

Paragon will not accept incoming radioactive material packages that require a Radioactive II or III DOT Warning label, without prior approval by the RSO.

5.3.4 Record the results of the external radiation survey on Form 008.

5.3.5 If the sample shipping container is not from a client whose samples are designated as "always prescreen," and is not labeled with any of the DOT classifications listed above, and if the external radiation survey results of the sample shipping container yields results are below two times the laboratory background level, then the samples are accepted for normal login processing per SOP 202. Prescreening is not required.

5.3.6 All sample shipping containers yielding external radiation exposure rate survey results less than 0.5 mR/hr may be processed. Open the sample cooler. ***If any samples containers are leaking or broken, contact the RSO immediately.***

5.3.7 Provisionally login samples (SOP 202) for clients whose samples are designated as "always prescreen," if the external sample shipping container radiation exposure rate is less than 0.5mR/hr. ***If the external sample shipping container radiation exposure rate is greater than 0.5mR/hr, notify the RSO immediately.***

5.3.8 If the client's samples are not designated as "always prescreen" and the radiation survey results are less than 0.5mR/hr but are greater than two times the laboratory background levels, then accept the samples for provisional login and prescreening.

5.3.9 If the item is a DOT classified radioactive material package and the criteria listed in Table 1 are not exceeded, then accept the package. If the shipment contains samples, then route the samples to prescreening (SOP 703). If the limits presented in Table 1 are exceeded, process the material per SOP 009.

5.3.10 Begin completing the Sample Condition Upon Receipt Form (Form 201). As described in SOP 202, acceptance or rejection of the samples is determined by the RSO based on the prescreening results.

5.4 SHIPPING CONTAINER WIPE TESTING

For all DOT classified radioactive material packages, the shipping container is also subjected to an external wipe test. ***After opening the shipping container, if any of the sample containers are leaking or broken, contact the RSO immediately.***

5.4.1 Wipe a filter paper or Rad-Wipe over a 4" x 4" square area of the container's external surface.

5.4.2 Count the wipe per SOP 010.

5.4.3 Record the results on Form 009 or retain printout from instrument.

5.5 WIPE TESTING OF SAMPLE CONTAINERS

This step applies to all packages from clients that may ship radioactive material samples to Paragon. The package may not need to be classified as a DOT Radioactive Material shipment.

5.5.1 Make a composite wipe over all the sample containers.

5.5.2 Count the wipe per SOP 010.

5.5.3 If the results exceed the limits indicated in Table 3, then each container must be wipe tested individually.

5.5.4 Record the results on Form 009 or retain printout from instrument.

Table 2: REMOVABLE EXTERNAL RADIOACTIVE CONTAMINATION LIMITS FOR OUTER SHIPPING CONTAINERS

Radionuclides	*dpm/cm^2*
Beta/Gamma emitting radionuclides; all radionuclides with half lives less than ten days; natural uranium; natural thorium; U-235; U-238; Th-232; Th-228; and Th-230 when contained ores or physical concentrates	22
All other alpha emitting radionuclides	2.2

Table 3: REMOVABLE EXTERNAL RADIOACTIVE CONTAMINATION LIMITS FOR SAMPLE CONTAINERS

Radionuclides	*dpm/100 c^{m2}*
Beta/Gamma emitting radionuclides;	200
All other alpha emitting radionuclides	20

NOTE: Sample control personnel should consult with the RSO if there is any uncertainty as to whether a shipment requires both external shipping and primary sample container surveys.

5.6 NOTIFICATION OF REGULATORY AUTHORITIES IN THE EVENT OF A PACKAGE THAT HAS BEEN INVOLVED IN AN TRANSPORTATION ACCIDENT

In the event a package received at or shipped to Paragon has been involved in an accident, the RSO must immediately notify the Radiation Control Division of the Colorado Department of Public Health and Environment Laboratory and Radiation Services Division and the U.S. DOT as per the requirements of 49 CFR.

6. QUALITY CONTROL (QC)

Applicable quality control procedures are detailed in SOP 014.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

7.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

7.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

7.1.3 The radioactive material check source must be stored in its container when not in use.

7.1.4 Food and drink are prohibited in all lab areas.

7.2 WASTE DISPOSAL

All used wipes that have radioactive material contamination shall be disposed of as Low Level Radioactive Waste.

Paragon Analytics

SAMPLE LOGIN / DOT SURVEY

Client _____ Workorder No. _____ Project/Site _____

Shipping Container ID ____ ____ ____ ____ ____ ____ ____ ____

External Micro R Meter Reading (μ R/hr) ____ ____ ____ ____ ____ ____ ____ ____

Background Micro R Meter Reading (μ R/hr)_____ Date _____ Initials _____

Notify RSO immediately if shipping container's meter reading is more than twice background reading!!

Samples received from clients designated as "always prescreen" must be routed through the prescreening process (see SOP 202).

If twice background is exceeded, RSO or designee will complete the following Table:

CLIENT SAMPLE ID	CONTAINER DESIGNATION	EXPOSURE RATE (μ R/hr)

Further action (e.g., prescreening, wipe testing per SOP 008, etc.) will be directed by the RSO. As applicable, sample disposition will be communicated via LIMS Project Specifications.

Where applicable, attach LB5100 prescreening and/or wipe testing results.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 009 REVISION 7

TITLE: INCOMING RADIOACTIVE MATERIAL PACKAGES THAT EXCEED REMOVEABLE RADIOACTIVE MATERIAL CONTAMINATION LIMITS

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1/12/07

QUALITY ASSURANCE MANAGER _____ DATE 1/12/07

LABORATORY MANAGER _____ DATE 1-12-07

HISTORY: Rev0, 10/26/92; Rev1, 3/31/94; Rev2, PCN #485, 6/03/95; Rev3, 3/15/99; Rev4, 2/11/02; Rev5, 4/04/03; Rev6, 2/13/04 and 11/10/05 (re-released w/o revision); Rev7, 1/12/07.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) mandates that the Radiation Safety Officer (RSO) be notified immediately when incoming samples or radioactive material packages fail to meet the regulatory criteria established for removable radioactive contamination. This SOP applies to excepted radioactive material packages, Low Specific Activity (LSA), and Radioactive I, II, and III radioactive material packages. The specific procedures used to conduct removable radioactive material contamination surveys of incoming radioactive material packages are detailed in SOP 008.

2. SUMMARY

The RSO must be notified immediately when incoming samples or radioactive material packages fail to meet the criteria set forth by the Colorado Radiation Health Regulation RH 17.15.8 and/or the United States Department of Transportation (US DOT) regulations contained in 49CFR 173.443. **The regulatory limit is 22 dpm/cm^2 for beta-gamma emitting radionuclides; radionuclides with half-lives of less than 10 days; natural uranium; natural thorium; and U-235, U-238, Th-232, Th-228 and Th-230 contained in ores or physical concentrates. The limit is 2.2 dpm/cm^2 for all other alpha emitting radionuclides.** Upon notification, the RSO discusses the problem with the appropriate Project Manager (PM). The RSO or PM contacts the client to resolve the situation.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP and to inform the Sample Receiving Manager and the RSO of any problems that may occur during the performance of these procedures.

3.2 It is the responsibility of the Sample Receiving Manager to ensure that the package has been properly decontaminated prior to release from the receiving area or handling by the general staff.

3.3 It is the responsibility of the RSO to ensure that the activity limits provided in this procedure are current and in compliance with applicable regulations.

4. APPARATUS AND MATERIALS

Ludlum Model 19 MicroRoentgen (Micro R) meter or equivalent

5. PROCEDURE

5.1 Perform a survey of incoming packages per SOP 008.

5.2 If contamination exceeds the limits indicated in Section 2.0 of this SOP, Table 5.1 of SOP 008, or Colorado RH 17.15.8, notify the Sample Receiving Manager and the RSO immediately.

5.3 The RSO promptly notifies the appropriate PM. The RSO or PM contacts the client to resolve the situation.

6. SAFETY, HAZARDS AND WASTE DISPOSAL

6.1 SAFETY AND HAZARDS

6.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

6.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), when handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

6.2 WASTE DISPOSAL will be performed in accordance with the Paragon Waste Management Plan

7. REFERENCES

6.1 "Rules and Regulations Pertaining to Radiation Control", Colorado Department of Public Health and Environment (CDPHE), 2001.

6.2 Code of Federal Regulations (CFR), Title 49, Chapter 1, Subchapter C, October 2002.

DOCUMENT REVISION HISTORY

1/12/07: Section 2, changed phrase **"The regulatory limit is 22 dpm/cm^2 for alpha-beta emitting radionuclides…"** to only include beta-gamma emitting radionuclides, not

alpha emitters. Section 3, added specific responsibilities for the RSO and Sample Receiving Manager. Added Section 4, APPARATUS AND MATERIALS. Section 5.2, referenced Waste Management Plan. Added DOCUMENT REVISION HISTORY.

Must Discard 30 Days from _____ (date printed)

STANDARD OPERATING PROCEDURE 010 REVISION 4

TITLE: **SURVEY OF LABORATORY AREAS FOR RADIOACTIVE CONTAMINATION**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 2/13/07

QUALITY ASSURANCE MANAGER _____ DATE 2/13/07

LABORATORY MANAGER _____ DATE 2-19-07

HISTORY: Rev0, 9/4/92; Rev1, 10/26/93; Rev2, 8/25/02; Rev3, 2/9/04 and 11/10/05; Rev4, 2/8/07.

re-released w/o revision 7/20/08 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedures used to survey any areas within the laboratory facilities (e.g., laboratories, storage areas) where radioactive materials have been or are being used. To comply with Paragon's radioactive materials license requirements, area surveys must be performed weekly in any area where radioactive materials have been used.

2. SUMMARY

To determine if removable radioactive contamination is present, the area must be surveyed using wipes and counted for both alpha and beta-emitting radioactive materials. Wipes should be taken over a 100 cm^2 area (~4inch x 4inch). Each wipe shall be analyzed using the appropriate counting equipment for the type of radiation suspected. The results shall be reported in units of dpm/100cm^2 area.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Facility, Sample, and Waste Control Manager to ensure that the surveys are performed properly and timely, to review the survey results, and to maintain the historical survey data for a period of at least two years after the survey is completed.

The Facility, Sample, and Waste Control Manager must ensure that any necessary decontamination procedures are followed, and must notify the Radiation Safety Officer (RSO) any time there is a survey result above the action level described in the Procedures section.

3.2 It is the responsibility of the Laboratory QA Manager, or designee, to maintain current and accurate maps of the facility, which may be copied from the LQAP or other source, and be used to perform these surveys.

3.3 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.4 It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. APPARATUS AND MATERIALS

4.1 removable radioactive material contamination survey laboratory maps

4.2 Defensap™ smears or 2" filter paper or equivalent

4.3 envelopes

4.4 laboratory gloves

4.5 planchets, 47mm

4.6 permanent-ink marker

4.7 Oxford LB-5100 gas flow proportional counter or equivalent

4.8 NE Electra with Dual Phosphor Alpha/Beta Probe

4.9 RadiacWash™ , or equivalent detergent with chelating agent

5. PROCEDURE

5.1 SURVEY LOCATIONS

5.1.1 All areas that could have been contaminated by radioactive material should be smeared (wipe tested). These areas include but are not limited to floors, walls, benchtops, and hoods.

5.1.2 Smear locations should be identified on the appropriate survey map for each specific laboratory.

5.2 PROPER SMEAR TECHNIQUES

5.2.1 Wipe smear paper with medium pressure over a 100cm^2 area (~ 10cm x 10cm or 4in x 4in).

5.2.2 Place smear in an envelope marked with the appropriate smear number or use an integrated smear/folder combination. The smear number should correspond to the location number on the removable radioactive material contamination forms or on the area maps.

5.3 SMEAR COUNTING

5.3.1 The smear should be counted for removable contamination in the Oxford LB-5100 gas flow proportional counter.

5.3.2 The smear sample is placed in a 47mm planchet and the smear ID is written on the bottom of the planchet. The smears are loaded and

counted in the Oxford LB-5100 gas flow proportional counter as directed by SOP 724.

5.3.3 The smears are counted for 1 minute or long enough to reach a minimum Lower Limit of Detection (LLD) of 10 dpm/100cm^2 for alpha and 20 dpm/100cm^2 beta-emitters.

5.3.4 The LB-5100 generates a report providing the activity in dpm/100cm^2, the 2 sigma total propagated uncertainty (TPU) in dpm/100cm^2, and the Minimum Detectable Activity (MDA) in dpm/100cm^2. The results shall be reviewed to determine any areas that exceed the Action Levels of 10 dpm/100cm^2 alpha, 100 dpm/100cm^2 beta, or in excess of 100dpm/100cm^2 combined alpha and beta contamination.

(a) CALCULATE BACKGROUND COUNT RATE:

$$R_b = \frac{C_b}{T_b}$$

where:

R_b = Background count rate (cpm)

C_b = Total background counts

T_b = Background count time (min)

(b) 2 SIGMA TOTAL PROPAGATED UNCERTAINTY:

$$2sTPU = \frac{2(\,SmpCts + (BkgCPM) + (SmpCts * Xtalk)\,)^{1/2}}{\text{Efficiency}}$$

(c) MDA CALCULATION:

$$MDA = \left(4.66\sqrt{\frac{R_b}{T_b}} + 2.71/T_b \right) \Big/ EFF$$

where:

R_b = Background count rate (cpm)

T_b = Background count time (min)

EFF = Instrument Counting Efficiency

5.3.5 Any area whose smears exceed the Action Levels shall be cleaned with RadiacWash™ and surveyed using an NE Electra with Dual Phosphor Alpha/Beta Probe. A confirmatory wipe test will be performed following the cleaning, and alpha-beta will be determined to verify that

the removable contamination levels are below the action levels. Repeat this process until the removable radioactive material contamination levels in the affected area are below the action levels.

6. SAFETY, HAZARDS AND WASTE DISPOSAL

6.1 SAFETY AND HAZARDS

6.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

6.1.2 Wear gloves, safety glasses, and lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or radioactive materials or within a laboratory area.

6.1.3 The radioactive material check source(s) must be stored in its container when not in use.

6.1.4 Food and drink are prohibited in all lab areas.

6.2 WASTE DISPOSAL

All used wipes that contain radioactive material contamination shall be disposed of as Low Level Radioactive Waste.

7. REFERENCES

7.1 "Rules and Regulations Pertaining to Radiation Control", Colorado Department of Health, Radiation Control Division, 2001.

1. SCOPE AND APPLICATION

Portable survey meters that detect contamination and radiation are available for personnel use to perform surveys on equipment, personnel or in areas where radioactive material is stored or analyzed. This Standard Operating Procedure (SOP) describes the methods and procedures used to ensure that the meters are functioning correctly, that proper calibration and performance checks are performed, and that surveys are performed in the proper manner.

2. SUMMARY

One of the most important aspects of an efficient and productive radiation protection program is pro-active contamination control. The control of personnel contamination is a significant part of this program. By following the procedures outlined in this SOP, the spread of contamination will be minimized.

All laboratory personnel who are engaged in preparing or analyzing samples or standards that may be radioactive, shall survey their hands, feet, and any other area suspected of contacting radioactive materials if so directed by LIMS special instructions or the Radiation Safety Officer (RSO). Additionally if a spill is suspected or occurs while aliquotting, the technician shall perform a survey of the area in question. Periodic surveys of sample storage areas for radiation are also performed to ensure that dose is in compliance with the State of Colorado Rules pertaining to Radiation Control.

Furthermore, all laboratory personnel who have entered a controlled area are responsible for performing a personal contamination survey upon leaving the controlled area. This survey is typically conducted using a hand and foot monitor (e.g., Berthold, SOP 029), or by a conducting a survey using the Electra as described herein.

All laboratory radiation and contamination surveys are conducted using a survey meter equipped with a dual phosphor alpha-beta scintillation detector (e.g., Electra), a meter equipped with a Sodium Iodide gamma scintillation detector (Micro R Meter), and

contamination swipes that are subsequently analyzed on a Gas Flow Proportional counter.

3. RESPONSIBILITIES

3.1 The RSO is responsible for maintaining an adequate supply of properly functioning radiation survey equipment. Any needed repairs or replacements shall be coordinated by the RSO, the RSO shall maintain meter service records. The RSO shall also coordinate the periodic surveys conducted of radioactive materials storage areas.

3.2 Project Managers are responsible for working with the RSO to create LIMS special instructions as necessary pertaining to samples to be processed for their projects.

3.3 It is the responsibility of all laboratory staff to consult the LIMS special instructions and to observe the requirements and procedures described in this SOP.

4. APPARATUS AND MATERIALS

4.1 NE Electra survey meter with 100cm^2 dual phosphor alpha-beta scintillation detector or equivalent

5. PROCEDURES

5.1 CALIBRATION OF PORTABLE HEALTH PHYSICS INSTRUMENTS
Any instrument that is at its calibration due date must be taken out of service and sent to an outside vendor for recalibration. The Steps below describe how this is accomplished.

5.1.1 When an instrument is due for calibration, remove the instrument from service and give it to the RSO. A temporary replacement instrument will be provided by the RSO.

5.1.2 The instrument will be packaged and shipped to a licensed outside vendor for calibration.

5.1.3 The vendor will perform the calibration. As appropriate, the vendor will calibrate the instrument's response to its attached check source, following calibration of the instrument. The vendor will affix a label to the instrument indicating the calibration date and the due date of the next calibration.

5.1.4 The vendor will return the instrument to Paragon. The vendor will supply a calibration certificate including all calibration data. The calibration certificate will be maintained by the RSO.

5.1.5 The temporary replacement instrument will be returned to the RSO once the re-calibrated instrument is returned to Paragon.

5.1.6 The daily instrument check (see below) must be performed before the instrument can be used.

5.2 PORTABLE HEALTH PHYSICS INSTRUMENTS PERFORMANCE CHECKS
Each portable survey instrument shall have a calibration or response check performed daily before use (document in logbook, Form 014). If the instrument fails the check, the instrument shall be checked again. If the instrument fails a third time, tag the instrument out according to SOP 317 and notify the RSO.

5.2.1 VISUAL INSPECTION

5.2.1.1 Confirm that the instrument has a sticker indicating calibration by an outside vendor within the last 12 months. If the instrument has not been calibrated by an outside vendor within the last 12 months, notify the RSO. Also, confirm that there are no placards indicating that the instrument has been removed from service (SOP 317).

5.2.1.2 Confirm that all instrument parts are present and that all detector windows are not perforated.

5.2.1.3 Visually inspect the cable connections at both the instrument and detector to ensure that all connections are tight and secure.

5.2.2 BATTERY CHECK

5.2.2.1 Verify that the batteries in the instrument are within the operating range specified on the dial of the instrument (Model 19 and 192) or by noting if the battery symbol lights up on the panel (Electra).

5.2.2.2 If the batteries are not in the operating range specified or the battery symbol lights up, change the batteries before use.

5.2.3 INSTRUMENT PERFORMANCE CHECK USING RADIOACTIVE MATERIAL CHECK SOURCE
The instrument must be checked using an appropriate radioactive material check source to ensure proper meter response. It is imperative that the proper check source be used with the appropriate probe (e.g., an alpha check source used with an alpha probe, or a gamma check source used with a gamma detector).

5.2.3.1 PERFORMANCE CHECK FOR GAMMA SCINTILLATION DETECTORS (MODEL 19 AND 192)

Place the active area of the check source directly on the detector. Hold the source in this position for approximately 20 seconds and observe the meter reading. The meter should read within plus or minus 10% of the reference reading obtained by exposing the instrument to the check source in a constant and reproducible manner 10 or more times. The average value will be used as the reference reading (ANSI N323A, 1997 Section 4.8).

The reference reading obtained upon receipt of the instrument from the calibration vendor must be verified against historical reference reading data before use. If the instrument is not functioning properly, the RSO should be notified in writing, and the instrument removed from service per SOP 317. Record the results in the appropriate instrument logbook (Form 014).

5.2.3.2 PERFORMANCE CHECKS AND INTEGRATED BACKGROUND AND EFFICIENCY DETERMINATIONS FOR NE ELECTRAS (DUAL PHOSPHOR ALPHA-BETA DETECTORS)

5.2.3.2.1 Performance Checks: Turn the instrument on and let it stabilize. Record the background count per minute (cpm) in the appropriate instrument log book containing (Form 219).

Place the detector over the active area of each source and record the cpm values for the large area alpha and beta check sources, and the alpha and beta electroplated planchet sources in the instrument logbook (Form 219). The meter should read within plus or minus 10% of the reference reading obtained by exposing the instrument to the check sources in a constant and reproducible manner, 20 or more times. The average value will be used as the reference reading (ANSI N323A, 1997 Section 4.8).

If the instrument is not functioning properly, the RSO should be notified in writing, and the instrument removed from service per SOP 317.

5.2.3.2.2 Background Determination for Integrated Counts: Push the integrate button and count the background for sixty (60) seconds. Record the background count for both alpha and beta on Form 219. For the alpha/beta scintillation detector, alpha results will be recorded on the left facing page and beta results on the right facing page of the logbook.

5.2.3.2.3 Alpha Efficiency Determination for Integrated Counts: The detector is placed directly on the alpha particle standard plate. Push the integrate button on the Electra and count the check standard for 60 seconds. Record the gross alpha counts on Form 219. Calculate the alpha efficiency as follows:

$$\alpha \text{ Efficiency} = \frac{\text{(Gross Alpha CPM - Alpha Background CPM)}}{\text{Alpha Source DPM}}$$

5.2.3.2.4 Beta Efficiency Determination for Integrated Counts: The detector is placed directly on the beta particle standard plate. Push the integrate button on the Electra and count the standard for 60 seconds. Record the gross beta counts on PAI Form 219. Calculate the beta efficiency as follows:

$$\beta \text{ Efficiency} = \frac{\text{(Gross Beta CPM - Beta Background CPM)}}{\text{Beta Source DPM}}$$

5.3 USE OF SURVEY METERS IN THE LABORATORY

If instructed by LIMS special instructions, all employees shall use an NE Electra Survey Meter to survey their hands, feet, and any other area suspected of contacting radioactive materials before leaving the laboratory. This survey is performed as follows:

5.3.1 SURVEY OF HANDS AND FEET

Verify that the instrument is functioning properly (e.g., the battery is charged, the instrument background is acceptable, and the instrument has been calibrated within the last 12 months). Use caution in handling the instrument with potentially contaminated hands to avoid

contaminating the instrument. Consult the RSO if you have any questions or if any problems arise.

5.3.1.1 Slowly pass each hand (front and back) over the active area of the detector. Keep the hand as close as possible without touching the detector (i.e., about 1cm or less distance).

5.3.1.2 Pass the active detector area over the sole of each foot.

5.3.1.3 Each hand or foot pass should be performed slowly, requiring at least 10 seconds to completed.

5.3.1.4 If radioactive material is detected in excess of 12cpm Alpha and 650cpm Beta, then decontamination of the affected areas is required. The first decontamination step is to wash with soap and water. Resurvey the area after washing. If the area is still contaminated, call the RSO or designee for instructions regarding further decontamination measures.

5.3.2 SURVEY OF LAB COATS PRIOR TO SENDING OFFSITE

A survey of lab coats shall be performed using an Electra prior to placing in the vendor removal basket. The survey should focus on the sleeves near the cuffs and the front waist area of the lab coats (areas where sample contact could be made).

5.3.2.1 Slowly pass the Electra over the area of interest (more easily done while wearing the lab coat).

5.3.2.2 If a hit at or above limits (see below) is detected, verify by resurveying. If activity is still found, notify the RSO or designee.

5.3.2.3 If no contamination is found, place lab coat in vendor removal basket.

5.3.2.4 If contamination is found in excess of 12cpm Alpha and 650cpm Beta, the RSO shall document and decontaminate as needed. If the lab coat can not be decontaminated, then it will be placed in the Radioactive waste container for disposal.

5.3.3 SURVEY OF EQUIPMENT AND AREAS

5.3.3.1 Slowly pass the Electra over the area or article of interest. Please note that some items are not practical to survey with a meter in this manner. This is due to shape or contours of the article or area. The article or area shall have enough of an accessible area to assure that any contamination if present

will be detected. If the instrument or article does not have an accessible area, a swipe survey shall be performed. Consult with the RSO for further directives.

5.3.3.2 Document any areas of contamination above 12cpm Alpha and 650cpm Beta on a Map of the area or article or as instructed by the RSO. These limits also apply to personnel contamination surveys using the Electra.

6. SAFETY, HAZARDS AND WASTE DISPOSAL

6.1 SAFETY AND HAZARDS

6.1.1 The building is equipped with safety showers, eyewash stations, fire extinguishers, fire blankets, and first aid kits. All laboratory personnel must be trained in the use and location of these items.

6.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), or handling materials or equipment potentially contaminated with chemicals or radioactive materials.

6.1.3 Food and drink are prohibited in all lab areas.

6.2 WASTE DISPOSAL

Any residual materials used in personnel or equipment decontamination operations shall be evaluated and, if indicated, be disposed of as Low Level Radioactive Waste.

Form 219r2.doc (7/18/07)

Attention:

Per SOP 012, all lab coats must be surveyed prior to leaving the building:

1.) **Survey your lab coat with an Electra before placing it in the dirty lab coat hamper.**

2.) **Concentrate on the ends of the sleeves and the waist area. However, the entire lab coat should be surveyed.**

3.) **Survey areas where the lab coat contacted sample material.**

Action Limits are:

Alpha 12cpm

Beta 650cpm

If these Limits are exceeded, place lab coat in a bag and notify the RSO or designee. Then a survey should be performed on the individual who wore the lab coat to verify that the individual is free of contamination.

STANDARD OPERATING PROCEDURE 015 REVISION 6

TITLE: DISPOSAL OF RADIOACTIVE WASTE

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 11/7/07

QUALITY ASSURANCE MANAGER _____ DATE 11/7/07

LABORATORY MANAGER _____ DATE 11-7-07

HISTORY: NEW, 11/10/93; Rev1, 5/30/97; Rev2, 2/03/00; Rev3, 4/03/02; Rev4, 3/17/03; Rev5, 9/22/03 and 7/18/05 (re-released without revision); Rev6, 11/7/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the procedures used to handle and dispose of radioactive and mixed wastes. This SOP applies to all radioactive waste streams in all laboratories.

Paragon has three general categories of waste streams: nonradioactive (hazardous), radioactive, and mixed hazardous/radioactive wastes. The handling and disposal of hazardous waste is addressed in SOP 003 - Management of Nonradioactive Hazardous Waste. Mixed waste is handled and disposed of according to both this SOP and SOP 003 because the waste is both hazardous and radioactive.

Paragon utilizes radioactive materials under a radioactive material license issued by the Colorado Department of Public Health & Environment (CDPHE), Radiation Control Division. Therefore, all regulatory references, in regards to radioactive materials and waste, are to the Colorado Radiation Control Regulations. These regulations are derived from those found in Chapter 10 of the Code of Federal Regulations (CFR).

2. SUMMARY

It is extremely important that the radioactive components of the waste streams are segregated from the nonradioactive (hazardous) components. If the waste streams are combined, a mixed waste containing both hazardous and radioactive components as defined by the Resource Conservation & Recovery Act (RCRA), may be created. The mixing of hazardous and radioactive wastes shall be systematically minimized in order to limit the production of mixed waste.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Technician to perform these procedures according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who perform this procedure to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. REAGENTS AND APPARATUS

4.1 Solidification Media

4.2 Waste Containers: Containers used for disposal of radioactive waste must be United Nations Specification (UN Spec). The types of containers authorized include UN Spec 5 gallon pail, 30 gallon open head drum, 30 gallon closed head drum, 55 gallon open head drum, 55 gallon closed head drum, and 85 gallon open head salvage drum.

4.3 Ludlum Model 1000 Scaler with Ludlum Model 43-10 Alpha Scintillation Detector or equivalent.

4.4 Ludlum Model 1000 Scaler with Ludlum Model 44-7 End Window Geiger-Mueller Detector or equivalent.

4.5 Tennelec Model LB5100 simultaneous Alpha and Beta Counter.

4.6 Bicron Electra with 100 cm^2 Dual Phosphor Alpha-Beta Scintillation Detector.

4.7 Ludlum Model 19 Micro R Radiation Survey Meter or equivalent.

4.8 Ludlum Model 3 Radiation Survey Meter With End Window G-M Detector or equivalent.

4.9 Filter papers for removable radioactive material contamination surveys.

4.10 Removable radioactive material contamination wipes that dissolve in liquid scintillation cocktail, for low energy beta removable contamination surveys.

5. PROCEDURES

5.1 WASTE DISPOSAL

5.1.1 Sample Disposal

Samples are collected for disposal after a specified archival time. The archival time is a function of the client contract (may be Paragon standard or otherwise). Paragon's standard archival time is 90 days past the date of invoice. Archival time may be extended according to client-specific requirements. Typically, the Paragon PM notifies the client before samples are disposed. Samples are disposed into a container that is specified for a particular waste stream (i.e., radioactive solid, radioactive liquid, mixed solid, mixed liquid). This container may be a Satellite Accumulation Area (SAA) container or a UN SPEC container. Movement of sample volume from the laboratory storage areas to archival, into SAAs, and through to final disposal is tracked in LIMS. SAA management is described in SOP 003.

5.1.2 Process Waste Disposal

Process waste generated at Paragon that is radioactive or mixed shall be placed into a container that is compatible with the waste stream. Mixed waste shall be placed into the container that is present in a Satellite Accumulation Area (SAA). When the SAA containers become full (refer to SOP 003), the contents shall be transferred into a UN SPEC container in a 90-Day Accumulation Area. The UN SPEC containers shall be compatible with the waste streams they contain.

5.1.3 Records of disposal are maintained by the Waste Compliance Officer.

5.2 RADIOACTIVE WASTE CLASSIFICATION FOR OFF-SITE DISPOSAL

There are three main types of radioactive waste that are addressed in this procedure: Low Level Radioactive Waste (LLRW), High Level Radioactive Waste (HLW), and Transuranic Waste (TRU). These waste types are defined in Colorado Radiation Control Regulations RH 14.2. LLRW radioactive waste will be for all practical purposes the only radioactive waste generated at Paragon. However, it is necessary to understand HLW and TRU waste in order to understand LLRW waste.

5.2.1 Low Level Radioactive Waste (LLRW)

LLRW is defined as waste other than that generated by US Government defense or research and development activities, HLW, TRU, byproduct material as defined in Section II e (2) of the Atomic Energy Act of 1954 (as amended on November 8, 1978), or wastes from extraction industries involving minerals other than radium. LLRW does not necessarily imply low levels of radioactive material concentrations. For example, limitations on activity concentrations for LLRW materials are in the Curie per gram range, that is well above environmental levels.

5.2.2 High Level Radioactive Waste (HLW)

HLW materials are materials such as irradiated reactor fuel, liquid wastes from reprocessing irradiated reactor fuels, or solids into which any of the above described liquid wastes have been converted. In short, HLW refers to materials that originated from operations involving nuclear fuels. Paragon will not, under any circumstances, generate High Level Radioactive Waste.

5.2.3 Transuranic Waste (TRU)

TRU materials are wastes containing transuranic elements in activity concentrations exceeding 100 nCi/gram (3700 Bq/gram). Disposal entities (e.g., the Benton County, Washington or Barnwell, South Carolina Radioactive Waste Disposal sites) may impose additional administrative limitations upon TRU activity concentration. The Radiation Safety Officer (RSO) can provide information on current limitations.

5.3 LOW LEVEL RADIOACTIVE WASTE DISPOSAL REQUIREMENTS

The main body of radioactive waste generated at Paragon is LLRW. PAR will not generate any HLW due to the nature of our operation and license restrictions. Also, it is unlikely that Paragon will generate TRU waste (e.g., material with any activity greater than 100 nCi/gram). Sample remainders that contain TRU waste will be returned to the client for final disposition. The LLRW waste generated at Paragon is composed of samples contaminated with radioactive material and laboratory process effluents contaminated with radioactive materials. The following requirements for preparing these wastes for disposal are in accordance with Colorado Radiation Control Regulations 4.22 through 4.26:

5.3.1 Determination of Radioactive Waste Class

The radioactive waste class (A, B or C) must be determined in accordance with Colorado Radiation Control Regulation RH 4.22. Paragon is required to determine the waste class based upon both the activity concentration of long-lived radionuclides for which institutional controls may not be totally effective, and the activity concentrations of the shorter-lived radionuclides for which institutional controls are effective. Based upon Paragon's radioactive materials license limitations, no class B or C waste shipments will ever be made. The requirements for Class B and C radioactive material waste shipments are beyond the scope of this SOP.

5.3.2 Class A Waste Classification Protocols

A waste may be classified as a Class A radioactive waste if it meets the following criteria:

- The activity concentrations of any radionuclide(s) present that are listed in Table 1 may not exceed 0.1 times the value in Table 1 of 10 CFR 61.55 and;
- The activity concentrations of any radionuclide(s) present that are listed in Table 2 of 10 CFR 61.55 may not exceed the activity concentration value in Table 2, Column 1 of 10 CFR 61.55 and/or;
- The radionuclide(s) present are not listed in either Table 1 of 10 CFR 61.55 or Table 2 of 10 CFR 61.55 and;
- The material is stable (e.g., soils) or unstable (e.g., waters).

5.3.3 Class A Radioactive Waste Disposal Requirements

- All waste must be packaged so as to meet the conditions of the license issued to the operator of the site to which the material is being sent for disposal. For example, Perma-Fix of Florida requires that all shipments of radioactive liquids be packaged in an over packed container.

- No wastes shall be packaged for disposal in cardboard or fiberboard boxes or containers.
- Liquid wastes with activity concentrations in excess of 0.002 uCi/g shall be packaged such that sufficient absorbent material is present to absorb twice the volume of the liquid.
- Solid waste containing liquids shall contain as little free standing and noncorrosive liquid as is reasonably achievable, but the total volume of the liquid shall not exceed 1% of the total volume.
- The waste shall not be readily capable of explosive detonation, explosive decomposition, reaction at normal temperatures and pressures, or of explosive reaction with water. Wastes may be shipped to a Temporary Storage and Disposal Facility (TSDF) for treatment and removal of the hazardous waste codes prior to disposal at a radioactive waste disposal facility.
- No waste shall be capable of generating quantities of toxic gases, vapors, or fumes that are harmful to persons transporting, handling, or disposing of the waste. This provision does not apply to radioactive gaseous waste packaged in accordance with Colorado Radiation Control Regulation RH 4.23.1.8.
- No waste shall be pyrophoric. Any pyrophoric materials contained in any waste material shall be treated, prepared, and packaged to be nonflammable and nonhazardous. Wastes may be shipped to a TSDF for treatment and removal of the hazardous waste codes prior to disposal at a radioactive waste disposal facility.
- Gaseous radioactive material wastes shall be packaged at a gauge pressure that does not exceed 1.5 atmospheres at 20 degrees Celsius, nor more than 100 curies (3700 GBq) of activity per container. It is extremely unlikely that Paragon will ever generate a gaseous radioactive waste.
- Waste containing hazardous, biological, pathogenic or infectious material shall be treated to eliminate the nonradiological hazards. Wastes will be shipped to a TSDF for treatment and removal of these additional waste codes prior to disposal at a radioactive waste disposal facility.

5.4 PREPARATION OF RADIOACTIVE MATERIAL FOR LLRW DISPOSAL

5.4.1 Collection of Radioactive Material

5.4.1.1 *Bulk Liquids Contaminated With Radioactive Material*
Radioactive Material may be deposited into a waste

accumulation container (e.g., sample remainders deposited into a UN Spec 20 Liter Jerry Can). The waste liquids may later be transferred to a larger UN Spec Container such as a tight head 55 gallon drum. The waste material will be characterized for radionuclide composition and activity at a later date.

5.4.1.2 *Radioactive Material Contaminated Solids*
Radioactive material solids contained in individual containers (e.g., soil or water samples in discreet sample containers), may be collected and composited into the waste container. The radionuclide composition and activity concentration will be determined by characterization of a composite sample or evaluation of the laboratory analyses for each sample.

5.4.1.3 *Liquid Scintillation Waste*
To the maximum extent practical, analytical operations involving Liquid Scintillation Counting (LSC) shall use LSC cocktails that do not qualify as hazardous materials. All LSC wastes will be collected in open head drums. The liquid scintillation waste is composed of the liquid scintillation vial, liquid scintillation cocktail, and dissolved sample. The LSC cocktail sample mixture shall not be removed from the vial and disposed of in bulk. The vials will be segregated into separate drums based upon classification as Exempted LSC Waste, LLRW, or Mixed LLRW. The Colorado Radiation Control Regulation 4.21 exempts tritium and carbon-14 in LSC cocktail waste from disposal concerns with respect to radioactive material provided the activity concentration is less than 0.05 uCi/gram (50,000 pCi/gram).

Additional requirements for liquid scintillation waste follow:

- Any samples with less than 0.05 uCi/gram (50,000 pCi/gram) of tritium or carbon-14 shall be deposited in the Exempted LSC Waste Drum. Exempted LSC wastes will be sent to a facility with a radioactive materials license for incineration. The resultant ashes will be disposed in a radioactive waste disposal facility.
- LSC vials containing tritium or carbon-14 in excess of 0.05 uCi/gram (50,000 pCi/gram) or any other radionuclides dissolved in nonhazardous cocktails, shall be deposited in the LLRW LSC Waste Drum. LLRW LSC wastes will be sent to a facility with a radioactive materials license for incineration.

Facilities that currently meet these requirements are Perma-Fix of Florida and DSSI in Kingston, Tennessee. The materials will be incinerated and the resultant ashes will be disposed in a radioactive waste disposal facility.

- LSC vials containing tritium or carbon-14 in excess of 0.05 uCi/gram (50,000 pCi/gram) or any other radionuclides dissolved in hazardous cocktails, shall be deposited in the Mixed LLRW LSC Waste Drum. The Mixed LLRW LSC wastes will be sent to a facility with a radioactive materials license and a TSDF permit for incineration. The materials will be incinerated, the EPA Hazardous Waste Codes removed as possible, and the resultant ashes disposed in a radioactive waste disposal facility or a radioactive/hazardous waste disposal facility as necessary.
- All types of LSC Vials shall be packaged in 55 gallon open head UN Spec drums. The empty drum shall have a 3" layer of a sorbent such as Floor dry poured onto the bottom. A 4-5 inch layer of LSC vials will then be added to the drum. Another 3" layer of floor dry will be added, then more vials, and so on until the drum is full.

5.4.2 Determination of Radionuclidic Composition and Activity

The concentration of radionuclides may be determined by analytical evaluation and/or process knowledge. If analytical evaluation is needed, sampling of the waste streams shall be performed. The minimum tests required for a complete analytical evaluation are given below:

- Gross Alpha/Beta
- Gamma Spectroscopy
- Tritium
- Carbon-14
- Radium-226
- Radium-228
- Strontium-90
- Technetium-99
- Isotopic Thorium

- Isotopic Uranium
- Isotopic Plutonium
- Am-241

The data from the above analyses or process knowledge will be used to fill out the Uniform Low Level Radioactive Waste Manifest.

5.4.3 Packaging of Radioactive Material

5.4.3.1 *Bulk Liquids Contaminated with Radioactive Material*
The following requirements apply to bulk liquids contaminated with radioactive material:

- Bulk liquids must be noncorrosive.
- Liquids with an activity concentration less than 0.002 uCi/g (2000 pCi/g) will be packaged in a Tight Head UN Spec container. The filled container will then be placed in a UN Spec Open Head Over pack container.
- Liquids with an activity concentration greater than 0.002 uCi/g (2000 pCi/g) will be packaged into a tight head UN Spec container with a maximum volume of 15 gallons. This 15 gallon container will be placed in a 55 gallon UN Spec Open Head Drum and surrounded with a sorbent material such as Floor Dry.

5.4.3.2 *Solid Low Level Radioactive Waste*
Solid LLRW will be packaged in a UN Spec container. The size of the drum used may be up to 55 gallon, as appropriate. The drum should have a liner in place. Any free liquids present in the soils must be less than 1% of the total volume and noncorrosive.

5.4.3.3 *Liquid Scintillation Waste*
The containers must be UN Spec 55 Gallon Open Head Drums.

5.4.4 Preparation of Radioactive Material Waste Packages for Shipment

5.4.4.1 A removable radioactive material contamination survey is performed according to PAR SOP 010 - Radioactive Contamination Area Surveys. The results must be within the limits required by 49 CFR 173.443. These limits are 22 dpm/cm^2 for beta-gamma radionuclides, all radionuclides with half lives less than 10 days, natural uranium, natural thorium

and U-235, U-238, Th-232, Th-228, and Th-230 when contained in ores and physical concentrates. The limit for any other alpha-emitting radionuclide is 2.2 dpm/cm^2.

5.4.4.2 External exposure rate measurement shall be taken at the container surface and at one meter from the container surface. Please see PAR SOP 008, Table 5.1 for external radiation level limits by shipment type.

5.4.4.3 *Manifest Preparation*
The manifest must contain information about the generator, waste characteristics, and other classification information. The information required is given in the following Sections:

- Generator Name, Address, and EPA ID #
- Weight of waste
- Physical form
- Waste Class A, Stable (S) or Unstable (U)
- Waste description
- Solidification media or absorbent material, if applicable
- Radionuclide(s)
- Chemical form
- Activity of each radionuclide
- Waste form
- Radiation exposure rates at the surface and at one meter from the container
- Quantity of waste to be shipped
- One time shipment or continuous
- Source material present (Kilograms), if applicable

6. SAFETY, HAZARDS, AND WASTE DISPOSAL

The safety hazards associated with this procedure involve potential spread of radioactive material contamination and moving the waste containers. Radioactive material contamination in the environment is a possibility during waste preparation operations. These operations shall be supervised by the RSO with appropriate monitoring and personnel protective equipment being utilized. Any operations involving moving containers (e.g., 55 gallon drums containing contaminated soil), shall utilize suitable moving devices such as barrel dollies and use of steel-toed shoes. Waste disposal procedures are addressed in the body of the procedure.

HISTORY: Rev0, 11/20/92; Rev1, 4/05/94; Rev2, PCN #478, 5/26/95; Rev3, 5/15/99; Rev4, 4/09/02; Rev5, 2/9/04 and 11/10/05 (re-released w/o revision); Rev6, 10/2/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the procedures used to perform a leak test for an electron capture detector (ECD). This SOP applies to radioactive materials sources in electron capture detectors that emit beta radiation. ***The leak tests must be performed every six months.*** Paragon does not possess any other radioactive material sealed sources that require leak testing as per Colorado Radiation Regulations 6 CCR 1007-1 (current version).

2. SUMMARY

There is always a possibility that sealed radioactive sources may leak radioactive materials. To prevent the spread of radioactive contamination, it is necessary to test these sources for leakage.

The leak test is performed by wiping all surfaces that contact or are in close proximity to the radioactive source. These areas include: detector housings, exits, and any openings that the source may contact. The wipe may be performed using a *NUC-WIPE*™ or other suitable wipe that will dissolve in the liquid scintillation counter (LSC) cocktail. The wiping media is placed in a scintillation vial and LSC cocktail is added. The wipe is allowed to dissolve, and then the vial is counted in a Beckman LS6000TA Liquid Scintillation Counter or comparable instrument. Finally, the amount of removable radioactive contamination is calculated.

3. RESPONSIBILITIES

3.1 The Organics Department Manager or designee is responsible for managing and performing all necessary ECD leak tests, and for taking appropriate corrective actions as necessary.

3.2 Paragon's Radiation Safety Officer (RSO) shall provide oversight for the requirements and procedures stated in this SOP, and shall maintain leak test records.

3.3 Radiochemistry Department staff shall analyze the leak test wipes in accordance with SOP 704, and submit the test results to the Organics Department Manager or designee.

3.4 It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. APPARATUS AND MATERIALS

4.1 *NUC-WIPE*™ or other wipe material that will dissolve in the LSC cocktail

4.2 Liquid scintillation vials, 20mL

4.3 Beckman LS6000TA Liquid Scintillation Counter or equivalent

5. REAGENTS

Liquid scintillation cocktail, Packard Ultima Gold™ LLT or equivalent

6. PROCEDURES

6.1 WIPE TEST

Obtain a *NUC-WIPE*™ or equivalent wipe and wipe all areas that are in contact with or in close proximity to the sealed source. Wipe every surface with a uniform medium pressure. Place the wipe in a 20mL LSC vial that is labeled with the sample identification number on the cap. Complete the following information on Form 040: date of test, the name of the individual performing the leak test, standard identification, and sample identification information.

6.2 LEAK TEST ANALYSIS

Add 20mL of the liquid scintillation cocktail to the LSC vial. The LSC vial shall be held for at least one hour prior to placing in the LSC instrument, in order to ensure dissolution of the wipe prior to counting.

6.3 LIQUID SCINTILLATION COUNTING

The vial shall be placed into the LSC and counted for at least 30 minutes to achieve a minimum detection limit of 0.005 microcuries per sample. The counting procedures are outlined in SOP 704. If the contamination is less than 0.005 uCi/sample, then it is considered within acceptable limits. If the contamination exceeds the 0.005 uCi/sample limit, then the detector must be tagged out of service and serviced by an entity licensed to receive and service ECD detectors.

6.4 LEAK TEST RECORD

A record of the leak test will be completed and filed in the radiation safety files. All test records including raw data and results will be maintained for inspection.

7. QUALITY ASSURANCE

Refer to SOP 704.

8. CALCULATIONS AND INTERPRETATION OF DATA

8.1 CALCULATIONS

Net Standard CPM = Gross STD CPM -- Background CPM

Efficiency =Net STD CPM / Ni-63 STD DPM

LLD = 4.66*(Bkg CPM/Count Time)$^{1/2}$ / (Eff * 2.22X10^{6} dpm/uCi)

Net Sample CPM = Gross Sample CPM -- Background CPM

Removable Activity(uCi) = Net Sample CPM/(Eff*2220000 dpm/uCi)

8.2 INTERPRETATION OF DATA

If the removable activity of the sample exceeds 0.005 µCi/sample , then the radioactive source is contaminated and must be removed from the laboratory, cleaned, and serviced.

9. SAFETY, HAZARDS AND WASTE DISPOSAL

9.1 SAFETY AND HAZARDS

9.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

9.1.2 Gloves, safety glasses, and a lab coat shall be worn in the laboratory areas.

9.2 WASTE DISPOSAL

Refer to SOP 704.

QUALITY ASSURANCE MANAGER _____ DATE 4/24/07

LABORATORY MANAGER _____ DATE 4-26-07

HISTORY: Rev0, PCN #217, 4/13/94; Rev1, 5/15/99; Rev2, 4/3/02; Rev3, 3/7/03; Rev4, 2/9/04 and 4/1/05; Rev5, 4/26/07.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the processes used to sample and monitor effluent releases from the laboratory facilities. The procedures that follow apply to sampling, analysis, and regulatory compliance for effluent released into the sanitary sewer system from Paragon's wastewater system.

2. SUMMARY

2.1 Paragon's wastewater system is composed of one 3000-gallon sump, two 8000-gallon holding tanks, and two pumps with a control panel. Water from laboratory operations flows into the sump and is pumped into one or both of the tanks. The tanks can be used independently by opening or closing the appropriate flow valves. The pumps are controlled via the control panel and they can be operated manually or automatically.

2.2 Boxelder Sanitation District is the local agency that oversees discharge of wastewater from Paragon. Boxelder Sanitation District's Prohibitions and Limitations on Wastewater Discharge, Part 8, is the document that governs the discharge of wastewater from Paragon. Radioactive components are addressed in Part 802 (I) of this document, which refers to the Colorado Department of Public Health and Environment (CDPHE) publication "Rules and Regulations Pertaining to Radiation Control".

2.3 The wastewater from Paragon's laboratory processes must have a pH between 5 and 10 before release (Boxelder Sanitation District, Prohibitions and Limitations on Wastewater Discharge 802 (O)). There are additional regulatory limits that must be complied with and documented. To comply with these regulations, waste determinations must be documented for waste discharged into the system from laboratory processes, and representative samples may be obtained, as appropriate, from the holding tanks for analysis.

2.4 All wastewater (excluding sanitary systems) from laboratory processes is neutralized in the wastewater system. The neutralized effluent is stored in holding tanks. Samples are taken from the holding tanks before any effluent is released to the sanitary sewer system. The samples are held until the end of the current month, and then analyzed for gross alpha and beta radioactivity, tritium, and total metals. The Waste Compliance Officer or the Radiation Safety Officer (RSO) may request additional analyses. The total metals analysis is performed on a composite sample from the entire sampling period. Results of the analysis are not needed prior to discharge in routine operations and conditions, because process knowledge of in-house samples and limitations of Paragon's radioactive materials license will keep discharges less than regulatory limits at a volume of 7800 gallons (approximate volume of daily discharge).

3. RESPONSIBILITIES

It is the responsibility of all personnel who work with these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. APPARATUS AND MATERIALS

4.1 baking soda or equivalent caustic material

4.2 nitric acid, HNO_3, concentrated

4.3 nitric acid, 20%

4.4 bottles, wide-mouth, plastic, 500mL

4.5 pH strips

4.6 transfer pipets, disposable, glass

5. PROCEDURES

5.1 TANK SAMPLING

5.1.1 Check the volume of the tank(s) using the gauges on the wall.

5.1.2 Isolate the tank to be discharged by opening the valve to the other tank and turning off the valve to the tank to be discharged.

5.1.3 Purge the discharge line by opening the discharge valve for 3 to 5 seconds.

5.1.4 Collect a sample using the sampling port.

5.1.5 Verify that the pH of the tank is between 5 and 10. If the pH needs to be adjusted, then refer to Section 5.2 for the procedure. Repeat steps 5.1.3 through 5.1.5 until pH is between 5 and 10.

5.1.6 Open the discharge valve to release contents of the tank. Discharge time is approximately 30 minutes, depending on the volume to be discharged. However, discharge time may be limited by Boxelder Sanitation District in order to control volume discharged into the system at any given time. Check with Boxelder Sanitation District for limitations on discharge time.

5.1.7 Complete the tank discharge log (Form 015) with the following information: sample ID number (TWMMDDYY), date, time, initial pH, tank number, volume discharged, and any comments. When more than one tank is sampled in a day, use -A, -B etc. for 1st and 2nd sample etc.

5.1.8 Label the sample bottle with the same information entered onto the tank discharge log.

5.1.9 Place the sample in a holding bin until the end of the sampling period. Close the discharge valve when the discharge is complete.

5.2 ADJUSTING THE pH

5.2.1 Baking soda should be added to the sump at regular intervals to maintain the pH at approximately 7.

5.2.2 If the pH of the tank is acidic (pH less than 5), add baking soda to the tank until the pH is within the release criteria (pH 5-10).

5.2.3 If the pH of the tank is basic (pH greater than 10), add acid (concentrated HNO_3) until the pH is within the release criteria (pH 5-10).

5.3 COMPOSITE SAMPLE

5.3.1 Obtain a small volume of approximately 5mL from each sample taken during the sample period.

5.3.2 Place the aliquoted volume from the samples in a 500mL plastic bottle preserved with 20% HNO_3.

5.4 SAMPLE ANALYSIS

5.4.1 Create a separate chain of custody log (Form 015) for the composite sample, and the group of tank samples taken during the sampling period.

5.4.2 Forward the samples and the chain of custody to the Sample Control Department for login and distribution.

5.4.3 Tank samples are to be analyzed for tritium and gross alpha and beta.

5.4.4 The composite sample is to be analyzed for total RCRA metals plus nickel, copper, and zinc.

NOTE: Additional analyses may be requested by the RSO and/or Waste Compliance Officer.

5.5 RECORDS

5.5.1 Copies of discharge logs/discharge chain of custody forms and logbooks, are forwarded to the Boxelder Sanitation District's Pretreatment Coordinator, if requested, at the end of the sampling period.

5.5.2 Copies of the results of the total metals analysis are forwarded to the Boxelder Pretreatment Coordinator, if requested, at the end of the sampling period.

5.5.3 Copies of results from the tritium and gross alpha/beta analyses and discharge logs are forwarded to Paragon's Radiation Safety Officer for review of compliance with the Colorado Department of Public Health publication, Rules and Regulations Pertaining to Radiation Control.

5.5.4 A logbook that details discharges via the sanitary sewer system, other than laboratory wastewater, is maintained by the Waste Compliance Officer. The Waste Compliance Officer reviews the data for compliance with RCRA 10CFR, and Prohibitions and Limitations on Wastewater Discharge, Part 8.

6. QUALITY ASSURANCE/MONITORING

All QA/QC requirements for specific analyses are included in the individual laboratory test procedures.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

7.1.1 The building is equipped with safety showers, eyewash stations, fire extinguishers, fire blankets and first aid kits. All laboratory personnel must be trained in the use and location of these items.

7.1.2 Gloves, safety glasses and a lab coat, shall be worn in the laboratory areas.

7.2 WASTE DISPOSAL

Not Applicable.

Form 015r3 (4/24/07)

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 024 REVISION 3

TITLE: DISPOSAL OF SHORT LIVED RADIONUCLIDES BY DECAY IN STORAGE

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ for _____ DATE _____

QUALITY ASSURANCE MANAGER _____ DATE 1/19/07

LABORATORY MANAGER _____ DATE 1-19-07

HISTORY: Rev0, 7/31/97; Rev1, 2/11/02; Rev2, 4/07/03; Rev3, 2/13/04, 3/10/05, 1/19/07 (re-release without revision).

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) describes the procedures used to manage the disposal of short-lived radionuclides by decay in storage. This SOP applies to disposal by decay in storage of short-lived radionuclides with half lives of 60 days or less.

2. SUMMARY

This procedure is used for disposal of radiochemical standards and samples that contain only known short-lived radionuclides and **DO NOT CONTAIN ANY CHEMICAL CONSTITUENT THAT WOULD MAKE IT A RCRA HAZARDOUS WASTE.** Any materials contaminated with radionuclides having a half life greater than 60 days must be disposed of as a Low Level Radioactive Waste (refer to SOP 015). These radionuclides ***with half lives less than 60 days*** will be stored until at least 10 half lives have elapsed. Following the decay period, the materials will be surveyed in a low background area to ensure that all radiation levels are indistinguishable from background levels. Prior to disposal, all radioactive material labels must be removed or defaced. The material may then be disposed in the normal (sanitary) trash.

3. RESPONSIBILITIES

It is the responsibility of the technician to perform these procedures according to this SOP and to inform the Radiation Safety Officer (RSO) and Waste Compliance Officer of any problems that may occur during the performance of these procedures.

4. APPARATUS AND MATERIALS

4.1 Ludlum Model 19 MicroRoentgen Meter or equivalent

4.2 NE Electra with DP6A Dual Phosphor Alpha/Beta Scintillation Detector or equivalent

4.3 Materials for defacing labels, including items such as black paint or permanent markers.

5. REAGENTS

None.

6. PROCEDURE

6.1 CLASSIFICATION OF MATERIALS FOR DISPOSAL BY DECAY IN STORAGE

Records are reviewed for radionuclide content to ensure that all radionuclides present have half lives of 60 days or less and **that there are no chemical constituents that would make the material a RCRA Hazardous Waste**. This data may be obtained from a Radioactive Material Standard Certificate that details radionuclide composition or from analytical reports on samples. However, when reviewing analytical reports, sample data must be available for **all** radionuclides to ensure that long lived radionuclides present in the sample are not missed. All materials that are classified as short-lived may be set aside for decay in storage.

6.2 DECAY IN STORAGE PERIOD

Materials that are classified as short-lived are set aside for a period of at least 10 half lives of the radionuclide with the longest half life. The total decay in storage time is calculated by multiplying the longest half life by a factor of 10. The earliest disposal date is calculated by adding the 10 times the half life to the current date. The disposal date is marked on the label.

6.3 STORAGE LOCATION

Materials that are set aside for decay in storage shall be kept segregated from other materials.

6.4 SURVEY PRIOR TO DISPOSAL

Following the decay in storage period, the material is removed to a low background area and surveyed with a Micro Roentgen Meter and a NE Electra with a Dual Phosphor Alpha/Beta Scintillation detector. In order, for the material to be disposed of, there can be no radiation detected above background. *The material must be indistinguishable from background.* If no radiation levels above background are found, the material is cleared for disposal.

6.5 REMOVAL OF LABELS OR MARKINGS INDICATING THE PRESENCE OF RADIOACTIVE MATERIAL

All labels or other marking that indicate the presence of radioactive material must be removed or defaced prior to disposal. The labels may be removed or defaced using black paint or permanent marker. The labels must be removed or defaced to prevent unnecessary public concerns resulting from radioactive material labels being discovered by a citizen or sanitary landfill personnel.

6.6 DISPOSAL

The decayed, surveyed, and defaced materials may disposed of in the normal (sanitary) trash providing the above conditions have been met *without exception*.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 SAFETY AND HAZARDS

7.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

7.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), or when handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

7.2 WASTE DISPOSAL

The waste generated by these procedures is disposed as described in SOP 003 - Management of Nonradioactive Hazardous Waste.

8. REFERENCES

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 026 REVISION 2

TITLE: RADIOACTIVE MATERIALS INVENTORY CONTROL USING LIMS

FORMS: NONE

APPROVED BY:
TECHNICAL MANAGER _____ DATE 2/9/07
QUALITY ASSURANCE MANAGER _____ DATE 2/9/07
LABORATORY MANAGER _____ DATE 2-9-07

HISTORY: Rev0, 9/22/03; Rev1, 3/24/05; Rev2, 2/9/07.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

Paragon Analytics operates under Radioactive Material Licensing conditions prescribed by the Colorado Department of Public Health and Environment (CDPHE), Laboratory and Radiation Services Division. These Radioactive Material Licensing conditions dictate that Paragon must control possession of radioactive material by both activity and volume. Paragon manages these requirements by performing radioactive material prescreening on samples and incoming radioactive materials. The data obtained from prescreening, plus other general, sample description information, is entered into Paragon's Laboratory Information Management System (LIMS). LIMS provides the Radiation Safety Officer (RSO) or designee with the means to efficiently monitor the total activity and volume of radioactive material in house.

2. SUMMARY

The backbone of radioactive material control at Paragon is the sample receipt process. Procedures for the initial receipt and login of samples are detailed in Paragon SOP 202. Per SOP 202, Sample Control staff arrange for the samples to be prescreened, as applicable, for radioactive material. Sample Control staff also enter all relevant sample information, including sample volume, into LIMS. As needed, the samples are prescreened per procedures outlined in Paragon SOP 703. The data obtained from the prescreen analysis of the samples is entered into LIMS by the Project Manager (PM) or the RSO. At this time, the RSO has the information necessary to manage the radioactive materials inventory.

3. RESPONSIBILITIES

3.1 Sample Control staff are responsible for the initial receipt and login of samples and for arranging for prescreen analyses, as detailed in SOP 202.

3.2 Qualified laboratory personnel are responsible for conducting the prescreen analyses as described in SOP 703.

3.3 The Project Manager (PM), RSO or designee is responsible for entering the prescreen data into LIMS.

3.4 The RSO is responsible for reviewing the prescreen data and ensuring that the conditions of the Radioactive Materials License are met.

4. APPARATUS AND MATERIALS

4.1 Prescreening instrumentation per SOP 703.

4.2 Paragon Analytics LIMS.

5. PROCEDURE

5.1 INITIAL SAMPLE RECEIPT

Samples are received and initially logged in by Sample Control staff per Paragon SOP 202. Samples that are designated for prescreening are held in the Sample Control Walk-In Cooler (RU #20), until the prescreen data is received by the PM, RSO or designee, and the samples are released to the lab.

5.2 SAMPLE PRESCREENING

Sample prescreening operations are conducted per Paragon SOP 703. The sample prescreen data are delivered to the PM, RSO or designee.

5.3 INPUT OF SAMPLE PRESCREEN DATA INTO LIMS

The PM, RSO or designee inputs the prescreen data into LIMS as follows:

5.3.1 From the LIMS main menu, select the 'Waste Management' menu option, then select 'Prescreen Rad Inventory'. Enter the sample workorder number in the order number field, then click on the 'Add Samples From Login' button.

5.3.2 The sample data will appear on the screen including workorder number, matrix, sample volume, activity concentration and total activity for alpha, beta, and tritium. Enter the activity concentrations from the prescreen report in pCi. LIMS will calculate the total activity for each sample and all samples in the workorder.

5.3.3 Click on the 'Evaluate Rad/Disposal' status button. This will assign handling classes and disposal type.

5.3.4 Click on the 'Activity Report (pCi)' button and review the report. ~~This report will be included with the LIMS Project Instructions to provide all laboratory staff with a detailed report of activity concentrations and total activities for each sample and the entire workorder.~~ ; correct as necessary DAS

5.3.5 The LIMS Project Instructions must now be generated. Go to the 'Sample Control' menu and click on the 'Potential Hazards' button.

Press Ctrl +F and input the workorder number in the dialog box. Then click 'Find'. The workorder information will appear on the screen.

5.3.6 Click the 'Prescreen Data Released' button, then the 'Handling Instructions Released' button, then click the 'Update HI Now Codes' (i.e., Handling Instructions Codes) button.

5.3.7 Click on the 'Preview Handling Instructions' button, and review the Project Instructions report; make any changes that are necessary.

5.4 EVALUATION OF RADIOACTIVE MATERIALS INVENTORY

The RSO or designee may check the radioactive materials inventory at any time by going to the LIMS 'Waste Management' menu and selecting 'RAD Inventory'. The total activities, license activity limit, % remaining, and the license balance information will be provided. Additionally, any workorder may be selected to review the associated activities.

5.5 REDUCTION OF RADIOACTIVE MATERIALS INVENTORY BY LABORATORY SAMPLE DISPOSAL

Samples are maintained in Paragon's radioactive materials inventory until disposal. In LIMS, samples are designated for disposal via the creation of a "waste package". The total activity for each sample in the disposal unit is automatically removed from the laboratory's radioactive materials inventory upon physical disposition of the "waste package". This is accomplished per the following procedures:

5.5.1 To add samples to a waste package in LIMS, go to the 'Waste Management' menu, then select 'Sample Disposal'.

5.5.2 Enter the workorder number in the order number field, then click on the 'Find' button. Double click on the samples that are to be disposed. The samples selected for disposal will appear in the 'Selected Bottles for Disposal' window to the right of the sample information.

5.5.3 Waste Management staff then physically creates the waste package by gathering together all of the samples in a particular waste stream to be disposed of per the identities listed in the LIMS waste package report generated in Step 5.5.2 above. The Waste Management staff will then dispose of the designated samples in the appropriate waste stream container.

5.5.4 Once the samples in the waste package have been physically disposed of, the Waste Management staff will indicate in LIMS that disposal is complete. LIMS will then automatically remove the samples from the radioactive materials inventory.

6. SAFETY, HAZARDS AND WASTE DISPOSAL

6.1 SAFETY AND HAZARDS

6.1.1 The building is equipped with safety showers, eyewash stations, fire extinguishers, fire blankets, and first aid kits. All laboratory personnel must be trained in the use and location of these items.

6.1.2 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), or handling materials or equipment potentially contaminated with chemicals or radioactive materials.

6.1.3 Food and drink are prohibited in all lab areas.

6.2 WASTE DISPOSAL

Wastes are disposed of in the manner that is appropriate to the waste stream; detailed procedures are provided in Paragon SOPs 003 and 015.

7. REFERENCES

2/9/07: References to SOP 201 removed since this SOP was combined with SOP 202 then retired. Added DOCUMENT REVISION HISTORY Section.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 027 REVISION 1

TITLE: PACKAGING SAMPLES FOR RETURN TO CLIENT

FORMS: NONE

APPROVED BY:
TECHNICAL MANAGER _____ DATE 9-11-06
QUALITY ASSURANCE MANAGER _____ DATE 9/8/06
LABORATORY MANAGER _____ DATE 9-11-06

HISTORY: Rev 0, 5/15/03 and 4/1/05; Rev1, 9/11/06.

re-released w/o revision 3/9/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the procedures for packaging samples to be returned to the client. The samples will be classified as one of the following groups prior to packaging: nonhazardous, hazardous, radioactive for transportation, and both hazardous and radioactive for transportation. The classified samples will be packaged according to both regulatory requirements and Paragon's requirements for the class of sample(s) being shipped.

2. SUMMARY

Samples to be packaged for return to the client are classified based upon analytical results, including sample prescreen results and historical or process knowledge as appropriate. All samples returned to the client by Paragon are packaged to ensure that the contents do not leak under conditions normally incident to transportation. All outgoing sample shipments meet, at a minimum, the requirements defined by Title 49 of the Code of Federal Regulations (49CFR) for general packaging. Further, sample shipments that are hazardous or hazardous and radioactive, meet the requirements of 49 CFR and/or International Air Transportation Association (IATA) Dangerous Goods Regulations. Hazardous samples are required to be shipped with specific types of outer and inner containment known as UN specification packaging. Because the process of hazard determination, labeling, manifesting, packing and shipping is complicated, a flow chart to help illustrate the process is included as Appendix A.

3. RESPONSIBILITIES

3.1 It is the responsibility of the technician to perform these procedures according to this SOP, applicable regulations, and to know what regulations are applicable to what shipping provider, and to complete all documentation required for review. Any anomalies or out-of-control events must be noted and corrective action taken and documented.

3.2 Only personnel who have completed Department of Transportation (US DOT) hazardous materials shipper training and who possess a working knowledge of US DOT and IATA hazardous material shipping regulations, may oversee the

preparation and shipment of samples with hazardous constituents. The Facilities/Waste Manager is responsible for ensuring that appropriate training has been provided and for retaining all shipping records.

3.3 The Paragon Project Manager (PM) is responsible for coordinating the shipment with the client, obtaining the correct address and any site-specific protocols for sample return.

4. APPARATUS AND MATERIALS

4.1 Plastic coolers (Coleman or equivalent)

4.2 Double-walled fiber board boxes, minimum burst strength of 275 psi or greater

4.3 Shipping tape, 2" width or greater

4.4 Plastic liners

4.5 Industrial heat sealing apparatus and accompanying poly bags

4.6 Zip-lock poly bags

4.7 Floor Dry™ sorbent material or equivalent

4.8 Bubble wrap bags

4.15 Whatman™ 42 filter papers (47mm), Rad-Wipe smears, or equivalent

4.16 47mm steel planchets

5. PROCEDURE

5.1 NOTIFICATION OF SAMPLES TO BE RETURNED TO CLIENT

Waste management personnel inform the Paragon PM when samples are available for return to client. Sample return and disposal information is maintained in the Paragon Laboratory Information Management System (LIMS). A written list, typically a LIMS printout, is forwarded to the PM. The PM obtains client

approval for sample return. The PM also obtains information regarding any client and/or site-specific protocols for sample return. After client approval for sample return has been received, the PM informs waste management personnel that they may package the samples for shipment.

5.2 CLASSIFICATION OF SAMPLES FOR TRANSPORTATION

5.2.1 Evaluate the samples for the presence of radioactivity. Create appropriate shipping documents as necessary based on the absence of or level of radioactivity present.

5.2.1.1 If the samples do not meet the requirements for radioactive as described in 49 CFR 173 or IATA Part 10.3, then the material is not considered radioactive for transportation. No special packaging for radioactive concerns is needed. However, Hazardous material regulation may still be applicable.

5.2.1.2 If the samples do meet the definition of radioactive material as described in 49 CFR 173 or IATA Part 10.3, they are considered radioactive materials for transportation purposes.

NOTE: Sample shipments that meet the definition of Class 7 Radioactive I, II or III hazards as defined in 49CFR or IATA require special handling in excess of this SOP. If a client has requested return of samples that meet these criteria, contact the RSO immediately.

5.2.1.3 DOT Excepted Packages for limited quantities of Class 7 are defined in 49 CFR 173.421. If the listed criteria is met, the package is exempt from packaging requirements and only needs the applicable UN number marked on the outside of the package and Radioactive on the inside container.

5.2.1.4 IATA Excepted Package is defined in IATA 10.5. These items must be shipped according to the limitations and specifications listed in Section 10.5.

5.2.2 Evaluate the samples to determine their hazardous materials status. Materials are considered to be hazardous for transportation by the US DOT if they possess any of the following characteristics:

- ***Explosive:*** The sample contains explosive materials capable of detonation or ignition. (Hazard Class 1)
- ***Flammable Gas:*** The sample is a gas that is capable of ignition. (Hazard Class 2)
- ***Flammable Liquid:*** The sample has a flash point of less than or equal to 141ºF (60.5°C). (Hazard Class 3)
- ***Flammable Solid:*** The sample is spontaneously combustible or dangerous when wet. This class includes solid materials that are capable of self-ignition, combustion, or reaction. (Hazard Class 4)
- ***Oxidizers:*** The sample contains materials that are capable of giving up oxygen that can enhance or accelerate the combustion of fuel sources. (Hazard Class 5)
- ***Poisons:*** The sample contains non-gaseous materials that are known to be so toxic as to provide a hazard to health during transportation. A list of these materials may be found in the Hazardous Materials Table, 49CFR172.101. (Hazard Class 6)
- ***Radioactive Materials:*** The sample meets the criteria prescribed in 49 CFR173 or IATA 10.3. (Hazard Class 7)
- ***Corrosive Liquid:*** The sample is a liquid with a pH of less than 2.0 or pH greater than 12.5. (Hazard Class 8)
- ***Miscellaneous Hazards:*** The sample is a material that presents a hazard to transportation, but does not meet the definition of any other hazard classes. A list of miscellaneous hazards may be found in the Hazardous Materials Table, 49CFR172.101. (Hazard Class 9)

5.2.2.1 If the sample does not possess any of the above listed characteristics, it is classified as **"non-hazardous"** with respect to transportation. No special documentation is required.

5.2.2.2 If the sample <u>does</u> possess one or more characteristics that classify it as a **"hazardous material"**, assemble the required documentation.

NOTE: Only personnel who have completed Department of Transportation, Hazardous Materials Shipper training and who possess a working knowledge of US DOT and IATA hazardous material shipping regulations may oversee the manifesting of samples with hazardous constituents. Directions for completion manifests can be found in 49CFR Subpart C and IATA Section 8. Preprinted documents are available to aid with manifest preparation.

- Obtain from the RSO a US DOT hazardous material manifest with emergency response information for ground shipments or an IATA Shippers Declaration of Dangerous Goods with emergency response information for air shipments.

- Obtain from the RSO the DOT Hazard Class Warning label and proper shipping name marking. This information is found in 49 CFR 172.101, columns 3 and 2 respectively, or the IATA Dangerous Goods Regulations, Section 4, columns C and B respectively.

- For shipments that include radioactive samples, ensure that the appropriate language listed in Section 5.2.1.2 of this procedure is included as additional handling information on either type of manifest.

5.3 SELECTION OF AN APPROPRIATE SHIPPING CONTAINER

5.3.1 If the sample shipment is classified as: Non-hazardous and Non-regulated (US DOT) with respect to radioactivity, Exempt (IATA) with respect to radioactivity **OR** Radioactive Material, Excepted Package-Limited Quantity of Material, UN2910, choose one of the following outer containers as appropriate to the sample matrix:

5.3.1.1 For soils and solids, choose a double-walled fiberboard box with burst strength of at least 275psi. Assemble with 2" polyethylene shipping tape. Secure the bottom flaps with at least two strips of tape and allow at least 3 inches of overhang on each side.

5.3.1.2 For non-regulated, exempt liquids, choose a plastic cooler or a UN specification 1A2 or 1H2 5-gallon drum. Note: the use of UN Specification containers is not required in this case, but may be more efficient in some situations.

5.3.1.3 For radioactive, excepted quantity liquids, choose a UN specification 1A2 or 1H2 5-gallon drum.

5.3.2 If the sample shipment is classified as hazardous, select the UN specification packaging system for the materials being shipped. UN specification 1A2 (steel drum with removable head), 1H2 (plastic drum with removable head), or 4G (fiberboard box) outer packages with glass or plastic inner packages are Paragon's preferred combination packaging systems and are typically kept in stock.

5.3.2.1 For ground shipments, consult column 8B of 49CFR172.101 to locate the packaging reference for 49CFR173. Go to that citation and choose the combination packing option appropriate for the shipment.

5.3.2.2 For air shipments, consult Section 4, column K of the IATA Dangerous Goods Regulations to locate the packaging instruction reference. Go to that citation in Section 5 of IATA and choose the combination packing option appropriate for shipment.

5.3.3 If either 49CFR or IATA regulations indicate requirement of a type of packaging that is not readily available, consult the Waste Management Officer or RSO for guidance.

5.3.4 If a 4G fiberboard box is the preferred combination packaging, assemble and pack the container according to manufacturer's instructions.

5.4 PACK THE CONTAINER

All samples are packed, at a minimum, according to the standard of strong outside packaging (49CFR171.8) that will not allow the contents to leak under the conditions normally incident to transportation. These instructions apply to all packagings other than UN 4G systems.

5.4.1 Line the interior of the chosen container with a plastic liner.

5.4.2 Wrap individual sample bottles in cushioning material. Use bubble wrap bags if available or bubble wrap sheets.

5.4.3 Place each sample container in secondary containment. Use a zip-lock bag for solid samples or a heat-sealed plastic bag for liquid samples.

5.4.4 For solid samples, place approximately 4" of additional cushioning material (e.g., bubble wrap, foam peanuts or foam sheeting) on the bottom and 2" of additional cushioning material along the sides of the package. Insert the sample containers, but do not over pack the container. Place cushioning material in the voids and on top of the package.

5.4.5 For liquid samples, add two inches of Floor Dry or other approved sorbent material to the bottom of the container. Add the bagged samples leaving enough space to allow sorbent material to completely surround samples. Cover the samples in Floor Dry. Ensure that the liquid sample material is compatible with the sorbent used through testing or process knowledge.

5.4.6 Seal the inner plastic liner with a knot or by twisting and taping with packing tape.

5.4.7 Place paperwork in a large zip-lock bag. If possible, tape the bag to the inside lid of the cooler or box. Otherwise, place the zip-lock bag on top of the shipment. Paperwork includes:

- Chain-of –custody;
- If required and assembled during step 5.2.1.2, letter of transmittal and "RADIOACTIVE" label;
- Any additional information provided by the PM according to client and site specific requirements.

If a "RADIOACTIVE" label is included, ensure that it is attached such that it will be visible immediately upon opening the package.

5.4.8 Seal the shipping container. For coolers and boxes, seal with shipping tape. Ensure that the shipping tape goes completely around the outside of the container.

5.5 LABEL THE CONTAINER

5.5.1 Place a double arrow label on the outside of the container to indicate package orientation.

5.5.2 Label package with Paragon's return address and the consignee's address.

5.5.3 If previously obtained from SOP section 5.2.2.2, place the proper DOT

Hazard Class Warning label on the opposite side of the container. Place the proper shipping name marking on the container above the DOT Hazard Class Warning label.

5.5.4 Place the completed Bill of Lading or IATA Shippers Declaration of Dangerous Goods in a poly envelope and affix to the package or to package 1 of a multiple piece shipment.

5.6 ADDITIONAL REQUIREMENTS FOR RADIOACTIVE MATERIAL SHIPMENTS

5.6.1 Perform a swipe test for removable contamination. Wipe a filter paper or Rad-Wipe over a 4" x 4" (100 cm^2) square area of the container's external surface. Count the wipe per SOP 010. The removable radioactive material contamination on the package must be less than 220dpm/100 cm^2 alpha and 2200dpm/100 cm^2 beta/gamma.

5.6.2 Survey the external surface of the package. Obtain a Ludlum Model 19 Micro Roentgen (Micro R) meter or equivalent. Verify that the daily instrument checks for calibration and background have been completed per SOP 007. Perform a survey of the container. The external dose rate reading must not exceed 0.5mRem/hour (500uRem/hour) at the surface of the package.

5.7 Ship the sample return package(s) by available carrier such as FEDEX Ground, FedEx, UPS (non-hazardous or excepted shipments), or an approved common carrier (truck line) for large shipments.

6. SAFETY AND HAZARDS AND WASTE DISPOSAL

6.1 SAFETY AND HAZARDS

6.1.1 The building is equipped with safety showers, eyewash stations, fire extinguishers, fire blankets and first aid kits. All laboratory personnel must be trained in the use and location of these items.

6.1.2 Wear gloves, safety glasses and a lab coat when working with any samples or chemicals or when handling materials or equipment potentially contaminated with chemicals.

6.1 WASTE DISPOSAL

All used wipes that have radioactive material contamination shall be disposed of as low level radioactive waste (LLRW).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 029 REVISION 2

TITLE: **CALIBRATION AND USE OF THE BERTHOLD LB 1043 AS HAND AND FOOT MONITORS**

FORMS: **221 (use current iteration)**

APPROVED BY:
TECHNICAL MANAGER _____ DATE 10/3/07
QUALITY ASSURANCE MANAGER _____ DATE 10/2/07
LABORATORY MANAGER _____ DATE 10/4/07

HISTORY: Rev1, 7/13/04 (re-released without revision 6/23/05); Rev2, 10/2/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) provides instructions for the calibration, performance checks, maintenance, and continuous use of the Berthold LB 1043 AS hand and foot monitors, located at the routine personnel exits from controlled laboratory areas at Paragon Analytics.

Laboratory staff use these monitors to survey for potential hand and foot contamination from alpha and beta particle-emitting radionuclides. The monitors are capable of discriminating between alpha and beta radiation, allowing for separate action levels for the two types of contamination. Other types of radiation, such as gamma and X-rays are not measured by this instrument.

This procedure is an integral part of the laboratory's efforts to keep the dose of ionizing radiation to the employee and members of the general public "As Low As Reasonably Achievable" (ALARA). The user is cautioned that this procedure is intended to supplement, not replace, other established ALARA practices as defined in the laboratory's Radiation Protection Plan (RPP). Users should note that detection levels for this type of instrumentation are relatively high, as compared to analytical detection limits achieved in the laboratory. Consequently, the user should be mindful that an instrument determination of "NOT CONTAMINATED" is not a definitive assessment of a lack of radioactive contamination. The consistent use of other ALARA practices, such as good housekeeping and the use of personal protective equipment, is critical.

2. SUMMARY

2.1 CALIBRATION AND ALARMS

The monitors are operated in a mode to provide raw count data, rather than calculated activity units (e.g., Becquerels); evaluation of counting efficiencies is done on a separate worksheet. NIST-traceable sources, manufactured to provide a 100cm^2 active surface area, are used in the calibration. A ^{241}Am source is used in the alpha efficiency calibration, and a ^{137}Cs source is used in the beta efficiency calibration. The monitors are calibrated to sound an alarm at a count rate that is

consistent with established activity action levels for alpha and beta contamination. Alpha and beta alarm levels are set separately.

2.2 WEEKLY PERFORMANCE CHECKS

Weekly performance checks are completed on each monitor while the instrument remains in service. The sources used for the weekly performance checks may be the same sources used for calibration, or they may be other sources, the use of NIST-traceable sources for the weekly performance check is not required. Acceptance criteria for weekly performance checks are established from the initial performance checks and may be updated, if necessary, after sufficient historical data is accumulated. Routine maintenance during the weekly checks may include replacing the P-10 gas cylinder, replacing the detector windows, and routine cleaning.

2.3 CONTINUOUS USE

Continuous operation of the hand and foot monitors involves the individual employees surveying themselves for hand and foot contamination prior to leaving the controlled laboratory areas.

3. RESPONSIBILITIES

3.1 Radiation Safety Officer (RSO)

3.1.1 It is the RSO's responsibility to provide adequate training to the Primary Instrument Technician to ensure that the Technician is able to demonstrate proficiency in the operation, calibration, and maintenance of the instruments. Demonstration of proficiency by the Technician shall include a hands-on demonstration, successful performance checks and recalibration, and a manual recalculation of results. The RSO shall maintain records of the proficiency demonstration.

3.1.2 It is the responsibility of the RSO to review and approve the calibration data to ensure that the proper alarm levels are set in the instruments, and to ensure that the hand and foot monitors are used.

3.1.3 In the event that a monitor is determined to be out of normal operating specifications, it is the RSO's responsibility to ensure that the instrument is removed from use (SOP 317), that the necessary services to return the instrument to use are procured, and to provide the employees with an alternate method for performing personal surveys.

3.2 Primary Instrument Technician

3.2.1 The Primary Instrument Technician will have completed all radiation safety training required for general laboratory personnel, and will have documented previous experience in the calibration and use of radiation detection instrumentation. The Primary Instrument Technician shall

provide a demonstration of proficiency (described above), before performing any procedure unsupervised.

3.2.2 It is the responsibility of the Primary Instrument Technician to perform the instrument calibrations, weekly instrument checks and routine maintenance, including replacement of the detector windows and weekly cleaning of the hand and foot detectors, as described in this SOP. In the event that the instrument fails to meet established acceptance criteria the primary instrument technician will remove the instrument from service, properly tag the instrument per SOP 317, and immediately notify the RSO.

The Primary Instrument Technician is responsible for maintaining an adequate supply of P-10 gas to ensure the continuous operation of the instrument during working hours, as well as overnights, weekends, and holidays. This allows for employees who may work off-shifts or non-routine schedules.

3.3 Each Employee

3.3.1 It is the responsibility of each employee to properly survey themselves before leaving a controlled laboratory area in which radiological materials may have been used.

In the event of an indication from the instrument that the employee is potentially contaminated, it is the employee's responsibility to minimize the extent of the laboratory contamination and help facilitate decontamination of themselves and the lab area.

DO NOT LEAVE THE LABORATORY AREA, remain in the immediate vicinity.

Travel only as far back into the lab area as necessary to call for assistance. Notify the RSO immediately!

3.3.2 As needed, each employee is responsible for providing any assistance the RSO may need to evaluate the extent of contamination, to decontaminate an employee or their clothing, and to identify the root cause of the incident.

3.3.3 In the event of an instrument malfunction, it is the employee's responsibility to use an alternate instrument to perform a personal survey before leaving the lab area, and to notify the RSO as soon as possible of the malfunction.

4. APPARATUS AND MATERIALS

4.1 Berthold LB 1043 AS hand and foot monitor.

4.2 Mylar film, 0.3 mg/cm^2, or equivalent.

4.3 P-10 gas, 90% argon + 10% methane, high purity.

4.4 Low pressure regulator, <0.1 mbar.

4.5 Tacky-Mat shoe cleaning mat, Lab Safety Supply 3BB-1631-5, or equivalent

5. PROCEDURE

5.1 OPERATING CONDITIONS

5.1.1 Proper instrument operation relies on the low flow of P-10 gas through the detectors. The line pressure for the P-10 supply should be less than 0.1 mbar (0.00145 lb/sq.in.). A low pressure regulator should be used and the flow rate should be adjusted so that the ball gauges on the front of the instrument read approximately "5" both in and out.

5.1.2 Each hand and foot monitor has a tacky-mat directly in front of the instrument. A new sticky surface should be exposed, or the mat should be replaced, at least weekly.

5.1.3 The instrument should be clean, especially the covers for the hand and foot detectors.

5.1.3.1 The hand detectors should be wiped at least weekly with a disinfecting agent, for sanitary maintenance.

5.1.3.2 The foot detectors should be gently blown or vacuumed at least weekly to remove visible dirt and debris. This helps to minimize the background measurements and optimize the detector sensitivity.

5.1.4 The mylar window coverings over the detectors must be intact and should be replaced as soon as any tear or puncture is noticed. This repair must be performed by the RSO or another qualified individual, and must be done per the instrument manufacturer's instruction manual.

5.2 CALIBRATIONS

5.2.1 The calibration of the instrument consists of determining the instrument efficiency coefficients and background count rates, and setting the appropriate alarm settings to achieve the following action levels:

Alpha	1000 dpm	hand	(= 16.7 dps)
Beta	4000 dpm	hand	(= 66.7 dps)

Alpha	2000 dpm	foot	(= 33.4 dps)
Beta	8000 dpm	foot	(= 133 dps)

5.2.2 See I:\oprtns\safety\hand and foot cals.xls (**Attachment 1**). Record the alpha and beta instrument background count rate for each detector, using the Steps outlined below. These values are recorded for informational purposes only, they are not used to set the threshold alarm levels in the instrument.

5.2.2.1 Approach the instrument without stepping on the foot platform.

5.2.2.2 Press the "DISPLAY" button on the front panel.

5.2.2.3 Read the detector 1 alpha background, and record the result.

5.2.2.4 Repeatedly press the "DISPLAY" button, recording the other background results in the appropriate spaces on the calibration worksheet.

5.2.3 Determine the alpha counting efficiencies for each detector as follows:

5.2.3.1 Obtain 100cm^2 surface area alpha and beta sources.

5.2.3.2 Record the decay-corrected current source activities on the calibration worksheet.

5.2.3.3 For each detector, place the alpha source housing against the detector grate, obtain a standard count over the pre-set count duration.

5.2.3.4 Using the "DISPLAY" button on the front panel (see Step 5.2.2 above), record the observed net count rate on the calibration worksheet.

5.2.3.5 Repeat this process until five observations are recorded for each detector.

5.2.3.6 Alternately, if the calibration sources are used for daily performance checks, the most recent five observations may be entered into the calibration worksheet.

5.2.3.7 In the specified column on the calibration worksheet, enter the average of the five readings.

5.2.3.8 Determine the individual detector efficiencies. Divide the

average result by the current source activity, in dps.

5.2.4 Repeat Steps 5.2.3 using the beta source.

5.2.5 Set the appropriate alarm level for each detector.

5.2.5.1 Using the threshold alarm levels in dps (see 5.2.1), multiply this number by the calculated detector efficiency (Steps 5.2.3 and 5.2.4) to obtain threshold alarm levels, in cps.

5.2.5.2 Calculate the average alpha and beta threshold alarm level for all four hand detectors. These values will be used to set the instrument.

5.2.5.3 Calculate the average alpha and beta threshold alarm level for both foot detectors. These values will be used to set the instrument.

5.2.5.4 Obtain the security lockout code from the RSO. This will allow the user to reset threshold count rates in the instrument.

5.2.5.5 Begin by entering the lockout code into the instrument keypad.

5.2.5.6 Using the flowchart in **Figure 1**, reset the threshold alarm levels to those calculated above. DO NOT CHANGE ANY OF THE PRE-SET INSTRUMENT SETTINGS, OTHER THAN THE THRESHOLD ALARM LEVELS, WITHOUT THE EXPRESS APPROVAL OF THE RSO.

5.2.5.7 Affix a label, shown at the bottom of Attachment 1, to the instrument indicating the date of calibration and the responsible Technician (the template for the label can be found at I:\oprtns\safety\hand and foot cals.xls). Any similar label with the same information is acceptable.

5.2.6 The instrument is now calibrated and ready for use.

5.3 WEEKLY PERFORMANCE CHECKS

Instrument background and efficiency checks are performed weekly. Results are recorded in the Hand and Foot Monitor Check Logbook (Form 221, **Attachment 2**), and are evaluated against established control limits.

5.3.1 Measure the instrument background count rates following the procedures described in Step 5.2.2, except that the results are entered

into the Hand and Foot Monitor Logbook (Form 221).

Control limits are established as follows:

5.3.1.1 Interim control limits are established after initial setup of the instrument or after significant service or repairs. Interim control limits are based on the initial background measurements taken for alpha and beta activity for each detector, and are calculated as:

initial value ± (initial value * 3/sqrt(bkg cps * ct time seconds))

5.3.1.2 If sufficient data is collected to establish historically derived limits (i.e., 20-30 data points), calculate the control limits as follows:

mean value ± (3*standard deviation)

5.3.2 Measure the instrument alpha and beta count rates. In this case, the sources used do not necessarily need to be NIST-traceable or have an area of 100cm^2, but the same sources must be used consistently. Follow the procedure described in Steps 5.2.3 (alpha) and 5.2.4 (beta) and enter the results into the Hand and Foot Monitor Logbook (Form 221). Control limits are established as follows:

5.3.2.1 Interim limits are based on the initial source count rate for alpha and beta activity for each detector, and are calculated as:

initial value ± (initial value * 3/sqrt(source cps * ct time seconds)).

5.3.2.2 If sufficient data is collected to establish historically derived limits (i.e., 20-30 data points), calculate the control limits as follows:

mean value ± (3*standard deviation)

5.3.3 In the event that any weekly performance check measurement is outside established control limits, the instrument is removed from service, per SOP 317, and corrective action is referred to the Radiation Safety Officer.

5.4 CONTINUOUS USE

Any employee working in a radiologically-controlled area must use the hand and foot monitor before leaving the area.

5.4.1 Approach the hand and foot monitor and wait until the display panel reads “READY”.

5.4.2 Step onto the pedestal and place both feet all the way forward until both shoes touch the front bar, activating the instrument’s optical sensors.

5.4.3 Place both hands into the hand openings far enough to push the finger-tip lever fully in. This causes the hand detectors to close around the employee’s hands and activates the switches at the employee’s wrists.

5.4.4 Remain still until the instrument completes the count, shows all detector symbols as green, and the display panel reads “NOT CONTAMINATED”.

5.4.5 The employee is free to leave the area.

5.4.6 If the instrument detects alpha or beta contamination above the threshold alarm levels determined above, or if the instrument malfunctions, the detector symbols will be shown as either yellow (malfunction) or red (contamination) and an audible alarm will briefly sound.

5.4.6.1 In the event of an indication from the instrument that the employee is potentially contaminated, it is the employee’s responsibility to minimize the extent of the laboratory contamination and help facilitate decontamination of themselves and the lab area.

DO NOT LEAVE THE LABORATORY AREA. Remain in the immediate vicinity. Travel only as far back into the lab area as necessary to call for assistance.

Notify the RSO immediately.

5.4.6.2 Provide any assistance the RSO may need to evaluate the extent of the contamination, decontaminate the employee or their clothing, and identify the root cause of the incident.

5.4.6.3 In the event of an instrument malfunction, it is the employee’s responsibility to use an alternate instrument to perform a personal survey before leaving the lab area, and to notify the RSO as soon as possible of the malfunction.

5.5 General instructions for the use of other hand-held survey equipment is provided in SOP 031.

HISTORY: Rev0, PCN #222, 4/14/94; Was retired, reactivated, reformatted and released without technical revision 7/7/2003; Rev1, 11/22/04 and 11/10/05 (re-released w/o revision).

re-released w/o revision 2/29/08 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps necessary for the safe operation of the Hydraulic Waste Compactor.

2. SUMMARY

Waste barrels are placed inside the compaction chamber. The door is shut and the waste is compacted at approximately 2500 psi.

3. RESPONSIBILITIES

3.1 This procedure shall be performed under the direction of the Waste Compliance Manager. The Waste Compliance Manager will perform all training of personnel that have been designated to operate this piece of equipment.

3.2 Two people are needed to perform this procedure. This is due to the fact that two individuals are needed to place the drum inside the compactor and for safety purposes during the operation of the machine.

3.3 Safety inspections shall be performed on the compactor quarterly, this inspection is to include but is not limited to: (1) hydraulic fluid level, (2) electrical cord condition, (3) plunger stability and (4) proper operation of the safety catch. The items shall be documented in a maintenance logbook or on a form signed and retained by the Waste Compliance Manger.

3.4 The instrument shall be operated only on level solid ground (e.g., a concrete pad).

3.5 If the instrument is contaminated with radioactive material, as described in Section 6.2, the Radiation Safety Officer (RSO) shall be notified and appropriate steps shall be taken to minimize the spread of the contamination. The machine shall be decontaminated as directed by the RSO.

4. APPARATUS AND MATERIALS

- Compactor
- Drum Dolly
- Lab Coat
- Drum Liners
- Gloves
- Steel Toe Boots
- Radiological Contamination Survey Swipes
- NE Electra

5. REAGENTS

Radiac Wash™

6. PROCEDURE

6.1 HAZARDOUS WASTE, RADIOACTIVE/MIXED WASTE PROCEDURE

6.1.1 Cover the plunger with a plastic barrel liner.

6.1.2 Place the drum inside the compaction chamber making sure that the bottom of the drum completely encircles the raised circular base plate.

6.1.3 Remove the bung and lid from the top of the barrel.

6.1.4 Cut the bottom off of a plastic barrel liner, pull one end over the top of the drum and attach it about 2 inches from the top. Pull the other end over the plunger and attach it just above the push plate. The plunger may need to be slightly lowered to accomplish this.

6.1.5 Completely close and latch the door with the door latch.

6.1.6 Push both hydraulic levers towards the back of the unit.

6.1.7 Turn on the electric motor on the back of the unit. This will start the compaction process.

6.1.8 When the pressure on the pressure gauge indicates about 2500 pounds per square inch (psi), pull the bottom lever forward to retract the plunger. You can also pull the lever forward after the desired compaction is complete.

6.1.9 When the plunger reaches the top of the unit, after the compaction, the top lever will automatically push forward to stop the process.

6.1.10 Turn the motor off when the process is complete.

6.1.11 Remove the drum liners from the drum and the plunger and place in the drum.

6.1.12 Perform radiation surveys as necessary per Section 6.2.

6.2 POST COMPACTION RADIATION SURVEYS

6.2.1 Remove the drum and perform a swipe survey the top outside of the drum and plunger.

6.2.2 Count the swipes and if the areas surveyed are contaminated above 10 dpm/100cm2 alpha and 100 dpm/100cm2 beta, notify the RSO for guidance on further surveys and decontamination efforts.

6.2.3 If decontamination is necessary, decontaminate the areas with Radiac Wash and water then resurvey. Repeat this process as necessary until limits are acceptable.

7. SAFETY, HAZARDS AND WASTE DISPOSAL

7.1 The employees implementing this procedure shall be trained to operate the unit in addition to reading and understanding this procedure.

7.2 Two individuals are needed to place most drums in the compactor, this process should be done so that both individuals are on either side of the drum.

7.3 If the instrument fails to operate in the manner prescribed above or if the procedure cannot be implemented as described above, stop the process and notify the Safety Manager and the Waste Compliance Manger.

7.4 Do not bypass the safety catch on the door latch.

7.5 Unplug the instrument after use and during maintenance checks.

STANDARD OPERATING PROCEDURE 052 REVISION 8

TITLE: DATA PACKAGE REVIEW PROCEDURES FOR STABLE CHEMISTRY METHODS

FORMS: NONE

APPROVED BY:
TECHNICAL MANAGER _____ DATE 9-11-06
QUALITY ASSURANCE MANAGER _____ DATE 9/8/06
LABORATORY MANAGER _____ DATE 9-11-06

HISTORY: Rev0, 12\4\92; Rev1, PCN #192, 3/31/94; Rev4, 4/12/00; Rev5, 9/20/02; Rev6, 4/22/04; Rev7, 3/9/06; Rev8, 9/11/06.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) describes the steps required to review laboratory data package reports generated by the Reporting Group. An overview of the tiered review process, which is supplemented by method-specific review checklists, is also discussed. Procedures for managing changes that need to be made to the data are also discussed.

2. SUMMARY

All analytical data generated at Paragon are extensively reviewed before submission to our clients. Raw data are reviewed for accuracy and completeness within each Department before being submitted to the Reporting Group. Reports generated by the Reporting Group are then reviewed at three distinct levels:

- ***first level report review*** - usually performed by the reporter who compiles the report
- ***second level report review*** - usually performed by the analyst who performed the work or a designee within the Department
- ***third level report review*** - performed by the Project Manager

Method-customized checklists that specify analytical and report review requirements, are used by the Reporting Group to perform the first level report review. After the first two levels of review have been performed and documented, the report is transmitted to the Reports Management Department where the client's report is finalized. The assigned Project Manager then performs the final review of the report before it is submitted to the client. Changes made to the data during the review processes, are made by authorized analysts, under the direction of Senior personnel. Documentation of these data changes occurs either by hand-annotation of review checklists, or via audit trails programmed into Lims. Should a client inquiry investigation (Project Manager is focal point of contact) result in resubmission of data, the appropriate changes are guided by Senior personnel with documentation occurring as a revised data package case narrative, completion of an NCR

(SOP 928) and /or audit trails in LIMS.

3. RESPONSIBILITIES

3.1 The Reporting Group is responsible for the generation, compilation, and first level review of the complete report. This Group must ensure that any computer automation used to calculate the final results is functioning properly and has been verified and documented.

3.2 The Department Manager, qualified analyst or other designee is responsible for the second level report review. This level of report review ensures that the reported data match the raw data and that all data are of acceptable quality and conform to the parameters of the applicable method.

3.3 It is the responsibility of all personnel who perform data review to document any anomalies, out-of control or non-compliant events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented in a Quality Assurance Summary Sheet (QASS), Non-Conformance Report (NCR), or narrative comment.

4. APPARATUS AND MATERIALS

This procedure requires access to the computer system(s) from which the report to be reviewed is generated. A hand calculator may be needed to perform manual calculations during the review process. Re-verification of software-generated or manually-generated values shall be documented.

5. PROCEDURE

5.1 DATA PACKAGE REVIEW

5.1.1 After the analytical review has been completed, the data are compiled into reports via work order number. Each report may contain: raw data, LIMS-generated summary forms, and supporting documentation (as required by the client). The reporter or analyst who performs the ***first level report review*** of the data package and report, follows the guidelines stated below. If any requirements are not met, corrective action must be taken before the data are submitted to our client.

<u>Calibration Data</u>

- Initial calibration (ICAL), initial calibration verification (ICV), and initial calibration blank (ICB) data are method compliant, analyzed at the correct frequency, and are completely documented (if applicable).
- Continuing calibration verification (CCV) and continuing calibration blank (CCB) data are method compliant, analyzed at the correct frequency, and are completely documented (if applicable).

QC Samples

- Method blanks (MB) contain no target compounds above the reporting limit (or another limit, as specified by the method or client, such as the MDL for drinking water samples analyzed in accord with compliance monitoring).
- All applicable QC sample recoveries are within control limits established by applicable method and/or client.

Samples and Miscellaneous

- Extraction and analytical holding times have been met.
- Applicable extraction SOP was followed and sample preparation information is correct.
- Sample dilutions and/or multipliers/divisors are correct.
- Units are correct.
- Internal standard (IS) areas are within control limits, if applicable.
- Surrogate standard (SS) recoveries are within control limits, if applicable.
- Dual column confirmation data are included and correct, if applicable.
- Quantitative results and units are correct.
- TIC information is included, if applicable.
- All manual re-integrations, with before and after chromatograms, are presented with the data, if applicable.
- Accompanying documentation (checklists, LIMS generated forms, if applicable, etc.) is complete and correct.

Specific review issues and strategies may be needed to address client specific requirements.

5.1.2 A ***second level report review*** shall be performed by the Department that generated the data. The reviewer may be another qualified analyst, Department Manager, or designee using the guidelines listed above.

5.1.3 Additionally, the first and second level report review verifies the following:

- All sample data are present (primary and secondary analyses, if appropriate).

- The raw data are consistent with the final report forms.
- Work order numbers, client names and client sample identifications are correct on all LIMS forms.
- QC data are present and complete.
- Significant figures are correct.
- All case narrative comments are documented correctly.
- The reporting limits are correct.
- All cross-outs are completed properly (one line cross-out, initialed and dated).
- Data qualifiers, if applicable, are present and correct.
- Data that are manually entered into LIMS are subject to 100% review to prevent data entry errors.
- Report contains all necessary accompanying documentation (e.g., percent moisture form, run sequence logs, extraction benchsheets, etc.)

5.1.4 The Reporting Group shall correct all reporting errors. If errors are brought to the attention of the reporting group prior to the report being sent to the client, the data may require analysts providing new electronic and hardcopy raw data, re-importing of the raw data, re-processing of imported data or manual correction of results. If data have already been provided to the client, originally provided data will permanently remain in the client's Workorder Review directory. After data has been corrected, new report forms may be provided, depending on the correction, and an electronic version of the report will be provided in the client's Workorder Review directory with some designation that the report is a resubmission. The final resubmission is based on the project manager and/or the client's request.

5.1.5 Significant discrepancies or errors should be brought to the attention of the responsible analyst and or Department Manager to ensure proper resolution of the situation. Examples include holding time violations, surrogate failures, calibration failures, or QC sample failures not documented by an NCR form.

5.2 FINAL REVIEW

5.2.1 Final review or ***third level report review*** is performed by the Project Manager using the following guidelines:

Introductory Section

- Review the cover letter.
- Address and addressee are correct.
- Project name and number are correct.
- Number and type of samples are correct.
- Choices of analyses/methods are correct.
- Sample cross-reference table is correct.

Review QC Sample Results

- Extraction dates identical for QC and field samples.
- Correct QC samples are present.
- QC recoveries (LCS, LCSD, MS, MSD) are within control limits or an explanation is given in the case narrative and the NCR form, if applicable.

Sample Results and Miscellaneous

- Analyte lists and reporting limits are correct.
- Concentration units match matrix type.
- Header information is correct.
- Client ID's match Chain of Custody.
- Sample results are consistent in comparable tests (e.g., BTEX by SW 8021 and SW 8260).
- Surrogate recoveries are in control.
- Results are reported to the correct significant figures.
- Qualifiers are correct and consistent.
- Results for all requested samples are included.

Case Narratives

- Client name and work order number are correct.
- Test name is correct.
- Grammar and spelling are correct.
- All discrepancies are noted.

Invoice

- Review the invoice for the correct number of samples, tests, and prices.

- Verify that the purchase order (PO) number, addressee, and address are correct.

5.3 CORRECTION OF ERRORS IN DOCUMENTS

During the course of processing and reviewing sample preparations and analysis results, it may be necessary to correct documentation errors. Detailed requirements for the correction of manual documentation errors are prescribed in **SOP 303**. Changes made to the data during the review process shall only be made by authorized analysts and under the supervision of Senior personnel. In summary, manual entries may not be obliterated by erasure, use of correction fluid, or other means. In order to maintain the integrity of the documentation generated by the laboratory, changes to documentation must be made in the following manner:

- A single line must be struck through the error so that the original text remains legible;
- A corrected entry must be made adjacent to the error; and
- The person making the change must initial and date the corrective entry.

If corrections to computerized data are required, Paragon's LIMS controls the ability to make data changes and provides an electronic audit trail for corrections that are made.

If not clearly evident, the reason for the data change must be indicated.

Recalculation Verification:

Verify the instrument concentration using the curve fit equation from the initial calibration. Use the appropriate equation below depending upon the type of curve fit that was used.

Linear calibration:

$A = mC + b$ or $C = (A - b)/m$

A = The instrument response in area counts.
m = The slope of the linear equation.
C = The concentration present at the instrument.
b = The intercept of the linear equation.

Lab Sample ID:_____
Analyte:_____

Average response factor calibration:

$C = A/R_f$

C = The concentration present at the instrument.
A = The instrument response in area counts.
R_f = The average response factor from the initial calibration.

GC/HPLC ICAL Data Review Checklist (Internal Standard)

Method:_____ Instrument ID:_____ Date analyzed:_____

first reviewer/date:_____ second reviewer/date:_____

	First Review			Second Review			
Initial Calibration Review QC Criteria	Y	N	NA	Y	N	NA	COMMENTS
Minimum of five point calibration analyzed?							
Are compounds properly identified and integrated?							
Manual integrations documented before and after?							
Internal standard recoveries within 50-200% criteria?							
Are average response factors used for quantitation?							
Are all the % RSDs <20%?							
Is the mean % RSD <20%?							
Are linear curve fits used for quantitation?							
Are all the corr. coef. >= 0.995 (R^2 = 0.990)							
Are quadratic curve fits used for quantitation?							
Minimum of six point calibration analyzed?							
Are all the CODs >= 0.990?							
Second source analytes (ICV) +/- 15% difference?							
One data point recalculated successfully?							
Additional comments:							

Recalculation Verification:

Verify a calibration factor in the ICAL using the equation below.

Response factor = $(A_s \times C_{is})/(A_{is} \times C_s)$

A_s = Peak area of the target analyte.
A_{is} = Peak area of the internal standard.
C_s = Concentration of the analyte.
C_{is} = Concentration of the internal standard.

Verify the instrument concentration of a second source (ICV) compound using the curve fit equation from the initial calibration. Use the appropriate equation below depending upon the type of curve fit that was used.

Average response factor calibration:

$C_s = (A_s \times C_{is})/(A_{is} \times RF)$

RF = Average response factor from the ICAL
A_s = Peak area of the target analyte.
A_{is} = Peak area of the internal standard.
C_{is} = Concentration of the internal standard.

Lab Sample ID:_____

Analyte:_____

Linear calibration:

$y = mx + b$ or $A_s/A_{is} = m(C_s/C_{is}) + b$ or $C_s = [(A_s / A_{is}) - b]C_{is}/m$

C_s = Concentration of the analyte.
m = The slope of the linear equation.
b = The intercept of the linear equation.

Lab Sample ID:_____

Recalculation Verification:

Verify the instrument concentration using the curve fit equation from the initial calibration. Use the appropriate equation below depending upon the type of curve fit that was used.

Average response factor calibration:

$C_s = (A_s \times C_{is}) / (A_{is} \times \overline{RF})$

A_s = Peak area of the target analyte.
A_{is} = Peak area of the internal standard.
C_{is} = Concentration of the internal standard.

Lab Sample ID:_____
Analyte:_____

Linear calibration:

$y = mx + b$ or $A_s/A_{is} = m(C_s/C_{is}) + b$ or $C_s = [(A_s / A_{is}) - b]C_{is}/m$

$\overline{RF}$ = Average response factor from the ICAL.
C_s = Concentration of the analyte.
m = The slope of the linear equation.
b = The intercept of the linear equation.

GCMS ICAL/CCAL Data Review Checklist (Volatiles)

Recalculation Verification:

1.) Verify a calibration factor in the ICAL using the equation below.

Response factor $= (A_s \times C_{is})/(A_{is} \times C_s)$

A_s = Peak area of the target analyte.
A_{is} = Peak area of the internal standard.
C_s = Concentration of the analyte.
C_{is} = Concentration of the internal standard.

Standard ID:_____
Analyte:_____

Standard ID:_____
Analyte:_____

2.) Verify the instrument concentration of a second source (ICV) compound using the curve fit equation from the initial calibration. Use the appropriate equation below depending upon the type of curve fit that was used.

Average response factor calibration:

$C_s = (A_s \times C_{is})/(A_{is} \times \overline{RF})$

A_s = Peak area of the target analyte.
A_{is} = Peak area of the internal standard.
C_{is} = Concentration of the internal standard.

Lab Sample ID:_____
Analyte:_____

Linear calibration:

$y = mx + b$ or $A_s/A_{is} = m(C_s/C_{is}) + b$ or $C_s = [(A_s/A_{is}) - b]C_{is}/m$

$\overline{RF}$ = Average response factor from the ICAL.
C_s = Concentration of the analyte.
m = The slope of the linear equation.
b = The intercept of the linear equation.

Lab Sample ID:_____
Analyte:_____

Quadratic calibration: (Back calculate the peak area using the target concentration)

$y = ax^2 + bx + c$ or $A_s/A_{is} = a(C_s/C_{is})^2 + b(C_s/C_{is}) + c$ or $A_s = [a(C_s/C_{is})^2 + b(C_s/C_{is}) + c]*A_{is}$

a = quadratic term
b = linear term
c = constant term

Are the LIMS run no.s correct?						
Recalculation Verification Performed?						
Please list samples not to be reported and a brief description why.						

Recalculation Verification:

Verify the instrument concentration using the curve fit equation from the initial calibration. Use the appropriate equation below depending upon the type of curve fit that was used.

Average response factor calibration:

$C_s = (A_s \times C_{is}) / (A_{is} \times RF)$

A_s = Peak area of the target analyte.

A_{is} = Peak area of the internal standard.

C_{is} = Concentration of the internal standard.

RF = Average response factor from the ICAL.

Lab Sample ID:_____

Analyte:_____

Linear calibration:

$A_s / A_{is} = m(C_s/C_{is}) + b$ or $C_s = [(A_s / A_{is}) - b] C_{is} / m$

C_s = Concentration of the analyte.

m = The slope of the linear equation.

b = The intercept of the linear equation.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 069 REVISION 8

TITLE: **MANAGING AND ARCHIVING CLIENT WORK ORDERS AND RECORDS, AND RETRIEVING ARCHIVED INFORMATION**

FORMS: **136**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 9.8.06
QUALITY ASSURANCE MANAGER _____ DATE 9/8/06
LABORATORY MANAGER _____ DATE 9/8/06

HISTORY: Rev1, 1/17/93; Rev2, 4/9/96; Rev3, 7/15/99; Rev4, 1/26/00; Rev5, 8/15/02; Rev6, 5/4/04; Rev7, 11/10/05 (combined with SOP 332); Rev8, 9/11/06. re-released w/o revision 3/12/09 DAS

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) addresses the initiation, movement and archiving of client workorders. Management of raw data and other laboratory records, such as logbooks, is also discussed. Retrieval of archived information is addressed. All laboratory records must be retrievable and kept in a manner that prevents their loss or deterioration. Various controls are in place that limits access to laboratory records.

2. OVERVIEW

Workorder folders are initiated by Sample Receiving personnel, processed by Login personnel, reviewed and released by the appropriate Project Manager (PM), then routed to Reports Management, where they are retained until the completed data package reports are signed-in by the laboratories. Following review by the PM, the data package reports are paginated, as needed, scanned, sent to the client (as hardcopy and/or on CD), and invoiced. After approximately three months, the completed workorder folders (which have been imaged as the official record for retention) are transferred to a vendor for secure document destruction.

Where possible, laboratory raw data is captured electronically. Data package reports are compiled electronically (by direct import or by the compilation of images). Where laboratory benchsheets are not provided for by the Laboratory Information Management System (LIMS), logbook (SOP 303) information is scanned to create image files. Other records, such as PM logs, quality assurance (QA) records, etc., may also be imaged for retention. Once a hardcopy record has been imaged as the official record, and the image verified, the hardcopy originals may be destroyed confidentially (i.e., shredded).

Image archives are managed by the Information Systems (IS) Manager, and are backed-up per procedures described in SOP 1401.

Paragon's records are retained for a minimum of seven years. Clients will be notified, in

writing, before any final data reports are permanently destroyed.

3. RESPONSIBILITIES

3.1 It is the responsibility of the Project Manager to assure that the client's data retention requirements are met by Paragon's archiving policies and procedures as described herein. As required by the client, the PM is also responsible for generating and reviewing the electronic data deliverable (EDD).

3.2 It is the responsibility of all staff who participate in records processes, to adhere to established standard operating procedures.

3.3 The QA Department is responsible for overseeing records generation, archiving, retrieval and retention procedures. The QA Department maintains the historical (pre-imaging) archive databases, and interfaces with the off-site storage and secure document destruction vendors.

4. PROCEDURES

4.1 WORKORDER INFORMATION

4.1.1 Workorder folders are initiated by Sample Receiving personnel as samples are received (SOP 202). The workorder folders are then forwarded to Login personnel, who enter the sample information into LIMS ~~(SOP 201)~~. 3/12/09 DAS

4.1.2 Following login, the workorder folder is given to the Project Manager for review. Corrections are made in LIMS as necessary, and, if not already done, the workorder is electronically dispatched/released. Sample Receiving personnel are contacted and directed to physically distribute the samples to the appropriate laboratories, if not already done.

4.1.3 The workorder folder is then routed to Reports Management, where the contents of the folder are scanned and posted to the network for laboratory reference. The workorder folder is then placed, sequentially, in designated hanging files.

4.1.4 As each laboratory's work is completed, reviewed (SOPs 052, 715) data package reports are "signed-in" to Reports Management. Reports Management staff track the receipt of each workorder component in LIMS. The workorder folder is retrieved from the hanging file and given to the Project Manager, along with the data package reports received.

4.1.5 The PM reviews the data package reports and interfaces with laboratory personnel as necessary, to resolve any discrepancies. The finalized reports are then given to Reports Management.

4.1.6 Reports Management personnel paginate the finalized data package reports, as needed, then scan them and post the images to the network.

Reports Management staff also generate data package cover letters and prepare the data package reports and/or CDs for shipment to the client.

4.1.7 After invoicing, the completed workorder folders are held in Reports Management in another designated file area for approximately three months, after which the files are purged (i.e., staged for the QA Department to obtain secure shredding).

4.2 EDD GENERATION AND RETENTION

4.2.1 Prior to project inception, the PM works with the IS Department to assure that the client's EDD requirements, if any, can be met.

4.2.2 After the laboratory analyses have been completed and the electronic data has been 'commit reviewed' in LIMS, the PM uses a specialized electronic application to generate the EDD. The compiled EDD is exported to a designated directory in LIMS.

4.2.3 The PM reviews/approves the EDD and electronically transmits the EDD to the client and/or works with Reports Management staff to copy and send the EDD on CD to the client. The network copy of the EDD is retained as an archived record.

4.3 IMAGED AND ELECTRONIC RECORDS

Archive images and electronic records are retained on Paragon's network for several months to provide easy 'read-only'access by laboratory personnel should questions arise. Images and designated electronic record directories are managed by the IS Manager and are backed-up daily and with the redundancy described in SOP 1401. If archived information is not readily available on the network, contact the IS and/or QA Manager for retrieval.

4.4 HISTORICAL HARDCOPY RECORDS

A database tracking system, managed by the QA Department, is used to manage Paragon records generated prior to current electronic imaging processes. These hardcopy records are maintained by an off-site vendor in a secure and environmentally-controlled atmosphere. Access to these records is limited. Should retrieval be required, a formal request to the QA Department (e-mail, Form 136) must be made.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 103 REVISION 7

TITLE: QUALIFICATION AND USE OF SUBCONTRACT LABORATORIES

FORMS: 202 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER _____ for DC DATE 8/13/07
QUALITY ASSURANCE MANAGER _____ DATE 8/12/07
LABORATORY MANAGER _____ DATE 8-13-07

HISTORY: NEW, 2/25/92; Rev1, 4/4/94; Rev2, 7/15/99; Rev3, 4/29/02; Rev4, 10/3/03; Rev5, 3/24/05; Rev6, 7/24/06; amended 9/13/06 (see DOCUMENT REVISION HISTORY); Rev7, 8/12/07.

1. SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to define the requirements for selecting and subcontracting another laboratory to perform analytical services for Paragon. Procedures for managing the subcontract laboratory relationship are defined, and procedures for shipping samples to the subcontract laboratory are discussed.

2. SUMMARY

Typically, the need to subcontract specific analyses is identified during bid response. Analyses may also need to be subcontracted in cases of emergency (e.g., Paragon instrument failure, unforeseen catastrophic event), etc. Based on applicable factors (e.g., type of analysis needed, sample matrix, required certifications, etc.), Paragon works with the client to identify suitable subcontract laboratories. The client selects the subcontract laboratory and Paragon's Project Manager (PM) makes the necessary arrangements with the other analytical facility. Paragon staff packages and ships the designated samples to the subcontract facility, observing chain-of-custody procedures and Department of Transportation (DOT) shipping requirements. Paragon's PM manages the subcontract facility relationship to ensure that all work is complete and satisfactory. Sample shipment paperwork and records of client communications pertaining to subcontracting are retained by the Paragon PM.

3. RESPONSIBILITIES

3.1 All staff involved with subcontract laboratory selection or packaging and shipping samples to a subcontracted facility are responsible for performing their task(s) in accordance with this SOP.

3.2 The Paragon PM is the point-of-contact with the client and is responsible for being aware of applicable client quality requirements and ensuring that these are requirements are met. Paragon Quality Assurance Department staff may be consulted as needed.

Paragon's PM is also the point-of-contact with the subcontracted laboratory. The PM is responsible for coordinating sample shipments with the subcontracted facility and with Paragon sample receiving and shipping staff. The PM is also responsible for coordinating, reviewing and reporting the subcontract data, for keeping the client informed should any issues arise, and for investigating and resolving those issues.

3.3 It is the responsibility of all personnel who work with samples involved with this process to note any anomalies or out-of-control events associated with sample handling. Corrective action must be taken and documented for any discrepancies noted.

4. PROCEDURE

4.1 IDENTIFYING THE NEED TO SUBCONTRACT ANALYSES

Paragon will request to subcontract analytical services when:

- Paragon is not able to perform the requested analyses.
- Instrument failure or excessive backlog prevents Paragon from performing the analyses in a timely manner.
- Any situation exists that would prevent the client's data quality objectives (DQOs) from being achieved.

4.2 DETERMINATION OF SUITABLE SUBCONTRACT LABORATORIES

4.2.1 Potential subcontract laboratories, including other DataChem facilities, will be identified using information obtained from professional journals, mass mailings, conferences, etc.

4.2.2 Laboratories may be initially pre-qualified by obtaining and reviewing relevant laboratory documentation, such as the laboratory's:

- Statement of Qualifications
- Quality Assurance Manual
- Certifications (e.g., State, Federal, radioactive materials license)
- recent Proficiency Test (PT) study results
- example hardcopy and/or electronic deliverables

4.2.3 A 'short list' of suitable subcontract facilities will be determined based on the specific client needs (e.g., type of analysis needed, sample matrix, required certifications, etc.). Further information (e.g., available capacity, cost, MDL information, etc.) pertinent to the client's requirements may be requested from the analytical laboratory and reviewed.

NOTE: In cases where Paragon was contracted to perform National Environmental Laboratory Accreditation Conference (NELAC) analyses, but must instead subcontract these analyses, the subcontract laboratory must also be NELAC-accredited for the analyses to be performed. Likewise, should Paragon need to subcontract DOD samples for analysis, DOD laboratory approval status is required for the subcontract laboratory for the analyses to be conducted. **Note also that the subcontract laboratory must receive project-specific approval from the DOD client before any samples are analyzed.**

4.3 FACILITY SELECTION / CLIENTAPPROVAL

Paragon's PM must receive permission from the client, in writing, prior to procuring and forwarding samples to the selected subcontract laboratory.

4.4 SUBCONTRACT LABORATORY AGREEMENT

At minimum, Paragon requires the terms of a subcontract agreement to include the following:

- Analytical method required
- Number and type of samples expected to be subcontracted
- Project-specific quality control requirements
- Deliverables required (hardcopy, electronic)
- Laboratory certification(s) required
- Price per analysis
- Turn around time required

Note that the client may request Paragon to conduct an on-site audit of the subcontracted facility.

4.5 CONTINUING QUALIFICATION

If the subcontract laboratory is routinely used to provide analytical services to Paragon, qualification will continue as long as the data provided is of known, documented, and appropriate quality.

4.6 PACKAGING AND SHIPPING SAMPLES

At the direction of the Paragon PM, Paragon staff packages and ships the designated samples to the subcontract facility. Chain-of-custody and Department of Transportation (DOT) shipping requirements must be observed.

4.6.1 A sample chain-of-custody (COC, Form 202) is prepared by the PM and given to the Sample Control Department. Note that some

subcontract laboratories provide their own forms to be used when submitting subcontracted work. In these instances, the subcontractor-supplied forms are used.

4.6.2 As appropriate to the matrices and analyses requested, the samples are held in a refrigeration unit (generally walk-in cooler RU #20) until the samples are packaged for shipment.

4.6.3 Sample Control staff gather the samples designated on the COC Form initiated by the PM, including any quality control samples, such as Trip Blanks. The samples are then packaged in an appropriate shipping container, including double-bagged ice or blue ice as required. Styrofoam peanuts and/or bubble wrap is used to cushion the samples, and fill-up the empty spaces inside the shipping container.

4.6.4 The COC is signed to release the samples to the commercial shipping carrier. The pink copy of the COC is retained by the laboratory and is forwarded to the PM for inclusion in the project's records. **(forward to Reports Management for inclusion in workorder image archive)** The white and yellow copies of the signed COC are placed inside the sample-shipping container.

For samples sent by commercial carrier, the sample-shipping container is sealed with strapping tape and chain-of-custody seals. Sample Control personnel release the prepared sample container to the commercial carrier.

NOTE: Where samples are hand-delivered to the subcontract laboratory, all pages of the COC are kept intact until the "Received By" signatures are obtained from the subcontract laboratory. The pink copy of the signed COC is returned to Paragon and forwarded to the PM for inclusion in the project's records.

4.7 MANAGEMENT OF SUBCONTRACT DATA

The Paragon PM is responsible for coordinating all subcontract data and ensuring that the deliverables received from the subcontracted facility are complete and correct. Should issues arise (e.g., quality of product, adherence to schedule, etc.), the PM shall ensure that the client is aware of these issues and shall keep the client apprised during the resolution process (if it is suspected that the subcontractor knowingly supplied deliverables of substandard quality, this also will be communicated to the client). Unless otherwise directed by the client, the Paragon PM will take the lead on corrective action investigation, assure that all issues are corrected completely, and that the final resolution satisfies all parties involved. The Paragon PM may issue a 'stop work' order or discontinue the use of services and/or payment until resolution can be successfully achieved.

The PM oversees the submission (reporting) of the subcontracted data to the client. Data that have been subcontracted must be clearly indicated as such in the client laboratory data package reports.

5. SAFETY AND HAZARDS

5.1 Some samples may be preserved with chemical preservatives. Appropriate cautions should be observed in the event of sample container breakage during processing.

5.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

6. REFERENCES

Current NELAC standard

Applicable client quality assurance documents

DOCUMENT REVISION HISTORY

7/24/06: Combined SOP 207 contents with SOP 103, added Form. Augmented RESPONSIBILITIES and PROCEDURE. Added DOCUMENT REVISION HISTORY.

9/13/06: Section 4.7 further augmented to strengthen investigation and correction, and to provide for discontinuance (suspension) until resolution achieved.

8/12/07: Laboratory DOD approval status and project-specific approval required when DOD samples need to be subcontracted, added to Section 4.2.3.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1100 REVISION 10

TITLE: **DETERMINATION OF TOTAL SUSPENDED SOLIDS (TSS or TOTAL NON-FILTERABLE RESIDUE) -- METHODS EPA 160.2 AND SM2540D**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 1/19/07
QUALITY ASSURANCE MANAGER _____ DATE 1/19/07
LABORATORY MANAGER _____ DATE 1-19-07

HISTORY: Rev0, PCN #224, 4/14/94; Rev1, PCN #490, 6/5/95; Rev2, 9/28/99; Rev3, 10/8/01; Rev4, 1/23/02; Rev5, 2/10/03; Rev6, 3/6/03; Rev7, 2/9/04 and 2/11/05 (re-released without revision), Rev8, 7/26/05; Rev9, 4/10/06; Rev10, 1/19/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- EPA Method 160.2 and Standard Method (SM) 2540D -- describe procedures for measuring Total Suspended Solids (TSS or Total Non-Filterable Residue), in drinking, surface, and saline waters and domestic and industrial wastes.

2. SUMMARY

An aliquot of well-mixed water sample is filtered through a tared pre-washed glass fiber filter under vacuum pressure. The residue retained by the fiber filter is dried to a constant weight in a drying oven maintained at 103-105°C. The weight of the dried residue (in mg) represents the TSS present in the sample aliquot.

NOTE: **The sample filtrate (i.e., the fluid that passes through the filter) may be used to determine Total Dissolved Solids (TDS) per SOP 1101.**

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or by the successful analysis of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard

criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for completeness, precision and accuracy is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 **It is very important that the samples be thoroughly mixed before each aliquot is withdrawn.** If a sample is allowed to stand, most of the sediment will usually begin to settle to the bottom of the container. Failure to obtain representative subsamples can bias results and cause variation between duplicate samples.

4.2 TSS results for samples high in dissolved solids, such as saline waters and brines, may be subject to high bias. Care must be taken to adequately wash the filter with deionized water to remove dissolved salts after the sample has passed through the filter.

4.3 **Too much residue will entrap water that will not be driven off during drying. A sample aliquot size that yields no more than 200mg residue must be used.**

4.4 **It is important to use the filtration material and apparatus and pre-washing and post-washing techniques and drying temperature as specified in this SOP because variations from these specifications are known to affect results.**

4.5 For TSS analysis, exclude large, floating particles or submerged agglomerates of non-homogeneous materials from the sample if it is determined that their inclusion is not desired in the final result.

5. APPARATUS AND MATERIALS

5.1 Glass fiber filter, 47mm, Gelman™ A/E or Whatman™ grade 934AH or equivalent

5.2 Filter funnel assembly (funnel, glass-fritted filter base, funnel clamp, vacuum source, 1L vacuum flask)

5.3 Analytical balance, 0.0001g sensitivity

5.4 Personal computer (PC), connected to the in-house network and with BalanceLink™ software installed

5.5 BalanceLink™ hardware to connect the analytical balance to the computer

5.6 Graduated cylinders, 10-500mL

NOTE: Use only labware whose graduated volume has been previously verified to deliver within ±3% of the stated volume.

5.7 Weighing pans (sample boats), aluminum, disposable, 2in diameter

5.8 Forceps

5.9 Drying oven, set to maintain 103-105°C

5.10 Desiccator with color indicating desiccant

5.11 Wash bottle

6. REAGENTS

6.1 Deionized (DI) Water, obtained from the laboratory's deionized water system

6.2 Pottery clay, dried and ground to pass through a 120-mesh sieve. *Shelf Life = 5 years or until contamination is evident.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples may be collected in either plastic or glass containers and should be collected according to an approved sampling plan.

7.2 Water samples must be kept cool (4-6°C) and should be analyzed as quickly as possible. Per Table 1 of Methods for the Chemical Analysis of Water and Wastes, 1983, a maximum holding time allowance of 7 days from date of collection is permitted.

8. PROCEDURE

8.1 FILTER PREPARATION

8.1.1 Label an aluminum weighing pan (sample boat) for each sample. Place a glass fiber filter into each sample boat. With each batch of twenty field samples or less processed as a unit, the following quality control (QC) samples must be prepared: one Method Bank (MB), one Laboratory Control Sample (LCS), one sample Duplicate (DUP).

8.1.2 Pre-wash filters by placing on filter assembly and passing 100mL of DI water through filter. Transfer filter to original weighing pan and place in oven at 103-105°C for approximately 1 hour. Place in desiccators and allow to cool for approximately 1 hour.

8.1.3 When available, it is most convenient and accurate to use the BalanceLink program that allows data from an analytical balance to be electronically entered into a spreadsheet datafile. To use this system, first open the appropriate template spreadsheet in Excel (e.g., i:\oprtns\wtchm\tss\template\tss1.xls); then open the BalanceLink™ program to create linkage between the computer and the analytical balance.

8.1.4 Redirect the electronic file to the year's directory, and rename the spreadsheet with a filename that uses a mmdd format. For example, if the preparation batch was performed on 2/14/04, the new filename would be i:\oprtns\wtchm\tss\ 2004\0214tss.xls. Enter pertinent information into the spreadsheet (e.g., date, analyst, sample IDs, sample volumes).

8.1.5 Using the computer's mouse, position the cursor on the "**Filter + Boat**" cell for the individual sample listed on the spreadsheet. For each sample, place the proper sample boat containing the fiber filter on the weighing pan of the analytical balance and close the door. Press the "**Print Scrn**" key on the PC keyboard. The weight in grams that appears on the computer screen, will be automatically entered into the spreadsheet.

NOTE: The analytical balance's calibration must be verified daily before use, per SOP 305.

A filter + boat weight must be obtained for each field and QC sample. Print out a copy of the spreadsheet to keep as a temporary hardcopy until the analyses are complete (this ensures that the information will be recoverable in the event of a power outage).

8.1.6 Store the boats and filters in a desiccator until used for sample processing.

8.2 SAMPLE PREPARATION

This test may be conducted simultaneously with the Total Dissolved Solids (TDS) component of SOP 1101. It is the residue trapped by the glass fiber filter during TDS filtrate preparation that can be used to test for TSS (so long as a tared glass fiber filter weight was obtained prior to filtering, and that the sample bottle was well shaken before an aliquot was taken). If using residue obtained during TDS preparation, proceed directly to Section 8.3.

8.2.1 Assemble the filtration apparatus (vacuum source, vacuum flask, filter base, filter, funnel and clamp). Select a previously identified and pre-weighed glass fiber filter and center it in the funnel. Turn on the vacuum. To ensure a good seal, pre-wet the filter with a small amount of DI water.

8.2.2 After mixing each sample thoroughly by shaking the sample bottle, measure an appropriate aliquot (see note below) into a graduated cylinder. *The graduated cylinder used must have been previously verified as capable of delivering ±3% of the stated volume.*

NOTE: For TSS measurement, two factors govern the aliquot volume used for a particular sample. These are: 1) the amount of non-filterable material in the sample, and 2) the required reporting limit for the analysis.

If the content of non-filterable solids in the sample is high, it may be necessary to decrease the aliquot volume to avoid overloading the filter. Total mg of TSS (non-filterable solids) must be limited to 200mg or less.

If the TSS content in the sample is low, the aliquot volume must be large enough to meet the required reporting limit. The standard reporting limit for TSS is 20mg/L, which requires an aliquot volume of 100mL. Some clients may request a lower reporting limit which will require a larger aliquot volume if the TSS content is low. Consult the LIMS program specifications for the required reporting limit.

8.2.3 For each sample, with the vacuum on, carefully pour the aliquot of sample contained in the graduated cylinder into the funnel so that the liquid is pulled through into the filtration flask. Use a wash bottle to rinse the graduated cylinder, the filter and the sides of the funnel twice with DI water. Allow the rinse water to pull through under vacuum.

8.2.4 Remove clamp and carefully remove funnel. Turn off the vacuum and use forceps to carefully transfer the filter + residue to the proper labeled, pre-weighed aluminum sample boat.

NOTE: Wash the filter assembly and glassware (e.g., funnel, graduated cylinder, vacuum flask) per SOP 334 - Glassware Cleaning Procedures and Maintenance of Glassware Used in The Organics and Inorganics Departments.

8.2.5 Repeat Steps 8.2.1 through 8.2.4 until all field and quality control samples are processed. Process 100mL DI water as a Method Blank. Select a field sample and process a second aliquot to serve as the DUP.

For the LCS, weigh out approximately 50mg (0.0500g) of dry pottery clay on the analytical balance. Use the PC's mouse to select the "Amt. Clay Weight for TSS Spike (g)" cell of the spreadsheet. Press the "Print Scrn" key on the PC keyboard. The weight in grams that appears on the computer screen, will automatically be entered into the spreadsheet. Quantitatively transfer the clay to a disposable beaker and add 100mL DI water; mix well. Process this clay-DI water slurry per Steps 8.2.1 through 8.2.4 to serve as the LCS.

8.3 SAMPLE DRYING AND WEIGHING

8.3.1 Place the boats + filters into a drying oven set to maintain 103-105ºC. Dry for at least one hour.

8.3.2 Remove the boats + dried filter residues from the oven and place in a desiccator. Allow to cool to room temperature.

8.3.3 Use the computer's mouse to select the appropriate "**Filter + Boat Residue**" cell on the spreadsheet. Weigh each boat + dried filter residue. For each, press the "**Print Scrn**" key on the PC keyboard to automatically enter the gross weight of the boat + dried filter residue into the spreadsheet. Repeat until all dried fiber filters have been weighed.

8.3.4 Replace the boats + dried filter residues in the 103-105ºC oven and heat for one hour. Cool the boats + dried filter residues (per Step 8.3.2) and weigh (per Step 8.3.3); repeating this Step (8.3.4) until a stable gross weight is obtained for each sample. A stable gross weight is achieved when the weight lost (upon further drying and cooling) is less than 4% of the previous weight recorded (particularly applicable in the case of high residue amounts), or when the weight change is less than ±0.5mg (particularly applicable in the case of low residue amounts), whichever has less statistical impact. In other words, the gross weight cannot be considered to be stable until it is determined that further drying and cooling does not significantly impact the reported value. **The gross weight must be measured at least twice for each sample.**

8.3.5 The spreadsheet will calculate the sample's Total Suspended Solids (TSS), which is equal to the final dried gross weight minus the tared boat + filter weight.

8.4 CALCULATIONS

8.4.1 If the weights were entered into the spreadsheet directly using BalanceLink™, the calculations will be performed automatically.

8.4.2 If the data were entered by hand, then the calculations must be performed manually. Use the following formula to calculate TSS results:

TSS (mg/L) = [(A - B) x 1000] x 1000/ sample volume (mL)

where:

A = final weight of boat + filter + residue (g)

B = tare weight of boat + filter (g)

9. QUALITY CONTROL (QC)

9.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), and laboratory duplicate (DUP). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

9.2 METHOD BLANKS

Method blanks (MB) are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed a method blank must be processed. For this procedure, the MB consists of 100mL DI water. The blank concentration found must be less than the reporting limit (usually 20mg/L).

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. Each time a batch of samples is analyzed, an LCS must be processed. A known amount of analyte is prepared and analyzed. For this method, 50mg of dry clay suspended in 100mL of DI water is used as the LCS. Results obtained are compared to results expected (see formula below), with the results expressed as percent recovery (%R).

$$\%R = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Target}}} \times 100$$

To be acceptable, the LCS recovery must be between 85% and 115% of the expected concentration.

9.4 LABORATORY DUPLICATE

A laboratory duplicate (DUP) is analyzed as a measure of the precision of the analytical results generated (see calculation below). Each time a batch of samples is

analyzed, a DUP must be processed. The precision between results for a sample and its duplicate is expressed as Relative Percent Difference (RPD). The RPD between a sample and its duplicate should not be greater than 15%.

$$RPD\ (\%) = \frac{|\ Result_x - Result_{Dup}\ |}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

10. DEVIATIONS FROM METHOD

Per Section 1.2 of Method EPA 160.2, the procedures described in this SOP are capable of determining total non-filterable residue (TSS) in the practical range of 4mg/L to 20,000mg/L. Paragon has established a standard reporting limit of 20mg/L for TSS (greater than the 4mg/L cited) based on the use of a standard 100mL sample aliquot volume. In order to capture the suggested minimum 1.0mg residue Section 7.2 of Method EPA 160.2 states, in effect, that the sample volumes should be increased. Note that Paragon does not vary sample aliquot size except where: (1) a client has specifically requested a reporting limit lower than 20mg/L (in this instance, a sample aliquot larger than 100mL is processed in situations where the client sample's TSS content is low); or (2) the client sample has high solids content which requires a sample aliquot of less than 100mL to limit the total mg of TSS to 200mg or less.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Aqueous residues shall be disposed of in the Aqueous Laboratory Waste satellite collection vessel.

11.2.2 Solid filtrate residues and any other solid residues shall be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

11.2.3 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Management Officer will provide specific procedures and materials for these samples.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- Methods EPA 160.3, EPA 160.4, and EPA 160.1 and Standard Methods SM2540B, SM2540E, and SM2540C -- describe procedures for measuring Total Solids (TS), Total Fixed Solids (TFS), Total Volatile Solids (TVS), and Total Dissolved Solids (TDS or Total Filterable Residue) in drinking, surface, and saline waters and domestic and industrial wastes.

2. SUMMARY

For Total Solids (Total Residue) determination, an aliquot of a well-mixed water sample is added to a pre-weighed beaker and evaporated to dryness at 103-105°C. The residue dry weight (in mg) represents the TS present in the sample aliquot.

For the Total Dissolved Solids (TDS or Total Filterable Residue) test, an aliquot of water sample is filtered through a glass fiber filter using vacuum pressure. The filtrate captured by the flask is evaporated and dried at 180±2°C to a constant weight. The filtrate residue dry weight (in mg) represents the TDS present in the sample aliquot.

For Total Fixed and Volatile Solids (Total Fixed and Volatile Residue) determination, the residue remaining from the TS or TDS test is ignited in a muffle furnace at 550°C. The loss in weight after ignition is reported as Total Volatile Residue. The weight of residue remaining after ignition is reported as Total Fixed Residue.

The determination of TDS and TSS may be performed simultaneously. See SOP 1100 for determination for Total Suspended Solids (TSS or Total Non-Filterable Residue).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or by the successful analysis of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for completeness, precision and accuracy is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Residues from highly mineralized waters that contain significant concentrations of hygroscopic salts (e.g., calcium, magnesium, chloride, and/or sulfate) will require prolonged drying, desiccation, and rapid weighing to limit the exposure to the ambient humidity.

4.2 Samples containing high concentrations of bicarbonate require careful and possibly prolonged drying at 180°C to ensure that all the bicarbonate is converted to carbonate.

4.3 Too much residue in the beaker will crust over and entrap water that will not be driven off during drying. Therefore, a sample aliquot size that yields no more than 200mg must be used. Electrical conductivity screening is performed prior to preparation in order to minimize this interference.

4.4 For TS analysis, exclude large, floating particles or submerged agglomerates of non-homogeneous materials from the sample if it is determined that there inclusion is not desired on the final result.

4.5 Negative errors in the volatile or fixed solids may be produced by loss of volatile matter during drying. Determination of low concentrations of volatile solids in the presence of high fixed solids may be subject to considerable error. **Measure for suspected volatile components by another test (e.g., total organic carbon).**

5. APPARATUS AND MATERIALS

5.1 Glass fiber filter, 47mm (Gelman™ A/E or Whatman™ grade 934AH)

5.2 Filter funnel assembly (funnel, glass-fritted filter base, funnel clamp, vacuum source, 1L vacuum flask)

5.3 Disposable syringes, various sizes

5.4 Acrodisc™ 25mm, 1µm glass fiber syringe filter, Pall Life Sciences, PN4523T or equivalent

5.5 Analytical balance, capable of weighing to 0.0001g

5.6 Personal computer (PC), connected to the in-house network and with BalanceLink™ software installed.

5.7 BalanceLink™ hardware to connect the analytical balance to the computer

5.8 Graduated cylinders, 10-500mL

NOTE: Use only labware whose graduated volume has been previously verified to deliver within ± 3% of the stated volume.

5.9 Pyrex™ beakers, 150-250mL

5.10 Forceps and/or heat resistant oven gloves

5.11 Drying oven (forced air), set at less than 100°C (~ 95°C)

5.12 Drying oven (convection), set to maintain 103-105°C

5.13 Oven (convection), with temperature set to maintain 180±2°C

5.14 Muffle furnace, with temperature set to maintain 550±50ºC

5.15 Desiccator with color indicating desiccant

5.16 Pipets, variable Eppendorf or equivalent, capable of 0.50mL to 5.0mL

5.17 Pipette tips, 1mL - 5.0mL

5.18 Conductivity meter with electrode, capable of reading in TDS and/or µmhos

5.19 Wash bottle

6. REAGENTS

6.1 Deionized (DI) Water

6.2 Sodium Chloride (NaCl), JT Baker, 3628-01 or equivalent reagent grade

6.3 TDS Spiking Solution, 40mg/mL: Transfer 40.0g of pre-dried NaCl into a 1000mL volumetric flask. Dissolve the salt and bring to volume with DI water. (Different volumes may be used as long as the ratio stays the same.) Store in polypropylene container. *Shelf Life = 1 year.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples may be collected in either plastic or glass containers and must be collected according to an approved sampling plan.

7.2 Water samples must be kept cool (4-6°C) and should be analyzed as quickly as possible. Per Table 1 of Methods for the Chemical Analysis of Water and Wastes, 1983, a maximum holding time allowance of 7 days from date of collection is permitted.

8. PROCEDURE

NOTE: Per Section 1.2 of Methods EPA 160.1 and EPA 160.3, these procedures are capable of determining TDS and TS residues in the practical range of 10mg/L to 20,000mg/L. Section 7.2.1 of Method EPA 160.3 (Total Solids) directs that the sample aliquot used should yield at least 25mg residue. Paragon has established a standard reporting limit of 20mg/L (greater than the 10mg/L cited) for TDS and TS, based on use of a 100mL sample aliquot volume. Note that where the client sample has high solids content, a smaller than 100mL sample aliquot may be processed in order to limit the solids to 200mg (maximum).

8.1 TOTAL SOLIDS

A conductivity meter can be used to screen a separate aliquot of sample in order to obtain information useful in determining appropriate sample size (record these screening readings in the Conductivity Screening Logbook, Form 1116). As a rule of thumb, if the conductivity measures below 2000µmhos, use the usual 100mL aliquot. Use a 25mL aliquot if the conductivity measures near to

5000µmhos, and a 10mL aliquot if the conductivity measures near to 10, 000µmhos. See **Table 1** below:

Table 1: GUIDELINES FOR SAMPLE ALIQUOT TO USE BASED ON CONDUCTIVITY SCREENING

Estimated Conductivity (umhos)	Estimated TDS (mg/L)	Volume For TDS Analysis (mL)	Max. Observed Wt. (mg)
0	0	100	0
</= 1300	< 1300	100	130
1301-3000	> 1300-3000	50	150
3001-6000	> 3000-6000	25	150
6001-12000	> 6000-12000	10	120
12001-30000	> 12000-30000	5	150
30001-50000	> 30000-50000	2	120
50001-150000	> 50000-150000	1	150

8.1.1 Label a 150-250mL Pyrex™ beaker for each sample. With each batch of twenty field samples or less processed as a unit, the following quality control (QC) samples must be prepared: one Method Bank (MB), one Laboratory Control Sample (LCS), and one sample Duplicate (DUP).

NOTE: If the sample(s) are to be subsequently tested for Total Volatile Solids (TVS), the beakers must first be numbered and conditioned in a muffle furnace at 550°C to ensure they are free of volatile organic residue and are at a constant weight. Cool and maintain the pre-conditioned beakers in a desiccator.

8.1.2 When available, it is most convenient and accurate to use the BalanceLink program that allows data from an analytical balance to be electronically entered into a spreadsheet datafile. To use this system, first open the appropriate template spreadsheet in Excel (e.g., i:\oprtns\wtchm\tds\ template\ts1.xls); then open the BalanceLink program to create linkage between the computer and the analytical balance.

8.1.3 Redirect the electronic file to the year's directory, and rename the spreadsheet with a filename that uses an mmdd format. For example, if the preparation batch were performed on 7/14/2005, the new filename would be i:\oprtns\wtchm\tds\ 2005\0714ts.xls. Enter pertinent information into the spreadsheet (e.g., date, analyst, sample IDs,

sample volumes).

8.1.4 Using the computer's mouse, position the cursor on the "**Empty Beaker Tare Weight (g)**" cell for the individual sample listed on the spreadsheet. For each sample, center the beaker on the weighing pan of the analytical balance and close the door. Press the "**Print Scrn**" key on the PC keyboard. The weight in grams that appears on the computer screen, will be automatically entered into the spreadsheet.

NOTE: The analytical balance's calibration must be verified per SOP 305 before use.

A tared empty beaker weight must be obtained for each field and QC sample. Print out a copy of the spreadsheet to keep as a temporary hardcopy until the analyses are complete (this ensures that the information will not be unrecoverable in the event of a power outage).

8.1.5 Using a graduated cylinder that is well rinsed with DI water between each use, add 100mL (or less) of well-mixed sample to the designated pre-weighed beaker. The graduated cylinder used must also have been previously verified as capable of delivering ±3% of the stated volume. Make sure the identity of the sample added, matches the sample identity labeled on the pre-weighed beaker.

8.1.6 Use 100mL DI water for the MB. Prepare a second aliquot of a selected field sample to serve as the DUP. For the LCS, use 100mL DI water into which 1.0mL of TDS spiking solution has been added (mix well before processing).

8.1.7 Pre-dry the sample beakers overnight in a forced-air oven set at less than 100°C (~ 95°C to prevent boiling and splattering of the sample). Allow the liquid to evaporate overnight.

8.1.8 After the water has evaporated, relocate the sample beakers to a convection oven (i.e., not forced-air), and continue drying at 103-105ºC for at least one hour.

8.1.9 Remove the sample beakers from the oven and place the beakers in a desiccator to cool for 1 or more hours.

8.1.10 Use the computer's mouse to select the appropriate "**Beaker + Residue Gross (g)**" cell on the spreadsheet. Place the corresponding dried sample beaker on the weighing pan of the analytical balance and close the door. Press the "**Print Scrn**" key on the PC keyboard to enter the

gross weight of dried sample into the selected cell of the spreadsheet. Repeat for each dried sample beaker.

8.1.11 Replace the dried sample beakers in the 103-105ºC convection oven and continue drying for about an hour. Cool (per Step 8.1.10) and weigh (per Step 8.1.11), repeating this Step (8.1.12) until a stable gross weight is obtained for each sample. A stable gross weight is achieved when the weight lost (upon further drying and cooling) is less than 4% of the previous weight recorded (particularly applicable in the case of high residue amounts), or when the weight change is less than ±0.5mg (particularly applicable in the case of low residue amounts), whichever has less statistical impact. In other words, the gross weight cannot be considered to be stable until it is determined that further drying and cooling does not significantly impact the reported value. The gross weight must be measured at least twice for each sample.

8.1.12 The spreadsheet will calculate the sample's Total Solids (TS), which is equal to the final dried gross weight minus the tared beaker weight.

8.1.13 If Total Fixed Solids (TFS) and Total Volatile Solids (TVS) are to be determined, proceed to Section 8.3.

8.2 TOTAL DISSOLVED SOLIDS (TDS; TOTAL FILTERABLE RESIDUE)
This test may be conducted simultaneously with SOP 1100 - Total Suspended Solids (TSS; Total Non-Filterable Residue). It is the filtrate from the TSS preparation that can be used directly to test for TDS.

8.2.1 A conductivity meter can be used to screen a separate aliquot of sample in order to obtain information useful in determining appropriate sample size (record these screening readings in the Conductivity Screening Logbook). As a rule of thumb, if the conductivity measures below 2000µmhos, use the usual 100mL aliquot. Use a 25mL aliquot if the conductivity measures near to 5000µmhos, and a 10mL aliquot if the conductivity measures near to 10,000µmhos. See **Table 1** above.

8.2.2 Label a 150-250mL Pyrex™ beaker for each sample. With each batch of twenty (20) or less field samples processed together as a unit, one MB, one LCS and a sample DUP must also be processed.

8.2.3 Open the appropriate template spreadsheet in Excel (e.g., i:\oprtns\wtchm\tds\template\tds1.xls); then open the BalanceLink program to create linkage between the computer and the analytical balance

8.2.4 Redirect the electronic file to the year's directory, and rename the spreadsheet with a filename that uses an mmdd format. For example, if the preparation batch were performed on 7/14/2005, the new filename would be i:\oprtns\wtchm\tds\2005\0714tds.xls.

Enter pertinent information into the spreadsheet (e.g., date, analyst, sample IDs, sample volumes).

8.2.5 Using the computer's mouse, position the cursor on the "**Beaker Weight**" cell for the individual sample listed on the spreadsheet. For each sample, center the beaker on the weighing pan of the analytical balance and close the door. Press the "**Print Scrn**" key on the PC keyboard. The weight in grams that appears on the computer screen, will be automatically entered into the spreadsheet.

NOTE: The analytical balance's calibration must be verified daily before use, per SOP 305.

A tared beaker weight must be obtained for each field and QC sample. Print out a copy of the spreadsheet to keep as a temporary hardcopy until the analyses are complete (this ensures that the information will not be unrecoverable in the event of a power outage).

8.2.6 Assemble the filtration apparatus (vacuum source, vacuum flask, funnel clamp, funnel, and filter base) and put a glass fiber filter in place. Turn on the vacuum. Pre-wet the filter using a small amount of DI water to ensure a good seal.

NOTE: If performing TDS only, a disposable syringe and Acrodisc™ 1μm glass fiber syringe filter may be used to filter the sample. If however, TSS will also be performed use the filtration apparatus discussed above.

NOTE: If the residue retained on the fiber filter is to be used to determine TSS, a tare weight of a pre-rinsed fiber filter must first be obtained (see Section 8.0 of SOP 1100).

8.2.7 If the filtrate from a previously prepared TSS sample is not available for use in conducting the TDS test, then prepare a filtered TDS sample by measuring-out an appropriate aliquot of sample in a graduated cylinder that has been well-rinsed with DI water between each use. The graduated cylinder used must also have been previously verified as capable of delivering ±3% of the stated volume.

8.2.8 With the vacuum on, carefully pour the aliquot of sample from the

graduated cylinder onto the fiber filter in the funnel, so that the liquid is pulled through the filter into a clean filtration flask. This pulled-through liquid (filtrate) is used to determine TDS. Rinse the graduated cylinder, the filter and the sides of the funnel twice with DI water wash bottle and allow the rinse water to pull through under vacuum.

8.2.9 Transfer the filtrate (i.e., the liquid contained in the filtration flask) to the proper pre-weighed beaker, being careful not to overfill the designated beaker. *Rinse the inside of the filtration flask well with a DI water wash bottle; add the rinsate to the pre-weighed beaker containing the sample filtrate.*

NOTE: If TSS is not to be determined, the glass fiber filter may be discarded. **Wash the filter assembly and glassware (e.g., funnel, graduated cylinder, vacuum flask assembly) per SOP 334 - Glassware Cleaning Procedures and Maintenance of Glassware Used in the Organics and Inorganics Departments.**

8.2.10 Reassemble the filter assembly and put another glass fiber filter in place, or if performing TDS only use the syringe and Acrodisc™ discussed above. Repeat Steps 8.2.6 and 8.2.7 until all field and quality control samples are processed. Process 100mL DI water as the Method Blank. Select a field sample and process a second aliquot to serve as the DUP. For the LCS, process 100mL DI water into which 1.0mL of TDS Spiking Solution has been added (mix well before processing).

8.2.11 Place the beakers + filtrate into a forced-air oven set at less than 100ºC (~ 95°C to prevent boiling and splattering of the sample). Allow the liquid to evaporate overnight.

8.2.12 After the water has evaporated, relocate the sample beakers to a convection oven set to maintain 180±2°C. Heat for at least one hour.

8.2.13 Remove the beakers containing the dried sample to a desiccator and allow beaker to cool to room temperature.

8.2.14 Use the computer's mouse to select the appropriate "**Beaker + Residue Gross (g)**" cell on the spreadsheet. When cool, weigh each beaker + dried sample. Press the "**Print Scrn**" key on the PC keyboard to enter the gross weight of the beaker + residue into the spreadsheet. Repeat until all dried samples have been weighed.

8.2.15 Replace the dried sample beakers in the 180±2 °C oven and heat for

one hour. Cool the dried sample beakers (per Step 8.2.13) and weigh (per Step 8.2.14), repeating this Step (8.2.15) until a stable gross weight is obtained for each sample. A stable gross weight is achieved when the weight lost (upon further drying and cooling) is less than 4% of the previous weight recorded (particularly applicable in the case of high residue amounts), or when the weight change is less than ±0.5mg (particularly applicable in the case of low residue amounts), whichever has less statistical impact. In other words, the gross weight cannot be considered to be stable until it is determined that further drying and cooling does not significantly impact the reported value. **The gross weight must be measured at least twice for each sample.**

8.2.16 The spreadsheet will calculate the sample's Total Dissolved Solids (TDS), which is equal to the final dried gross weight of filtrate minus the tared beaker weight.

8.2.17 If Total Fixed Solids (TFS) and Total Volatile Solids (TVS) are to be determined, proceed to Section 8.3.

8.3 TOTAL FIXED AND VOLATILE SOLIDS

8.3.1 Place the labeled beaker containing the dried TS or TDS sample residue into a pre-warmed muffle furnace set at 550±50ºC. Heat for 15-20 minutes.

8.3.2 Remove the beakers with muffled residue from the furnace and cool initially in air until most of the heat has dissipated. Then place the beakers with muffled residue in a desiccator until cooled to room temperature.

8.3.3 Use the computer's mouse to select the appropriate "**Beaker + Muffled Residue (g)**" cell on the spreadsheet. Place the corresponding sample beaker containing muffled residue on the weighing pan of the analytical balance and close the door. Press the "**Print Scrn**" key on the PC keyboard to enter the weight into the selected cell of the spreadsheet. Repeat for each sample beaker containing muffled residue. The loss of weight following ignition when muffled is reported as mg/L Total Volatile Solids (TVS). The weight of residue remaining after ignition is reported as mg/L Total Fixed Solids (TFS).

8.4 CALCULATIONS

8.4.1 If the weights were entered into the spreadsheet directly using BalanceLink™, the calculations will be performed automatically.

8.4.2 If the data are entered by hand, then the calculations must be performed manually. Use the following formula to calculate TS results:

TS (mg/L) = [(A - B) x 1000] x 1000 / sample volume (mL)

where:

A = final weight of beaker + residue (g)

B = tare weight of beaker (g)

8.4.3 Total volatile solids are calculated using the following formula:

TVS (mg/L) = [(A _ B) x 1000] x 1000 / sample volume (mL)

where:

A = weight of beaker + residue before ignition (g)

B = weight of beaker + residue after ignition (g)

8.4.4 Total fixed solids are determined by subtracting the amount of TVS from the amount of TS or TDS as shown below:

TFS (mg/L) = [(A _ C) x 1000] x 1000 / sample volume (mL)

where:

A = weight of beaker + residue before ignition (g)

C = weight of beaker (g)

8.4.5 Total dissolved solids are calculated using the following formula:

TDS (mg/L) = [(D - E) X 1000] x 1000 / sample volume (mL)

where:

D = weight of beaker + dried filtrate residue (g)

E = tare weight of beaker (g)

9. QUALITY CONTROL (QC)

9.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), and laboratory duplicate (DUP). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

9.2 METHOD BLANKS

Method blanks (MB) are analyzed to demonstrate that interferences from the analytical system and glassware are under control. Each time a batch of samples is analyzed, a MB must be processed. For this procedure, the MB consists of 100mL DI water. The blank concentration found cannot exceed the analyte reporting limit (usually 20mg/L).

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. Each time a batch of samples is analyzed, a LCS must be processed. A known amount of analyte is prepared and analyzed. For this method, 1.0mL of TDS spiking solution (40mg/mL) added to 100mL DI water is used as the LCS. Results obtained are compared to results expected, with the results expressed as percent recovery (%R), as shown below

$$\%R = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Target}}} \times 100$$

Based on procedures outlined in this SOP, a final concentration of 400mg/L is expected for the LCS. To be acceptable, the LCS recovery must be between 85% and 115% of the expected concentration (i.e., between 340 and 460mg/L).

9.4 LABORATORY DUPLICATE

A laboratory duplicate (DUP) is analyzed as a measure of the precision of the analytical results generated (see calculation below). Each time a batch of samples is analyzed, a DUP must be processed. The precision between results for a sample and its duplicate is expressed as Relative Percent Difference (RPD), and is calculated as follows:

$$\text{RPD (\%)} = \frac{| \text{Result}_x - \text{Result}_{\text{Dup}} |}{\frac{(\text{Result}_x + \text{Result}_{\text{Dup}})}{2}} \times 100$$

The RPD between a sample and its duplicate should not be greater than 15%.

10. DEVIATIONS FROM METHOD

10.1 Total Solids Methods EPA 160.3 (Section 7.1) and SM2540B (Section 3a); and Total Dissolved Solids Methods EPA 160.1 (Section 7.2) and SM2540C (Section 3b) discuss preconditioning the sample drying containers at 180±2°C before use. Paragon does not perform this pre-conditioning step because the laboratory uses Pyrex glass beakers (i.e., not ceramic containers).

10.2 Total Dissolved Solids Methods EPA 160.1 (Section 7.3) and SM2540C (Section 3d) call for the sample to be well mixed before processing. For samples with visibly settled solids, Paragon does not mix the sample before processing, unless

TSS analysis is also to be performed. Only the supernatant liquid is used for the TDS test.

10.3 As noted in Section 8.0 Procedure, Section 1.2 of Methods EPA 160.1 and EPA 160.3 state that these procedures are capable of determining TDS and TS residues in the practical range of 10mg/L to 20,000mg/L. Section 7.2.1 of Method EPA 160.3 (Total Solids) directs that the sample aliquot used should yield at least 25mg residue. Paragon has established a standard reporting limit of 20mg/L (greater than the 10mg/L cited) for TDS and TS, based on use of a 100mL sample aliquot volume. Note that Paragon does not vary sample aliquot size processed except where ~~(1) a client has specifically requested a reporting limit lower than 20mg/L (in this instance, a sample aliquot volume larger than 100mL is processed in situations where the client samples solids content is low); and~~ (2) the client sample has high solids content thus requiring that a smaller than 100mL sample aliquot volume be processed in order to limit the solids to about 200mg.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.3 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 Aqueous residues shall be disposed of in the Aqueous Laboratory Waste satellite collection vessel.

11.2.2 Solid filtrate residues and any other solid residues shall be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

11.2.3 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Health and Safety Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

2/9/04: Updated format.

3/25/05: Re-released without revision.

7/26/05: Added reference Program Specification directive in "Responsibilities".

4/10/06: Added DOCUMENT REVISION HISTORY.

1/19/07: Updated Section 3. Corrected text ('200mg maximum' rather than 'approximately'). Corrected Section 8 text (don't need to press 'Enter' key to commit value to spreadsheet).

Analytical Method: EPA 160.3, 160.1, 160.4 and SM2540B, 2540C, 2540E	**Parameter:** Total Solids, Total Dissolved Solids (TDS), Total Fixed and Volatile Solids		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Method Blank (MB)	One per each batch of ≤20 field samples	MB must not contain TS, TFS, TVS or TDS at a concentration greater than the analyte reporting limit (RL)	Check all calculations. If no computation errors are found, prepare a fresh MB and analyze. Associated samples must also be reanalyzed.
Laboratory Control Sample (LCS)	One per batch of ≤20 field samples	Results obtained must agree between 85% and 115% of solids content added	Check calculations and preparation for documentable errors. If no errors are found, reanalyze. Associated samples must also be reanalyzed.
Laboratory Duplicate (DUP)	One per batch of ≤20 field samples	RPD must be ≤15%	Check all calculations for errors. If no errors are found, discuss with Department/Project/QA Managers.

STANDARD OPERATING PROCEDURE 1104 REVISION 6

TITLE: POTENTIOMETRIC DETERMINATION OF (SIMPLE) FLUORIDE IN WATER AND SOIL USING AN ION SELECTIVE ELECTRODE -- METHODS EPA 340.2, SW9214 AND SM4500-F C

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER Steve Wortman DATE 7/21/08

QUALITY ASSURANCE MANAGER Deb Echerts DATE 7/20/08

LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: Rev0, PCN #463, 4/20/95; Rev1, 4/29/02; Rev2, 12/6/02; Rev3, 2/9/04 and 2/11/05 (re-released without revision); Rev4, 7/26/05; Rev5, 4/10/06; Rev6, 7/18/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- EPA 340.2, SW9214, and SM4500-F^- C -- describe the measurement of fluoride (F^-) in drinking, ground, and surface waters and domestic and industrial wastes by use of an ion selective electrode (ISE). *Note that the procedure outlined in this SOP is for the determination of simple fluoride, not total or dissolved fluoride, as the analysis is not preceded by a distillation step.* The introduction to Method 4500-F^- explains that distillation prior to analysis removes interfering ions thereby reducing measurement error. Method 4500-F^- provides for fluoride determination *without* distillation in cases where interfering ions are not present in excess of the tolerances of the method. The introduction to Method 340.2 states that distillation is required for CWA/NPDES monitoring, but is *not* required for SDWA monitoring. As provided for in Method SW9214, solid matrix samples may also be analyzed by this procedure by first creating an aqueous sample extract.

2. SUMMARY

Fluoride is determined potentiometrically using a fluoride combination ISE and a pH meter with an expanded millivolt (mV) scale. Total Ionic Strength Adjustment Buffer (TISAB) is mixed with standards and samples to adjust the test solution's ionic strength and buffer it to a pH of 5-5.5. The TISAB contains a chelating agent that breaks up metal-fluoride complexes. An electrode potential develops when the sensing element in the ISE (a lanthanum fluoride crystal) contacts the F^- ions contained in the test solution. This potential, which depends on the level of free F^- ions in solution, is measured against a constant reference potential with a mV meter. Calibration is performed by measuring a series of standards and plotting mV vs fluoride concentration using an electronic spreadsheet.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP

and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the workorder file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these procedures to note any anomalies or out-of-control events. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 The fluoride electrode is affected by temperature. It is important that all sample and standard solutions be at the same temperature (preferably ambient room temperature) when measurements are made with the electrode.

4.2 In solutions with a pH below 5, hydronium ions [H^+] complex a portion of the fluoride [F^-] ions, forming HF or HF_2^-, which cannot be detected by the electrode. For most solutions, adding TISAB will maintain a pH above 5.

4.3 Fluoride forms stable complexes with several polyvalent cations (e.g., Si^{+4}, Fe^{+3} and, most notably, Al^{+3}). The CDTA chelating agent contained in the TISAB will preferentially complex aluminum (Al) and iron (Fe) and release free fluoride (F^-). The TISAB solution is effective for sample solutions containing Al or Fe at concentrations >100mg/L.

4.4 The user should be aware of potential interferences from colloidal substances. If colloidal substances are apparent, then the samples may be filtered.

5. APPARATUS AND MATERIALS

5.1 Fluoride combination ISE, Orion Model 96-09 or equivalent (note that a reference electrode is contained within the body of the probe in a combination electrode)

5.2 Specific ion meter with expanded scale capable of reading to 0.1mV, Accumet 50 pH meter or equivalent

5.3 Magnetic stir plate

5.4 Magnetic stir bars, Micro (i.e., 1/2" length by 3/16" wide), Teflon™-coated

5.5 Disposable blood cell-counter vials, or equivalent, 20mL

5.6 Centrifuge tube, polypropylene, disposable, 50mL

5.7 Volumetric and pipette dispensers, Eppendorf™ or equivalent, capable of dispensing 0.01-5.0mL

5.8 Analytical balance, 0.0001g sensitivity, verified per SOP 305

5.9 Volumetric flask, 1000mL

5.10 TCLP tumbler for soil preparation

6. REAGENTS AND STANDARDS

NOTE: Only ACS grade or better chemicals may be used. Unless otherwise noted, reagents must be stored in polypropylene containers.

6.1 Deionized (DI) water. Obtained from the laboratory deionized water system.

6.2 Ottawa (Silica) Sand. EMD, SX0075-3 or equivalent. *Shelf Life = Indefinite.*

6.3 ISE Filling Solution: Purchased from Orion (Single Junction Reference Electrode Filling Solution, catalog # 90-00-01). *Shelf Life = Per expiration date stamped on bottle by manufacturer.*

6.4 Low-level TISAB Solution: In a 1L polypropylene bottle containing approximately 500mL of DI water and a magnetic stir bar, add 58g sodium chloride (NaCl), 57mL glacial acetic acid, and 4g of CDTA ($C_6H_{10}[N(CH_2CO_2H)_2]_2 \bullet H_2O$). Stir on a stir plate to mix and dissolve the components. Adjust to pH to 5.0-5.5 using 10N sodium hydroxide (NaOH). Dilute to 1L using DI water. *Shelf Life = 1 year.*

6.5 TISAB IV Solution: Used for samples containing high concentrations of Al and/or Fe. To 800mL of DI water in a 1L polypropylene bottle, add a magnetic stir bar, 230g of sodium tartrate ($Na_2C_4H_4O_6 \bullet 2H_2O$), 242g TRIS hydroxymethyl-aminomethane (a.k.a. THAM), and 84mL concentrated hydrochloric acid (HCl). Stir on a stir plate for 30-60 minutes to thoroughly mix and dissolve the components. Dilute to 1L using DI water. *Shelf Life = 1 year.*

6.6 Fluoride (F^-) Stock Solution, 10,000mg/L, (first source only): Made in-house from Sodium Fluoride (NaF) salt. In a 500mL volumetric flask containing approximately 250mL DI water, dissolve 11.0500g of anhydrous NaF salt then dilute to mark with DI water. The **first source** NaF stock solution is used to

prepare the 1000mg/L **first source** Fluoride solution. *Shelf life = 1 year from creation.*

6.7 Fluoride (F^-) Solution, 1000mg/L, (first and second sources): Purchased as a prepared solution or made in-house by dilution of the 10,000mg/L Fluoride Stock Solution, as follows - transfer 50.0mL of 10,000mg/L Fluoride Stock Solution into a 500mL volumetric flask and bring to mark using DI water. Store in refrigerator. *Shelf life = 1 year from creation or opening.*

6.8 Fluoride Calibration Standards (per **Table 1** below): Made in-house on each day of calibration by dilution of the first source 1000mg/L Fluoride Solution.

To prepare each calibration standard, pipet 10.0mL DI water into a 20mL vial. Before pipetting the appropriate aliquot of fluoride solution into the vial, first remove an equivalent volume of DI water from the vial using the pipet, so that the final volume contained in the vial is 10.0mL. Exception: 0.5mg/L calibration standard. Use an initial volume of 20.0mL DI water; remove water and add fluoride solution so that final volume is 20.0mL. (Remove 10mL before processing for analysis so that all standard volumes processed for analysis are 10mL).

TABLE 1: CALIBRATION STANDARD PREPARATION

VOLUME OF 1000mg/L FLUORIDE STANDARD USED (mL)	CONCENTRATION OF FINAL SOLUTION (ppm)	FINAL VOLUME OF CALIBRATION STANDARD (mL)
0.01	0.5	20
0.01	1.0	10
0.05	5.0	10
0.10	10.0	10
0.20	20.0	10

6.9 Initial Calibration Verification (ICV) Standard, 5.0mg/L F^-: Pipet 10.0mL of DI water into a 20mL capacity disposable vial. Using the pipet, withdraw 0.05mL of DI water and replace with 0.05mL **second source** 1000mg/L Fluoride solution.

NOTE: This standard solution is also used to prepare the aqueous LCS in the same manner.

6.10 Continuing Calibration Verification (CCV) Standard, 10.0 mg/L F^-: Pipet 10.0mL of DI water into a 20mL capacity disposable vial. Using the pipet, withdraw 0.10mL of DI water and replace with 0.10mL **first source** 1000mg/L Fluoride solution. **A CCV is analyzed after every 10 samples and at the end of every analytical sequence.**

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples should be collected according to an approved sampling plan.

7.2 Per Section 6.0 of Method SW9214, samples must be collected in polyethylene containers.

7.3 No chemical preservation is required for aqueous or solid samples; samples should be chilled (4±2°C).

7.4 No maximum holding time allowance is established for solid samples. Aqueous samples should be analyzed within 28 days after collection.

8. SAMPLE PREPARATION

8.1 AQUEOUS EXTRACTION OF SOLID MATRIX SAMPLES AND ASSOCIATED QUALITY CONTROL (QC) SAMPLE PREPARATION

8.1.1 Weigh a 4.0g representative aliquot of moist sample into a labeled 50mL disposable polypropylene centrifuge tube.

8.1.2 Prepare a Method Blank (MB) by weighing 4.0g clean silica sand into a labeled 50mL disposable polypropylene centrifuge tube. One method blank must be prepared for each batch of twenty (or fewer) solid matrix environmental samples processed together as a unit.

8.1.3 Prepare a Blank Spike/Laboratory Control Sample (LCS) by weighing 4.0g clean silica sand into a labeled 50mL disposable polypropylene centrifuge tube. Add 0.40mL of 1000mg/L F^- solution (second source). One LCS must be prepared for each batch of twenty (or fewer) solid matrix environmental samples processed together as a unit. The concentration of the LCS is expected to be 100.0mg/kg F^-.

8.1.4 Prepare a Matrix Spike/Matrix Spike Duplicate (MS/MSD) set by selecting one sample representative of the batch and weighing additional 4.0g aliquots of sample into two labeled 50mL disposable polypropylene centrifuge tubes. Add 0.16mL of 1000mg/L Fluoride solution (first source) to each MS/MSD tube. One MS/MSD set must be prepared for each batch of twenty (or fewer) solid matrix environmental samples processed together as a unit. The concentration of the MS and MSD is expected to be 40.0mg/kg F^-.

8.1.5 To all of the above, add 40.0mL DI water.

8.1.6 Cap the prepared samples and shake for 1 hour on the TCLP tumbler.

8.1.7 Centrifuge the aqueous extracts for about 15 minutes at approximately 3500rpm.

8.1.8 If filtering is required due to presence of suspended material, then filter extract through a 0.45µm filter disk prior to analysis.

8.2 AQUEOUS FIELD AND ASSOCIATED QC SAMPLE PREPARATION

8.2.1 Aliquot 10mL of each aqueous sample or previously prepared solid sample extract (including associated QC samples) into a designated 20mL vial.

8.2.2 Prepare the aqueous Method Blank (MB) by aliquotting 10mL of DI water into a labeled 20mL vial. One method blank must be prepared for each batch of twenty (or fewer) aqueous matrix environmental samples processed together as a unit. This blank is also used as the Initial Calibration Blank (ICB); one ICB must be analyzed following the daily initial calibration. This blank is also used as the Continuing Calibration Blank (CCB). CCBs are analyzed following CCVs.

8.2.3 The ICV as discussed in Section 6.9 is used as the aqueous LCS.

8.2.4 Prepare an aqueous Matrix Spike/Matrix Spike Duplicate (MS/MSD) set by selecting one aqueous sample representative of the batch and aliquotting an additional 10.0mL aliquot of sample into each of two labeled 20mL vials. Add 0.04mL of 1000mg/L Fluoride solution (first source) to each MS/MSD vial. One MS/MSD set must be prepared for each batch of twenty (or fewer) aqueous matrix environmental samples processed together as a unit. The concentration of the MS and MSD is expected to be 4.0mg/L F^-.

8.2.5 If filtering is required due to presence of suspended material, then filter extract through a 0.45µm filter disk prior to analysis.

9. PROCEDURE

NOTE: While preparing samples and standards, condition the electrode by soaking (with stirring), in aliquots of low and high standard (with 10mL TISAB added).

9.1 Examine ISE and rinse outside with DI water. Add filling solution each day before use through filling hole. Shake electrode as you would shake down the fluid in a thermometer. The filling solution level should be at least one inch above the level of sample to ensure proper flow rate.

NOTE: If necessary, empty filling solution by pushing down of top of electrode and allowing it to drain completely. Rinse with deionized water and shake dry. Re-fill with fresh filling solution.

9.2 Connect electrode to meter and turn meter on by pressing “standby”. Switch to connected channel (Channel A) by pressing “channel”. Press “mV” to select mV mode. Press “expand” to display decimal place. Press “meas./monitor” to select measurement mode.

9.3 Prepare standards as indicated in Section 6 of this SOP; prepare samples as indicated in Section 8 of this SOP.

9.4 Add 10mL of TISAB IV reagent (i.e., 1:1 ratio with sample aliquot) and a stir bar to all sample and standard vials.

NOTE: Routinely, TISAB IV is used for F^- analysis. If necessary the Low-level TISAB buffer solution may be substituted.

Per Section 8.0 of Method 340.2, the amount of buffer may not be adequate for industrial waste samples. If the pH of the sample is >9, add 1N HCl to adjust to pH 8.3.

9.5 Analyze standards and samples per the following run sequence:

1. 0.5mg/L F^- calibration standard
2. 1.0mg/L F^- calibration standard
3. 5.0mg/L F^- calibration standard
4. 10.0mg/L F^- calibration standard
5. 20.0mg/L F^- calibration standard
6. ICV, 5.0mg/L F^- (second source)
7. ICB
8. Preparation (Method) Blank.
9. Laboratory Control Sample (LCS)
10-18. maximum of 8 Field Samples (including MS/MSD)
19. CCV
20. CCB
21-30. maximum of 10 Field Samples (including QC samples, as applicable)
31. CCV
32. CCB
33. repeat Steps 21 through 32

9.6 Select the lowest standard and place on the stir plate. Set the stir rate. Rinse the ISE with DI water and shake of the excess (DO NOT dry by wiping).

Place the electrode in the solution to be measured. Press “mV” to start the measurement. The monitor on the meter displays a “key” symbol and produces a slight “beep” when the reading has been reached. Do not record reading. Instead, press “mV” again, and repeat measurement (this ensures that no previous sample memory or drift occurs). Record the meter reading (in mV) in the LIMS template.

NOTE: Avoid stirring before immersing the electrode because air can become entrapped around the crystal and cause erroneous readings.

9.7 Repeat the step above until all standards and samples have been analyzed. Refer to QC Table at end of SOP for acceptance limits and associated corrective actions.

10. CALCULATIONS

10.1 COMPUTING THE STANDARD CURVE

Prepare a standard curve by plotting the observed mV reading versus log[F^-] for each calibration standard. This is most conveniently accomplished by using the spreadsheet template located in LIMS and renaming it as the appropriate analytical batch ID (example: FL060415-1A).

10.1.1 Enter the mV data obtained for each solution analyzed into the spreadsheet. Also, enter additional data as necessary (i.e., sample identification, volumes or weights, dilution, etc.)

10.1.2 Use the spreadsheet to perform a linear regression analysis between mV and log[F^-] for the calibration standards. The correlation coefficient (r^2) for the regression must be $\geq$0.995. Additionally, for the working concentration range of this procedure (i.e., 0.5-20mg/L), a plot of log[F^-] vs. electrode potential should be linear with a slope of about 59mV per unit change in log[F^-]. In other words, a ten-fold change in concentration should result in about a 59mV change in potential.

10.2 CALCULATING SAMPLE CONCENTRATION

10.2.1 The F^- concentration in water samples is calculated as follows:

$$\text{Concentration } (\mu g/mL) = A \times D$$

where:

A = 10^(mV*slope + intercept); where the slope and intercept are obtained from the linear regression equation

D = Dilution Factor (as applicable)

10.2.2 The F^- concentration in soil samples is calculated as follows:

$$\text{Concentration } (\mu g/g) = \frac{A \times D \times V}{W}$$

where:

A = 10^(mV*slope + intercept); where the slope and intercept are obtained from the linear regression equation

D = Dilution Factor (as applicable)

V = Extract Volume (40mL if this SOP is followed without deviation)

W = Dry weight of sample extracted; (4.0g * percent solids if this SOP is followed without deviation)

11. QUALITY CONTROL

11.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or fewer field samples associated with one unique set of batch QC samples that are processed together as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike and duplicate (MS/MSD). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

11.2 METHOD BLANKS

Method blanks (MBs) are analyzed to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the MB consists of 10.0mL of deionized water or 4.0g clean sand. Any analyte concentration found in the blank must be less than the analyte reporting limit.

11.3 LABORATORY CONTROL SAMPLE

The Laboratory Control Sample (LCS) is analyzed to measure the accuracy of the method. A known amount of analyte is spiked into an aliquot of representative clean matrix and analyzed. For this method, 10.0mL of DI water (representative of aqueous samples) and 4.0g clean sand (representative of solid samples) are used as the clean matrices.

LCS results obtained are compared to results expected using the equation presented below:

$$\text{Percent Recovery (\%R)} = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Expected}}} \times 100$$

where:

$\text{Conc}_{\text{Found}}$ = analyte concentration found in the LCS

$\text{Conc}_{\text{Expected}}$ = anticipated analyte concentration based on known amount spiked

To be acceptable, LCS recovery must be between 90% and 110% (aqueous matrix) and 85% and 115% (soil matrix) of the expected concentration..

11.4 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Matrix spikes (MSs) consist of representative field samples into which known concentrations of target analyte(s) are spiked. MSs are analyzed as a means of determining the effect of matrix on target analyte detection.

The matrix spike is prepared in duplicate (MSD) to serve as a laboratory duplicate, which is analyzed to measure the precision of the analysis.

Analyte recovery for the MS/MSD pair is calculated as shown below:

$$\%R = \frac{\text{Concentration}_{Found} - \text{Concentration}_{Sample}}{\text{Concentration}_{Target}} \times 100$$

where:

$Conc_{Found}$ = analyte concentration found in the MS or MSD
$Conc_{Sample}$ = analyte concentration found in the native field sample
$Conc_{Target}$ = analyte concentration anticipated based on known amount spiked

The advisory quality control limits for MS/MSD recovery are set at 85-115%.

Precision is evaluated as the Relative Percent Difference (RPD) between a sample and it's duplicate. RPD is calculated as shown below:

$$RPD\ (\%) = \frac{|\ Result_x - Result_{Dup}\ |}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

The RPD should be $\leq$15% to be accepted.

Advisory acceptance criteria for all spikes and duplicates should be met. If MS/MSD recovery or RPD criteria are not met, the result of the LCS analyses must be carefully considered. If the LCS results are acceptable, sample matrix interference is suspected and a notation n the narrative comments is made.

11.5 Note that performance of a method detection limit (MDL) study, is not applicable to this procedure.

12. DEVIATIONS FROM METHOD

12.1 Section 6.0 of Method 340.2 and Section 3.0 of SM4500-F C refer to distilled water for the preparation of standards and reagents. Paragon uses deionized (DI) water generated by the in-house laboratory deionization system. It has been demonstrated (through PT sample analysis, etc.), that Paragon's DI water is free of F^-, and meets the requirements of ASTM Type I and II water.

12.2 Paragon's stock and calibration standards are made in concentrations that differ somewhat from those described in Section 6.0 of Method 340.2 and Section 3.0 of SM4500-F C. Both Methods cite approximately 0.1 to 10mg/L F^- or greater (up to 1000mg/L) as the Method's operational range. Paragon standards bracket a range of approximately 0.5 to 20mg/L F^-.

12.3 The volume of reagents created or sample aliquots processed may differ from the amounts depicted in the Method references. Component ratios remain the same. These changes were implemented for waste minimization purposes.

12.4 Section 7.0 of Method SW9214 states that the ISE solution should be changed if the electrode has not been used for a week. Per manufacturer's instruction, Paragon checks the ISE and adds solution as needed before each use. The ISE solution is changed on an as needed basis.

12.5 Section 7.0 of Method SW9214 states that the ISE should be conditioned in a 10.0mg/L fluoride solution for 24 hours before each use. Paragon conditions the ISE prior to use using aliquots of low and high standard (or a range of standards), containing TISAB.

12.6 Section 8.5 of Method SW9214 states that the acceptance limits for matrix spiked recovery must be 75-125%, and if these criteria are not met, the sample must be analyzed using the method of standard additions. Paragon observes matrix spiked advisory limits of 85-115% and does not employ the method of standard additions.

12.7 As described in Method SW9214, solid matrix samples may also be analyzed by this procedure by first creating an aqueous sample extract. Section 8 of this SOP describes the solid preparation procedure. Paragon notes that Method EPA 340.2 is applicable to the measurement of fluoride in drinking, surface and saline waters, domestic and industrial wastes (Section 1.1).

13. SAFETY, HAZARDS AND WASTE DISPOSAL

13.1 SAFETY AND HAZARDS

13.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

13.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

13.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

13.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

13.1.5 All flammable compounds must be kept away from ignition sources.

13.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

13.1.7 Food and drink are prohibited in all lab areas.

13.2 WASTE DISPOSAL

13.2.1 The aqueous solutions generated by the analyses or the aqueous supernatant of solid samples shall be disposed of in the Aqueous Laboratory Waste.

13.2.2 The solid residues are to be disposed of the Contaminated Soils and Solids Waste.

13.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

13.2.4 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Management Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

2/9/04: Updated format.

7/26/05: Added reference Program Specification directive in "Responsibilities".

4/10/06: Added 10,000mg/L Fluoride Stock Solution to Section 6. Added DOCUMENT REVISION HISTORY.

7/18/08: Minor clerical corrections. TISAB shelf-life (6.5) changed from indefinite to 1yr. Nuance to 'measure twice' added to 9.6. MDL discussion clarified/updated.

Analytical Method: E 340.2; SW9214; SM4500-F C	**Parameter:** Potentiometric Determination of Fluoride in Aqueous Samples with Ion-Selective Electrode		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point (plus blank); first source	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); second source	Once after each initial calibration; concentration different from CCV; at or below midpoint of curve	Response must agree within $\pm$10% of expected value	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); first source	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis); at or below midpoint of curve	Response must agree within $\pm$10% of expected value	Check that calculations and preparation are correct, evaluate/ correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Blanks: Method Blank (MB), Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	The MB may be run initially as part of the calibration curve, the ICB is run following the calibration curve. CCBs are run following the CCV (after every ten samples), and to close an analytical run sequence	Fluoride content of the blank must not exceed reporting limit (RL); RL usually 0.5mg/L F^-	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Laboratory Control Sample (LCS)	Matrix specific. One LCS must be prepared and analyzed per $\leq$20 environmental samples of similar matrix	Results must agree within $\pm$10% of expected value for aqueous sample analyses; within $\pm$15% for solid matrix extract analyses	Check all calculations. If no computation errors are found, prepare a fresh LCS and analyze. If criteria are still not met, system must be recalibrated and all samples associated with the failed LCS must be reanalyzed.
Matrix Spike (MS)	One per batch of $\leq$20 field samples	Recoveries should meet advisory limits of $\pm$15% of the expected values; client-specified criteria may apply	Compare with LCS results and check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (laboratory) Duplicate	One per batch of $\leq$20 field samples of similar matrix	(See MS recovery criteria above) RPD advisory limit is $\leq$15; client-specified criteria may apply	(See MS recovery criteria above). For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1106 REVISION 7

TITLE: BICARBONATE, CARBONATE, HYDROXIDE AND TOTAL ALKALINITY BY TITRATION -- METHODS EPA 310.1 AND SM2320B

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER Steve Workman DATE 7/21/08

QUALITY ASSURANCE MANAGER Deb Zaheta DATE 7/20/08

LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: Rev0, PCN #286, 12/6/94; Rev1, 9/22/99; Rev2, 1/10/02; Rev3, 12/17/02; Rev4, 2/13/04 (format updated) and 3/25/05 (re-released without revision); Rev5, 7/26/05; Rev6, 4/10/06; Rev7, 7/18/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- USEPA Method 310.1 and Standard Method SM2320B -- are used to determine alkalinity in environmental water samples. By titrating to two endpoints (i.e., pH 8.3 and pH 4.5), the alkalinity can be speciated into bicarbonate (HCO_3^-), carbonate ($CO_3^=$), and hydroxide (OH^-). For each constituent, the results of the analysis are expressed as mg $CaCO_3$/L. These procedures are suitable for determining all concentration ranges of alkalinity, however, sample size used should be evaluated to avoid requiring titration volumes greater than 100mL.

2. SUMMARY

The alkalinity of a water sample is its quantitative capacity to neutralize a strong acid to a designated pH. The measured alkalinity, therefore, depends on the endpoint pH used. For most surface waters, alkalinity is primarily a function of bicarbonate (HCO_3^-), carbonate ($CO_3^=$), and hydroxide (OH^-) content. The concentration of these constituents can be calculated when the sample is titrated to two endpoints, pH 8.3 and pH 4.5.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or by the successful analysis of a proficiency test sample.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy and completeness and is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

NOTE: ***The sample may not be altered in any way to remove interferences.***

4.1 Soaps, oily matter, suspended solids, or precipitates may cause a sluggish response with the pH meter or make colored indicators difficult to see. It may be necessary to allow additional time between titrant additions to let the electrode come to equilibrium.

4.2 Substances, such as salts of weak acids, present in large amounts may cause interferences in the electrometric pH measurements.

4.3 Samples with high concentrations of mineral acids (e.g., mine wastes and associated receiving waters), should be analyzed by alternative methods (such as ASTM D-1067).

5. APPARATUS AND MATERIALS

5.1 Beakers, Pyrex™, 150mL

NOTE: *An appropriate beaker size which keeps the air space above the solution to a minimum should be used.*

5.2 Pipettes, plastic transfer

5.3 Volumetric flasks, Class A, 500mL and 1L

5.4 Top loading balance capable of reading to 0.01g, and verified per SOP 305

5.5 Accumet pH/mV Meter 50, or equivalent, capable of reading to ± 0.05 pH units

5.6 pH electrode, glass, combination style with reference electrode contained within probe body

5.7 Magnetic stir plate

5.8 Magnetic stir bars, Teflon-coated

5.9 Adjustable Eppendorf™ Pippette (or equivalent), capable of delivering 1.0mL; *operate observing requirements contained in SOP 321*.

6. REAGENTS

6.1 Deionized (DI) water.

6.2 pH Buffers (4.01, 7.00, 10.01): Orion 910104, 910107, 910110 or equivalents (first source); RICCA Chemical Co. #1551-16 or equivalent (second source). Store in polypropylene. *Shelf life = 1 year.*

6.3 Phenolphthalein Indicator Solution: VWR, Cat. No. VW3341-2 or equivalent. Store in polypropylene. *Shelf life = 1 year.*

6.4 Bromocresol Green Indicator Solution: EM Science, 2800 or equivalent. Dissolve 0.5g of bromocresol green sodium salt in 500mL of DI water. Store in polypropylene. *Shelf life = 1 year.*

6.5 Hydrochloric Acid (HCl), 0.1N: JT Baker, 9530-33 (concentrated) or equivalent. Purchased from a commercial vendor or made in-house by diluting 8.3mL of concentrated HCl to 1L with DI water. Store in polypropylene. *Shelf life = 1 year or until degradation is evident.*

6.6 Hydrochloric Acid (HCl), 0.02N: Purchased from a commercial vendor or made in-house by diluting 200mL of 0.1N HCl to 1L with DI water. Standardization of this solution is carried out for each usage by titrating against the standard base (i.e., THAM). Store in polypropylene. *Shelf life = 1 year or until degradation is evident (i.e., same a parent, above).*

6.7 Tris(hydroxymethyl)aminomethane (THAM), 0.20N: JT Baker, 4099-06 or equivalent. Dry about 15g primary standard THAM at about 100°C for 1-2 hours and cool in a desiccator. Transfer 12.114g of the dried THAM to a 500mL volumetric flask. Add 200-300mL of DI water to the flask and swirl to dissolve the salt. Fill to the mark with DI water and mix thoroughly. Store in polypropylene. *Shelf life = 1 year.*

6.8 Sodium Carbonate Standard Solution (Na_2CO_3), 0.20N: JT Baker, 3604-01 or equivalent. Dry about 10g primary standard Na_2CO_3 at 250°C for 4 hours and cool in a desiccator. Transfer 5.300g of the dried Na_2CO_3 to a 500mL volumetric flask. Fill to the mark with DI water and mix thoroughly. Store in polypropylene. *Shelf life = 1 year.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples may be collected in either plastic or glass containers and must be collected according to an approved sampling plan. The sample containers should be filled as full as possible to minimize headspace.

7.2 Water samples should be kept refrigerated (0-6°C) from the time of collection until analysis. The samples must be analyzed within 14 days after collection.

8. PROCEDURE

8.1 STANDARDIZATION OF TITRANT

8.1.1 Calibrate the pH meter according to manufacturer's instructions by using pH buffers 4.01, 7.00 and 10.01. On the Accumet 50 pH meter, push "standardize" on the meter and select choice #2, "clear existing standards". Place the probe in first pH buffer, push "standardize" and select choice #1, "update or add standard". Enter buffer value and push "ENTER". Let the probe sit in the buffer solution for 1-2 minutes, then push enter. Repeat these steps for next two buffers concentrations. Discard the buffer aliquots after each day's use.

8.1.2 Pipette 1.00mL of 0.20N THAM into a 150mL beaker containing 100mL DI water. Add a stir bar, and approximately 2mL bromocresol green indicator. Place the beaker + contents on the laboratory balance and tare the balance.

8.1.3 Place the beaker + contents on a stir plate. Adjust the stir plate control so that the beaker's contents mixes slowly.

8.1.4 Place the pH probe in the beaker. Using the pH meter and color indicator as reference points, titrate to a pH of 4.5 by adding 0.02N HCl dropwise. When the color of the solution turns from blue to green, the endpoint has been reached. Place the beaker + titrated contents on the balance and record the weight of the titrant used on the LIMS benchsheet.

8.1.5 Repeat Steps (8.1.2 - 8.1.4) twice more for a total of three standardization replicates. The average of the standardization results will be calculated to determine the titrant's concentration.

NOTE: Because people see colors/interpret endpoints differently, Paragon policy is that the same analyst who standardizes the acid, analyzes the samples.

8.2 TITRATION OF SAMPLES

NOTE: Allow all samples to come to room temperature before preparation and analysis.

8.2.1 Place a 150mL beaker containing a stir bar on the top loading balance. Tare the balance. Gravimetrically pipet a 100mL aliquot of sample (or less if a smaller sample size is required) into the beaker. Record the sample volume on the benchsheet. If less than a 100mL aliquot of sample is used, bring to a final gravimetric volume of 100mL with DI water.

8.2.2 With the beaker + contents still on the balance, add 1-2 drops of phenolphthalein solution. If the pH of the beaker's contents is greater than 8.3, the contents will turn pink in color. Re-tare the balance.

NOTE: If no pink color appears initially upon the addition of phenolphthalein (swirl beaker to mix contents), add approximately 2mL bromocresol green indicator solution. Re-tare the balance and proceed to Step 8.2.5.

8.2.3 Move the sample beaker to the stir plate and submerge the pH probe in the sample solution. Adjust the stir control so that the beaker's contents mix slowly.

8.2.4 Add 0.02N HCl dropwise to the prepared sample beaker until the solution turns clear and the pH meter reads 8.3. Place the beaker with titrated sample on the top loading balance and record the amount of titrant used on the bench sheet. Add approximately 2mL bromocresol green indicator solution; re-tare the balance.

8.2.5 Place the beaker + contents containing the bromocresol green indicator on the stir plate; submerge the pH probe in the sample solution. Titrate by adding 0.02N HCl dropwise until the color of the sample solution turns from blue to green and pH meter reads 4.5.

8.2.6 Move the beaker and titrated contents to the top loading balance and record the amount of titrant used on the bench sheet.

NOTE: Rinse the pH probe with DI water between each sample solution processed.

8.2.7 Laboratory Duplicate (DUP): Select one sample per batch of 20 or less field samples processed as a unit, and prepare a second aliquot of that sample to serve as the laboratory duplicate. Process as described in Steps 8.2.1 through 8.2.6 above.

8.2.8 Initial Calibration Verification (ICV); Laboratory Control Sample (LCS); Continuing Calibration Verification (CCV): Prepare this check sample by transferring 1.00mL of 0.20N sodium carbonate standard solution to a 150mL beaker containing a stir bar; dilute to 100mL with DI water. Titrate as described in Steps 8.2.1 through 8.2.6.

The ICV aliquot is analyzed at the beginning of each day's analysis following standardization of the HCl titrant. One LCS is to be analyzed per batch of 20 or less field samples processed as a unit. If more than twenty field and quality control (QC) samples are analyzed, the analysis of one CCV must follow.

8.2.9 Blanks - Initial Calibration Blank (ICB); Method Blank (MB); Continuing Calibration Blank (CCB): Aliquot 100mL of DI water into a 150mL beaker. Prepare and titrate as described in Steps 8.2.1 through 8.2.6.

Blanks are run to demonstrate that interferences from the analytical system, glassware and reagents are under control. Analyze one blank (ICB) following the ICV. Analyze one blank per batch of twenty or less field samples processed as a unit (MB). A CCB must follow each CCV analyzed.

NOTE: When reporting laboratory quality control sample results, report as Total Alkalinity.

8.2.10 ANALYTICAL RUN SEQUENCE
The alkalinity determinations should be run in the following sequence:

1. ICV
2. ICB
3. MB
4. LCS
5. DUP
6. 17 field samples

If more than 17 field samples are analyzed, the sequence must continue as follows:

7. CCV
8. CCB
9. - 11. three more field samples (from same batch)

If a second batch of samples is to be analyzed, the sequence repeats beginning with a MB, LCS, DUP, 14 field samples, CCV/CCB, etc.

8.3 CALCULATIONS

8.3.1 CALCULATION OF HCL TITRANT

$$C_{HCl} = \frac{(C_{THAM})(V_{THAM})}{V_{HCl}}$$

where:

C_{HCl} = concentration of HCl titrant, N or eq/L
C_{THAM} = concentration of THAM standard, N or eq/L; (equals 0.20N if preparation is followed without deviation)
V_{THAM} = volume (mL) of THAM standard titrated; (equals 1.0mL if SOP is followed without deviation)
V_{HCl} = volume (mL) of HCl titrant required to reach endpoint

Therefore:

$$C_{HCl} = \frac{(0.20\ N)(1.0mL)}{V_{HCl}}$$

Average the results of the three replicate standardizations to calculate the HCl titrant concentration.

8.3.2 CALCULATION OF ALKALINITY

$$C_{Alk} = \frac{(C_{HCl})(V_{HCl}) \times 50{,}000}{(V_S)}$$

where:

C_{Alk} = concentration of alkalinity (in sample), mg $CaCO_3$/L
C_{HCl} = concentration of HCl titrant, N or eq/L
V_{HCl} = volume (mL) of HCl titrant required to reach endpoint
V_S = volume (mL) of sample titrated
50,000 = conversion factor (eq/L to mg $CaCO_3$/L)

8.3.3 To speciate the alkalinity in terms of bicarbonate (HCO_3^-), carbonate ($CO_3^{=}$) and hydroxide (OH^-), the following relationships are used:

Result of Titration (as $CaCO_3$)	Hydroxide Alkalinity (as $CaCO_3$)	Carbonate Alkalinity (as $CaCO_3$)	Bicarbonate Alkalinity (as $CaCO_3$)
P = 0	0	0	T
P < 1/2T	0	2P	T-2P
P = 1/2T	0	2P	0
P > 1/2T	2P-T	2(T-P)	0
P = T	T	0	0

where:

P = volume of acid required to reach phenolphthalein endpoint
T = total volume of acid required to reach bromocresol green endpoint

$$[HCO_3^-] = \frac{(T - 2P)(C_{HCl}) \times 50{,}000}{(V_S)}$$

$$[CO_3^{=}] = \frac{(2P)(C_{HCl}) \times 50{,}000}{(V_S)} \quad \textit{when } P \leq 1/2\ T$$

$$[CO_3^{=}] = \frac{2(T-P)(C_{HCl}) \times 50{,}000}{(V_S)} \quad \textit{when } P > 1/2\ T$$

$$[OH^-] = \frac{(2P - T)(C_{HCl}) \times 50{,}000}{(V_S)} \quad \textit{when } P > 1/2\ T$$

$$[OH^-] = \frac{(T)(C_{HCl}) \times 50{,}000}{(V_S)} \quad \textit{when } P = T$$

NOTE: In all cases, the concentration is reported as mg $CaCO_3$/L.

9. QUALITY CONTROL (QC)

9.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or less field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB; *or initial calibration blank, ICB or continuing calibration blank, CCB*), laboratory duplicate (DUP) and laboratory control sample (LCS; *or initial calibration verification standard, ICV or continuing calibration verification standard, CCV*). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

9.2 BLANKS

Blanks are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank (MB) should be processed. Three types of blanks exist for this procedure - MB, initial calibration blank (ICB) and continuing calibration blank (CCB). The ICB is run following the ICV. A CCB must be run following each CCV analyzed. All blanks consist of 100mL DI water. The blank concentration found must be less than the reporting limit (usually 5mg $CaCO_3$/L).

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. It consists of an aliquot of clean matrix (in this instance, 100mL DI water), into which a known amount of analyte is spiked (see Step 8.2.8). For this method, the same spike process is used to create the Initial Calibration Verification (ICV) standard and the Continuing Calibration Verification (CCV). The ICV aliquot is analyzed at the beginning of each day's analysis following standardization of the HCl titrant. One LCS is to be analyzed per batch of 20 or less field samples processed as a unit. If more than twenty field and QC samples are analyzed, the analysis of one CCV must follow (refer to Step 8.2.10 - Analytical Run Sequence).

Results obtained for these check samples are compared to results expected. The mathematical evaluation is expressed as percent recovery, %R, calculated as follows:

$$\%R = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Target}}} \times 100$$

To be acceptable, percent recovery must be between 85% and 115% of the expected concentration.

9.4 LABORATORY DUPLICATE

A second aliquot of one sample per batch of twenty (20) or less field samples processed as a unit is prepared and analyzed as a laboratory duplicate. The laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. The duplicate results are compared mathematically (shown below), with the precision expressed as Relative Percent Difference (RPD)

$$\text{RPD (\%)} = \frac{|\ \text{Result}_x - \text{Result}_{Dup}\ |}{\frac{(\text{Result}_x + \text{Result}_{Dup})}{2}} \times 100$$

For this procedure, the RPD should not be greater than 15%.

10. DEVIATIONS FROM METHOD

10.1 Section 5.1 of Method EPA 310.1 and Section 3a of Method SM2320B describe the creation of 0.05N sodium carbonate (Na_2CO_3) standard solution. This SOP provides for a sodium carbonate standard solution that is approximately 4 times stronger (0.20N).

10.2 As described in Section 5.2 of Method E310.1 and Section 3b of Method SM2320B, Paragon does not boil the sodium carbonate (Na_2CO_3) standard solution aliquot during standardization of the 0.1N and 0.02N HCl standard acid solutions. Further, Paragon standardizes the 0.02N HCl with THAM, as described in Section 8.1 of this SOP. The successful completion of proficiency testing (PT) studies has demonstrated that these practices do not affect the accuracy of the pH results generated.

10.3 As described in Section 6.3.2 of Method E310.1 and in the General Discussion of Method SM2320B, for low alkalinities (those less than 20mg $CaCO_3$/L), Paragon does not determine the equivalence endpoint by continuing the titration of the 4.5 pH endpoint to determine the amount of standard acid required to reduce pH by exactly 0.30 pH units.

10.4 Both Method E310.1 and SM2320B recommend analysis as soon as possible. Paragon strives to analyze all alkalinity samples as soon as possible after receipt, however, a 14-day from date of collection maximum holding time allowance is allowed (per Table 1 of Methods for Chemical Analysis of Water and Wastes, citation source for Method E310.1).

10.5 In contrast to Section 4b of SM2320B (generation of a potentiometric titration curve), Paragon uses a series of pH buffers (4.01, 7.00 and 10.01) to standardize the pH meter.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire

extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The aqueous solution left over from the titration shall be disposed of in the Aqueous Laboratory Waste satellite collection vessel.

11.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.3 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Health and Safety Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

2/13/04: Updated format.

7/26/05: Added reference Program Specification directive in "Responsibilities".

4/10/06: Added DOCUMENT REVISION HISTORY.

7/18/08: Minor clerical corrections. Policy note added to 8.1.

Analytical Method: E310.1; SM2320B	**Parameter:** Alkalinity		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Calibration: Analyte content is determined by direct concentration (obtained by calculation from titration) The titrant is standardized each day of use.	Daily; each day of use	Titrant must calculate to be between 0.18-0.22 N	If titrant does not meet concentration criteria; prepare fresh and standardize via three replicate analyses.
Initial Calibration Verification (ICV); run within the established range of the method	Daily; each day of use	Results for the ICV must agree within ±15% of the expected (true) value	If ICV criterion not met, check for preparatory and calculation errors; remake and reanalyze. If ICV criterion is still not met, prepare titrant fresh and standardize via three replicate analyses. Reanalyze ICV.
Continuing Calibration Verification (CCV); run within the established range of the method	Run to bracket each batch of environmental samples processed	Results for the CCV must agree within ±15% of the expected (true) value	If CCV criterion not met, check for preparatory and calculation errors; remake and reanalyze. All samples run since the last acceptable CCV must also be reanalyzed.
Blanks: Method Blank (MB), Initial Calibration Blank (ICB), Continuing Calibration Blank (CCB)	One MB per each batch of ≤20 field samples and each time a reagent is changed. One ICB run immediately following ICV. One CCB run following each CCV analysis	No blank's alkalinity may exceed the reporting limit (RL); RL usually 5mg $CaCO_3$/L	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All associated samples must also be reanalyzed.
Laboratory Control Sample (LCS)	One per batch of ≤20 field samples	Results obtained must agree between 85% and 115% of expected (known) alkalinity concentration	Check calculations and preparation for documentable errors. If no errors are found, remake and reanalyze. All associated samples must also be reanalyzed.
Laboratory Duplicate (DUP)	One per batch of ≤20 field samples	RPD must be ≤15%	Check all calculations for errors. If no errors are found, discuss with Department/Project/QA Managers.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- SW9010B, SW9013, SW9014; EPA 335.1, EPA 335.2; the CLP Inorganic SOW ILMO4.0; and SM4500-CN I -- describe procedures to extract and quantify cyanide in waters, soils, and various wastes and waste leachates. Cyanide that is present either as soluble salts or in complexed forms is detected.

Total cyanide, total cyanide extractable from solids and oils, cyanide amenable to chlorination, and/or weak and dissociable cyanide can be determined by the procedures outlined in this SOP. These procedures are written to address trace analyses (cyanide concentrations <1000ppm), but may also be used to determine minor (1000-10,000ppm) and major (>10,000ppm) concentrations of cyanide by adapting the sample preparation techniques (e.g., employment of sample dilution) or determinative techniques (e.g., use of the titration procedure provided for in Methods EPA 335.2, SW9010B and SW9014, in lieu of colorimetric development, where cyanide concentrations are significant).

Procedures presented in the CLP Inorganic SOW ILMO4.0 are based on total cyanide Method EPA 335.2. The CLP Inorganic SOW also provides for the direct analysis (i.e., without extraction) of solid matrix samples. The extraction procedure for total cyanides in solid or oil matrices contained in this SOP references Method SW9013. The reflux-distillation preparation for liquid samples or extracts described by this SOP references Methods SW9010B and EPA 335.2. The spectrophotometric determination of cyanide described herein references Methods SW9010B, SW9014 and EPA 335.2.

Procedures for the determination of cyanide amenable to chlorination contained in this SOP reference Methods SW9010B and EPA 335.1. The procedures for the determination

of weak and dissociable cyanide described by this SOP reference Method SM4500-CN I.

2. SUMMARY

Cyanide, as hydrocyanic acid (HCN), is released from samples containing cyanide by means of a reflux-distillation process conducted under acidic conditions. The released cyanide is absorbed in a scrubber containing sodium hydroxide (NaOH) solution. It is critical that the amount of sodium hydroxide solution in the scrubber is the same for all standards and samples processed. The amount of cyanide contained in this basic scrubber solution is then determined colorimetrically. The colorimetric reaction involves the formation of cyanogen chloride (CNCl) by reaction with chloramine-T. It is essential that the same amount of chloramine-T is added to all standards and samples processed. Then pyridine-barbituric acid is added as a color development reagent. The colored complex is detected by measuring absorbance at 578nm with a spectrophotometer. Methods SW9010B, SW9014 and EPA 335.2 alternately provide for the use of pyridine-pyrazolone (instead of pyridine-barbituric acid) as the color development reagent. If pyridine-pyrazolone is used, the time required for color development is longer (40 minutes rather than 8 minutes) and the samples must be read at 620nm (rather than 578nm).

To determine cyanide amenable to chlorination, two sample aliquots (one carried through a chlorination process, and one that is not) are processed. The amount of cyanide amenable to chlorination is determined by calculation (i.e., amount CN present in unchlorinated aliquot - amount CN remaining in chlorinated aliquot).

Liquid samples or extracts for determination of weak and dissociable cyanide are prepared by distillation under less acidic conditions than those established for total and amenable cyanide determination. Different preparatory reagents are also used. Colorimetric reaction, development and reading are the same as with total and amenable cyanide determination.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the preparation and analysis according to this SOP and to complete all documentation required for review.

3.2 Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this method. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, and/or the successful analysis of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon’s standard

criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 Final review and sign-off of the data are performed by the Department Supervisor or qualified designee. Initialing and dating the file indicate that this review for precision, accuracy and completeness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated with the handling, preparation or analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Oxidizing agents such as chlorine decompose most cyanides. Interference from chlorine can be removed by adding an excess of sodium arsenite ($NaAsO_2$) to the sample prior to preservation and storage. Sodium arsenite reduces the chlorine to chloride, which does not interfere. Alternatively, an excess of ascorbic acid may be used to remove the residual chlorine.

4.2 Sulfides interfere by producing hydrogen sulfide (H_2S) during distillation. Sulfide interference can be removed by adding an excess of bismuth nitrate [$Bi(NO_3)_3$] to the sample before distillation (to precipitate the sulfide). Samples that contain hydrogen sulfide, metal sulfides, or other compounds that may produce hydrogen sulfide during the distillation, should be treated by the addition of bismuth nitrate.

4.3 Nitrate and nitrite at levels higher than 10mg/L may react with some organic compounds to generate hydrogen cyanide (HCN) yielding high results. During the distillation, nitrate and nitrite will form nitrous acid, which will react with some organic compounds to form oximes. These compounds, once formed, will decompose under test conditions to generate HCN. The possibility of interference from nitrate and nitrite is eliminated by pretreatment with sulfamic acid just before distillation.

4.4 Thiocyanate has been reported to be an interference when present at very high levels. Concentrations of 10mg/L were not found to interfere.

4.5 Where titration (rather that colorimetric development) is used as the determinative step, fatty acids, detergents, surfactants, and other compounds may interfere. When these substances are present in large concentrations, foaming may occur during distillation, thus making the endpoint of the titration difficult to detect.

Section 6.8 of Method SW9010B and Section 5.3 of Method EPA 335.2 describe procedures for the removal of these interferent substances.

4.6 Some unidentified organic chemicals may oxidize or form breakdown products during chlorination, yielding higher results for cyanide *after* chlorination than before chlorination. This may lead to a negative value for cyanides amenable to chlorination after distillation for some wastes (e.g., steel industry, petroleum refining, pulp and paper processing). Method 4500CN I (Dissociable Cyanide) is recommended where these interferences occur.

4.7 Some metal-cyanide complexes may be sensitive to ultraviolet light. Sample processing under incandescent light is recommended to prevent photodecomposition.

5. APPARATUS AND MATERIALS

5.1 Midi-Dist™ cyanide distillation system, Model 110-10R or equivalent, containing Midi glassware (e.g., reflux impingers, tubes and cold fingers; absorption impingers and tubes), all connective tubing, a flow meter and a heating block

5.2 vacuum source for operation of the Midi-Dist™ system

5.3 water source for operation of the Midi-Dist™ system

5.4 spectrophotometer, Sequoia-Turner, Model 340 or equivalent

5.5 cuvettes, optically matching, 1 inch diameter, Bausch & Lomb or equivalent

5.6 cuvette stand

5.7 analytical balance, capable of weighing to 0.0001 gram

5.8 top-loading balance, capable of weighing to 0.01 gram

5.9 volumetric flasks, glass, Class A, 100mL, 500mL and 1L sizes

5.10 magnetic stir plate

5.11 magnetic stir bars, Teflon™-coated

5.12 pipets, variable Eppendorf™ or equivalent and disposable pipet tips

5.13 pipets, plastic, disposable

5.14 beakers, glass, 250mL

5.15 beakers, plastic, disposable, 100mL

5.16 pH paper, narrow-range (acidic) and narrow-range (basic), or wide-range (0-14)

5.17 indicator paper, KI-starch

5.18 test paper, lead acetate

5.19 centrifuge tubes, 50 and 250mLs, disposable (used in the extraction of cyanide from solid and oil matrices)

5.20 centrifuge, capable of producing 3500rpm rotation

5.21 tumbler, rotary

5.22 filtration apparatus (vacuum pump, funnel, filter discs or glass wool)

6. REAGENTS AND STANDARDS

6.1 reagent water, laboratory deionized (DI)

6.2 clean silica sand

6.3 ascorbic acid, reagent grade, fine powder

6.4 Sodium hydroxide solution, 10N: Used for sample preservation and pH adjustment during sample preparation. Dissolve 40g NaOH in a final volume of 100mL using DI water. Shelf Life = 1 year.

6.5 Calcium hypochlorite solution, 0.35M: Used in determining cyanide amenable to chlorination. Use DI water to dissolve 5g $Ca(OCl)_2$ and bring to full volume in a 100mL Class A volumetric flask. **Store in an amber bottle; shake well before using**. Shelf Life = 1 month.

6.6 Magnesium chloride solution, 2.5M, 51% (w/v): Used as an anti-foaming agent during distillation. Obtained from a commercial vendor or made in-house by dissolving 510g $MgCl_2 \bullet 6H_2O$ in DI water and bringing to full volume in a 1L Class A volumetric flask. Shelf Life = 1 year.

6.7 Bismuth nitrate solution, 0.062M: Used prior to distillation to remove sulfide interferences. Dissolve 30g $Bi(NO_3)_3$ in 100mL of DI water. Add 250mL glacial acetic acid, stir. Bring to full volume in a 1L Class A volumetric flask. Shelf Life = 1 year.

6.8 Sulfamic acid solution, 0.4N: Used for the removal of nitrate/nitrite interferences. Use DI water to dissolve 40g NH_2SO_3H and bring to full volume in a 1L Class A volumetric flask. Shelf Life = 1 year.

6.9 Sodium hydroxide solution, 0.25N: Used as the scrubber solution and scrubber solution diluent; also used to prepare the working calibration standards. Dissolve 10g NaOH in a final volume of 1L using DI water. Shelf Life = 1 year.

6.10 Sulfuric acid solution 18N, 50% (v/v): Used to establish acidic conditions for distillation. Carefully add 100mL concentrated H_2SO_4 to 100mL DI water. Shelf Life = 1 year.

6.11 Sodium phosphate monobasic buffer solution, 1M: Dissolve 138g of $NaH_2PO_4 \bullet H_2O$ in 1L of DI water. ***Refrigerate.*** Shelf Life = 1 year.

6.12 Standard silver nitrate titrant, 0.0192N: Obtained from a commercial vendor or prepared in-house. Use DI water to dissolve 3.2647g dried $AgNO_3$ and bring to full volume in a 1L Class A volumetric flask. Shelf Life = 1 year.

6.13 p-Dimethylaminobenzalrhodanine indicator, reagent grade: Obtained from a commercial vendor or made in-house by dissolving 0.020g p-dimethylamino-benzalrhodanine in a final volume of 100mL acetone (spectral grade). Shelf Life = 1 year.

6.14 Stock potassium cyanide standard, 1000mg/L CN: Use 0.25N NaOH solution to dissolve 0.2504g potassium cyanide (KCN) salt and bring to final volume in a 100mL Class A volumetric flask. ***Refrigerate.*** Shelf Life = 1 year.

NOTE: ***Two stock solutions (one each) are prepared from two independent sources of KCN salt (i.e., "first source" and "second source").***

The concentration of each of the stock potassium cyanide standard solutions (i.e., **first source** and **second source**) must be verified when made. Use the standardization procedure following to verify the stock solutions (*Note: this titration standardization procedure is detailed in SM4500-CN D)*:

6.14.1 Transfer 10.0mL of potassium cyanide stock standard to a 250mL beaker. Dilute to about 100mL using DI water.

6.14.2 Add a few drops of the p-dimethylaminobenzalrhodanine indicator solution.

6.14.3 Add a clean magnetic stir bar to the beaker and place the beaker + contents on the analytical balance; tare the balance.

6.14.4 Put the beaker + contents on a magnetic stir plate. Begin agitation.

6.14.5 Titrate with 0.0192N $AgNO_3$, adding dropwise, to the first change in color (i.e., from yellow to salmon). Reweigh the beaker + contents and record the weight change in the appropriate logbook (weight change equals amount of titrant added).

6.14.6 Titrate three replicate aliquots for each stock standard and average the results for each.

6.14.7 An aliquot of DI water (DI water blank) is also titrated according to the procedure described above.

6.14.8 Use the average result obtained for each stock standard to calculate the CN concentration as follows:

$$\text{mg } CN^- / L = \frac{(A - B) \times 1000^*}{C}$$

where:

A = mL standard 0.0192N $AgNO_3$ required for aliquot of stock

B = mL standard 0.0192N $AgNO_3$ required for DI water blank

C = mL CN- stock standard titrated**

* NOTE: 1.0mL 0.0192N $AgNO_3$ = 1.0mg CN^-

** (C = 10.0mL, if this SOP is followed without deviation)

6.14.9 The titration verification must yield results within ±2% (i.e., between 980 and 1020mg/L CN) in order for the stock standards to be acceptable. If this criterion is not met, the stock standards must be remade.

6.15 Intermediate potassium cyanide standard solution, 10mg/L: Add 1.00mL of 1000mg/L cyanide stock solution to 99.00mL of 0.25N NaOH. ***Store in a refrigerator (4±2°C).*** *Shelf Life = 3 months.*

NOTE: ***Prepare intermediate potassium cyanide standards from both of the first and second source stock KCN standard solutions. The first source 10mg/L intermediate potassium cyanide standard solution is used to spike the MS/MSD samples and to create the low and high distillation check standards. The second source 10mg/L intermediate potassium cyanide standard solution is used to prepare the ICV standard.***

6.16 See Section 8 for directions for making the daily working calibration standards.

6.17 Chloramine-T solution: Dissolve 1g of chloramine-T in 100mL of DI water. *Prepare fresh each day of use.* ***Refrigerate until ready to use****.*

6.18 Pyridine-barbituric acid solution: Place 7.5g of barbituric acid in a graduated container (i.e., marked at 125mL) and add a minimal amount of DI water necessary to wash the sides of the flask and wet the barbituric acid. Add 37.5mL of pyridine and mix. Add 7.5mL of concentrated HCl, mix and cool to room temperature. Dilute to 125mL with DI water and mix. ***Store in an amber glass bottle and refrigerate.*** *This reagent is stable for about 6 months; if a precipitate forms on the bottom of the container, discard and prepare fresh reagent*

6.19 Methyl red indicator: Used in the determination of weak and dissociable cyanide. Dissolve 0.10g methyl red sodium salt in 100mL of DI water. Shelf Life = 1 year.

6.20 Acetic acid solution, 1:9: Used in the determination of weak and dissociable cyanide. Mix 1 volume of glacial acetic acid with 9 volumes of DI water. Shelf Life = 1 year.

6.21 Acetate buffer: Used in the determination of weak and dissociable cyanide. Dissolve 41.0g sodium acetate trihydrate ($NaC_2H_3O_2 \bullet 3H_2O$) in 50mL DI water. Add glacial acetic acid (approximately 50mL) to yield a solution of pH 4.5. Shelf Life = 1 year.

6.22 Zinc acetate solution, 100g/L: Used in the determination of weak and dissociable cyanide. In a 100mL volumetric flask, dissolve 10g zinc acetate, $Zn(C_2H_3O_2) \bullet H_2O$, and bring to full volume with DI water. Shelf Life = 1 year.

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIME

7.1 All samples should be collected according to an approved sampling plan.

7.2 Plastic or glass containers may be used.

7.3 Oxidizing agents, such as chlorine, decompose most cyanide forms. To determine whether oxidizing agents are present, test a drop of sample with KI-starch indicator paper. A blue color indicates the need for treatment. To treat, add 0.1N sodium arsenite ($NaAsO_2$) solution, a few mL at a time, until a drop of sample produces no color on the KI-starch indicator paper. Add an additional 5mL of the 0.1N $NaAsO_2$ solution per each liter of sample. Ascorbic acid can be used as an alternative, although it is not as effective as sodium arsenite. Add a few crystals of ascorbic acid at a time (gently swirl after each addition), until a drop of sample produces no color on KI-starch indicator paper. Then add an additional 0.5g of ascorbic acid powder per each liter of sample volume.

7.4 Aqueous samples must be preserved by adding 2mL of 10N NaOH per L of sample volume (Method EPA 335.2) or sufficient 50% NaOH solution (Methods SW9010B and SM4500-CN B) until the pH of the sample is equal to or greater than 12 at the time of collection.

Carbonate in high concentration may affect the distillation procedure by causing the violent release of carbon dioxide with excessive foaming when reflux-distilled under acid conditions, thereby causing the pH of the absorption solution to be reduced. Calcium hydroxide (CaOH) should be used in lieu of NaOH to preserve samples suspected to contain significant carbonate amounts.

7.5 Samples should be kept cool (i.e., 4±2°C).

7.6 To meet Paragon holding time requirements, analyses must be completed within 14 days of sample collection.

8. PROCEDURE

8.1 EXTRACTION PROCEDURE FOR SOLID SAMPLES - Method SW9013

8.1.1 EXCEPTIONS

8.1.1.1 If the sample is a homogeneous fluid or slurry that does not separate or settle in the distillation flask when agitated but mixes so that the solids are entirely suspended, then the sample may be analyzed directly (per Method SW9010B) without an extraction step.

8.1.1.2 The sample may be analyzed directly (without extraction) per Method SW9010B if it is known to contain 50µg/g cyanide or greater. Direct preparation for analysis can be accomplished by placing 1g of sample in the distillation flask and diluting to 50mL with 0.25NaOH.

8.1.2 Samples that contain free water may be filtered and separated into aqueous and solid components. The non-aqueous component may then be extracted and an aliquot of the extract combined with an aliquot of the filtrate in proportion to the composition of the sample (see Method SW9013, Section 7.0 for details). Alternately, the components may be analyzed separately with cyanide concentrations reported for each component.

8.1.3 The solid sample preparation procedure outlined below must be followed for clients requesting SW9013 - Cyanide Extraction Procedure for Solids and Oils. If Method SW9013 preparation for solid samples is not specified, the direct analysis alternative procedure (i.e., 1.0g sample added directly to the Midi-Dist™ apparatus as provided for in the Section 7.0 of the CLP SOW ILMO4.0) may be followed.

8.1.3.1 Place 10g of representative solid sample into a clean, labeled 250mL disposable centrifuge tube.

8.1.3.2 Prepare a method blank (MB) by placing 10g clean sand into a clean, labeled 250mL disposable centrifuge tube.

8.1.3.3 Add 195mL DI water and 5mL of 10N NaOH to each centrifuge tube.

NOTE: If heavy grease is present, 20mL of reagent grade n-hexane may be substituted for 20mL DI water in order to prevent an emulsion from forming.

8.1.3.4 Cap tube and shake for 1 minute. Check pH using indicator paper.

8.1.3.5 If pH <12, add 10N NaOH dropwise until pH is at least 12. Recap tube and shake for 1 minute. Check pH. Repeat this step as necessary until pH does not drop.

8.1.3.6 Place sample tubes into a 2L plastic jar(s) so that they can be placed onto the rotary tumbler. Extract by tumbling for 16 hours.

8.1.3.7 Centrifuge tubes at 3500rpm for 15 minutes or filter the extract using the vacuum pump, buchner funnel and glass fiber filter setup.

8.1.3.8 Proceed with pretreatment for cyanides amenable to chlorination (Section 8.3) or proceed with the distillation and analysis of weak and dissociable cyanide (Section 8.5) or proceed directly with total cyanide analysis (Section 8.4), as applicable.

8.2 VERIFICATION OF AQUEOUS SAMPLE pH

Test the pH of each aqueous field sample by using a clean disposable transfer pipet to place a drop of aliquot onto a piece of pH test paper. Compare the paper's color to the pH packet's color standard chart and determine the sample's pH. Record result on LIMS benchsheet. The sample pH must be 12 or greater. If not, consult with the Project Manager for client direction as to how to proceed.

8.3 PRETREATMENT FOR CYANIDE AMENABLE TO CHLORINATION

8.3.1 Because cyanides amenable to chlorination is determined by subtracting the sample's total cyanides result from the amenable cyanides result, two identical sample aliquots are required to determine cyanides amenable to chlorination. Prepare two 50mL sample aliquots (or sample aliquots diluted to 50mL with DI water), into two labeled 100mL disposable beakers. *Only one of the sample aliquots is subjected to alkaline chlorination.*

A chlorinated batch <u>duplicate</u> (DUP) must also be prepared. Choose one sample per batch of twenty and prepare another 50mL aliquot for alkaline chlorination for that sample.

8.3.2 Dispense 50mL of DI water into a labeled 100mL disposable beaker to serve as the <u>method blank</u> (MB).

<u>NOTE</u>: ***The following procedures must be performed under incandescent light only because $K_3[Fe(CN)_6]$ may decompose under fluorescent light causing a false positive response for cyanide amenable to chlorination. For this reason and because of the possibility of toxic***

gases being evolved, this procedure must be performed in a fume hood.

8.3.3 Place a Teflon™-coated magnetic stir bar into each beaker to be subjected to alkaline chlorination, put the beakers on a stir plate and begin gentle agitation.

8.3.4 Add calcium hypochlorite solution dropwise (while maintaining a pH between 11 and 12 by adding 10N NaOH dropwise) until an excess of chlorine is present -- indicated by KI-starch paper turning blue upon testing. Maintain an excess of chlorine for one hour while gently agitating the sample continuously. Periodically test for excess chlorine with KI-starch paper and add additional calcium hypochlorite as necessary.

Also, periodically test pH using pH test paper to ensure that a pH between 11 and 12 is maintained; add 10N NaOH dropwise as necessary.

8.3.5 After one hour, add 0.05g portions of ascorbic acid until the KI-starch paper shows no residual chlorine (i.e., does not turn blue). Add 0.05g of excess ascorbic acid to ensure the presence of excess reducing agent.

8.3.6 Distill each chlorinated sample aliquot (along with the other aliquot of sample that was not subjected to alkaline chlorination) per Section 8.3 below.

Following spectrophotometric determination, the difference of cyanide content in the unchlorinated sample aliquot minus that of the chlorinated sample aliquot is the amount of cyanide amenable to chlorination for that sample.

8.4 DISTILLATION (TOTAL AND AMENABLE CYANIDE)

8.4.1 One method blank and one sample duplicate were prepared per each batch of twenty samples subjected to alkaline chlorination.

One sample duplicate must also be prepared for total cyanides by CLP SOW ILMO4.0. Select one sample per batch of twenty and dispense an additional aliquot to serve as the sample duplicate.

One method blank and one matrix spike/matrix spike duplicate (MS/MSD) set must be prepared for each batch of twenty samples to be distilled for total cyanide analysis. Sample volume permitting, select one sample per batch of twenty (aqueous or solid samples) and dispense two additional sample aliquots to serve as the basis for the

MS/MSD set. For solid samples not specified to be prepared by Method SW9013, weigh two 1.0g sample aliquots into two cyanide reflux tubes and add 0.25N NaOH to the 50mL marking for each to serve as the basis for the MS/MSD set.

To create a method blank for solid samples not specified to be prepared by Method SW9013 and/or solid samples processed via CLP SOW ILMO4.0, place 1.0g clean sand into a separate labeled cyanide reflux tube and fill with 0.25N NaOH to the 50mL marking.

8.4.2 Sample aliquots are tested for interferences and treated as needed. Sample aliquots are then distilled, followed by color development and measurement using a spectrophotometer.

8.4.2.1 Sulfide Test To test for the presence of sulfide interfering compounds in the sample, use a clean disposable transfer pipet to place a drop of sample on a piece of lead acetate paper. If the paper's color turns black, the presence of sulfide interference is indicated and the sample needs to be treated. Record the sulfide test result on the LIMS benchsheet.

For each sample yielding positive sulfide interference test results, add 1mL of 0.062M bismuth nitrate solution to each dispensed aliquot. Add a Teflon™-coated magnetic stir bar to the beakers, transfer to a stir plate, and carefully mix for about three minutes. Repeat the lead acetate paper test.

Add additional bismuth nitrate solution, mix and repeat the lead acetate paper test as necessary until all sulfide interferences are removed.

8.4.2.2 Oxidizing Agent Test To test for the presence of oxidizing agents in the sample, use a clean disposable transfer pipet to place a drop of sample on a piece of KI-starch indicator paper. A blue color indicates the presence of oxidizing agent interference and the need for sample treatment. Record the oxidizing agent test result on the LIMS benchsheet.

For each sample yielding positive oxidizing agent interference test results, add 0.05g ascorbic acid to each dispensed aliquot. Add a Teflon™-coated magnetic stir bar to the beakers, transfer to a stir plate, and carefully mix for about three minutes. Repeat the KI-starch indicator paper test.

Add 0.05g increments of ascorbic acid and repeat the KI-starch indicator paper test as necessary until a drop of aliquot produces no color on the KI-starch indicator paper. Then add an excess of 0.05g of additional ascorbic acid.

8.4.3 Place each prepared sample aliquot, including chlorinated sample aliquots, method blanks, duplicates and MS/MSDs, into separate, labeled cyanide reflux tubes.

8.4.4 Spike all the MS/MSD aliquots with 0.5mL of **first source** 10mg/L intermediate potassium cyanide standard solution. Expected concentrations for the MS/MSD samples is 0.10mg/L CN (aqueous samples), 5.0mg/Kg CN (solid samples)

8.4.5 Paragon prepares both high and low distilled standards with each batch of cyanide samples processed as a check of the effectiveness of the distillation procedure. Concentrations of these distilled standards are compared to similar values on the calibration curve to ensure that the distillation technique is reliable.

Prepare the aqueous and Method SW9013 extract low (0.2mg/L) and high (0.4mg/L) distillation standards (which also serve as the laboratory control samples, LCSs) by pipetting 1.0mL and 2.0mL of the **first source** 10mg/L intermediate potassium cyanide standard solution, respectively, into separate, labeled cyanide reflux tubes. Dilute to the 50mL mark with 0.25N NaOH.

To create the low (5.0mg/Kg CN) and high (20.0mg/Kg CN) distillation standards for solid matrices prepared by CLP SOW ILMO4.0, add 1.0mL and 2.0mL of the first source 10mg/L intermediate potassium cyanide standard solution to two separate 1.0g aliquots of clean sand placed into separate, labeled cyanide reflux tubes. Dilute to the 50mL mark with 0.25N NaOH.

NOTE: Additional distilled quality control samples (e.g., independent calibration verification standard, ICV) may be required based on client request. A distilled ICV is required by CLP SOW ILMO4.0 protocol.

To prepare the ICV for distillation, pipet 0.5mL of **second source** 10mg/L intermediate potassium cyanide standard solution into a labeled cyanide reflux tube and dilute to the 50mL mark with 0.25N NaOH. The expected concentration of this ICV standard is 0.10mg/L CN.

In addition to the distilled ICV, CLP SOW ILMO4.0 protocol requires that a reference soil sample with certified CN^- concentration be analyzed with each sample batch. A 1.0g aliquot of this reference soil (brought to the 50mL mark with 0.25N NaOH) is distilled and analyzed.

8.4.6 To all prepared aqueous sample or aqueous extract aliquots, add 1.0g of clean Ottawa sand. The clean sand is used in lieu of Teflon™ boiling chips; on-going successful Performance Testing (PT) analysis results show no adverse impact to method performance. The sand is not reused. No ottawa sand needs to be added to prepared field or quality control samples already containing 1.0g of soil or ottawa sand.

8.4.7 Add 50mL of 0.25N NaOH to each gas absorber tube.

8.4.8 Connect the reflux impingers, absorption impingers and cold fingers. Recheck all fittings.

8.4.9 Turn on the cooling water and adjust the flow rate indicated on the flow meter to 60GPH across the Midi-Dist™ unit.

8.4.10 Turn on the vacuum and adjust the valve until the level of bubbles in the gas absorber tube at each station is about 12cm above the 50mL mark.

8.4.11 If a sample is known or suspected to contain nitrate or nitrite, or if the sample aliquot was treated with bismuth nitrate to remove sulfide interferences, add 5mL of 0.4N sulfamic acid through the air inlet tube. Allow to mix for about three minutes.

8.4.12 Use a pre-calibrated repeat pipettor to slowly inject 5mL of 50% (v/v) H_2SO_4 solution through each air inlet. Wait approximately 5 minutes while the acid mixes with the sample.

Sufficient acid must be added to bring the sample solution pH to <2. Very basic or highly buffered samples may require additional acid.

Add an additional 3mL of 50% (v/v) H_2SO_4 solution or check the pH if the sample aliquot's pH is suspect.

8.4.13 To control excessive foaming during distillation, add 51% MgCl2 solution to the sample through the air inlet, as needed.

8.4.14 Turn on the heating block (red switch). This will heat the block to 123-125°C. Adjust the timer to 105 minutes. The timer will automatically turn off the block heater.

8.4.15 After the heaters have turned off, allow the unit to cool 15 minutes (continue the vacuum).

8.4.16 Lift the fritted absorber impinger from the absorption tube. Disconnect the absorber-to-reflux connection. Disconnect the absorption impinger from the vacuum. Repeat for all Midi-Dist™ stations.

8.4.17 Turn off the vacuum valve.

8.4.18 Seal the absorber tubes and store at 4±2 °C until colorimetric development and analysis. Make sure each tube is properly labeled with sample identity.

8.4.19 Disconnect the Midi-Dist™ glassware and clean the distillation apparatus per the manufacturer's instructions.

8.5 DISTILLATION (WEAK AND DISSOCIABLE CYANIDE) - METHOD SM 4500-CN I

The distillation for weak and dissociable cyanide is carried out under *slightly* acidic (pH 4.5 - 6.0) conditions. Preparative steps such as checking pH, checking for interferences, preparation of quality control samples, staging aliquots in CN reflux tubes, and other set-up procedures are conducted as described in the previous Sections. Continue by following the distillation procedure outlined in Section 8.4 above with the following exceptions:

8.5.1 Do not add sulfamic acid solution because NO_2^- and NO_3^- do not interfere.

8.5.2 Do not add H_2SO_4 or $MgCl_2$, instead, add 1mL each of the acetate buffer and zinc acetate solutions, followed by 2-3 drops of methyl red indicator.

8.5.3 Rinse the air inlet tube with DI water and allow the air to mix the reflux tube's contents. If the solution is not pink, add 1:9 acetic acid dropwise through the air inlet tube until a pink color persists.

8.5.4 Complete the distillation as described in Section 8.4 above, with the exception that the pH of the samples do not need to be checked following distillation.

8.6 MANUAL SPECTROPHOTOMETRIC DETERMINATION

A series of calibration standards are prepared then developed colorimetrically. Absorbance at 578nm is read on a spectrophotometer. A standard curve is then calculated by plotting the absorbance for each standard vs. the standard's concentration.

8.6.1 Standard Curve Use 0.25N NaOH to prepare the calibration standards (made each day of use) in optically matching 1-inch diameter spectrophotometer cuvettes as described in the chart below.

Standard Concentration (mg/L)	Volume of 10 mg/L Intermediate Standard (mL)	Final Volume[ii] (mL)
0	0	10
0.01	0.010	10
0.05	0.050	10
0.10	0.10	10
0.20 (CCV)[i]	0.20	10
0.30	0.30	10
0.40	0.40	10
0.50	0.50	10
0.10 (ICV)[iii]	0.10	10

[i] From first source 10mg/L intermediate potassium cyanide standard solution.

[ii] Note that calibration standards are prepared directly in 1-inch, optically matched cuvettes.

[iii] From second source 10mg/L intermediate potassium cyanide standard solution.

8.6.2 Standard Curve for Samples Containing Sulfide Per all method references, the method of standard additions (MSA) must be used for the analysis of all samples that suffer from matrix interferences (e.g., samples that contain sulfides). MSA is not required where interferences have been successfully removed during pretreatment. Details regarding MSA performance are provided in Method SW9014 (Section 7.4) and Method EPA 335.2 (Section 8.9).

8.6.3 Color Development and Absorbance Measurements

NOTE: The steps below *must* be performed in a fume hood.

8.6.3.1 For each distilled sample, pipet 10mL of scrubber solution (contained in the sealed absorber tube) into a pre-labeled 1-inch diameter, optically matched spectrophotometer cuvette.

8.6.3.2 Color development and absorbance measurements are performed in the following sequence:

1. 0.00 mg/L cal std

2. 0.01 mg/L cal std
3. 0.05 mg/L cal std
4. 0.10 mg/L cal std
5. 0.20 mg/L cal std
6. 0.30 mg/L cal std
7. 0.40 mg/L cal std
8. 0.50 mg/L cal std
9. ICV
10. ICB (calibration blank)
11. Preparation blank (distilled method blank)
12. LCS (distilled standards low and high; followed by the known reference material)
13. MS
14. MSD
15. Chlorinated amenable cyanide sample duplicate

16-22 up to six field samples.

23. CCV (0.20 mg/L calibration standard, 1st Source)
24. CCB (calibration blank)
25. up to ten more field or QC samples, then CCV, CCB (repeated until all samples are analyzed)

NOTE: No more than ten field or QC samples may be analyzed between the ICV/ICB and first CCV/CCB set, or between successive CCV/CCB sets. A CCV/CCB set must close out the run sequence.

8.6.3.3 Add 3.0mL of 1M NaH_2PO_4 buffer solution to each cuvette.

NOTE: After this solution is added, the cyanide in the sample is no longer stable and the color development steps must be continued without delay.

8.6.3.4 Add 1.0mL of chloramine-T reagent to each cuvette and mix well.

8.6.3.5 After 1 to 2 minutes, add 1.0mL of pyridine-barbituric acid and 5.0mL of DI water; mix well immediately.

NOTE: All spectrophotometer checks must be performed per manufacturer's instructions prior to use.

8.6.3.6 After the red color has fully developed (usually about 8 to 15 minutes), read absorbance at 578nm using the spectrophotometer. Establish an instrument range from 0 to 100 % T or 0.00 to 2.000 absorbance.

8.6.4 Plotting the Standard Curve Prepare the standard curve by plotting the absorbance of each standard versus the standard's cyanide concentration (mg/L). This may be done using a spreadsheet program on a personal computer. Proceed with standard curve evaluation and calculations as described in the following Section.

8.7 CALCULATIONS

Perform a linear regression analysis of the plotted standard curve. The regression equation for the standard curve must have a correlation coefficient (r^2) that is $\geq$ 0.995. If this criterion is not met, check the standards preparation data, plotting and computation for errors. If no errors are found, the calibration standards can be rerun. If the criterion is still not met, the analysis must be halted, new calibration standards prepared, and a new calibration curve generated.

8.7.1 Calculate the cyanide concentration in aqueous samples as follows:

$$\text{Concentration of CN (mg/L)} = A \times D$$

where:

A = mg/L of CN in distillate as determined from the regression analysis

D = dilution factor (if dilution was necessary to produce a response within the calibration range)

8.7.2 Calculate the cyanide concentration in solid samples as follows:

$$\text{Concentration of CN (mg/Kg)} = \frac{A \times D \times V}{W \times E}$$

where:

A = mg/L of CN in distillate as determined from the regression analysis

D = dilution factor (if dilution was necessary to produce a response within the calibration range)

V = volume of distillate solution (liters); if this SOP is followed exactly, V = 0.050 L

W = wet sample weight (g)

E = correction factor for moisture content (i.e., % solids/ 100, as determined per SOP 642)

8.7.3 Once the concentration of total cyanide and amenable cyanide have been determined via the calculations shown above, the concentration of cyanide amenable to chlorination can be determined as follows:

Concentration CN Amenable to Chlorination	=	Concentration of Total CN (Unchlorinated aliquot)	-	Concentration of Total CN (Chlorinated aliquot)

9. QUALITY CONTROL (QC)

9.1 BLANKS

One preparation (i.e., method blank) per type of matrix analyzed must be carried through the entire preparation, reflux-distillation and analytical processes to determine if any contamination or memory effects are occurring. For this procedure, the preparation blank consists of DI water only (aqueous samples) or DI water + clean sand (solid matrix samples not processed by Method SW9013 extraction). A clean sand (+ 50mL DI water) solid matrix method blank is prepared and processed during the Method SW9013 extraction procedure. No blank may yield positive results greater than the analyte reporting limit (usually 0.01mg/L CN; 0.50mg/Kg CN). If this criterion is exceeded, the analyst should determine the cause of the problem, correct it and reanalyze the sample batch.

9.2 SPIKE RECOVERIES

Laboratory control samples (LCSs) consist of clean matrices (i.e., DI water or clean sand), which are spiked with a known amount of target compound. In some cases (e.g., CLP SOW ILMO4.0), pre-spiked reference samples are commercially available for use. LCS analyses are performed to evaluate the accuracy of the analytical system.

Matrix spike (MS) samples consist of additional sample aliquots, which are spiked with a known amount of target compound. MS analyses are performed to determine the effect of sample matrix interferences.

Spiked samples are evaluated based on percent recovery (%R), which is a calculation of the amount of target analyte yielded vs. the amount of target analyte anticipated. The following equation is used to calculate spike recovery:

$$\%R = \frac{Concentration_{Found} - Concentration_{Aliquot}}{Concentration_{Anticipated}} \times 100$$

where:

$Conc_{Found}$ = amount of target analyte yielded by the spiked analysis

$Conc_{Aliquot}$ = amount of target analyte found in the *unspiked* aliquot (i.e., "zero" for clean LCS matrix aliquots; or concentration of target analyte calculated to be present in the unspiked sample matrix aliquot)

$Conc_{Anticipated}$ = amount of target analyte expected to be yielded based on known amount spiked

The spiked LCS results should agree within ±15% of the anticipated value for aqueous samples (i.e., 85-115 % recovery), and within vendor-specified limits for solid reference samples. *Note that other acceptance criteria may be applicable as requested by the client.* The advisory control limits for the matrix spiked analyses are set at 75-125% recovery.

If established spike recovery quality control criteria are not met, check all calculations and spike preparations for errors. If no errors are found, the sample batch must be reanalyzed for LCS exceedances. Narrate if sample matrix interference is suspected as the cause of MS (or MSD) exceedance.

9.3 DUPLICATE PRECISION

A sample duplicate is prepared for amenable cyanide determinations and for cyanide analyses per CLP SOW ILMO4.0 protocol. Also, generally the matrix spike sample is prepared and analyzed in duplicate. Duplicates are analyzed to measure analytical precision. Precision is evaluated in terms of Relative Percent Difference (RPD), which is calculated as follows:

$$RPD\ (\%) = \frac{|\ Result_{Sample} - Result_{Dup}\ |}{\frac{(Result_{Sample} + Result_{Dup})}{2}} \times 100$$

Generally, an RPD of ≤20 is set as the quality control limit. This RPD limit is not applicable for matrix spiked duplicates whose native (i.e., unspiked) concentration of target analyte is greater than 5X the analyte's reporting limit.

If the RPD quality control criterion is not met, check all calculations and spike preparations for errors. Consult with the Department, Project and Quality Assurance Managers if the RPD criterion is not met for duplicates. Narrate if sample matrix interference is suspected as the cause of the RPD limit not being met for an MS/MSD set.

9.4 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall be conducted in the manner prescribed by the method (e.g., per defined spike levels, etc.) and shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study shall be performed as needed and at a minimum, annually.

10. DEVIATIONS FROM METHODS

10.1 Note that Paragon utilizes a Midi-Dist™ apparatus for distillation in lieu of a round bottom flask setup.

10.2 Section 7.7 of Method SW9013 describes the use of 50% NaOH (added in 5mL increments as needed) to maintain a pH of 12 or greater during the extraction of cyanide in solid and oil matrices. Instead, this SOP prescribes the addition of 10N NaOH dropwise to achieve adequate pH adjustment.

10.3 Section 4.1 of Method EPA 335.1 and Section 7.1.2 of Method SW9010B describe the use of 1.25N NaOH to maintain a pH between 11 and 12 during the chlorination process for cyanides amenable to chlorination. Instead, this SOP prescribes the addition of 10N NaOH dropwise to achieve adequate pH adjustment.

10.4 Section 7.1.4 of Method SW9010B discusses the use of sodium arsenite to remove all residual chlorine after the amenable cyanide chlorination process. As described in Section 4.3 of Method EPA 335.1, Paragon uses ascorbic acid to neutralize all residual chlorine generated in the amenable cyanide chlorination process.

10.5 Section 8.0 of Method EPA 335.2 and Section 7.2.1 of Method SW9010B indicate that 1.25N NaOH is to be used as the reflux scrubber solution. Paragon utilizes 0.25N NaOH as the reflux scrubber solution. Successful Proficiency Test (PT) sample studies show that this practice does not impair sample results.

10.6 Per Section 8.8 of Method EPA 335.2, 1.25N NaOH is used in the creation of working cyanide standards; 1N NaOH is used in the creation of working cyanide standards per Sections 5.3.7 of Method SW9014. Paragon uses 0.25N NaOH to create the working cyanide standard solutions. This provides for the same matrix as the distillates that are trapped in 0.25N NaOH.

10.7 To remove sulfide interferences, Section 8.2 of Method EPA 335.2 describes the addition of lead acetate to the reflux scrubber and Section 4.2 of the CLP SOW ILMO4.0 discusses the use of powdered cadmium carbonate. Per Method SW9010B (Sections 3.3 and 7.2.3), this SOP prescribes the use of 0.062M bismuth nitrate solution to remove sulfide interferences.

10.8 The referenced methods discuss addition of sulfamic acid powder to the sample prior to distillation for the removal of nitrate/nitrite interferences. To provide for better delivery into the Midi-Dist™ system, Paragon uses a 0.4N sulfamic acid solution instead.

10.9 The referenced methods describe the use of Teflon™ boiling chips during the distillation process. Paragon uses 1.0g of clean silica sand in lieu of boiling chips. On-going successful Performance Testing (PT) performance has shown no adverse impact to method performance.

10.10 Section 8.7.1 of Method EPA 335.2 and Section 7.2.2 of Method SW9014 cite the addition of 2mL chloramine-T reagent and 5mL pyridine-barbituric reagent during the color development process (Paragon uses 1mL each because smaller volumes are developed colorimetrically). Also, Section 7.2.2 of Method SW9014 discusses using KI-starch paper to test for excess chlorine following the addition of the 2mL chloramine-T reagent, with additional increments of 0.5mL chloramine-T added until chlorine residual is achieved and with a final excess of 0.5mL chloramine-T added. Paragon does not test for chlorine residual. The generation of successful Proficiency Test (PT) sample results have shown that these practices do not adversely affect sample results.

10.11 Section 8.8.2 of Method EPA 335.2 and Section 8.6 of Method SW9010B recommended that at least two standards (a high and a low) be distilled and compared to similar values on the curve to ensure that the distillation technique is reliable. Both method references state that if the distilled standards do not agree within ±10% of the undistilled standards, the analyst should find the cause of the apparent error before proceeding. It is Paragon's policy (per Section 8.3 of Method SW9010B and Section 7.2.2.1 of the CLP SOW ILMO4.0), that the distilled check standards must yield values within ±15% of the expected value. It is Paragon's interpretation that the conflicting criterion given in Method SW9010B (Section 8.6 vs Section 8.3) be resolved in favor of the looser ±15% criterion.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples),

handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids). All flammable compounds must be kept away from ignition sources.

11.1.5 The cyanide standard solution preparations, distillations, and color development processes shall be handled/conducted only in a properly functioning fume hood.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The basic scrubber solution and all remnants from the color development process shall be disposed of in the Aqueous Laboratory Waste Satellite collection vessel.

11.2.2 The acidified distillate remnants shall be disposed of in the Acidic Aqueous Laboratory Waste Satellite collection vessel.

11.2.3 Any solid residues are to be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

11.2.4 All empty solvent bottles or reagent are to be disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.5 Certain clients may require the return of their sample remainders. The Waste Compliance Officer will provide specific procedures and materials for these handling these sample remainders where return to the client applies.

DOCUMENT REVISION HISTORY

2/9/04: Updated format.

8/25/04: Separated out Drinking Water procedures and added reference Program Specification directive in "Responsibilities".

4/10/06: Updated controlled form benchsheet references to LIMS. Added DOCUMENT REVISION HISTORY.

7/5/06: Augmented "Interferences" to address difficulties with amenable cyanide analysis in soils.

1/19/07: Section 6 changes: Shelf-life of magnesium chloride solution changed from 5yrs to 1 year; stock potassium cyanide standard needs standardized only when made. Section 8 changes: Since it is not required by any referenced method, the directive to check pH after distillation has been removed.

Analytical Method: SW 9010B, 9013, 9014; E 335.1, 335.2; OLMO4.0; SM4500-CN I	**Parameter:** Total and Amenable Cyanide by Distillation; Weak and Dissociable Cyanide		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 7-point (plus blank)	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$ 0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze calibration standards. If quality control acceptance criterion still not met, analyses cannot proceed; a new suite of calibration standards must be prepared and analyzed. Analyses cannot proceed until an acceptable initial calibration curve is generated.
Independent Calibration Verification (ICV); second source standard; at or below midpoint	Once after each initial calibration	Results must agree within $\pm$15% of corresponding value generated by the initial calibration	If QC criterion not met, prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); first source; at or below midpoint	Run to bracket a set of 10 analyses, and to end any run sequence (must be followed by a CCB analysis)	Response must agree within $\pm$15% of corresponding value generated by the initial calibration	Check for preparation and calculation errors; evaluate/correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Blanks: Method (Preparation, MB) Also run as an Initial Calibration Blank (ICB) and Continuing Calibration Blanks (CCBs)	One method blank per batch of twenty or less environmental samples processed. ICB run immediately following calibration curve. CCB run following the CCV to bracket a set of ten analyses and to close a run sequence	CN content of the blank must be less than the analyte reporting limit (RL); RL usually 0.01mg/L CN; 0.50mg/Kg CN	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Distilled LCS (low and high distillation check standards)	One low and one high prepared and analyzed per batch of $\leq$ 20 field samples	Distilled LCS result must agree within ±15% of non-distilled ICV result	Check data for preparation or calculation errors. If no errors are found, the distillation of these standards and all associated samples in the batch must be repeated.
Distilled ICV; second source ICV subjected to reflux-distillation (run per CLP protocol and by client	Once per analytical run sequence	Distilled ICV result must agree within ±15% of non-distilled ICV result (see Section 10.0 - Deviations, of	If QC criterion not met, check for preparation errors or instrument malfunction. If distilled low and high LCS criteria also not met,

Analytical Method: SW 9010B, 9013, 9014; E 335.1, 335.2; OLMO4.0; SM4500-CN I	**Parameter:** Total and Amenable Cyanide by Distillation; Weak and Dissociable Cyanide		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
request); at or below midpoint		this SOP)	repeat distillation for all samples in batch.
Matrix Spike (MS) and Matrix Spike Duplicate (MSD)	One set prepared and analyzed per batch of ≤20 field samples	Recoveries should meet control limits of 75-125 % RPD between duplicates should be ≤20	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Sample Duplicate (DUP)	One prepared and analyzed per batch of ≤20 field samples.	RPD should be ≤20	For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/Project/QA Managers (narrate if sample matrix interferences are suspected as the cause of the RPD limit not being met for an MS/MSD set).
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL) and per procedures prescribed by the method	As needed; at a minimum annually	Positive result < the analyte reporting limit (RL)	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).

Must Discard 30 Days from _____ (date printed)

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1112 REVISION 5

TITLE: **DETERMINATION OF REACTIVE CYANIDE AND SULFIDE -- EPA METHOD SW846 CHAPTER 7**

FORMS: **NONE**

APPROVED BY:
TECHNICAL MANAGER Steve Workman DATE 4/12/06
QUALITY ASSURANCE MANAGER Deb Schenk DATE 4/11/06
LABORATORY MANAGER K Gillis DATE 4-12-06

HISTORY: Rev0, 6/2/97; Rev1, 4/6/01; Rev2, 8/15/02; Rev3, 2/13/04 and 3/25/05 (re-released without revision); Rev4, 7/26/05; Rev5, 4/10/06.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- USEPA SW846 Chapter 7 -- describe the determination of reactive cyanide and sulfide in solid and aqueous wastes. The data user should note that the USEPA has formally withdrawn their guidance and requirements for the performance of this method, as it is likely to underestimate the sample's potential to liberate free cyanide and sulfide under waste management conditions. No alternative procedure is being supported. Paragon informs our clients of this context in our reactivity data package case narratives.

2. SUMMARY

An aliquot of waste contained within a closed gas generation system is acidified to a low pH. Hydrocyanic acid (HCN) and hydrogen sulfide (H_2S) are released as gases from the acidified waste and are trapped in a basic scrubber solution. The amount of cyanide trapped by the scrubber solution is developed colorimetrically and measured by manual spectrophotometric determination (Method SW 9014 referenced). The amount of sulfide trapped by the scrubber solution is quantified by an iodometric titration (Method SW 9034 referenced).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training

review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/ analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated wit the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

Interferences are undetermined.

5. APPARATUS AND MATERIALS

5.1 GAS GENERATION AND TRAPPING SYSTEM

5.1.1 flasks, round bottom, three-neck with 24/40 ground glass joints, 500mL

5.1.2 gas scrubbers made from a 250mL side-arm flask and a one-hole stopper. A piece of plastic tubing that extends nearly to the bottom of the flask when the stopper is in place is inserted through the stopper. The other end of the plastic tubing connects to one neck of the round bottom flask by an elbowed gas inlet adapter with 24/40 ground glass joint.

5.1.3 addition funnels, 250mL, equipped with a pressure equalizing tube, and a stopcock valve possessing a 24/40 ground glass joint and Teflon™ sleeve. Connects to one neck of the round bottom flask.

5.1.4 nitrogen gas provided via two-stage regulation and with an in-line needle valve for controlling gas flow. Connected to addition funnel by an elbowed gas inlet adapter possessing a 24/40 ground glass joint.

5.1.5 gas flow meter

5.1.6 magnetic stir plates and 1.5" egg-shaped stir bars (Teflon™ coated)

5.1.7 top-loading (capable of weighing to 0.1g) and analytical (capable of weighing to 0.0001g) balances

5.1.8 volumetric graduated cylinders, 100, 250, 500mL and 1L sizes

5.1.9 beakers with lids, plastic, disposable, 100mL

5.1.10 ground glass stoppers, 20/40; connects to one neck of round bottom flask

5.1.11 volumetric flasks, glass, Class A, 100 and 500mL sizes

5.1.12 pressure clips for ground glass connections and round bottom holders

5.2 CYANIDE DETERMINATION EQUIPMENT

5.2.1 Sequoia-Turner, Model 340 spectrophotometer or equivalent

5.2.2 cuvettes, optically matched, 1-inch diameter, Bausch & Lomb or equivalent

5.2.3 pipets, variable, Eppendorf™ or equivalent, with disposable dispensing tips

5.2.4 vortex mixer

5.3 SULFIDE DETERMINATION EQUIPMENT

5.3.1 magnetic stir plate and magnetic stir bars (Teflon™ coated).

5.3.2 pH paper, narrow-range acidic or wide range (0-14), EMD, Cat. 1.09580 and Cat. 1.09590 or equivalents, or pH meter, Corning Model 320 or equivalent

5.3.3 top loading balance, capable of weighing to 0.01g

5.3.4 pipets, variable, Eppendorf™ or equivalent with disposable dispensing tips

5.3.5 beakers, Pyrex™, 150mL

6. REAGENTS

6.1 Deionized (DI) water, laboratory-generated.

6.2 Nitrogen gas, 0.99% or greater purity.

6.3 Sulfuric Acid, (H_2SO_4) Solution, 18N, 50% (v/v): EMD, SX1247-2 or equivalent. Carefully add 100mL concentrated H_2SO_4 to 100mL DI water (volume may differ as long as 1:1 ratio remains the same). *Shelf Life = 1 year.*

6.4 Sulfuric Acid (H_2SO_4) Solution, 0.01N: Add 1.0mL of 50% H_2SO_4 to DI water and dilute to 1800mL. Stopper and invert carefully several times to mix. *Shelf life = 1 year.*

6.5 Sodium Hydroxide (NaOH), 0.25N: JT Baker, 3722-07 or equivalent. Dissolve 10g NaOH in DI water and dilute to 1L. *Shelf life = 1 year.*

6.6 p-Dimethylaminobenzalrhodanine Indicator, reagent grade: Obtained from a commercial vendor or made in-house by dissolving 0.020g p-dimethylaminobenzal rhodanine (JT Baker, J431-02 or equivalent) in a final volume of 100mL acetone (spectral grade). *Shelf Life = 1 year.*

6.7 Standard Silver Nitrate ($AgNO_3$) Titrant, 0.0192N: Obtained from a commercial vendor or prepared in-house (JT Baker, J431-02 or equivalent). Use DI water to dissolve 3.2647g dried $AgNO_3$ and bring to full volume in a 1L Class A volumetric flask. *Shelf Life = 1 year.*

6.8 Sulfide Spiking Solution, approximately 4000mg/L sulfide: Dissolve 15.0g $Na_2S \bullet 9H_2O$ (GFS Chemicals, Item No. 1040 or equivalent) in DI water and bring to 200mL volume. Store in a refrigerator (4±2°C). *Shelf life = 1 year.*

6.9 The salt used in preparing the sulfide spiking solution is very hygroscopic and cannot be used as a primary standard. Therefore, an aliquot of sulfide spiking solution must be analyzed in order to determine the exact concentration of the prepared sulfide LCS. Standardize the sulfide spiking solution daily as needed as follows:

6.9.1 Place a 0.50mL aliquot of the sulfide spiking solution into a beaker and dilute to approximately 100mL using DI water. Add 2mL of 6N HCl, then add an additional 2mL 6N HCl.

6.9.2 Place the beaker on a balance and tare the balance. Add approximately 15mL of standardized standard iodine solution. The beaker's contents should be yellow. Record the weight change caused by the addition of the standard iodine solution. Add 2-4 drops of starch indicator. The beaker's contents should be dark blue. Tare the balance.

6.9.3 Titrate with standardized sodium thiosulfate solution. Continue to add sodium thiosulfate dropwise until the beaker's contents become clear. Record the total volume of sodium thiosulfate titrant used.

6.9.4 Compute the value as follows:

$$\text{Reactive Sulfide (mg/L)} = \frac{[(A \times B) - (C \times D)] \times 16{,}000}{S}$$

where:

A = normality of the iodine solution
B = volume of iodine solution used (mL)

C = normality of the sodium thiosulfate solution
D = volume of sodium thiosulfate used (mL)
S = volume of Sulfide Spiking Solution

6.10 Sodium Phosphate Monobasic (NaH_2PO_4) Solution (sodium dihydrogenphosphate solution), 1M: Dissolve 138g of $NaH_2PO_4 \bullet H_2O$ (GFS Chemicals, Item No. 735 or equivalent) in 1L of DI water. Store in a refrigerator (4 ± 2°C). *Shelf Life = 1 year.*

6.11 Chloramine-T solution: Dissolve 1g of chloramine-T (Mallinckrodt, 0614-58 or equivalent) in 100mL of DI water. *Refrigerate until ready to use; prepare fresh each day of use.*

6.12 Potassium Iodide, KI, reagent grade: JT Baker, 3162-01 or equivalent. *Shelf-life = 5 years.*

6.13 Hydrochloric Acid (HCl), 6N: JT Baker, 9530-33 or equivalent. Dilute 500mL concentrated HCl to 1L. *Shelf life = 1 year.*

6.14 Starch Indicator, 2 %: VWR, Cat. No. VW3638-2 or equivalent. *Shelf-life = 1 year or as stated by manufacturer.*

6.15 Standard Potassium Biiodate ($KH(IO_3)_2$) Solution, 0.025N: Dissolve 0.4062g of $KH(IO_3)_2$ salt (EM Science, PX1351-2 or equivalent) in 500mL of DI water. Store in polypropylene. *Shelf-life = 1 year.*

6.16 Sodium Thiosulfate ($Na_2S_2O_3$) Solution, approximately 0.025N: Dissolve 3.95g of $Na_2S_2O_3$ anhydrous (EM Science, SX0820-1 or equivalent) and 0.4gof NaOH in 1L of deionized water. Store in polypropylene. *Shelf-life = 1 year.*
Standardize against $KH(IO_3)_2$ once before use, as directed below:

6.16.1 Place 10.00mL standard potassium biiodate ($KH(IO_3)_2$) solution in a 200mL beaker.

6.16.2 Dilute to about 100mL with DI water.

6.16.3 Add approximately 2g of potassium iodide (KI) pellets.

6.16.4 Add 4-5 drops of 50% sulfuric acid (H_2SO_4).

6.16.5 Add 2-3 drops of starch indicator.

6.16.6 Tare the beaker + contents on a top loading balance.

6.16.7 Titrate with standard potassium biiodate solution on stirplate until the solution turns from blue to colorless.

6.16.8 Record the amount of titrant used.

6.16.9 Repeat three times and compute the average of the three replicates calculated as follows:

sodium thiosulfate conc (eq/L) = (0.025) *(10.00) / (V)

where:

V = volume of sodium thiosulfate required to reach endpoint

0.025 = normality of potassium biiodate solution titrated

10.00 = volume of potassium biiodate solution titrated

6.17 Pyridine-barbituric Acid Solution: Place 7.5g of barbituric acid in a graduated container (i.e., marked at 250mL) and add a minimal amount of DI water necessary to wash the sides of the flask and wet the barbituric acid. Add 37.5mL of pyridine and mix. Add 7.5mL of concentrated HCl, mix and cool to room temperature. Dilute to 180mL with DI water and mix. ***Store in an amber glass bottle and refrigerate. This reagent is stable for approximately 6 months.*** If a precipitate forms on the bottom of the container, discard and prepare fresh reagent.

6.18 Standard Iodine (I_2) Solution: Dissolve 25g of Potassium Iodide, KI (reagent grade) in 800mL of deionized water. Add 3.2g of iodine crystals and dissolve. Dilute to 1L with deionized water. Store in polypropylene. *Shelf-life = 1 year.* **Standardize against $Na_2S_2O_3$ daily before use as follows:**

6.18.1 Add approximately 100mL of deionized water and a stir bar to a clean plastic container.

6.18.2 Place the container + contents on a stir plate and cautiously add approximately 2.0mL of 6N HCL.

6.18.3 Place the container + contents on a top loading balance and tare the balance. Add approximately 2.5mL of standard iodine solution and record the weight to the nearest 0.01g in the laboratory logbook.

6.18.4 Add 2-3 drops of starch indicator and tare the balance again.

6.18.5 Place the container on a magnetic stir plate and titrate to a colorless endpoint using the standardized sodium thiosulfate solution.

6.18.6 Place the container and contents back on the balance and record the weight of the titrant used

6.18.7 Repeat three times and compute the average value, calculated as follows:

Iodine conc (eq/L) = (CTh) * (VTh) / (VI)

where:

CTh = concentration (eq/L) of sodium thiosulfate

VTh = volume of sodium thiosulfate required to reach endpoint

VI = volume of iodine solution titrated

7. PRIMARY AND INTERMEDIATE CYANIDE STANDARDS

7.1 Cyanide Stock Solutions, 1000mg/L cyanide, (first and second source): Dissolve 0.2504g Potassium Cyanide (KCN) salt into 100mL of 0.25N NaOH. **Store in a refrigerator (4 ± 2°C).** *Shelf life = 1 year.*

NOTE: Two stock solutions (one each) are prepared from two independent sources of KCN salt (i.e., "first source" and "second source").

7.2 Verify the concentration of each of the potassium cyanide stock solutions (i.e., first source and second source) when made, as follows:

NOTE: As referenced in Section 5.4.2 of SW846 9014, this titration standardization procedure is detailed in SM 4500-CN D.

7.2.1 Transfer 10.0mL of potassium cyanide stock solution to a 250mL beaker.

7.2.2 Dilute to about 100mL using DI water.

7.2.3 Add a few drops of the p-dimethylaminobenzalrhodanine indicator solution.

7.2.4 Add a clean magnetic stir bar to the beaker. Place the beaker + contents on the analytical balance and tare the balance.

7.2.5 Put the beaker + contents on a magnetic stir plate. Begin agitation.

7.2.6 Titrate with 0.0192N $AgNO_3$, adding dropwise, to the first change in color (i.e., from yellow to salmon). Reweigh the beaker + contents and record the weight change (weight change equals amount of titrant added).

7.2.7 Titrate three replicate aliquots for each stock solution and average the results for each.

7.2.8 An aliquot of DI water (DI water blank) is also titrated according to the procedure described above.

7.2.9 Use the average result obtained for each stock solution to calculate the CN concentration as follows:

$$\text{mg } CN^- / L = \frac{(A - B) \times 1000^*}{C}$$

where:

A = mL standard 0.0192N $AgNO_3$ required for aliquot of stock

B = mL standard 0.0192N $AgNO_3$ required for DI water blank

C = mL CN^- stock standard titrated**

* NOTE: 1.0mL 0.0192N $AgNO_3$ = 1.0mg CN^-

** C = 10.0mL, if this SOP is followed without deviation

7.2.10 The titration verification must yield results within ±2% (i.e., between 980 and 1020mg/L CN) in order for the stock solutions to be acceptable. If this criterion is not met, the stock solutions must be remade.

7.3 Intermediate Potassium Cyanide Standard solutions, 10mg/L: Dilute 5mL of 1000mg/L cyanide stock solution to 500mL with 0.25N NaOH. *Shelf Life = 3 months.* Store in a refrigerator (4±2°C).

NOTE: Prepare intermediate potassium cyanide standards from both of the first and second source stock CN standard solutions.

8. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

8.1 All samples must be collected according to an approved sampling plan.

8.2 Samples containing, or suspected to contain sulfide or a combination of sulfide and cyanide wastes, should be collected with minimum aeration and the containers filled completely, without headspace, and capped.

8.3 It is suggested that samples containing cyanide and/or sulfide wastes be tested as soon as possible.

8.4 Water samples can be preserved for reactive cyanide analysis by adjusting the sample to pH>12 using a strong base. Water samples can be preserved for the analysis of reactive sulfide by adding zinc acetate, and adjusting the sample pH to >9. It should be noted that the addition of preservatives dilutes the sample, increases the ionic strength, and possibly changes other physical or chemical characteristics of the waste. These changes may affect the rate of release of HCN or H_2S.

8.5 Samples should be stored under refrigeration in the dark until analysis.

9. PROCEDURE

9.1 GAS GENERATION AND TRAPPING

NOTE: Due to the evolution of hazardous gases, this procedure must be carried out under a ventilated fume hood.

9.1.1 Prepare one Method Blank (MB = 10.0g deionized water), one cyanide Laboratory Control Sample (LCS-CN = 10.0g of 1000ppm first source cyanide stock solution), one Sulfide Laboratory Control Sample (LCS-S = 5.0g of sulfide spiking solution, to a final weight of 10.0g with deionized water), and one sample duplicate (DUP) for each batch of 20 or less environmental samples.

9.1.2 Add 10.0g of sample to a round bottom flask.

9.1.3 Add 100mL of 0.25N NaOH to the side arm flask scrubber apparatus and assemble with stopper and tubes.

9.1.4 Add an egg-shaped stirbar to each flask and place the flask on a stir plate. Attach scrubber apparatus. Connect 250mL addition funnel with cock valve in off position and fill with 0.01N H_2SO_4. Place gas inlet tube in top of addition funnel. Place glass stopper in third opening of flask and attach pressure clips to ground glass connections in order to fully close system.

9.1.5 Turn on nitrogen gas and adjust the flow of nitrogen using the needle valve. Check the flow rate using a flow meter attached to the scrubber outlet. The flow rate should be about 60mL/min.

9.1.6 With the nitrogen flowing, add 250mL of 0.01N H_2SO_4 by opening the cock valve on the addition funnel. Begin stirring while the acid is being added. Adjust stir rate to achieve adequate stirring (the stirring should not be fast enough to create a vortex; the stirring speed must remain constant throughout the gas evolution process). Start the 30-minute gas generation period.

9.1.7 After 30 minutes, discontinue the nitrogen flow and disconnect the scrubber. Disassemble the apparatus in reverse order of set up. Transfer the trap solutions to labeled 100mL disposable beakers.

9.1.8 Determine the amounts of reactive cyanide and sulfide trapped in the scrubber solution as discussed in the following sections.

9.2 DETERMINATION OF CYANIDE IN THE SCRUBBER SOLUTION

9.2.1 CYANIDE CALIBRATION STANDARDS

Use 0.25N NaOH to prepare the cyanide calibration standards in optically matching 1-inch diameter spectrophotometer cuvettes as described below. *Calibration standards are made daily for each day of analysis*:

Standard Concentration (mg/L)	Volume of 10mg/L Intermediate Standard (first source) (mL)	Final Volume (mL)
0	0	10
0.01	0.010	10
0.05	0.050	10
0.10	0.10	10
0.20	0.20	10
0.30	0.30	10
0.40	0.40	10
0.50	0.50	10
0.10 (ICV)[i]	0.10	10

[i] From second source 10mg/L Intermediate Potassium Cyanide Standard Solution. ICV concentration is 0.10mg/L CN.

9.2.2 CYANIDE COLOR DEVELOPMENT AND ABSORBANCE MEASUREMENTS

- The steps below must be performed in a fume hood.
- Perform the color development and absorbance measurements in the following sequence:

(1) 0.00mg/L cal std
(2) 0.01mg/L cal std
(3) 0.05mg/L cal std
(4) 0.10mg/L cal std
(5) 0.20mg/L cal std
(6) 0.30mg/L cal std
(7) 0.40mg/L cal std
(8) 0.50mg/L cal std
(9) ICV (2nd Source; 0.10mg/L)
(10) ICB (calibration blank)
(11) Preparation blank (prepared method blank)

(12) LCS-CN

(13) DUP

(14-20) up to seven field samples

(21) CCV (0.20mg/L calibration standard, 1st Source)

(22) CCB (calibration blank)

(23-32) up to ten more field or QC samples, then CCV, CCB (repeated until all samples are analyzed)

- No more than ten field or QC samples may be analyzed between the ICV/ICB and first CCV/CCB set, or between successive CCV/CCB sets. A CCV/CCB set must close out the run sequence.
- Place a 10mL aliquot (in 0.25N NaOH matrix) of each prepared sample into a separate 1-inch diameter, optically matched spectrophotometer cuvette.

  NOTE: The LCS scrubber solutions will need to be diluted 40 fold prior to color development. This is accomplished by placing a 0.25mL aliquot of the LCS scrubber solution into a cuvette, and diluting it to 10mL with 0.25N NaOH.

- Add 3.0mL of 1M NaH_2PO_4 solution to each cuvette containing standard or prepared sample.

  NOTE: After this solution is added, the cyanide in the sample is no longer stable and the color development steps must be continued without delay.

- Add 1.0mL of chloramine-T reagent to each cuvette and mix well using the vortex mixer.
- After 1 to 2 minutes, add 1.0mL of pyridine-barbituric acid reagent and 5.0mL of DI water and mix well immediately.
- After the red color has fully developed (usually about 8 to 15 minutes), read absorbance at 578nm using the spectrophotometer. Establish an instrument range from 0 to 100 %T or 0.000 to 2.000 absorbance.

  NOTE: All spectrophotometer checks must be performed per manufacturer's instructions prior to use.

9.2.3 CYANIDE STANDARD CURVE PREPARATION

Prepare a standard curve by plotting the absorbance of each standard (on a scale of 0.00 to 2.00 units) versus the standard's cyanide concentration (on a scale of 0 to 500µg/L). Perform a linear regression analysis (Note: A spreadsheet program on a personal computer may be used for plotting and regression analysis.) The linear regression correlation coefficient must be ≥0.995 for the calibration curve to be accepted.

9.2.4 DETERMINATION OF REACTIVE CYANIDE SAMPLE CONCENTRATIONS

Determine the concentration of reactive cyanide in each sample as follows:

$$\text{Reactive CN (mg/Kg)} = \frac{(A) \times (D) \times (V)}{W}$$

where:

A = µg/L CN in scrubber solution, determined from regression analysis

D = dilution factor if dilution was required to produce a response within the calibrated range

V = volume of scrubber solution (L); if this SOP is followed exactly, V = 0.200 LW = sample weight (g)

9.3 DETERMINATION OF SULFIDE IN THE SCRUBBER SOLUTION

The amount of scrubber solution available to be analyzed by gravimetric titration for reactive sulfide must be accurately known. Usually 90mL of scrubber solution is available since 10mL of the 100mL total scrubber solution is used for the cyanide analysis. Determine the amount of reactive sulfide in each scrubber solution as follows:

9.3.2 Transfer an aliquot (usually 90mL) of the scrubber solution into a beaker of suitable size. Add a clean Teflon-coated magnetic star bar and place the beaker on a magnetic stir plate.

9.3.3 The scrubber solution must be acidified to a pH of 2 prior to proceeding with the titrimetric determination. Using pH electrode or pH test strips, add 2mL of 6N HCl to the trap solution and check the pH. Continue adding 6N HCl until the pH drops to below 2. Pipet an additional 2mL of 6N HCl into the trap solution.

9.3.4 Place the beaker of adjusted pH solution on the balance and tare. Add

standard iodine solution to the beaker in 2.0mL increments until a yellow color persists. Record the total volume (in mL) of the standard iodine solution added. Add 2-4 drops of starch indicator solution. The color should now be blue-black. Re-tare the balance.

9.3.5 Add Standard Sodium Thiosulfate Solution dropwise until the blue-black color disappears and the sample turns clear. Record the weight change caused by the addition of titrant.

9.3.6 Calculate the concentration of reactive sulfide in the sample as follows (Note: A spreadsheet program on a personal computer may be used for calculating concentrations):

$$\text{Reactive Sulfide (mg/Kg)} = \frac{[(A \times B) - (C \times D)] \times 16{,}000}{W \times \frac{V}{T}}$$

where:

A = normality of the iodine solution

B = volume of iodine used (mL)

C = normality of the sodium thiosulfate solution

D = volume of sodium thiosulfate used (mL)

W = sample weight (g)

V = volume of scrubber solution titrated

T = total volume of scrubber solution

10. QUALITY CONTROL (QC)

10.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or less field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory duplicate (DUP) and laboratory control sample (LCS). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

10.2 BLANKS

Blanks are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank (MB) must be processed. All blanks (including initial calibration blanks and continuing calibration blanks, as applicable), must be free of positive analyte results greater than the analyte reporting limit.

10.3 LABORATORY CONTROL SAMPLE
The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. The results obtained are compared to results expected. Acceptance criteria are based on client's requirements and are often quite wide (e.g., 0%-200%).

10.4 LABORATORY SAMPLE DUPLICATE
The laboratory sample duplicate is analyzed as a measure of the precision of the analytical results generated. For this procedure, the Relative Percent Difference (RPD) between a sample and its duplicate should not be greater than 20%. RPD is calculated as shown below:

$$\text{RPD (\%)} = \frac{|\text{Result}_x - \text{Result}_{Dup}|}{\frac{(\text{Result}_x + \text{Result}_{Dup})}{2}} \times 100$$

Advisory acceptance criteria for all duplicates should be met. If RPD criteria are not met, check calculations. Narrate if sample inhomogeniety is suspected.

10.5 METHOD DETECTION LIMIT STUDY
Not Required. *Reactive* cyanide is a process defined parameter, and as such no viable verification standard exists. The LCS employed here is a check of cyanide *measurement* capability and does not reflect the presence of cyanide in a potentially reactive state (i.e., MDL not relevant because preparatory extraction steps cannot be captured).

11. DEVIATIONS FROM METHOD

11.1 Section 5.4 of SW-846 Chapter 7 Reactive Cyanide discusses a check sample called a cyanide reference solution (made from KCN and KOH and standardized against $AgNO_3$). Paragon uses the cyanide stock solution (made from KCN and NaOH) to create the laboratory control (check) sample. This cyanide stock solution is standardized against $AgNO_3$.

11.2 Paragon creates a stronger sulfide reference solution (sulfide spiking solution) than that specified in Section 5.4 of SW-846 Chapter 7 Reactive Sulfide. The method directs that 4.02g of $Na_2S{\bullet}9H_2O$ is dissolved in and brought to a 1L final volume with reagent water. Paragon uses 15g of $Na_2S{\bullet}9H_2O$ brought to 200mL using DI water.

11.3 Section 7.1 of the SW-846 Chapter 7 Reactive Cyanide and Sulfide procedures direct that 50mL of 0.25N NaOH solution plus a sufficient amount of organic-free reagent water for adequate depth be used as the scrubber solution. Paragon uses 100mL of undiluted 0.25N NaOH for an adequate depth of scrubber solution.

11.4 Section 8 of the SW-846 Chapter 7 Reactive Cyanide and Sulfide procedures depict calculations to determine the *rate* of release of HCN or H_2S gas. Paragon measures the *amount* of HCN or H_2S gas released.

11.5 Paragon does not perform matrix spike analyses for reactive cyanide or reactive sulfide. These QC analyses are not stipulated in SW846 Chapter 7.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

12.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

12.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.5 All flammable compounds must be kept away from ignition sources.

12.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name; NFPA Health, Flammability, and Reactivity ratings, and date.

12.1.7 Food and drink are prohibited in all lab areas.

12.2 WASTE DISPOSAL

12.2.1 Solid residues shall be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

12.2.2 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

12.2.3 Certain clients may require that the samples and residues from their analyses be returned to them. The Waste Compliance Officer will address these sample returns.

DOCUMENT REVISION HISTORY

7/26/05: Added reference Program Specification directive in "Responsibilities".
4/10/06: Discussed in "Introduction" EPA's withdrawal of this method guidance. Added DOCUMENT REVISION HISTORY.

Analytical Method: EPA SW846, Chapter 7	**Parameter:** Reactive Cyanide and Sulfide in Wastes		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration - minimum 5-point plus blank (cyanide)	As needed (i.e., at on-set of analyses or repeated when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification - ICV (cyanide)	Once after each initial calibration	Response must agree within ±15% of initial calibration	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Method Blank (MB) Initial Calibration Blank - ICB and Continuing Calibration Blank – CCB (cyanide)	The MB may be run initially as part of the calibration curve (as applicable). (cyanide) The ICB is run following the calibration curve. CCBs are run following the CCV (after every ten samples), and to close an analytical run sequence	Analyte content of the blank must not exceed the analyte reporting limit (RL)	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Continuing Calibration Verification - CCV (cyanide)	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis)	Response must agree within ±15% of initial calibration	Check that calculations and preparation are correct, evaluate/ correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Laboratory Control Sample (LCS)	One LCS must be run per 20 environmental samples processed	No acceptance limits have been established for the reactive cyanide or sulfide LCSs.	Check calculations and preparation for documentable errors. If no errors are found, reanalyze. Associated samples must also be reanalyzed.
Laboratory Duplicate (DUP)	One sample DUP must be run per batch of 20 or less environmental samples processed	RPD between the sample and its duplicate should be $\leq$20.	For RPDs outside of QC limit, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.

STANDARD OPERATING PROCEDURE 1113 REVISION 11

TITLE: DETERMINATION OF INORGANIC ANIONS BY ION CHROMATOGRAPHY -- METHODS EPA 300.0 AND SW9056

FORMS: 1116 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER Steve Workman DATE 3/7/08

QUALITY ASSURANCE MANAGER [signature] DATE 3/7/08

LABORATORY MANAGER [signature] DATE 3-7-08

HISTORY: Rev0, 7/29/97; Rev1, 7/28/99; Rev2, 4/6/01; Rev3, 1/23/02; Rev4, 3/2/02; Rev5, 4/17/02; Rev6, 12/16/02; Rev7, 4/22/04; Rev8, 3/10//05; Rev9, 4/10/06; Rev10, 8/11/07; Rev11, 3/6/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- Methods EPA 300.0 and SW9056 -- are used to determine the concentration of selected ions in environmental water samples and in aqueous extracts of environmental solid samples. An Ion Chromatograph (IC) is used to separate and detect the anions. Paragon typically uses this procedure to determine the following anions: Chloride (Cl^-), Bromide (Br^-), Fluoride (F^-), Nitrate (NO_3^-), Nitrite (NO_2^-), Sulfate ($SO_4^{=}$), and Orthophosphate (PO_4^{3-}).

2. SUMMARY

The anions are separated and measured using an analytical system consisting of an autosampler, pump, and an IC containing ion exchange columns, a suppressor device, and a conductivity detector.

Small volumes of sample (typically 5mL) are injected via the autosampler into the IC to flush and fill the 25µL sample loop. The contents of the filled sample loop are then injected into a bicarbonate-carbonate eluent stream, which is pumped through a series of two ion exchange columns. The anions of interest are separated by the two ion exchange columns and then carried by the eluent stream through a third (suppressor) column. The suppressor column reduces the anions to their acid form, and also reduces the background conductivity of the eluent. Next, the eluent stream passes through a conductivity detector, and its signals are captured and maintained by a microprocessor (PC). The anions are identified based on retention times and are quantitated using an external standard calibration method.

Solid samples must first be extracted using deionized (DI) water prior to determination.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the ability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or by the successful analysis of a proficiency test sample.

3.3 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the workorder file indicate that this review for precision, accuracy and completeness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work, and documentation of measures taken to remediate the data.

3.4 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Samples that contain particles larger than 0.45µm and reagent solutions that contain particles larger than 0.20µm require filtration to prevent damage to instrument columns and flow systems.

4.2 Constituents that elute at retention times close to the retention times of analytes may interfere. Sample spiking with the analyte of interest can be used to solve most interference problems associated with retention times.

4.3 Large concentrations of an anion can cause interference by causing poor resolution or by overloading the capacity of the column. Sample dilution can be used to solve most interference problems associated with column overloading.

4.4 Several of the anions (NO_3^-, Cl^-, $SO_4^{=}$) are commonly found in the laboratory in concentrated acids and can easily cause contamination. Clean glassware and reagents are critical in order to prevent the occurrence of a noisy baseline or contamination of samples.

5. APPARATUS AND MATERIALS

5.1 Dionex DX-120 Ion Chromatograph (IC), or equivalent, equipped with an autosampler, eluent pump and conductivity detector

5.2 Dionex AS-14 or AS-14A anion exchange analytical columns with AG-14 or AG-14A guard columns, or equivalents

5.3 Anion ASRS-Ultra self-regenerating suppressor column, 4mm, or equivalent

5.4 Dionex *PeakNet* software, or equivalent

5.5 Dionex auto sampler vials ("PolyVials") with filter caps, 5mL, with appropriate 6-vial cassette holder

5.6 centrifuge tubes, polypropylene, disposable, 50mL

5.7 filter disks, 0.45 and 0.7µm

5.8 insertion tool for the PolyVial filter caps

5.9 Eppendorf™ adjustable pipettor, or equivalent, operated per SOP 321 requirements

5.10 volumetric flasks, various sizes, Class A

5.11 analytical balance, capable of weighing to 0.0001g, verified per SOP 305

5.12 conductivity meter

5.13 TCLP-type rotary tumbler

5.14 PolyVials, disposable, 10mL with caps

5.15 vortex mixer

6. REAGENTS – Only reagent grade or better chemicals may be used!

6.1 Deionized (DI) water, obtained from the laboratory's deionized water system

6.2 Helium (He) compressed gas, high purity grade or better

6.3 Eluent Solution Concentrate, 0.1M $NaHCO_3$ + 0.35M Na_2CO_3 (for AS-14/ AG-14): Dissolve 8.4g of sodium bicarbonate ($NaHCO_3$) and 37.1g sodium carbonate (Na_2CO_3) in DI water and dilute using DI water to 1000mL final volume. *Store at room temperature. Shelf Life = 1 year.*

0.1M $NaHCO_3$ + 0.8M Na_2CO_3 (for AS-14A/ AG-14A): Dissolve 8.4g of Sodium bicarbonate ($NaHCO_3$) and 84.8g sodium carbonate (Na_2CO_3) in DI water and dilute using DI water to 1000mL final volume. *Store at room temperature. Shelf Life = 1 year.*

6.4 Eluent Working Solution: Dilute the eluent concentrate solution 100-fold using DI water. Usually, 10mL of concentrate is diluted to a final volume of 1L. *Make fresh daily. Store at room temperature.*

7. STANDARDS

Two Stock Solutions (i.e., "first source" and "second source") are required for each analyte to create the necessary calibration and spiking solutions. Standard and spiking solutions may be prepared in-house from ACS reagent grade materials or can be purchased as certified solutions from a commercial vendor. Paragon's Standards and Solutions database is used to document and manage all standards in use at Paragon. **All anion standards are to be kept refrigerated at 4±2°C and Nitrite standards have shelf life of one month.** *Consult the Standards and Solutions database for the concentrations and traceability of the Nitrite (NO_2^-) and anion (Cl^-, Br^-, F^-, NO_3^-, $SO_4^=$, PO_4^{3-}) standards and solutions used in this procedure.*

8. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

8.1 Samples should be collected according to an approved sampling plan.

8.2 Samples should be collected in clean plastic or glass bottles. The volume collected should be sufficient to provide a representative sample and to allow for the analysis of quality control samples (i.e., matrix spike and duplicate).

8.3 Samples requiring analysis of nitrate, nitrite, and orthophosphate must be kept cool (4±2°C) and must be analyzed within 48 hours of collection.

8.4 Samples requiring analysis of bromide, chloride, fluoride and sulfate should be kept cool (4±2°C) and must be analyzed within 28 days of collection.

9. PROCEDURE

9.1 PREPARATION OF CALIBRATION STANDARDS

Calibration standards (see compositions below) are prepared by diluting the first source anion intermediate standard at five different levels using eluent working solution as the diluent. An eluent working solution blank is used as the 6th calibration point.

ANION CALIBRATION STANDARDS (mg/L)

Analyte Standard	#1 1000X	#2 100X	#3 25X	#4 10X	#5 5X
F^-	0.05	0.5	2	5	10
Cl^-	0.1	1	4	10	20
Br^-	0.1	1	4	10	20
NO_2^- as N	0.05	0.5	2	5	10
NO_3^- as N	0.1	1	4	10	20
PO_4^{3-} as P	0.1	1.0	4	10	20
$SO_4^=$	0.5	5	20	50	100

Calibration standard #4 (first source) is also used as the continuing calibration verification (CCV) standard. The "second source" intermediate anion standard is used to prepare the independent calibration verification (ICV) standard. With the exception of Nitrite, the ICV is made at concentrations half that of the CCV (concentration of Nitrite is 2.0mg/L).

9.2 SYSTEM START-UP AND SHUT-DOWN

9.2.1 Turn on gas and set He regulator to 2psi.

9.2.2 Turn on power by depressing the white button on the front of the instrument.

9.2.3 From the "Main Menu" window in *PeakNet*, click on the "**PEAKNET RUN**" icon. In the Peak Net Run window, select the "**DIRECT CONTROL**" icon. In the Direct Control window, click to start the pump, eluent pressure and SRS/cell.

9.2.4 The eluent flow rate should be set at 1.20mL/min for AS-14 or 1.00mL/min for AS-14A column/guard column. Check this manually by using a graduated cylinder to collect eluent from the waste line and calculate the flow rate from the volume expelled over the time period collected.

9.2.5 Allow the pressure to stabilize for about 30 minutes before starting an analytical sequence.

9.2.6 To shut down system, turn off the pump, eluent pressure and SRS/cell from the "**DIRECT CONTROL**" window. Turn off power (white button on main panel) and close gas tank valve OR:

<u>NOTE</u>: Turn on and off by pressing Local/Remote on front panel to highlight Local and manually press pump, eluent pressure and SRS/ cell.

9.3 EXTRACTION OF SOLID SAMPLES

9.3.1 Weigh 4.0g of sample into a 50mL polypropylene centrifuge tube. Add 40mL DI water.

9.3.2 Mix the suspension thoroughly and tumble using a rotary tumbler (TCLP-type) for about 60 minutes.

9.3.3 Centrifuge the resulting slurry for about 15 minutes.

9.3.4 Filter the supernatant as necessary using a 0.7μm filter disk and/or a 0.45μm filter disk.

9.4 SCREENING AQUEOUS SAMPLES AND SOLID SAMPLE EXTRACTS

Samples should be screened prior to analysis using a conductivity meter. Record screening results in logbook (Form 1116). The electrical conductivity of an aqueous solution is directly related to the concentration of total dissolved solids (TDS). The type of meter used is capable of converting conductivity to estimated TDS in mg/L.

9.4.1 It may be necessary to dilute a sample/extract prior to injection into the IC in order to protect the instrument and provide for sample analysis within the instrument's calibrated linear range. Samples/extracts should be diluted with eluent working solution as necessary so that solutions injected into the instrument do not exceed 1000mg/L estimated TDS (the sample screening information is used to determine the extent of dilution required). Visual appearance of the sample/extract, historical data, or additional information provided by the client may also provide information used to determine the extent of dilution needed.

NOTE: Use a small amount of eluent concentrate instead of eluent working solution as diluent when needed, to ensure that <1% volume change is effected overall.

9.4.2 Prepare aliquots of each pre-filtered sample or extract for analysis in 5mL Dionex vials; dilute as necessary per discussion above. Place filter caps half way down on vials and vortex. Use insertion tool to push cap down fully on vials. Load vials into cassettes for the autosampler.

9.5 SEQUENCE SET-UP

9.5.1 Analytical sequences are set-up using the *PeakNet* Chromatography Software. A new "**SCHEDULE**" is created for each day. Typically this schedule is renamed from the previous day's schedule and then edited to create the new schedule. Sample, sample type, method, and data file must be filled out correctly to save properly.

9.5.2 Each day's data are stored in a new subdirectory named for the day, using a yymmdd format (e.g., 050214). A typical daily analytical sequence is shown below:

1 - 6	calibration standards (when ICAL is performed)
7	ICV
8	ICB
9	MB
10	LCS
11 – 18	8 samples, may include MS/MSD

19 CCV
20 CCB

An analytical sequence can continue indefinitely by repeating Steps 9 – 20, so long as the quality control criteria are met. No more than 10 samples/extracts (including QC samples) may be analyzed between calibration verifications (i.e., CCV, CCB set). One Method Blank, one LCS, and one MS/MSD pair must be analyzed per twenty environmental samples of like matrix. A CCV, CCB set must close the analytical sequence. A CCV, CCB is used to initiate analysis when an ICAL is not performed.

At the end of the sequence, the autosampler stops, but the eluent pressure and SRS/cell pump will continue to run until stopped manually; unless stop method (Stop.met) is placed at the end of the schedule in the method column.

9.6 PEAKNET METHOD

A "**METHOD**" is created in *PeakNet* when calibration is needed. The method is a subprogram, which controls the events that take place throughout the analytical sequence (trigger autosampler, operate injection valve, start and end data acquisition, etc.) The method contains the integration parameters that are used in processing the raw data. The method also contains a table with the calibration curves and retention time windows for each analyte. This table is updated each time a new calibration is established. However, retention times may be updated as necessary using the information obtained from the first calibration verification check run that day.

9.7 DATA ACQUISITION AND PROCESSING

9.7.1 AUTOSAMPLER OPERATION

- Place cassette on autosampler facing inward.
- Press **"**Hold/Run**"** button (on autosampler) to advance cassette to injection port.
- Then press "Load" (on autosampler).
- After the autosampler "Load" button light begins to blink, click on the "Start" icon in the *PeakNet* "**RUN**" window.

Usually, a new injection is made every 10 minutes. Each chromatogram is stored in a separate file. Filenames are automatically given to each chromatogram based on information that is entered when the sequence is created (i.e., a filename prefix, and a value for the counter). The filename prefix is the date of acquisition, and the counter is set to add one for each injection (e.g., 060209_005.dxd designates the 5th injection made on February 9th).

9.7.2 Data processing (integration, peak identification, quantitation) is performed after the chromatograms have been acquired. It is important to review the integration to ensure that baselines are drawn correctly. In cases where it is necessary to modify a baseline, the raw data must include printouts of the chromatogram before and after the baseline correction (refer to SOP 939 for further directives). Only values that fall between the lowest and highest calibration standards are reported. Samples yielding results that exceed the highest standards should be diluted and reanalyzed. Results are reported in mg/L. Report NO_2^- as N, NO_3^- as N, and PO_4^{3-} as P.

9.8 RUN LOG

A record of each day's analyses is entered into the instrument "**SCHEDULE**". The following information is recorded:

- Date of analysis
- Analyst's initials
- Solution ID (including any dilutions)
- Filename
- Schedule ID

9.9 MAINTENANCE AND TROUBLESHOOTING

9.9.1 A maintenance logbook is used to record all information concerning instrument maintenance. The logbook documents all repairs and symptoms of problems.

9.9.2 The fritted disks (sometimes called "bed supports") at the ends of the guard and analytical columns should be changed periodically. The system backpressure will gradually increase over a period of many days or weeks as the fritted disks become clogged with small particles.

9.9.3 In blanks (ICBs, CCBs, MBs), small peaks may be observed in the retention time windows for various anions after analyzing samples high in dissolved salts. This problem is most frequently encountered with orthophosphate. Carryover effect can be addressed via the following:

- Carryover may be lessened or prevented by setting up the autosampler to pass an aliquot of eluent working solution through the sample loop between sample injections. To accomplish this, a vial of eluent working solution is placed between each vial containing a sample or standard in the autosampler. The autosampler recognizes the added vial to be a "rinse vial" because the filter cap is pushed down to the first position using the special insertion tool.

- The sample loop and the tubing that carries the sample solution from the autosampler to the IC can be cleaned with 0.1N HCl using a syringe with a luer lock connector. All traces of HCl must be removed from the system by rinsing the line thoroughly with DI water before analyzing samples.

9.9.4 The guard column will need to be replaced more frequently than the analytical column. Generally, the guard column is replaced about three times for each analytical column that is used over approximately a 1-year period. Overlap of peak retention times is a sign that the analytical column needs replacing.

10. QUALITY CONTROL (QC)

10.1 DEFINITION OF ANALYSIS BATCH

An analysis batch is defined as a group of twenty (20) or less field samples of like matrix that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike and duplicate (MS/MSD). All QC samples must be carried through all stages of the sample preparation and measurement steps.

10.2 METHOD BLANKS

Method blanks (MBs) are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. The blank concentration found must be less than the analyte reporting limit.

10.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) should contain all the analytes of interest and is analyzed to measure the accuracy of the method. To be acceptable, the LCS recovery must be between 90% and 110% of the expected concentration for each analyte of interest for aqueous samples, and between 85% and 115% of the expected concentration for each analyte of interest for solid sample extracts.

10.4 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Matrix spikes (MS) consist of field samples into which known concentrations of target analytes are injected and analyzed as a means of determining the effect of matrix on target analyte detection. The matrix spike duplicate (MSD) serves as a laboratory duplicate analysis. All of the analytes of interest should be spiked. Analyte recovery for matrix spikes is calculated as shown below:

$$\text{MS \% Recovery} = \frac{(C_{found} - C_{native})}{C_{added}} \times 100$$

where:

C_{found} = analyte concentration found in the spiked sample
C_{native} = native analyte concentration found in the unspiked sample
C_{added} = spike added analyte concentration

The quality control acceptance limits for MS/MSD recovery vary (consult LIMS Program Specifications).

The MSD is analyzed as a measure of the precision of the analytical results generated. The Relative Percent Difference (RPD) between a sample and its duplicate should not be greater than 20% (or as specified by client criteria). RPD is calculated as shown below:

$$RPD = \frac{| Result_x - Result_{Dup} |}{(Result_x + Result_{Dup}) / 2} \times 100$$

Acceptance criteria for all spikes and duplicates should be met. If MS/MSD recovery or RPD criteria are not met, results of the laboratory control sample analyses must be carefully considered. If LCS results are acceptable, sample matrix interference is suspected and a notation in the narrative comments is made.

10.5 LINEARITY STUDY

A linearity study must be performed at minimum, every six months, or whenever there is a significant change in operator, background, or instrument response. The study must consist of a blank and a minimum of three standards. The range of the linearity study is generally broader than that defined as the linear calibration range, since the purpose of the linearity study is to verify the instrument's overall capabilities. All verification results must agree within ±10% of expected values.

10.6 RETENTION TIME WINDOW (RTW) STUDY

Analyte retention time window studies are conducted periodically, at minimum upon column change out. An analyte RTW study is performed by noting the variations in analyte retention times yielded in the various concentrations of standards run across the course of a day. The analyte RTW study is typically accomplished when initial calibrations are performed. The width of the RTW is established for each analyte based on three times the standard deviation of the analyte retention times noted during the study. Subsequent CCVs are evaluated against these established times and windows, and are acceptable if the RT has not drifted more than 10%. The CCV RT may be used to re-center the window, so long as the 10% drift criterion has been met. If the 10% drift criterion is exceeded, a new ICAL is performed. RTWs are used to identify target analytes,

11.1 Section 7.3.3 of Method SW846 9056 describes instrument calibration by the use of a first order (linear) calibration curve. Paragon employs **the type of curve fit that best fits the data generated for each analyte. Typically, a linear calibration curve may be used for fluoride, whereas** a second order (quadratic) calibration curve, **consisting of** ~~with typically~~ six points ~~for all IC analytes~~ (`zero' point response included; curve not forced through zero), **may be used for other analytes,** based on historical experience that this type of calibration curve (quadratic) provides a better fit of the **analyte** calibration data.

however, the experience of the analyst must also weigh heavily in the interpretation of chromatograms.

10.7 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study shall be performed as needed (i.e., whenever there is a significant change in operator, background, or instrument response) and at a minimum, every 6 months.

11. DEVIATIONS FROM METHOD

11.1 Section 7.3.3 of Method SW846 9056 describes instrument calibration by the ~~use~~ of a first order (linear) calibration curve. Paragon employs ~~a second~~ order (quadratic) calibration curve with typically ~~six points~~ for all IC analytes ('zero' point response included; curve ~~not~~ forced through zero) based on historical experience ~~that this~~ type of calibration curve (quadratic) provides a better fit of ~~the~~ calibration data.

11.2 Paragon notes that Method EPA 300.0, Section 7.3, prescribes an eluent concentration of 1.7mM sodium bicarbonate and 1.8mM sodium carbonate. Paragon uses an eluent concentration of 0.1M sodium bicarbonate and 0.35M sodium carbonate when using AS-14 columns, and an eluent concentration of 0.1M sodium bicarbonate and 0.8M sodium carbonate when using AS-14A columns, per the application information given with each Dionex column. This eluent profile enables run time to be decreased while maintaining adequate peak resolution throughout the analysis.

12. SAFETY, HAZARDS AND WASTE DISPOSAL

12.1 SAFETY AND HAZARDS

12.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

12.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

12.1.3 Wear gloves, safety glasses and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) and when handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

12.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.5 All flammable compounds must be kept away from ignition sources.

12.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name; NFPA Health, Flammability, Reactivity ratings; and date.

12.1.7 All gas cylinders shall be secured at all times. The valve stem cap must be installed in the absence of a regulator.

12.1.8 Food and drink are prohibited in all lab areas.

12.1 WASTE DISPOSAL

12.2.1 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as "empty" prior to disposal.

12.2.2 Certain clients may require that the samples and residues from their analyses be returned to them. The Waste Disposal Officer will address these sample returns.

DOCUMENT REVISION HISTORY

4/10/06: Added reference Program Specification directive in "Responsibilities". Added clarification and detail regarding equipment operation. Added DOCUMENT REVISION HISTORY.

8/11/07: Included discussion of particulates and filtering as INTERFERENCES 4.1. Clarified (Section 9.1, 9.5.2) that ICALs are conducted as needed (see QC Table), not daily. Also clarified that eluent working solution (not DI water) is used as the basis for calibration standards and IC rinses (Section 9.9.3), and for diluting samples/extracts when necessary (Section 9.4.1). Also that a blank comprises the 6^{th} point of the calibration curve.

3/7/08: Clarified Section 10.6.

Analytical Method: E 300.0; SW9056	**Parameter:** Determination of Anions by Ion Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Retention Time Window (RTW) Study	Performed initially and as necessary (i.e., redone when required as part of troubleshooting when daily RTWs do not agree within ±10% of expected values)	Analyte RTWs established as three times the standard deviations of the analyte retention times noted in the various concentrations of standards run during the course of the day's study	If analyte retention time not reproducible, identify and correct problem. Perform a new initial calibration. Analyte RTWs must agree within ±10% of expected values.
Linearity check; minimum of three standards and a blank; run to verify the range of capability of the instrument	At minimum every six months; whenever a significant change in operator, background, or instrument response occurs	All verification data results must agree within ±10% of expected values	Evaluate/correct instrument malfunction; reanalyze until acceptable results are generated.
Initial Calibration; minimum 6-point (includes blank, but curve not forced through zero)	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	**First or** Second order quadratic fit calibration curve generated electronically by instrument software. Coefficient of Determination (r^2) of the calibration curve equation must be ≥ 0.99	Evaluate/correct instrument malfunction, prepare a fresh set of calibration standards, and reanalyze initial calibration to obtain an acceptable curve.
Independent Calibration Verification (ICV); second source at or below midpoint	Run immediately following initial calibration	Analyte concentration must agree within ±10% of expected values for both Methods SW9056 and 300.0; analyte retention time must agree within ±10%	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Initial Calibration Blank (ICB)	Run immediately following the ICV	Anion content of ICB must not exceed analyte reporting limit (RL)	Check all calculations. If no computation errors are found, prepare a fresh ICB and analyze. Sample analysis cannot proceed until a successful ICB is analyzed.
Method Blank (MB)	One per each batch of ≤20 field samples of like matrix; one each time a reagent is changed	Anion content of MB must not exceed analyte reporting limit (RL) Exception: Samples with analyte concentrations >10X amount found in blank may be reported and narrated.	Prepare a fresh MB and analyze to confirm whether or not system contamination is present. If contamination in the MB is still present above the RL, perform system maintenance, analyze a CCV/CCB set, and re-analyze all samples associated with the failed MB that were not reportable.
Laboratory Control Sample (LCS)	One per batch of ≤20 field samples.	Results obtained must agree within ±10% of expected (known) analyte concentration for aqueous samples; within ±15% of known analyte concentration for solid sample extracts	Check calculations and preparation for documentable errors. If no errors are found, reanalyze. Associated samples must also be reanalyzed.

Analytical Method: E 300.0; SW9056	**Parameter:** Determination of Anions by Ion Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
Quality Control Check	Frequency	Acceptance Criteria	Corrective Action
Continuing Calibration Verification (CCV) at or below midpoint	Brackets each set of 10 field sample/QC sample analyses	Analyte concentration must agree within ±5% Method SW9056 and within ±10 % Method 300.0; analyte retention time must agree within ±10%	Rerun CCV. If CCV still not compliant, evaluate/correct instrument malfunction and recalibrate. Samples analyzed after a failed CCV must be reanalyzed. If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Continuing Calibration Blank (CCB)	Analyzed immediately following each CCV.	Anion content of CCB must not exceed analyte reporting limit (RL) Exception: Samples with analyte concentrations >10X amount found in blank may be reported and narrated.	Prepare a fresh CCB and analyze. If contamination in the CCB is still present above the RL, perform system maintenance, analyze a CCV/CCB set, and re-analyze all samples associated with the failed CCB that were not reportable.
Matrix Spike (MS) and Matrix Spike (Laboratory) Duplicate	One MS/MSD set per batch of ≤20 field samples (this provides an average frequency of one per ten samples per Method SW9056 requirements).	Recoveries should meet client criteria for the spiked compounds. RPD for the MS DUP should meet advisory limit of ≤20%	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, and associated LCS is within control limits, then sample matrix effects are the most likely cause. Note in narrative. For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	At minimum every six months; whenever a significant change in operator, background, or instrument response occurs	Positive result < the analyte reporting limit (RL)	Determine the reason for failure and correct problem. Repeat the MDL study. Consult the Department / Project / QA Managers. The managers may determine that an adjustment to the RL is needed.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1117 REVISION 3

TITLE: **TOTAL ORGANIC CARBON IN SOIL BY RAPID DICHROMATE OXIDATION -- MSA WALKLEY-BLACK METHOD**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 7-27-05
QUALITY ASSURANCE MANAGER _____ DATE 7/24/05
LABORATORY MANAGER _____ DATE 7-27-05

HISTORY: Rev0, 8/15/99; Rev1, 4/29/02; Rev2, 2/14/04 (format updated) and 3/29/05 (re-released without revision); Rev3, 7/26/05 (Program Spec. reference added). **Re-released w/o revision 8/15/07 DAS**

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- MSA Walkley-Black (1996) -- are used to determine the concentration of total organic carbon (TOC) in soil and other soil-like matrices. Rapid dichromate oxidation is the process by which TOC content is determined.

2. SUMMARY

Organic matter in soil is oxidized by treatment with a hot mixture of potassium dichromate ($K_2Cr_2O_7$) and sulfuric acid (H_2SO_4) according to the following reaction:

$$2Cr_2O_7^{2-} + 3C + 16H^+ \rightarrow 4Cr^{3+} + 3CO_2 + 8H_2O$$

After the reaction, the excess (unreacted) dichromate ($Cr_2O_7^{2-}$) is quantified by titration with standard ferrous sulfate ($FeSO_4^{2-}$) solution. The $Cr_2O_7^{2-}$ consumed during the reaction with the soil is assumed to be equivalent to the organic carbon (C) in the soil.

The heat of dilution generated by mixing concentrated H_2SO_4 with $K_2Cr_2O_7$ solution is satisfactory for oxidizing about 75% of the organic C in most soils. In accordance with the analytical method, a correction factor of 1.3 is used to account for the incomplete combustion.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training

review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/ analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 It is assumed that C in soil organic matter has an average valence of zero and that each C atom undergoing oxidation to CO_2 releases four electrons. Therefore, the gram equivalent weight of C in this reaction is 3.0g /eq. If the average valence of C in the sample is different from zero, the average gram equivalent weight of C will be different from 3.0g /eq.

4.2 If present, ferrous iron (Fe^{2+}) will be oxidized to ferric iron (Fe^{3+}) and, therefore, consume $Cr_2O_7^{2-}$. This could potentially bias results high.

4.3 Significant amounts of Cl^- may consume $Cr_2O_7^{2-}$ by forming chromyl chloride (CrO_2Cl_2). This could potentially bias results high.

4.4 The higher oxides of manganese (largely MnO_2) can compete with $Cr_2O_7^{2-}$ for oxidizable substances. This could potentially bias results low.

4.5 The heat of dilution generated by mixing concentrated H_2SO_4 with $K_2Cr_2O_7$ solution is satisfactory for oxidizing about 75% of the organic C in most soils. In accordance with the analytical method, a correction factor of 1.3 is used to account for the incomplete combustion.

5. APPARATUS AND MATERIALS

5.1 Erlenmeyer flasks, 500mL

5.2 beaker, 150mL

5.3 graduated cylinder, Class A, 200mL capacity

5.4 magnetic stir bars, Teflon™ coated

5.5 magnetic stir plate

5.6 Eppendorf™ pipet and repeater pipet (or equivalent), capable of delivering 5.0mL

5.7 transfer pipets, plastic, disposable

5.8 analytical balance, capable of weighing to ± 0.0001g

5.9 top loading balance, capable of weighing to ± 0.01g

6. REAGENTS - Only ACS grade or better chemicals may be used.

6.1 Deionized (DI) water. Obtained from the laboratory deionized water system.

6.2 Ottawa Sand. Inert. EMD, SX0075-3 or equivalent. *Shelf Life = Indefinite.*

6.3 Sulfuric Acid (H_2SO_4), concentrated: EMD, SX1247-2 or equivalent. *Shelf Life = Per expiration date stated by manufacturer on label.*

6.4 Potassium Dichromate ($K_2Cr_2O_7$), 0.167M (1.00N): Mallinckrodt, 6770-02 or equivalent. Transfer 49.04g $K_2Cr_2O_7$ (dried at 105°C) to a 1L volumetric flask. Dissolve and bring to volume with deionized water. *Shelf Life = 1 year.*

6.5 "Ferroin" Indicator (*o*-Phenanthroline-ferrous complex), 0.025M: Obtain from a commercial vendor or dissolve 14.85g *o*-phenanthroline monohydrate and 6.95g $FeSO_4 \bullet 7H_2O$ in 1L of water. *Shelf Life = 1 year or per expiration date stated by manufacturer on label.*

6.6 Ferrous Sulfate, 0.5N: JT Baker, 2074-05 or equivalent. Dissolve 140g $FeSO_4 \bullet 7H_2O$ and 15mL concentrated H_2SO_4 in 1L water. Standardize this reagent each day before use by titrating against 1.00N $K_2Cr_2O_7$. *Made daily each day of use.*

6.7 Organic Carbon Standard, 20mg C/mL: JT Baker, 2959-00 or equivalent. Transfer 4.25g of Potassium Hydrogen Phthalate (KHP) to a 100mL volumetric flask. Dissolve and bring to volume with deionized water. Store in refrigerator. *Shelf Life = 1 year.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples must be collected according to an approved sampling plan.

7.2 Samples should be held in the dark at 4±2°C to minimize possible microbial decomposition.

7.3 There is no established maximum holding time allowance for TOC in solids by this method. A 28-day hold time is recommended based on aqueous sample analysis methodologies.

8. PROCEDURE

8.1 FIELD AND QUALITY CONTROL (QC) SAMPLE PREPARATION

8.1.1 Appropriate sample size is determined by actual organic carbon content. When the prepared sample is titrated, ≥ 2mL of titrant should be required to reach the endpoint. If less than 2mL of titrant is needed, the sample is to be reanalyzed using one-tenth the sample size.

The sample aliquot's organic carbon content must not exceed 10 grams (see chart below). Use a maximum aliquot (10g) for samples with <0.25% organic C. If a sample aliquot consumes more than 90% of the dichromate added (i.e., requires less than 2mL titrant to reach endpoint), the sample must be reanalyzed using one tenth less soil.

Familiarization with samples through prior project experience and observation or other data may be used to determine the initial sample size for analysis.

% Organic C	Amount of Soil to Use
0.025 - 0.25%	10g
0.25 - 2.5 %	1.0g
2.5 - 25 %	0.10g

8.1.2 All test information and data are recorded on a laboratory benchsheet.

8.1.3 Label a 500mL Erlenmeyer flask. Weigh the empty flask on the top loading balance, record the weight, tare the balance while the flask is still on it. Measure a ground aliquot of soil (per chart above) into the flask. Record the weight of the sample aliquot.

Select one sample that is representative of the sample batch and prepare a second aliquot to serve as the laboratory Duplicate. One laboratory duplicate must be prepared for each batch of 20 or fewer environmental samples processed together as a unit.

8.1.4 Prepare a Method Blank (MB) with every batch of 20 samples or less, by transferring 10g of clean sand into a designated pre-weighed 500mL Erlenmeyer flask.

8.1.5 One Laboratory Control Sample (LCS) must be prepared with every batch of 20 samples or less. To prepare the LCS, transfer 10g of clean sand to a labeled pre-weighed Erlenmeyer flask. Add 0.5mL of 20mgC/mL standard. Expected concentration of the LCS is 1000mg/kg TOC.

8.2 SAMPLE DIGESTION

NOTE: Sample digestion **must** be performed in the fume hood!

8.2.1 Use a repeater pipet to add 10.0mL of 1.00N $K_2Cr_2O_7$ to each sample flask. Swirl the flask gently to disperse the soil.

8.2.2 Rapidly add 20mL of concentrated H_2SO_4, directing the stream into the soil suspension (a bottle pump dispenser may be used). Immediately swirl the flask gently until the soil and reagents are mixed, then more vigorously for approximately one minute.

CAUTION! The contents of the flask will become very hot when the acid is mixed into the dichromate solution. Use extreme care when adding the concentrated H_2SO_4. Proper eye and hand protection MUST be used!

8.2.3 Allow the hot flask + contents to stand in the fume hood approximately 30 minutes. Use a graduated cylinder to add 200mL DI water and swirl.

8.2.4 Allow the flask + contents to cool to room temperature and any suspended sediments to settle. Reweigh each flask and record in the laboratory logbook.

8.2.5 Tare a 150mL beaker containing a stir bar. Gravimetrically weigh 100g of digested sample into the beaker. Record the sample weight in the laboratory logbook.

8.3 TITRANT STANDARDIZATION

8.3.1 Three aliquots for titration must be prepared. Transfer a 5.00mL aliquot of 1.00N $K_2Cr_2O_7$ into each of three 150mL beakers. Add 100mL DI water. **IN THE FUME HOOD**, rapidly add 10mL of concentrated H_2SO_4 to each beaker. Swirl for approximately one minute. Allow beakers to cool to room temperature. Add 2-3 drops of ferroin indicator. Place the beaker + contents on the balance and tare the balance. Place the beaker onto a magnetic stir plate and agitate at a rate sufficient to thoroughly mix.

8.3.2 While still mixing on the stirplate, use a transfer pipet to carefully add $FeSO_4$ solution dropwise until the endpoint is reached (solution color changes from green to dark red). Reweigh the beaker + contents. Record the amount of $FeSO_4$ solution added.

8.3.3 Repeat the steps above for the remaining two aliquots prepared for standardization.

8.3.4 Calculate the concentration of the $FeSO_4$ solution as follows:

$$[FeSO_4] = (Con_{Cr})\,(V_{Cr}) / (V_F)$$

where:

$[FeSO_4]$ = concentration of $FeSO_4$ titrant (in N or eq/L)
Con_{Cr} = concentration of $K_2Cr_2O_7$ solution (as 1.00N or in eq/L)
VCr = volume (mL) of $K_2Cr_2O_7$ solution titrated; 5.00mL
V_{Fe} = volume (mL) of titrant required to reach endpoint

8.3.5 Average the results of the three standardizations to determine the concentration of the $FeSO_4$ solution.

8.4 SAMPLE DETERMINATION

8.4.1 To the 100g of sample digestate solution, add 2-3 drops of ferroin indicator to each beaker. Place the beaker + contents on the balance and tare the balance. Move the beaker to the stir plate. While stirring, use a transfer pipet to carefully dispense standardized $FeSO_4$ solution dropwise into the beaker until the endpoint is reached (the endpoint is the point at which the beaker solution color changes from green to dark red).

Reweigh the beaker + contents. Record the amount of $FeSO_4$ solution on the laboratory benchsheet (an amount ≥ 2mL should be required). If less than 2mL of $FeSO_4$ titrant is needed, the sample must be reprepared and reanalyzed using one-tenth the initial sample size.

NOTE: If experience shows that the endpoint of the titration cannot be easily discerned because of the suspended soil in the beaker, the sample suspension can be filtered through acid resistant filter paper (e.g., Whatman #41) under vacuum prior to analysis.

8.4.2 Calculate the organic C concentration in each sample using an Excel spreadsheet or as follows (record result in laboratory benchsheet):

$$\text{Organic C, \%} = [(V_{Cr} * Con_{Cr}) - R * (V_{Fe} * Con_{Fe})] * (0.003)\ (100) / (W_S) * 1.3$$

where:

V_{Cr} = volume (mL) of $K_2Cr_2O_7$ solution; (if this SOP is followed without deviation, V_{Cr} = 10.0mL

Con_{Cr} = concentration of $K_2Cr_2O_7$ solution, N (if this SOP is followed without deviation, Con_{Cr} = 1.0N)

R = sample Volume Ratio (total final sample wt. / wt. of aliquot titrated)

V_{Fe} = volume of $FeSO_4$ to reach endpoint

Con_{Fe} = concentration of $FeSO_4$ titrant (in N or eq/L)

0.003 = constant that converts meq to grams of C

100	=	constant that converts ratio to percent
W_S	=	dry sample weight (g) [moist wt*((100 - %moisture)/100)]
1.3	=	correction factor to account for incomplete carbon oxidation

9. QUALITY CONTROL (QC)

9.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or less field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory duplicate (DUP) and laboratory control sample (LCS). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

9.2 Method Blanks (MBs) are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the MB consists of an aliquot of clean Ottawa sand. The result for the MB must be < 0.025% organic C (which was established as the lower limit of detection during the initial method demonstration).

9.3 The Laboratory Control Sample (LCS) is analyzed to measure the accuracy of the method. A known amount of analyte is prepared and analyzed. Results obtained are compared to results expected. To be acceptable, the organic carbon found in the LCS must be between 70% and 110% of that added. NOTE: These interim control limits were established as ±20% centered around an average 90% recovery rate (as determined during the initial method demonstration), and are subject to revision.

Calculate the percent recovery (%R) for the LCS as follows:

$$\text{LCS } \%R = (Con_{found} / Con_{expected}) * 100$$

where:

Con_{found}	=	Calculated concentration of TOC in LCS
$Con_{expected}$	=	Concentration of TOC expected in LCS (if this SOP is followed without deviation, $Con_{expected}$ = 1000.0mg/kg TOC)

9.4 A laboratory duplicate (DUP) is analyzed as a measure of the precision of the analytical results generated. The Relative Percent Difference (RPD) between a sample and its duplicate should not be greater than 30%. RPD is calculated as follows:

$$RPD\ (\%) = \frac{|Result_X - Result_{Dup}|}{\frac{(Result_X + Result_{Dup})}{2}} \times 100$$

10. DEVIATIONS FROM METHOD

This SOP meets the requirements of the MSA Walkley-Black method. There are no known deviations from the method.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 The aqueous solution left over from the titration shall be disposed of in the Acidic Aqueous Laboratory Waste satellite collection vessel.

11.2.2 The solid residues shall be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.4 Certain clients may require that the samples and residues from their analyses are returned. The Waste Compliance Officer will address these samples.

11.2.5 The radioactive aqueous solution left over from the titration shall be disposed of in the Mixed Radioactive Aqueous Acidic Laboratory Waste (Contains Chrome) satellite collection vessel.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1119 REVISION 6

TITLE: **DETERMINATION OF TOTAL PHOSPHORUS AND ORTHO-PHOSPHATE IN WATER – METHODS EPA 365.2 AND SM4500-P B(5) and E**

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 10/16/07
QUALITY ASSURANCE MANAGER _____ DATE 10/8/07
LABORATORY MANAGER _____ DATE 11-5-07

HISTORY: Rev0, 9/22/99; Rev1, 8/22/02; Rev2, 2/10/03; Rev3, 3/6/03; Rev4, 2/9/04, 3/29/05; Rev5, 7/26/05, 8/15/07; Rev6, 10/8/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- EPA Method 365.2 and Standard Methods SM4500-P B(5) and E -- are used to determine total phosphorus (P) and ortho-phosphate content in environmental water samples. These methods are applicable to the analyses of drinking, surface, and saline waters and domestic and industrial wastewaters.

2. SUMMARY

Phosphorus (P) occurs in natural waters and wastewaters mostly in the form of phosphates. These are commonly classified as ***orthophosphates, condensed phosphates,*** and ***organically bound phosphates.*** Orthophosphate reacts with ammonium molybdate and antimony potassium tartrate in an acid medium to form a heteropoly acid-phosphomolybdic acid complex that is reduced to intensely colored molybdenum blue with ascorbic acid. The color intensity is proportional to the orthophosphate concentration. Orthophosphate is the only form of phosphorus that forms a blue color in this test. The results of this test are expressed in units of "mg phosphorus per L" (mg P/L) of sample.

Total phosphorus refers to the phosphorus measured colorimetrically after a sample has been digested by the persulfate digestion method with sulfuric acid to convert polyphosphates and organic phosphorus compounds to orthophosphate. Because phosphorus may occur in combination with organic matter, a digestion method to determine total phosphorus must be able to oxidize organic matter effectively to release phosphorus as orthophosphate.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicates that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 High concentrations of dissolved iron may cause precipitation of and subsequent loss of phosphorus.

4.2 Arsenate reacts with the molybdate reagent to produce a blue color similar to that formed with orthophosphate. Arsenate concentrations as low as 0.1mg/L arsenic can interfere with the determination of orthophosphate.

4.3 Hexavalent Chromium (Cr^{+6}) and Nitrite (NO_2^-) interfere to give results biased low (approximately 3%) at concentrations of 1mg/L and biased low (approximately 10-15%) at 10mg/L.

4.4 The procedure is highly susceptible to contamination from phosphate-containing detergents and hand contact. ***All glassware, graduated cylinders, funnels, etc., used for sample preparation, standard preparation, or any phase of the analysis must be rinsed with 10% Sulfuric (H_2SO_4), Hydrochloric (HCl) or Nitric (HNO_3) acid solution three times followed by three rinses with DI water before use.***

5. APPARATUS AND MATERIALS

5.1 Sequoia Turner UV/VIS Spectrophotometer 340 or any filter photometer suitable for measurements at 650nm with a light path of 1.0cm or longer

5.2 Spectrophotometer cuvettes, optically matched, 1 inch diameter

5.3 Vortex mixer

5.4 Disposable, polypropylene beakers, 100mL

5.5 Top loading balance capable of reading to 0.01g

5.6 Analytical balance capable of weighing to 0.0001g

5.7 Eppendorf® pipettes, various sizes

5.8 Repeater pipettor capable of delivering 1.0-4.0mL

5.9 Disposable transfer pipettes

5.10 Hot plate, large or small (depending on amount of samples to be prepared)

5.11 Watch covers, Pyrex®

5.12 Beakers, Pyrex®, 250 or 150mL

NOTE: ***Use only designated acid-washed Pyrex® beakers and watch covers. These should be dedicated for phosphorus analysis only. See Section 4.4 above.***

6. REAGENTS

6.1 Deionized (DI) water

6.2 Phosphorus Stock Standard, 1000 or 10000mg phosphorus/L (**First Source**): Purchase from a commercial vendor or prepare by dissolving pre-dried potassium phosphate (KH_2PO_4) in DI water. The potassium phosphate salt should be dried in an oven at 105°C for at least one hour and then cooled to room temperature in a desiccator prior to weighing. Weigh the salt to the nearest 0.0001g using an analytical balance. Consult the Standards Database for current formulas. Example: To create 10000mg/L standard, dissolve 10.9840g KH_2PO_4 salt in 250mL DI water. *Shelf-life = One year from date of purchase or preparation.*

6.3 Intermediate Phosphorus Standard, 100mg phosphorus/L (**First Source**): Dilute the stock standard discussed above as necessary to create 100mg/L intermediate phosphorus standard. Example: A 100mg/L standard may be created by diluting 5mL of the 10000mg/L standard to a final volume of 500mL with DI water. *Shelf-life = One year from date of preparation or when parent standard expires.*

6.4 Phosphorus Stock Standard, 1000 or 10000mg phosphorus/L (**Second Source**): Purchase from a commercial vendor or prepare standard as discussed in Section 6.2 above. The salt used must be from a different source than the salt used for the first

source stock standard (i.e., from a different vendor or a different lot if from the same vendor). *Shelf-life = One year from date of purchase or parent preparation.*

6.5 Intermediate Phosphorus Standard, 100mg phosphorus/L (**Second Source**): Dilute the 2nd source stock standard as necessary to create 100mg/L intermediate standard. See Section 6.3 above. *Shelf-life = One year from date of parent preparation.*

NOTE: All phosphorus standards must be stored in polypropylene bottles at 4°C.

6.6 Sulfuric Acid (H_2SO_4), Concentrated. EMD, SX1244-5 or equivalent.

6.7 Sulfuric Acid Solution, 50%: In a 1.5L Pyrex® beaker, *slowly and cautiously* add 500mL concentrated H_2SO_4 to 500mL DI water, or any volume as long as ratio stays the same (1:1). Mix cautiously. Cool the beaker and contents in a cold water bath. *Shelf-life = One year from date of preparation.* **Store in a bottle that previously contained concentrated sulfuric acid and/or polypropylene bottles.**

6.8 Sulfuric Acid Solution, 11N: In a 1L Pyrex® beaker, *slowly and cautiously* add 220mL 50% H_2SO_4 to 140mL DI water or 310mL concentrated H_2SO_4 to 600mL DI water. Allow cooling and bring to 1000mL final volume. *Shelf-life = One year from date of preparation.*

6.9 Sulfuric Acid Solution, 5.0N: In a 500mL Pyrex® beaker, *slowly and cautiously* add 100mL 50% H_2SO_4 to 260mL DI water or 70mL concentrated H_2SO_4 to 500mL final volume with DI water. *Shelf-life = One year from date of preparation.*

6.10 Ammonium Persulfate $(NH_4)_2S_2O_8$, reagent grade. GFS Chemicals, Item No. 843 or equivalent.

6.11 Phenolphthalein Indicator: VWR, Cat. No. VW3341-2 or equivalent. Purchase from a commercial vendor or prepare by dissolving 0.5g of phenolphthalein in a solution of 50mL ethyl or isopropyl alcohol and 50mL of DI water. *Shelf-life = Per expiration date indicated on label by manufacturer.*

6.12 Sodium Hydroxide (NaOH), 10N: JT Baker, 3722-07 or equivalent. Slowly add 400g NaOH pellets to 800mL of DI water in a 1L Pyrex® beaker. Cool and dilute to volume with DI water. *Shelf-life = One year from date of preparation.*

6.13 Antimony Potassium Tartrate [$K(SbO)C_4H_4O_6 \bullet 1/2\ H_2O$] Solution: JT Baker, 0864-04 or equivalent. In a 500mL volumetric flask, dissolve 1.3715g $K(SbO)C_4H_4O_6 \bullet 1/2\ H_2O$ in approximately 400mL DI water. Bring to 500mL final volume with DI water. *Shelf-life = One year from date of preparation.* **This solution must be stored in an amber glass bottle at 4°C.**

6.14 Ammonium Molybdate [$(NH_4)_6Mo_7O_{24} \bullet 4H_2O$] Solution: Kodak, Cat. 136 5824 or equivalent. For each 15mL of solution, dissolve 0.60g $(NH_4)_6Mo_7O_{24} \bullet 4H_2O$ in 15mL of DI water. Prepare fresh for each usage. Transfer to a polypropylene bottle and store at 4°C until ready for use.

6.15 Ascorbic Acid, 0.1M: JT Baker, 0936-07 or equivalent. For each 30mL of solution, dissolve 0.53g of ascorbic acid in 30mL of DI water. *Prepare fresh for each usage.*

6.16 Combined Coloring Reagent: To prepare 100mL of reagent, mix the following in the order and volumes shown:

NOTE: Mix after adding each reagent, if turbidity forms, shake and allow to stand a few minutes until the turbidity disappears before proceeding.

1. 50mL H_2SO_4, 5N
2. 5mL Antimony Potassium Tartrate solution
3. 15mL Ammonium Molybdate solution
4. 30mL Ascorbic Acid solution

Other volumes of combined coloring reagent can be prepared as long as the various components are mixed in the same proportions as above. *Prepare fresh for each usage.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 Samples must be collected according to an approved sampling plan.

7.2 For Total Phosphorus, water samples are preserved by acidification with H_2SO_4 to pH < 2. The samples must be analyzed within 28 days from collection and preservation.

7.3 Samples for ortho-Phosphate are not acidified and must be kept chilled at 4±2°C. The samples must be analyzed within 48 hours of collection.

8. PROCEDURE

8.1 AMMONIUM PERSULFATE DIGESTION FOR TOTAL PHOSPHORUS

8.1.1 Prepare samples by measuring a well mixed 50mL aliquot (or smaller volume diluted to 50mL with DI water) into a 150mL acid-rinsed Pyrex® beaker.

8.1.2 Prepare a Preparation (Method) Blank by measuring 50mL DI water into a 150mL acid-rinsed Pyrex® beaker. One blank is to be prepared for each set of twenty field samples or less processed as a unit.

8.1.3 Prepare a Blank Spike (Laboratory Control Sample, LCS) by measuring 50mL DI water into a 150mL acid-rinsed Pyrex® beaker. Spike with

0.25mL of 100mg/L Intermediate Phosphorus Standard (**Second Source**). One LCS is to be prepared for each set of twenty field samples or less processed as a unit.

8.1.4 Prepare a Matrix Spike and Matrix Spike Duplicate (MS/MSD): The matrix spike duplicate serves as the laboratory duplicate. For one of the samples in the batch, measure two additional 50mL aliquots into two 150mL acid-rinsed Pyrex® beakers. Spike each of the two additional aliquots with 0.125mL of 100mg/L Intermediate Phosphorus Standard (**First Source**).

8.1.5 To all the field and QC samples prepared above, add 1mL of 11N H_2SO_4.

8.1.6 To all the field and QC samples prepared above , add 0.4g of ammonium persulfate.

8.1.7 Cover with an acid-rinsed Pyrex® watch cover. Boil gently on a hot plate until a final volume of approximately 10mL is reached (approximately one hour). **Do not allow the samples to boil dry.**

8.1.8 Allow to cool. Rinse watch glass cover with DI water directly into sample beaker in order to collect any residue on cover. Add DI water as necessary to bring sample volume to approximately 20mL.

8.1.9 pH Adjustment. Add 2-3 drops of phenolphthalein indicator. While "swirling" beaker, carefully add 10N NaOH dropwise until the sample solution just turns pink.

8.1.10 Using a top loading balance, transfer the prepared sample to a clean, tared disposable polypropylene beaker. Use a wash bottle filled with DI water to rinse the sides of the digestate beaker and collect the rinsate in the plastic prepared sample beaker. Dilute to a final volume of 50mL by adding DI water until the final solution weight = 50.1g.

NOTE: In some samples a precipitate may form at this stage, but **do not filter**. Shake samples well for any subsequent subdividing of the sample. The precipitate (which is possibly calcium phosphate) redissolves under the acidic conditions of the colorimetric analysis.

8.1.11 Proceed to Section 8.3 for Colorimetric Analysis.

8.2 PREPARATION FOR ORTHO-PHOSPHATE ANALYSIS

8.2.1 If the sample is turbid, it may be filtered through a 0.45µm porosity filter.

8.2.2 Prepare samples by measuring a 20mL aliquot (or smaller volume diluted to 20mL with DI water) into acid washed clean optically matched spectrophotometer cuvettes.

8.2.3 Prepare a Preparation (Method) Blank by measuring 20mL DI water into an acid washed clean spectrophotometer cuvette. One blank is to be prepared for each set of twenty field samples or less processed as a unit.

8.2.4 Prepare a Blank Spike (Laboratory Control Sample, LCS) by measuring 20mL DI water into an acid washed clean spectrophotometer cuvette. Spike with 0.05mL of 100mg/L Intermediate Phosphorus Standard (**Second Source**). One LCS is to be prepared for each set of twenty field samples or less processed as a unit.

8.2.5 Prepare a Matrix Spike and Matrix Spike Duplicate (MS/MSD). The matrix spike duplicate serves as the laboratory duplicate. For one of the samples in the batch, measure two additional 20mL aliquots into two acid washed clean spectrophotometer cuvettes. Spike each of the two additional aliquots with 0.05mL of 100mg/L Intermediate Phosphorus Standard (**First Source**).

8.2.6 If necessary, adjust the pH of the sample as follows: Add 1 drop of phenolphthalein indicator to 20mL of sample. If a pink color develops, add 5N H_2SO_4 solution dropwise to just discharge the color.

8.2.7 Proceed to the Colorimetric Analysis in Section 8.3.

8.3 COLORIMETRIC ANALYSIS - TOTAL PHOSPHORUS AND ORTHO-PHOSPHATE

8.3.1 Standard Curve: Prepare calibration standards in acid washed clean optically matched spectrophotometer cuvettes by diluting aliquots of 100mg/L Intermediate Phosphorus Standard (First Source) in DI water as described below:

Final Concentration of Calibration Standard (mg P/L)	Volume of 100mg P/L Intermediate Standard (mL)	Final Volume of Calibration Standard (mL)
0.00 (CCB)	0.00	20.0
0.05	0.01	20.0
0.10	0.02	20.0
0.25	0.05	20.0
0.50 (CCV)	0.10	20.0
0.75	0.15	20.0
1.00	0.20	20.0

8.3.2 Prepare an Initial Calibration Verification (ICV) check standard in an acid washed clean spectrophotometer cuvette by diluting 0.05mL of 100mg /L Intermediate Phosphorus Standard (Second Source) to 20.0mL with DI water.

8.3.3 Prepare an Initial Calibration Blank (ICB) by placing a 20mL aliquot of DI water into a clean acid washed spectrophotometer cuvette.

8.3.4 Transfer a 20mL aliquot of each digested sample or prepared sample into an optically matched acid washed spectrophotometer cuvette.

NOTE: Digestates and/or prepared samples may contain color. If color interference is an issue, take absorbance reading before coloring in order to subtract "initial" color from "final" color.

8.3.5 To each standard and sample add 4.0mL of Combined Coloring Reagent. Mix well.

NOTE: If any undissolved material is remaining in cuvette after combining color reagent, mixing, and allowing to develop, allow material to settle or filter using a 0.45µm porosity filter before analysis.

8.3.6 After the blue color has fully developed (approximately 10 minutes; not to exceed 30 minutes), measure the absorbance of the colored standards and samples with the spectrophotometer at a wavelength setting of 650nm. Absorbance measurements are performed in the following sequence:

(1) 0.00mg/L cal std.
(2) 0.05mg/L cal std.
(3) 0.10mg/L cal std.
(4) 0.25mg/L cal std.
(5) 0.50mg/L cal std.
(6) 0.75mg/L cal std.
(7) 1.00mg/L cal std.
(8) ICV (0.25mg/L Second Source)
(9) ICB (Initial Calibration Blank
(10) Preparation Blank
(11) LCS
(l2) maximum of 8 samples including MS, MSD
(13) CCV (0.50mg/L First Source)
(14) CCB (Continuing Calibration Blank
(15) maximum of 10 samples

(16) CCV (0.50mg/L First Source)
(17) CCB
(18) maximum of 10 samples
(19) CCV
(20) CCB

The analytical sequence of CCV, CCB, 10 samples, may be repeated so long as continuing calibration standard and blank quality criteria are met. The sequence must end with a CCV and CCB.

8.3.7 For each sample, the measured absorbance must not exceed the absorbance obtained for the high calibration standard (1.00mg/L). If this does occur, another aliquot of the sample solution must be diluted with DI water and the colorimetric analysis must be repeated so that the measured absorbance is within the calibration range.

8.4 CALCULATIONS

8.4.1 Record total phosphorus preparation information in Aqueous Extration logbook (e.g., standards used, reagents, QC information ect.). Enter calibration data in LIMS to perform a linear regression analysis (measured absorbance versus concentration for each calibration standard). The regression equation for the calibration standards must have a correlation coefficient (r^2) $\geq$ 0.995.

8.4.2 For each solution analyzed, calculate the phosphorus concentration from the measured absorbance using the spreadsheet.

8.4.3 Results of the ICV and CCVs must agree within ±10% of their know concentrations (0.50mg/L P for CCV's and 0.25mg/L P for ICV).

8.4.4 Calculate the phosphorus concentration in the water samples as follows:

$$\text{phosphorus mg/L} = A \times D$$

where:
A = mg/L of phosphorus determined in solution in cuvette
D = Dilution factor if dilution was necessary to produce a response within the calibration range

8.4.5 Results of the ICB and CCBs must be below the reporting limit (RL) for the method (usually 0.05mg phosphorus/L).

9. QUALITY CONTROL (QC)

9.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or less field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike and duplicate (MS/MSD). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

9.2 METHOD BLANKS

Method blanks (MB) are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank must be processed. For this procedure, the method blank is run as an Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB). The blank is prepared as discussed in Section 8. See QC Table for acceptance limits.

9.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. A known amount of analyte is prepared and analyzed. For this method, the LCS is prepared as described in Section 8. Results obtained are compared to results expected. See QC Table for acceptance limits.

9.4 MATRIX SPIKE AND MATRIX SPIKE DUPLICATE

Matrix spikes (MS) consist of field samples into which known concentrations of target analytes are spiked and analyzed as a means of determining the effect of matrix on target analyte detection. The matrix spike duplicate (MSD) serves as a laboratory duplicate analysis. Analyte recovery for the MS/MSD pair is calculated as shown below:

$$\%R = \frac{\text{Concentration}_{\text{Found}} - \text{Concentration}_{\text{Sample}}}{\text{Concentration}_{\text{Target}}} \times 100$$

where:

$\text{Conc}_{\text{Found}}$ = analyte concentration found in the MS or MSD sample
$\text{Conc}_{\text{Sample}}$ = analyte concentration found in the field sample
$\text{Conc}_{\text{Target}}$ = target (anticipated) analyte concentration based on amount spiked

See QC Table for advisory limits.

The laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. RPD is calculated as shown below:

$$\text{RPD (\%)} = \frac{|\text{Result}_x - \text{Result}_{\text{Dup}}|}{\frac{(\text{Result}_x + \text{Result}_{\text{Dup}})}{2}} \times 100$$

Advisory acceptance criteria for all spikes and duplicates should be met. If MS/MSD recovery or RPD criteria are not met, results of the laboratory control sample analyses must be carefully considered. If LCS results are acceptable, a sample matrix interference is suspected and a notation in the narrative comments is made.

9.5 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and near the analyte reporting limit (RL). The MDL study should be performed as needed and at a minimum, annually.

10. DEVIATIONS FROM METHOD

10.1 Section 6.2 of Method EPA 365.2 and Section 2b of SM4500-P C recommend the use of hot 1:1 HCl (followed by distilled water rinse) for the pre-treatment of glassware used for phosphorus analysis. Paragon uses an acid wash bath (H_2SO_4, HCl, or HNO_3), followed by three rinses of DI water to pre-treat glassware dedicated to phosphorus analysis.

10.2 Paragon creates a stock phosphorus solution 80X stronger than that resulting from the reagent recipe given in Section 7.8 of Method EPA 365.2 and Section 3f of SM4500-P E. The concentrations of the subsequent standard phosphorus solutions differ between the two referenced methods: 0.5mg/L Method EPA 365.2; 2.5mg/L SM4500-P E (Paragon uses a 100mg/L standard phosphorus solution). Likewise, the range of the calibration standards created from the standard phosphorus solution differs between the two referenced methods (0.00 – 0.50mg/L Section 7.9 of Method 365.2; 0.15 – 1.30mg/L SM4500-P E Section 4c). Note that the range of the calibration standards used by Paragon (0.00 – 1.00mg/L) falls within the range prescribed by the two referenced methods.

10.3 Section 7.10 of Method EPA 365.2 and Section 5a (4) of SM 4500-P B provide for the use of 1N NaOH solution to adjust the pH of the ammonium persulfate digestate. Paragon uses a stronger (10N) NaOH solution in order to minimize change to sample digestate volume.

10.4 Section 8 of Method EPA 365.2 describes the use of a pH meter to ensure pH adjustment of the ammonium persulfate digestate to 7.0±0.2 pH units. Use of a pH meter is not discussed in SM4500-P B Section 5. Paragon does not use a pH meter to determine the ammonium persulfate digestate pH.

10.5 Per Section 5c of SM4500-P B, distilled water is used to adjust the final volume of the ammonium persulfate digestate to 100mL. Paragon uses DI water to adjust to a final volume of 50mL, which is the final volume described in Section 8.1.4 of Method EPA 365.2. Section 8.1.4 of Method EPA 365.2 suggests filtering if the sample digestate is not clear, whereas Section 5c of SM4500-P B directs NOT to

filter the digestate. Paragon does not filter the prepared ammonium persulfate digestates, but may filter or allow the settling of any particulate matter after the colored digestate solution has been well mixed.

10.6 Section 9.1.1 of Method EPA 365.2 directs that blanks and calibration standards be processed exactly as the samples (samples prepared for total phosphorus analysis are subjected to ammonium persulfate digestion; samples prepared for ortho-phosphate analysis are not digested). Section 5c of SM4500-P B (Persulfate Digestion Method) directs that the calibration curve be created from standards that are carried through the persulfate digestion procedure. Paragon uses a singular calibration curve to process both total phosphorus and ortho-phosphate samples and does not subject the calibration standards to ammonium persulfate digestion.

10.7 Section 4a of SM4500-P E provides for the reading of absorbance at 880nm, whereas absorbance readings at 650 or 880nm are provided for in Section 8.3.2 of Method EPA 365.2. Paragon reads absorbance of the prepared samples at 650nm.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

11.1.2 Read the MSDS before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.2 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Compliance Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

2/9/04: Updated format.

3/29/05: Re-released without revision.

7/26/05: Program specification language added.

8/15/07: Added DOCUMENT REVISION HISTORY Section.

10/8/07: Corrected shelf life from 3 months to one year, intermediate standards, Sections 6.3 and 6.5. Updated QC Section 9 language and QC Table.

Analytical Method: E365.2; SM4500-P B(5) & E	**Parameter:** Phosphorus by Ascorbic Acid Method		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point	Once per analytical sequence.	Correlation coefficient (r^2) for linear regression must be $\geq$0.995.	Evaluate/correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); second source; at or below midpoint	Daily prior to sample analyses	Must agree within $\pm$10%D of calibration curve for analyses to proceed	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); first source; at or below midpoint	Brackets each set of 10 field sample analyses	Must agree within $\pm$10%D of calibration curve for analyses to proceed	Evaluate/correct instrument malfunction as needed and reanalyze. If CCV still non-compliant, recalibrate using a new curve. Samples analyzed after a failed CCV must be reanalyzed. If holding times are an issue, complete a Non Conformance Report (NCR) and notify the PM for sample disposition.
Method Blank (MB); Initial Calibration Blank (ICB)	One per each batch of $\leq$20 field samples; one each time a reagent is changed	Phosphorus content of MB must not exceed reporting limit (RL); RL usually 0.05mg phosphorus/L, or as otherwise specified in applicable LIMS program specification	Check all calculations. If no computation errors are found, prepare a fresh MB and analyze. Associated samples must also be reanalyzed.
Continuing Calibration Blank (CCB)	One per each set of $\leq$10 field samples	Phosphorus content of CCB must not exceed RL (usually 0.05mg phosphorus/L)	Check all calculations. If no computation errors are found, prepare a fresh MB and analyze. Associated samples must also be reanalyzed.
Laboratory Control Sample (LCS)	One per batch of $\leq$20 field samples	Results obtained must agree between $\pm$10% of expected (known) ortho-phosphate concentration and between $\pm$20% of expected (known) total phosphorus concentration, or as otherwise specified in applicable LIMS program specification	Check calculations and preparation for documentable errors. If no errors are found, reanalyze. Associated samples must also be reanalyzed.
Matrix Spike (MS)	One per batch of $\leq$20 field samples	Results obtained should agree within $\pm$10% of expected ortho-phosphate concentration, and $\pm$20% of expected total phosphorus concentration, or as otherwise specified in applicable LIMS program specification	Check calculations and preparation for documentable errors. If no errors are found, reanalyze. Associated samples must also be reanalyzed.
Matrix Spike (laboratory) Duplicate	One per batch of $\leq$20 field samples	(See MS recovery criteria above)	(See MS recovery criteria above). For RPDs outside of QC limits, check

Analytical Method: E365.2; SM4500-P B(5) & E	**Parameter:** Phosphorus by Ascorbic Acid Method		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
		RPD should be ≤20%, or as otherwise specified in applicable LIMS program specification	all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	As needed; at a minimum annually	Positive result < the analyte reporting limit (RL)	Determine the reason for failure and fix problem with the analytical system. Repeat the MDL study. Consult with the Department/Project/QA Managers. The managers may determine that an adjustment to the RL is needed.

LABORATORY MANAGER _____ DATE 5-1-07

HISTORY: Rev0, 11/20/99; Rev1, 4/29/02; Rev2, 2/10/03, Rev3, 2/9/04 and 3/29/05; Rev4, 7/26/05; Rev5, 4/27/07.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- Methods EPA 376.1 and SM4500-S^2 F -- describe a procedure to determine the concentration of total sulfides in drinking, surface, and saline waters and domestic and industrial wastes. Acid soluble sulfides are not measurable by these methods (copper sulfide is the only common sulfide in this class).

Total sulfide includes dissolved H_2S and HS^-, as well as acid-soluble metallic sulfides present in suspended matter. Dissolved sulfide is that remaining after suspended solids have been removed by flocculation and settling. This procedure may also be used for the analysis of dissolved sulfides following proper sample pretreatment (see SM.4500-S^2 B).

Information regarding qualitative testing for sulfides is presented in Section 4 of the introduction to Method 4500-S^2 F. This information may be particularly useful when testing for sulfides in industrial wastes.

2. SUMMARY

Samples are preserved with zinc acetate to yield zinc sulfide. Excess standard iodine is quantitatively added to a sample aliquot. Under acidic conditions, the iodine oxidizes the sulfide in the sample to sulfur. The excess unreacted iodine is then back titrated with standard sodium thiosulfate solution in the presence of starch (used as an indicator).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of

Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.3 Paragon's LIMS program specification system and associated project analyte nicknames are the means by which client-specific requirements for sample preparation, analysis, data evaluation and reporting are communicated to the laboratory. This system includes automated electronic controls where possible. The criteria defined in the program specification supercede Paragon's standard criteria. It is the responsibility of all personnel who work with samples or data involving this method, to consult the applicable LIMS program specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/ analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

The iodometric method suffers from interferences by reducing substances that react with iodine, including thiosulfate, sulfite, and various volatile organic compounds, both solid and dissolved. Per SM4500-S^2 C, these interferences may be eliminated by first precipitating zinc sulfide, and then removing the supernatant and replacing it with deionized water.

5. APPARATUS AND MATERIALS

5.1 specimen cups, polypropylene, 250mL

5.2 transfer pipets, plastic

5.3 stir plate

5.4 magnetic stir bars

5.5 top loading balance, 0.01g sensitivity

5.6 pH meter (Accumet 50 or equivalent) or pH test strips capable of reading pH <2

5.7 Eppendorf ™ Pippette or equivalent, adjustable, capable of delivering 0.50- 1.0mL

6. REAGENTS

NOTES: Only ACS grade or better chemicals may be used.

Reagents may be stored in polypropylene containers.

6.1 Deionized (DI) water. Obtained from the laboratory deionized water system.

6.2 Sulfuric Acid (H_2SO_4) solution, 50% (18N): EMD, SX1244-5 or equivalent. Carefully add 100mL concentrated H_2SO_4 to 100mL deionized water, or different volumes as long as same ratio of 1:1. *Shelf Life = 1 year.*

6.3 Standard Iodine (I2) Solution, 0.0250N: JT Baker, 3162-01 or equivalent. Dissolve 25g of Potassium Iodide (KI) in 800mL of DI water. Add 3.2g of iodine crystals and dissolve. Dilute to 1L with DI water. *Shelf Life = 1 year.* **NOTE: *Standardize against $Na_2S_2O_3$ solution daily before use.***

6.4 Starch Indicator, 2%: VWR, Cat. No. VW3638-2 or equivalent. *Shelf-life = per expiration date indicated on label by manufacturer.*

6.5 Hydrochloric Acid (HCl), 6N: JT Baker, 9530-33 or equivalent. Carefully add a measured volume of concentrated HCl to an equal volume of DI water (1:1 dilution). *Shelf Life = 1 year.*

6.6 Standard Potassium Biiodate [$KH(IO_3)_2$] Solution, 0.025N: EM Science, PX1351-2 or equivalent. Dissolve 0.4062g of $KH(IO_3)_2$ salt in 500mL of DI water. *Shelf Life = 1 year.*

6.7 Sodium Thiosulfate ($Na_2S_2O_3$) Solution, approximately 0.025N: EM Science #SX0820-1 or equivalent. Dissolve 3.95g of anhydrous $Na_2S_2O_3$ and 0.4g of NaOH in 1L of DI water. *Shelf Life = 1 year.* **NOTE: *Standardize against $KH(IO_3)_2$ once before use.***

6.8 Sulfide (Na_2S) Spiking Solution: Dissolve 15g of Sodium Sulfide ($Na_2S \bullet 9H_2O$) in 200mL of deionized water. *Shelf Life = 1 year.* **NOTE: *Standardize daily before use.***

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

Sample container, preservation techniques and holding times may vary and are dependent on sample matrix, method of choice, regulatory compliance, and/or specific contract or client request. Listed below are the holding times and the references that include container and preservation requirements for compliance with the Safe Drinking Water Act (SDWA) and the Clean Water Act (CWA):

7.1 All samples must be collected according to an approved sampling plan. Samples of 500mL or larger may be collected in either plastic or glass containers and should be chilled (4±2°C).

7.2 During collection and prior to preservation and precipitation of the sulfide by zinc acetate, the samples should not be agitated. Sulfide may be volatilized by

aeration and any oxygen inadvertently added to the sample may convert the sulfide to an unmeasurable form.

7.3 Aqueous samples must be preserved by adding 2.0mL of 2N Zinc Acetate Solution [$Zn(C_2H_3O_2)_2 \bullet 2\ H_2O$] and 1.5 mL of 20% Sodium Hydroxide Solution (NaOH) per 500mL sample.

7.4 To meet holding time requirements, analysis must be completed within 7 days of collection.

Regulation	Holding Time	Reference
SDWA	7 days	EPA-570/9-82-002
CWA	7 days	CFR 40 Part 136.3

8. STANDARDIZATION OF REAGENTS

8.1 STANDARDIZATION OF SODIUM THIOSULFATE ONCE BEFORE USE AS FOLLOWS:

8.1.1 Transfer 10.00mL standard potassium biiodate [$KH(IO_3)_2$] solution into a 200mL beaker.

8.1.2 Dilute to about 100mL with DI water.

8.1.3 Add approximately 2g of potassium iodide (KI) pellets.

8.1.4 Add 4-5 drops of 50% sulfuric acid (H_2SO_4).

8.1.5 Add 2-3 drops of starch indicator.

8.1.6 Tare the beaker + contents on a top loading balance.

8.1.7 On the stir plate, add sodium thiosulfate solution drop wise until the beaker's contents turns from blue to colorless.

8.1.8 Record the amount of $Na_2S_2O_3$ solution used.

8.1.9 Repeat twice more and average the results of the three replicates. Calculate the concentration of the sodium thiosulfate solution as follows:

$$\text{Sodium thiosulfate conc (eq/L)} = (0.025) * (10.00) / (V)$$

where:

0.025 = normality of potassium biiodate solution titrated

10.00 = volume of potassium biiodate solution titrated

V = volume of sodium thiosulfate solution required to reach endpoint

8.2 STANDARDIZATION OF STANDARD IODINE (I_2) SOLUTION DAILY BEFORE EACH USE AS FOLLOWS:

8.2.1 Add approximately 100mL of DI water to a plastic specimen cup containing a stir bar.

8.2.2 Place on stir plate and add approximately 2.0mL of 6N HCl.

8.2.3 Place on top loading balance and tare container and contents. Add approximately 2.5mL of the iodine standard solution and record the weight to the nearest 0.01g.

8.2.4 Add 2-3 drops of starch indicator and tare container and contents on balance.

8.2.5 Place on a magnetic stir plate and add $Na_2S_2O_3$ solution drop wise until a colorless endpoint is reached.

8.2.6 Place the container and contents back on the balance and record the weight of the titrant used.

8.2.7 Repeat twice more. Calculate the concentration of the standard iodine solution as follows (this calculation can be conveniently carried out using the spreadsheet template located at i:\oprtns\wtchm\sulfide\ template\s1.xls).

$$\text{Iodine conc (eq/L)} = (CTh) * (VTh) / (VI)$$

where:

CTh = concentration (eq/L) of sodium thiosulfate solution

VTh = volume of sodium thiosulfate required to reach endpoint

VI = volume of iodine solution titrated

8.3 STANDARDIZATION OF SULFIDE SPIKING SOLUTION DAILY BEFORE EACH USE AS FOLLOWS:

8.3.1 Add approximately 100mL of DI water to a plastic specimen cup containing a stir bar.

8.3.2 Pipet 0.50mL of the prepared Sulfide Spiking Solution into the container.

8.3.3 Place container on stir plate and add approximately 2.0mL of 6N HCl.

8.3.4 Place container on top loading balance and tare the container and contents.

8.3.5 Add standard iodine solution until a brown color persists (8-15mL). Record standard iodine solution weight to the nearest 0.01g.

8.3.6 Add 2-3 drops of starch indicator and tare container and contents on balance.

8.3.7 Place on a magnetic stir plate and add $Na_2S_2O_3$ solution drop wise until a colorless endpoint (color change from dark blue to clear) is reached.

8.3.8 Weigh the container and contents; record the weight, to the nearest 0.01g, of the titrant used.

8.3.9 Repeat twice more and average the result of the three replicates.

8.3.10 Calculation the concentration of the sulfide spiking solution as follows (the spreadsheet template located at i:\oprtns\wtchm\sulfide\template\s1.xls may be used).

$$\text{mg sulfide / L} = [(A*B)-(C*D)]*16000$$

where:

A = volume (mL) of iodine solution

B = normality of iodine solution

C = volume (mL) of sodium thiosulfate solution

D = normality of sodium thiosulfate solution

16000 = constant which converts meq/mL to mg/L

9. FIELD AND QUALITY CONTROL (QC) SAMLE PREPARATION AND ANALYSIS

9.1 Prepare an Initial Calibration Verification standard (ICV), a Laboratory Control Sample (LCS), and a Continuing Calibration Verification (CCV) standard by transferring about 200mL of DI water each to three plastic cups. Pipet 0.50mL of the standardized Sulfide Spiking Solution into each container as needed.

9.2 Prepare two solutions to serve as an Initial Calibration Blank (ICB) and Method Blank (MB) by transferring approximately 200 mL of DI water to a clean plastic cup. **Note:** Prepare Continuing Calibration Blanks (CCBs) in this same manner as needed.

9.3 Prepare each field sample by mixing the sample thoroughly in the original capped container, then transferring 200mL of the well-mixed sample into a labeled plastic cup. Select a sample representative of the batch and prepare an additional aliquot to serve as the laboratory duplicate. One duplicate sample (DUP) must be prepared for every twenty or fewer environmental samples processed together as a unit.

NOTE: If dissolved sulfides is to be determined, suspended solids must first be

removed (see SM4500-S^2 B).

9.4 The sulfide determinations should be performed in the following analytical sequence:

1.	ICV
2.	ICB
3.	MB
4.	LCS
5.	DUP
6 - 22	17 field samples

If more than 17 field samples are analyzed, the sequence must continue as follows:

23.	CCV
24.	CCB
25. - 27.	3 more field samples (from same batch)

If a second batch of samples is to be analyzed, the sequence repeats beginning with a MB, LCS, DUP, 14 field samples, etc.

9.5 Place each cup on a stir plate and add a stir bar. Add approximately 2.0mL of 6N HCl and check the pH of the solution using a pH test strip. **NOTE:** The pH of the solution must be 2 or less. Add additional 6N HCl as necessary.

9.6 Place the cup on the top loading balance and tare the container and contents.

9.7 Add standard iodine solution to the sample until a brown color persists (approximately 2.5mL if non-detect).

9.8 Weigh the container and contents on the balance. Record the weight of the iodine solution added.

9.9 Add 2-3 drops of starch indicator and tare container and contents on balance.

9.10 Place on stir plate and titrate to a colorless endpoint by adding standardized sodium thiosulfate solution drop wise.

9.11 Place the container and contents back on the balance and record the weight of the titrant used.

9.12 Calculate the amount of sulfide in the field or quality control sample using the spreadsheet template located at i:\oprtns\wtchm\sulfide\template\s1.xls. The template calculates the sulfide concentration based on the following equation:

$$\text{mg sulfide / L} = \frac{[(A * B) - (C * D)] * 16000}{\text{mL sample}}$$

where:

A = volume (mL) of iodine solution

B = normality of iodine solution

C = volume (mL) of sodium thiosulfate solution

D = normality of sodium thiosulfate solution

16000 = constant that converts meq/mL to mg/L

10. QUALITY CONTROL

10.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed together as a unit. Batch QC samples are defined as the method blank (MB), laboratory duplicate (DUP) and laboratory control sample (LCS). All quality control samples must be carried through all stages of the sample preparation and measurement steps.

10.2 BLANKS

Blanks are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. Each time a batch of samples is analyzed or there is a change in reagents, a method blank (MB) must be processed. The Initial Calibration Blank (ICB) is run following the ICV. A CCB must be run following each CCV analyzed if more than twenty field and QC samples are analyzed. All blanks consist of 200mL DI water. See QC Table for acceptance limits.

10.3 LABORATORY CONTROL SAMPLE

The laboratory control sample (LCS) is analyzed to measure the accuracy of the method. It consists of an aliquot of clean matrix (in this instance, 200mL DI water), into which a known amount of analyte is spiked. One LCS must be analyzed per batch of 20 or fewer field samples processed together as a unit.

Results obtained are compared to results expected. The mathematical evaluation is expressed as percent recovery, %R, calculated as follows:

$$\%R = \frac{\text{Concentration}_{\text{Found}}}{\text{Concentration}_{\text{Target}}} \times 100$$

See QC Table for acceptance limits.

10.4 LABORATORY DUPLICATE

A second aliquot of one sample per batch of twenty (20) or fewer field samples processed together as a unit is prepared and analyzed as a laboratory duplicate

(DUP). The laboratory duplicate is analyzed as a measure of the precision of the analytical results generated. The duplicate results are compared mathematically (shown below), with the precision expressed as Relative Percent Difference (RPD):

$$RPD\ (\%) = \frac{|\ Result_x - Result_{Dup}\ |}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

For this procedure, the RPD must not be greater than 20%.

11. DEVIATIONS FROM METHOD

Section 6.0 of Method EPA 376.1 directs that if the sample has been precipitated (i.e., if Zinc Acetate has been added), the reagents are to be added to the original sample container. Paragon processes samples by adding reagents to a well-mixed aliquot of sample.

12. SAFETY HAZARDS AND WASTE

12.1 SAFETY AND HAZARDS

12.1.1 Read the MSDS prior to preparing standards or using any solvents or reagents for the first time.

12.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

12.1.3 Any chemicals with a Threshold Limit Value of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

12.1.4 Any non-original containers be used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

12.2 WASTE DISPOSAL

12.2.1 Solid filtrate residues and any other solid residues are disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

12.2.2 All empty solvent or reagent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

12.2.3 Certain clients may require that the samples and sample residues from their samples are segregated and returned to the client's location. The

Waste Compliance Officer will provide specific procedures and materials for these samples.

7/6/05: LIMS program specification language added.

4/27/07: Minor format updates. Added DOCUMENT REVISION HISTORY.

Analytical Method: EPA 376.1; SM4500-S^{2-} F	**Parameter:** Determination of Total Sulfides in Water		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Calibration: Analyte content determined by direct concentration (obtained by calculation from titration). Titrant is standardized each day of use	Daily; each day of use	Titrant must calculate to be to be approximately 0.025N	If titrant does not meet concentration criteria; prepare fresh and standardize.
Initial Calibration Verification (ICV); second source	Daily; each day of use Run following standardization and before any samples are analyzed	Results for the ICV must agree within ±20% expected value	If ICV criterion not met, check for preparatory error (remake if necessary); reanalyze. If ICV still fails, reagents must be remade and re-standardized.
Continuing Calibration ; Verification (CCV); first source	Run to bracket each set of 20 environmental samples processed	Results for the CCV must agree within ±20% expected value	If CCV criterion not met, check for preparatory error (remake if necessary); reanalyze. All field and quality control samples run since the last acceptable CCV must also be reanalyzed.
Laboratory Control Sample (LCS)	One per batch of ≤20 samples	Concentration results obtained must agree between 80% and 120% of expected value	Check calculations and preparation for documentable errors. If no errors are found, reanalyze. Associated samples must also be reanalyzed.
Blanks: Method Blank (MB), Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	The MB may be run initially as the ICB that is run following the ICV. CCBs are run following the CCVs	Sulfide content of any blank must not exceed the analyte reporting limit (typically 2mg/L S^2)	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Laboratory Duplicate (DUP)	One per batch of ≤20 samples	RPD must be ≤20%	Check all calculations for errors. If no errors are found, discuss with Department/Project/QA Managers.

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1121 REVISION 6

TITLE: DETERMINATION OF HEXAVALENT CHROMIUM IN SOLID MATRICES USING ALKALINE DIGESTION (METHOD SW3060A) AND ANALYSIS BY METHOD SW7196A

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER _____ DATE 3/7/08
QUALITY ASSURANCE MANAGER _____ DATE 3/7/08
LABORATORY MANAGER _____ DATE 3-7-08

HISTORY: Rev0, 3/27/00; Rev1, 3/2/02; Rev2, 10/15/02; Rev3, 2/9/04 (format update) and 3/18/05 (re-released without revision); Rev4, 7/26/05 (Program Spec. reference added); Rev5, 6/26/06; Rev6, 3/7/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- SW3060A and SW7196A -- describe the alkaline digestion and determination of hexavalent chromium (Cr^{+6}) in soils, sludges, sediments and similar waste materials.

2. SUMMARY

This method uses an alkaline digestion to solubilize both water-insoluble and water soluble Cr^{+6} compounds in solid and waste samples. An aliquot of sample is digested for sixty minutes at 90-95°C in a solution of sodium hydroxide and sodium carbonate. This solubilizes the Cr^{+6} and stabilizes it against reduction to Cr^{+3}.

The Cr^{+6} in the alkaline extract is determined colorimetrically by reaction with diphenylcarbazide (DPC). This reaction is highly selective for Cr^{+6}. Addition of an excess of DPC yields a red-violet complex whose absorbance is measured photometrically at 540nm.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 The stability of Cr^{+6} in a solid sample is governed by the oxidizing/reducing tendency (redox potential) of the sample matrix. The redox potential of a particular sample matrix may be sufficiently low to favor the reduction of Cr^{+6} to Cr^{+3}. Under such circumstances, low matrix spike recovery of Cr^{+6} should not be interpreted as a failure of the analysis. Rather, failure to recover spiked Cr^{+6} in a particular sample matrix should be viewed as evidence that Cr^{+6} is not stable in that matrix and, therefore, native Cr^{+6} should not be expected.

4.2 Various organic constituents may be brought into solution when a soil sample is carried through the alkaline digestion procedure, resulting in a yellow to dark brown colored extract. The color can contribute to the absorbance measured on the spectrophotometer and thereby cause a high bias to the results if not accounted for. Furthermore, dissolved organics can interfere with the colorimetric determination of Cr^{+6} with diphenylcarbazide. It may be necessary to dilute the extract in order to alleviate this interference. Color can be accounted for by taking a sample's initial absorbance reading and subtracting it out from the sample's final absorbance reading after the addition of diphenylcarbazide.

4.3 Although not typically found in the alkaline digestates of soils, certain substances may interfere in the analytical methods for Cr^{+6} if the concentrations of these interfering substances are high and the Cr^{+6} concentration is low. Hexavalent molybdenum and mercury salts react to form color with diphenylcarbazide; however, the red-violet intensities produced are much lower than those for chromium at the specified pH. Concentrations of up to 200mg/L of hexavalent molybdenum and mercury can be tolerated. Vanadium interferes strongly, but concentrations up to 10 times that of chromium will not cause trouble.

4.4 For waste materials or soils containing soluble Cr^{+3} concentrations greater than four times the laboratory Cr^{+6} reporting limit, Cr^{+6} results obtained using this method may be biased high due to method-induced oxidation. The addition of Magnesium (Mg^{2+}) in a phosphate buffer to the alkaline extraction solution has been shown to suppress this oxidation.

5. APPARATUS AND MATERIALS

5.1 UV/VIS Spectrophotometer, Sequoia Turner™ Model 340 or equivalent. Suitable for measurements at 540nm with a light path of 1.0cm or longer.

5.2 analytical balance, capable of weighing to 0.0001g, verified per SOP 305

5.3 laboratory balance, top loading, capable of weighing to 0.1g, verified per SOP 305

5.4 pH meter with electrode and proper calibration buffer solutions

5.5 centrifuge capable of achieving approximately 3500rpm

5.6 water bath, capable of maintaining a temperature of 90-95°C

5.7 vortex mixer

5.8 magnetic stir plate and stir bars

5.9 repeater pipet, variable Eppendorf™ or equivalent

5.10 cuvettes, optically matched, 1-inch diameter

5.11 centrifuge tubes, polypropylene with screw-cap closures, 50mL

5.12 volumetric flasks, Class A, 500mL and 1L sizes

5.13 beakers, polypropylene with snap tight lid, 220mL

5.14 graduated cylinder, 50mL capacity (delivered volume verified by laboratory)

5.15 syringe, outfitted with a 0.45µm or 0.7µm filter disk

5.16 magnetic wand

5.17 thermometer, for checking water bath temperature

6. REAGENTS

6.1 Deionized (DI) water obtained from the laboratory DI water system

6.2 Ottawa sand, clean/inert, EMD, SX0075-3 or equivalent

6.3 Lead Chromate ($PbCrO_4$), powdered, JT Baker, 0970-01 or equivalent

6.4 pH paper, basic, capable of reading pH 11–13, EM Science, Cat. #9585 or equivalent

6.5 Sulfuric Acid, (H_2SO_4), 10%: Dilute 20mL of 50 % H_2SO_4 (1:1 ratio with DI water) to a final volume of 100mL with DI water. Alternately, dilute 10mL of conc. H_2SO_4 to a final volume of 100mL with DI water. EMD, SX1247-2 or equivalent. ***Store in a polypropylene bottle.*** *Shelf Life =1 year.*

6.6 Acetone, Burdick & Jackson, Cat. 010-4 or equivalent.

6.7 Nitric Acid, (HNO_3), 2N : Dilute 100mL of concentrated HNO_3, JT Baker, 9598-34 or equivalent, to a final volume of 700mL using DI water. ***Store in a polypropylene bottle.*** *Shelf Life = 1 year*

6.8 Diphenylcarbazide (DPC) Solution: Dissolve 0.25g, EM Science, DX2200-1 or equivalent, 1,5-diphenylcarbazide in 50mL of reagent grade acetone. ***Store in a brown glass bottle in the refrigerator.*** Discard when the solution becomes discolored (approx. 3 months).

6.9 Magnesium Chloride ($MgCl_2$) Solution, 2.5M, 51% (w/v): GFS Chemicals, item no. 724 or equivalent. Dissolve 51.0g $MgCl_2 \bullet 6\ H_2O$ in DI water and diluting to 100mL. ***Store in a polypropylene bottle.*** *Shelf Life = 1 year or as indicated by vendor.*

6.10 Potassium Phosphate Buffer: Mallinckrodt, 7100-02 or equivalent. Dissolve 68.0g reagent grade KH_2PO_4 and 87.1g K_2HPO_4 in DI water and dilute to 1L**.** ***Store in a polypropylene bottle.*** *Shelf Life = 1 year.*

6.11 Sodium Hydroxide (NaOH)/Sodium Carbonate ($NaCO_3$) Digestion Reagent: Dissolve 20.0g reagent grade NaOH and 30.0g anhydrous $NaCO_3$ in 1L of DI water. ***The pH must be 11.5 or greater; if not, discard.*** *Shelf Life = 1 month.*

6.12 Cr^{+6} Stock Standard, 500mg/L (**First Source**): Purchase as a certified stock solution from a commercial vendor or prepare by dissolving 0.1414g dry Potassium Chromate ($K_2Cr_2O_7$) in DI water using a 100mL Class A volumetric flask and diluting to full volume with additional DI water. Mix thoroughly. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 1 year.*

6.13 Cr^{+6} Intermediate Standard, 10mg/L (**First Source**): Dilute 2.0mL of first source 500mg/L Cr^{+6} stock standard to 100mL with DI water. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 3 months.*

6.14 Cr^{+6} Stock Standard, 500mg/L (**Second Source**): Purchase as a certified solution from a commercial vendor or prepare by dissolving 0.1414g dry $K_2Cr_2O_7$ in DI water using a 100mL Class A volumetric flask. Bring to volume using DI water, mix thoroughly. If purchased, the certified solution must be from a different vendor than the first source stock standard. If prepared in-house, the $K_2Cr_2O_7$ salt must be from a different vendor, if possible, or at least a different lot number than

the salt used to prepare the first source stock standard. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 1 year.*

6.15 Cr^{+6} Intermediate Standard, 10mg/L (**Second Source**): Dilute 2.0mL of second source 500mg/L Cr^{+6} stock standard to 100mL with DI water. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 3 months.*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples must be collected according to an approved sampling plan.

7.2 Samples should be collected in containers that do not contain stainless steel.

7.3 Samples should be stored at 4±2°C until analyzed.

7.4 The holding time for hexavalent chromium in solids is 30 days from collection. "Hexavalent chromium has been shown to be quantitatively stable in field-moist soil samples for 30 days from sample collection. In addition, Cr^{+6} has been also been shown to be stable in the alkaline digestate for up to 168 hours (i.e., 7 days) after extraction from soil." (SW3060A, Section 6.4).

8. PROCEDURE

NOTE: A batch is defined as twenty (20) field samples or less of like matrix. One of each of the laboratory quality control (QC) samples outlined below [i.e., Method Blank, Blank Spike/LCS, MS/MSD set (soluble), MS/MSD set (insoluble), and post-digestion spike], must be prepared for each batch of field samples to be analyzed.

8.1 ALKALINE DIGESTION

8.1.1 For each sample, weigh 2.5g of well-mixed moist sample into a 50mL disposable polypropylene centrifuge tube.

8.1.2 Method Blank. Weigh 2.5g clean silica sand into a 50mL disposable polypropylene centrifuge tube.

8.1.3 Laboratory Control Sample (LCS). Weigh 2.5g clean silica sand into a 50mL disposable polypropylene centrifuge tube. Spike with **0.25mL** of 500mg/L Cr^{+6} stock standard (**second source**). **Be certain to have another person witness the spiking.**

8.1.4 Soluble Matrix Spike/Matrix Spike Duplicate (MSs/MSDs). For one of the samples in the batch, spike two duplicate 2.5g aliquots with **0.25mL** of 500mg/L Cr^{+6} stock standard (**first source**). **Be certain to have another person witness the spiking.**

8.1.5 Insoluble Matrix Spike/Matrix Spike Duplicate (MSn/MSDn). For one of the samples in the batch, spike two duplicate aliquots with 10 - 20mg of powdered $PbCrO_4$. The amount of $PbCrO_4$ added must be weighed on an analytical balance and recorded in the Aqueous Extractions logbook to the nearest 0.0001g. **Be certain to have another person witness the spiking.**

8.1.6 To all of the above, add the following:

- 50mL of Sodium Hydroxide (NaOH)/Sodium Carbonate ($NaCO_3$) Digestion Reagent using a 50mL volume-verified graduated cylinder
- 0.50mL of Potassium Phosphate Buffer Solution
- 0.75mL of 51% $MgCl_2$ Solution

8.1.7 Cap each tube and mix by shaking for at least five minutes. Place each tube into the steam bath, maintained at 90-95°C (check temperature and record in laboratory logbook) and heat for one hour. During this hour, sequentially remove each sample from the steam bath, agitate and replace (approximately every 5 minutes). Continue the sequential agitation of the samples for the entire one-hour heating period.

8.1.8 After one hour of heating and agitating, remove the field and QC samples from the steam bath and let cool to room temperature. Manually agitate periodically.

8.1.9 Centrifuge for about 15 minutes at about 3500rpm.

8.1.10 Label a 220mL beaker for each field and laboratory QC sample prepared. Place a labeled 220mL polypropylene beaker on a top loading balance and tare the balance. Transfer the appropriate supernatant liquid (from the digestion tube) into the beaker. **Do not tare the balance at this time; it is critical that the balance is not disturbed.** Remove the beaker with contents from the balance and add a stir bar.

8.1.11 Place a calibrated pH probe (see manual for further instruction) into the digestate solution and, while stirring, add 2N HNO_3 drop wise until the pH = 7.5±0.5. **CAUTION: Carbon dioxide will be evolved, perform in fume hood.**

8.1.12 Using a magnetic wand on the outside of the beaker, remove the stir bar. Rinse the stir bar repeatedly with DI water during removal. Place the beaker with contents back on the previously tared balance.

Gravimetrically bring the sample solution to a 100mL final volume with DI water (100.0mL = 102.74g).

8.1.13 Attach the beaker's lid and mix well by swirling (careful, the capped beaker will build up pressure slightly).

8.2 COLORIMETRIC ANALYSIS OF STANDARDS AND SAMPLES

8.2.1 STANDARD CURVE PREPARATION

Prepared fresh on each day of analysis. Use DI water to achieve the final volume. Prepare working standards in optically matching 1" spectrophotometer cuvettes as described below:

Standard Concentration (mg/L Cr^{+6})	Volume of 10mg/L Cr^{+6} Intermediate Std (mL)	Final Volume (mL)
0	0	20.0
0.01	0.02	20.0
0.05	0.10	20.0
0.10	0.20	20.0
0.30 (CCV)**	0.60	20.0
0.50	1.00	20.0
0.10 (ICV)*	0.20 *	20.0

* Independent Calibration Verification (ICV). The ICV must be prepared from a second source that is independent of that which is used to prepare the calibration standards. ***Use the Second Source 10mg/L Intermediate Standard.*** An Initial Calibration Blank (ICB), consisting of a 20.0mL aliquot of DI water, must be analyzed immediately following the ICV.

** This standard is also analyzed repeatedly as the Continuing Calibration Verification (CCV). A Continuing Calibration Blank (CCB), consisting of a 20.0mL aliquot of DI water, must be analyzed immediately following each CCV.

8.2.2 POST-DIGESTION SPIKE RECOVERY STUDY

Alkaline soil digestates are often yellow to dark brown in color due to the presence of dissolved organic matter. Dissolved organic matter can interfere with the colorimetric determination of Cr^{+6}. The interference can often be overcome by diluting the digestates prior to analysis.
Note: All samples (including QC samples) are diluted 5X initially.

The level of further dilution necessary to overcome the interference is determined by conducting a Cr^{+6} post-digestion spike recovery study, at various levels of dilution, as follows:

- The alkaline digestate for the sample that was selected as the MS/MSD sample is usually used for the post-digestion spike.

- Transfer 16.0mL of DI water into each of two labeled 1-inch spectrophotometer cuvettes Using a pipet, remove 0.50mL of water from one of the cuvettes and replace it with 0.50mL of 10mg/L intermediate Cr^{+6} standard (first source). **Be certain to have another person witness the spiking.**

- Pipet a 4.0mL aliquot of the selected sample digestate into each cuvette. Adjust to a 20mL final volume using DI water. Mix using the vortex mixer. Note that use of a 4.0mL aliquot of digestate brought to a 20.0mL final volume constitutes a 5-fold dilution.

- To both cuvettes, add 0.5mL of 10% H_2SO_4; mix well.

- Measure the absorbance of both the unspiked and spiked post-digestion aliquots (at 540nm using the spectrophotometer. Record these "initial" readings in LIMS. **These absorbance readings are due to the native color of the sample and will be subtracted from the absorbance readings measured after adding DPC color reagent.**

- Add 0.20mL DPC color reagent to both cuvettes, mix. After allowing about 10 minutes for the reddish color to develop and stabilize, measure the absorbance of both aliquots at 540nm. Record the "final" readings in LIMS.

- An acceptable initial calibration must be generated before the Post-Digestion Recovery Study results can be evaluated (see following Sections). Evaluate the Post-Digestion Recovery Study results as discussed in Section 8.2.4 below.

- If the Post-Digestion Recovery Study results do not meet the 85-115% control criteria, the additional actions that may be taken are contingent upon the analyst's judgment, the particular set of circumstances, and client input.

  Typically the study is repeated on a further diluted aliquot of the same digestate, until satisfactory recovery is achieved. All samples are then diluted at the same level of dilution, based on the successful post-digestion spike study results. The analyte reporting limit for the diluted sample analyses is elevated accordingly.

Overall though, the objective is that any further actions taken are representative of the client's sample matrix. Consequently, for failures affecting samples in a batch that are from several client sources, several actions may be necessary. Confer with the Project Manager(s). The appropriate course of action will be developed at the time needed, particular to the circumstance.

8.2.3 STANDARD/SAMPLE DEVELOPMENT

NOTE: Be sure to properly adjust spectrophotometer. Insert the proper stray light filter into position. Adjust the wavelength to 540nm. Insert the DI water blank cuvette into the cuvette holder. While in TRANS MODE, press and hold the ZERO SET button while adjusting the ZERO knob until the display indicates 0.00. Set MODE switch to ABS and adjust 100%T/A knobs to exactly 0.000. If further information is required see Barnstead/Thermolyne Corp. Operator's Reference Manual, Model 340 Digital Spectrophotometer.

- Transfer a 4.0mL aliquot (or smaller volume if it was determined that a greater dilution is necessary) of each digestate into a 1-inch diameter spectrophotometer cuvette. Bring to a 20.0mL final volume using DI water. Use of a 4.0mL aliquot of digestate brought to a 20.0mL final volume represents a 5-fold dilution.

- Add 0.5mL of 10% H_2SO_4 to each cuvette and mix using the vortex mixer. Measure the absorbance of the samples at 540nm using the spectrophotometer. Record these "initial" readings in LIMS. This absorbance reading is due to the native color of the sample and will be subtracted from the absorbance reading measured after adding DPC color reagent.

- Add 0.20mL DPC solution to the cuvettes and vortex.

- Allow the cuvettes to stand until a stable reddish color has developed (about 10 minutes).

8.2.4 ANALYTICAL SEQUENCE

Use the spectrophotometer (set at 540nm) to read the absorbance of each of the cuvette's contents. Record each reading. The following analytical sequence must be observed:

- Absorbance measurements must begin with the calibration standards, immediately followed by the ICV/ICB.

- Analyze the Post-Digestion Study samples. The recovery quality control limits for these samples is 85-115 %. If the Post-Digestion Recovery Study results exceed these limits, address as discussed in Section 8.2.2.

- After the ICV and ICB have been analyzed, **up to ten** samples (i.e., Method Blank, BS/LCS, post-digestion spike study, field samples, etc.) can be analyzed. Prepare digestates (or dilutions thereof), develop and analyze as previously discussed. Note: Insoluble MS/MSD's should require 100X dilution.

- ***The continuing calibration verification (CCV) standard, followed by the Method Blank as the Continuing Calibration Blank (CCB), must be analyzed between each set of ten samples, and at the close of the analytical sequence.***

  NOTE: To be acceptable, no blank may yield results greater than the analyte reporting limit.

- Continue to analyze samples in sets of ten or less followed by the analysis of the CCV/CCB pair until all samples have been analyzed.

8.3 EVALUATION OF THE CALIBRATION CURVE

8.3.1 Prepare a standard curve by plotting the observed absorbance versus the standard concentration for each calibration standard. Enter the information into the LIMS system.

8.3.2 Enter the absorbance data obtained for each solution analyzed (calibration standards, QC samples and field samples). Also, enter additional data as necessary (e.g., identification, sample volumes or weights, dilutions, percent solids, etc.) This information is also entered into the LIMS system.

8.3.3 Using LIMS evaluate the linear regression analysis between absorbance and Cr^{+6} concentrations for the calibration standards. The correlation coefficient (r^2) for the regression must be ≥ 0.995.

8.3.4 Evaluate the ICV sample. The ICV result must agree within ± 10 % of the expected value.

8.3.5 Evaluate the ICB sample result (result must be less than analyte reporting limit).

8.3.6 Evaluate the CCV results. The CCV result must agree within ±10% of the expected value.

8.3.7 Evaluate the CCB results (results must be less than analyte reporting limit).

NOTE: *Acceptance criteria and corrective actions are summarized in the attached QC Summary Table.*

8.4 CALCULATION OF SAMPLE CONCENTRATION

The Cr^{+6} concentration in the samples is calculated as follows:

$$Cr^{+6}\ \text{Concentration (mg/Kg)} = \frac{(C * 100 * 20)}{(A * 2.5 * S)}$$

where:

C	=	Concentration of Cr^{+6} (mg/L) in cuvette
A	=	Aliquot (mL) of digestate pipetted into the cuvette
20	=	final volume (mL) of solution in cuvette
100	=	final volume (mL) of digestate
2.5	=	moist weight (g) of soil digested
S	=	ratio of solids in sample (% solids/100)

8.5 CALCULATION OF POST-DIGESTION SPIKE RECOVERY

8.5.1 For both aliquots, subtract the "initial" absorbance reading from the "final" absorbance reading to obtain a "corrected" absorbance reading.

8.5.2 Enter the corrected absorbance into the spreadsheet to calculate the solution Cr^{+6} concentration.

8.5.3 Calculate the post-digestion spike recovery as follows:

$$\text{Post-Digestion Spike (\% R)} = \frac{(S - N)}{0.25} * 100$$

where:

S = Cr^{+6} concentration (mg/L) in spiked aliquot

N = Cr^{+6} concentration (mg/L) in unspiked aliquot

0.25 = amount of Cr^{+6} spike added (mg/L); 0.25 if this SOP is followed without deviation

8.5.4 The Post-Digestion Spike recovery acceptance limits are 85-115%. If the recovery falls outside of this range, the digestate post-digestion spike recovery study must be repeated at greater levels of dilution until

acceptable recovery is achieved. Results of the spike recovery study are extrapolated to determine appropriate levels of dilution for the other samples in the prep batch. In other words, the other samples in the batch must be diluted such that the "initial" absorbance reading (i.e., the absorbance measured before adding DPC reagent), is not greater than the initial absorbance reading for the post-digestion spike sample at the level of dilution that was necessary for acceptable recovery.

9. QUALITY CONTROL (QC)

NOTE: *Acceptance criteria and corrective actions are detailed in the attached QC Summary Table.*

9.1 BLANKS

Method blanks (MBs) are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. For this procedure, the MB consists of clean silica sand that has been digested as described previously in this SOP. The blank must not yield positive results greater than the reporting limit (usually 2.0mg/Kg Cr^{+6}).

9.2 SPIKED SAMPLES

The nature and evaluation of Post-Digestion Spike samples are discussed in previous Sections.

9.2.1 Blank/Laboratory Control Spike (LCS) samples consist of clean matrices which are spiked with a known amount of target compound. For this SOP, silica sand is used as the clean matrix. LCS analyses are performed to evaluate the accuracy of the analytical system.

9.2.2 For this SOP, the matrix spiked samples (MSs/MSDs and MSn/MSDn) consist of aliquots of selected field sample into which known concentrations of target analytes are spiked and analyzed as a means of determining the effect of matrix on target analyte detection. The spiked sample analyses are performed to determine the effect of sample matrix interferences.

9.2.3 EVALUATION OF SPIKED SAMPLE RESULTS

Spiked samples are evaluated based on percent recovery (%R), which is a calculation of the amount of target yielded vs. the amount of target anticipated. The following equation is used to calculate spike recovery:

$$\%R = \frac{Concentration_{Found} - Concentration_{Aliquot}}{Concentration_{Anticipated}} \times 100$$

where:

$Conc_{Found}$ = amount of target yielded by the spiked analysis

$Conc_{Aliquot}$ = amount of target found in the unspiked aliquot ("zero" for clean LCS matrix aliquots; sample results for sample matrix aliquots)

$Conc_{Anticipated}$ = amount of target expected to be yielded based on amount spiked

The control limits established for the LCS analysis are 80-120 %.

Advisory limits for the MS/MSD analysis are set at 75-125 % of the anticipated value.

9.2.4 DUPLICATE PRECISION

The matrix spiked samples are prepared and analyzed in duplicate to measure analytical precision. Precision is evaluated in terms of Relative Percent Difference (RPD), and is calculated as follows:

$$RPD\ (\%) = \frac{|\ Result_x - Result_{Dup}\ |}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

An RPD of $\leq$20 is set as the advisory quality control limit.

9.3 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study should be performed as needed and at a minimum, annually.

10. DEVIATIONS FROM METHOD

10.1 According to Section 8.5 of Method SW3060A, "An acceptance range for matrix spike recoveries is 75-125 %. If the matrix spikes are not within these recovery limits, the entire batch must be rehomogenized/redigested/reanalyzed." This SOP does not require redigestion of samples when matrix spike recoveries are outside of the 75-125 % limits. Rather, recoveries outside these limits are attributed to matrix effects and the results are narrated and flagged in the data report accordingly (see also comments in Interferences Section).

10.2 Method SW3060A suggests the need for sample characterization and suggests "additional analytical parameters" such as pH, ferrous iron, sulfides, oxidation-reduction potential (ORP), total organic carbon (TOC), biological oxygen demand (BOD) and chemical oxygen demand (COD). Paragon considers these additional analyses to be beyond the scope of this analysis.

10.3 Unlike Method SW3060A, Section 8.4, this SOP does not prescribe that a sample duplicate be prepared and analyzed. In this SOP, a measure of analytical precision is provided by the RPD calculated for the soluble MS/MSD.

10.4 Section 8.6.2 of Method SW3060A prescribes that if the post-digestion spike recovery is outside of 85-115 %, either the Method of Standard Additions (MSA) is used or that additional analytical parameters should be considered in order to interpret the results. In this SOP, when a post-digestion spike is outside of 85-115% recovery, the spike is repeated on the diluted sample aliquot of the selected sample digestate. The level of dilution must be increased until satisfactory recovery is achieved. Furthermore, the other samples in the batch must be diluted according to the results from the post-digestion spike recovery study. Other corrective measures may be applied contingent upon the particular circumstance and client input.

10.5 Section 5.2 of Method SW7196A describes the creation of the chromium stock solution as dissolving 0.1414g $K_2Cr_2O_7$ in DI water and bringing the solution to a 1L final volume. Paragon creates a 10-times stronger chromium stock standard by dissolving 0.1414g $K_2Cr_2O_7$ in DI water and bringing the solution to a 100mL final volume. Furthermore, Section 5.3 of Method SW7196A describes the creation of the standard chromium solution by diluting 10.0mL of chromium stock solution to a 100mL final volume. Paragon creates the standard chromium solution by diluting 2.0mL of the chromium stock solution to a 100mL final volume. Therefore, at 10mg/L Cr^{+6}, Paragon's standard chromium solution is 2-times stronger than that provided for in the Method.

10.6 Section 7.1 of Method SW7196A prescribes that the colorimetric analysis of calibration standards and samples be performed in 100mL volumetric flasks (standards and samples are brought to 100mL using DI water). Paragon uses a 20.0mL final sample volume and conducts the color development directly in the 1-inch diameter spectrophotometer cuvettes.

10.7 In Section 7.2.1, Method SW7196A indicates that the method is suitable for the analysis of hexavalent chromium ranging in concentration from 0.5 to 5mg/L Cr^{+6}. Paragon's modifications to the Method (e.g., the use of more concentrated chromium standards), enables a typical calibration range of 0.010 to 0.50mg/L Cr^{+6} (2.0-100mg/Kg Cr^{+6}, correspondingly) to be achieved.

10.8 In Section 7.3.1, Method SW7196A indicates that the spike added concentration for the interference check standard should not be less than 30mg/L Cr^{+6}. This SOP prescribes a spike added concentration of 0.25mg/L Cr^{+6}, which is appropriate for the analytical range of Paragon's analysis.

10.9 Based on sample volumes and reagent strengths cited in the Methods, Section 4e of Method SM3500-Cr B and Section 7.1 of Method SW7196A prescribe the

addition of 2.0mL diphenylcarbazide to the 100mL final sample volume for color development. In accordance with reagent strengths, the 20.0mL final sample volume employed, and color development carried-out directly in the spectrophotometer cuvettes (all discussed above), Paragon uses 0.20mL of diphenylcarbazide to achieve color development.

10.10 Section 8.5 of Method SW7196A calls for the analysis of one matrix spike replicate OR one replicate sample for every ten samples. Paragon accomplishes this by preparing and analyzing one matrix spike/matrix spike duplicate per batch of 20 samples.

10.11 Section 7.1 of Method SW7196A discusses correcting sample absorbance by subtracting out the absorbance of the reagent water blank. Paragon does not correct absorbance readings using the reagent water blank because a 0.0 standard (consisting of reagent water) is incorporated as part of the calibration curve.

10.12 Section 7.1 of Method SW3060A suggests the use of a temperature blank to monitor the inferred temperature of the alkaline digestates while housed in the 90-95°C water bath. Paragon does not employ a temperature blank but directly monitors the water bath with a NIST-traceable verified glass thermometer.

10.13 Section 7.6 of Method SW3060A discusses filtration of the alkaline digestates. Paragon spins the digestates in a centrifuge to achieve effective control of solids interferences.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled, at a minimum, with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 All aqueous solutions may be disposed of in the Aqueous Laboratory Waste satellite collection vessel.

11.2.2 Solid residues may be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.4 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Health and Safety Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

7/26/05: Added reference Program Specification directive in "Responsibilities", updated format.

6/26/06: Added thermometer to equipment list and direction to record water bath temperature. Added DOCUMENT REVISION HISTORY.

3/7/8: Provided for additional corrective measures for failed post-digestion spike analyses (Sections 8.2.2, last bullet; 8.2.3 edited post-digestion spike bullet; edited comment 10.4).

Analytical Method: SW3060A & 7196A	**Parameter:** Alkaline Digestion and Analysis of Hexavalent Chromium (Colorimetric) in Solid Matrices		**Summary of Quality Control Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point (plus blank)	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); second source; at or below the midpoint	Once after each initial calibration	Response must agree within $\pm$10% of initial calibration	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); at or below the midpoint	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis)	Response must agree within $\pm$10% of initial calibration	Check that calculations and preparation are correct, evaluate/correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	ICB is run following the ICV; CCB is run after each CCV and to close a run sequence	Cr^{+6} content of the blank must be < RL; RL usually 2.0mg/Kg Cr^{+6}(which corresponds to 0.01mg/L without conversion to solid matrix units)	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Method Blank (MB)	One per batch of $\leq$20 field samples	Cr^{+6} content of the blank must be < RL; RL usually 2.0mg/Kg Cr^{+6}	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples must also be reprepared and analyzed.
Blank (laboratory control) Spike (BS, LCS)	One per batch of $\leq$20 field samples	Recoveries must be within $\pm$20% of expected values	Check for documentable errors (e.g., calculations and spike preparation). If no computation errors are found, prepare a fresh spike and analyze. If quality criteria still not met, all field and quality control samples must be reprepared and analyzed.
Matrix Spike (MSs or MS)	One per batch of $\leq$20 field samples	Recoveries should be within $\pm$25 % of expected values	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (laboratory) Duplicate (MSDs or MSDn)	Matrix-specific; one prepared for each sample batch of $\leq$20 field samples	(See MS recovery criteria above). RPD should be $\leq$20.	(See MS recovery criteria above). For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department and QA Managers.
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	As needed; at a minimum annually.	Positive result < the analyte reporting limit (RL).	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1122 REVISION 6

TITLE: DETERMINATION OF HEXAVALENT CHROMIUM BY METHODS SW7196A, SM3500-Cr-B

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER Steve Workman DATE 7/21/08

QUALITY ASSURANCE MANAGER Deb Schenk DATE 7/20/08

LABORATORY MANAGER [signature] DATE 7/21/08

HISTORY: Rev0, 3/27/00; Rev1, 3/2/02; Rev2, 10/15/02; Rev3, 2/9/04 (format update) and 3/18/05 (re-released without revision); Rev4, 7/26/05; Rev5, 6/26/06; Rev6, 7/18/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the method it references -- SW7196A, and SM3500-Cr B -- describe the determination of hexavalent chromium (Cr^{+6}) in environmental water samples. This procedure can also be applied to aqueous extracts of various solid samples and certain domestic and industrial wastes, provided that no interfering substances are present.

2. SUMMARY

Cr^{+6} in an aqueous sample or extract is determined colorimetrically by reaction with diphenylcarbazide (DPC). Addition of an excess of DPC in acid solution yields a red-violet complex whose absorbance is measured photometrically at 540nm. This reaction is highly selective for Cr^{+6}. A dilute calcium chloride solution is used to leach Cr^{+6} from soils and other solid samples to create an aqueous extract (NOTE: This is an alternate method for Cr^{+6} in soil prepared by alkaline digestion. If alkaline digestion by Method SW3060A is required, see PAR SOP 1121).

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision,

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, completeness and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 The stability of Cr^{+6} in an aqueous solution will be governed by the oxidizing/reducing tendency (redox potential) of the sample matrix. The redox potential of a particular sample matrix (water, aqueous extract) may be sufficiently low to favor the reduction of Cr^{+6} to Cr^{+3}. Under such circumstances, low matrix spike recovery of Cr^{+6} should not be interpreted as a failure of the analysis. Rather, failure to recover spiked Cr^{+6} in a particular sample matrix should be viewed as evidence that Cr^{+6} is not stable in that matrix and, therefore, native Cr^{+6} should not be expected.

4.2 If not accounted for, turbidity and/or color in waters or aqueous extracts will cause a high bias in the analysis because suspended particles will block light in the light path of the spectrophotometer and thereby contribute an absorbance signal that is not due to Cr^{+6}. Turbid or colored samples should be filtered or centrifuged to remove or reduce cloudiness as much as possible. If turbidity and/or color is not filtered out, it can be accounted for by taking initial absorbance readings and subtracting it out from the final absorbance reading after the addition of diphenylcarbazide. Most soil extracts prepared by this SOP are free of turbidity because clay particles usually flocculate in 0.01M $CaCl_2$ solution.

4.3 Darkly colored waters and aqueous extracts may require dilution prior to color development with diphenylcarbazide. The reporting limit for the analysis must be raised accordingly.

4.4 The Cr^{+6} reaction with diphenylcarbazide is usually free from interferences. However, certain substances may interfere if the chromium concentration is relatively low. Hexavalent Molybdenum (Mo) and Mercury (Hg) salts also react to form color with the reagent. However, the red-violet intensities produced by these other metal salt reactions are much lower than those for chromium at the specified pH. Concentrations of up to 200mg/L of hexavalent Mo and Hg can be tolerated. Vanadium interferes strongly, but concentrations up to 10 times that of chromium will not cause trouble.

4.5 Iron may contribute a yellow color when it is present at a concentration greater than 1mg/L. However, the ferric iron color is not strong and difficulty is not normally encountered if the absorbance is measured photometrically at the appropriate wavelength.

4.6 Use of new and/or unscratched glassware (i.e., cuvettes) will minimize chromium adsorption on glass surfaces during the oxidation process. Do not use glassware previously treated with chromic acid. Thoroughly clean glassware with nitric or hydrochloric acid to remove chromium traces.

5. APPARATUS AND MATERIALS

5.1 UV/VIS Spectrophotometer, Sequoia Turner Model™ 340 or equivalent. Suitable for measurements at 540nm with a light path of 1.0cm or longer

5.2 analytical balance, capable of weighing to 0.0001g, verified per SOP 305

5.3 TCLP tumbler, or equivalent (for mechanical agitation)

5.4 centrifuge capable of achieving approximately 3500rpm

5.5 vortex mixer

5.6 repeater pipet, variable Eppendorf™ or equivalent, operated per SOP 321

5.7 cuvettes, optically matched, 1-inch diameter

NOTE: Wash with nitric or hydrochloric acid before use.

5.8 centrifuge tubes, polypropylene with screw-cap closures, 50mL

5.9 volumetric flasks, Class A, 100mL, 500mL and 1L sizes

5.10 graduated cylinder, 50mL capacity (delivered volume verified by laboratory)

5.11 syringe, outfitted with a 0.45µm or 0.7µm filter disk

6. REAGENTS

6.1 Deionized (DI) water: Obtained from the laboratory DI water system

6.2 Ottawa sand, clean/inert, EMD, SX0075-3 or equivalent

6.3 Acetone, Burdick & Jackson, Cat. 010-4 or equivalent

6.4 Nitric Acid, (HNO_3), 2N : Dilute 100mL of concentrated HNO_3, JT Baker, 9598-34 or equivalent, to a final volume of 700mL using DI water. ***Store in a polypropylene bottle.*** *Shelf Life = 1 year.*

6.5 Sulfuric Acid, (H_2SO_4), 4N 10%: Dilute 20mL of 50 % H_2SO_4 (1:1 ratio with DI water) to a final volume of 90 - 100mL with DI water. Alternately, dilute 10mL of conc. H_2SO_4 to a final volume of 100mL with DI water. EMD, SX1247-2 or equivalent. ***Store in a polypropylene bottle.*** *Shelf Life = 1 year.*

6.6 Calcium Chloride ($CaCl_2$) Solution, 0.01M: Dissolve 1.47g $CaCl_2 \bullet 2H_2O$, JT Baker, 1332-01 or equivalent, in 1L of DI water. ***Store in a polypropylene bottle.*** *Shelf Life = 1 year.*

6.7 Diphenylcarbazide (DPC) Solution: Dissolve 0.25g of EM Science, DX2200-1 or equivalent, 1,5-diphenylcarbazide in 50mL of reagent grade acetone***. Store in a brown glass bottle and refrigerate. Discard when the solution becomes discolored (approx. 3 months).***

6.8 Cr^{+6} Stock Standard, 500 mg/L (**First Source**): Purchase as a certified stock solution from a commercial vendor or prepare by dissolving 0.1414g dry Potassium Chromate ($K_2Cr_2O_7$) in DI water using a 100mL Class A volumetric flask and diluting to full volume with additional DI water. Mix thoroughly. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 1 year.*

6.9 Cr^{+6} Intermediate Standard, 10mg/L (**First Source**): Dilute 2.0mL of first source 500mg/L Cr^{+6} stock standard to 100mL with DI water. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 3 months, or when parent expires (whichever is shorter).*

6.10 Cr^{+6} Stock Standard, 500mg/L (**Second Source**): Purchase as a certified solution from a commercial vendor or prepare by dissolving 0.1414g dry $K_2Cr_2O_7$ in DI water using a 100mL Class A volumetric flask. Bring to volume using DI water, mix thoroughly. If purchased, the certified solution must be from a different vendor than the first source stock standard. If prepared in-house, the $K_2Cr_2O_7$ salt must be from a different vendor than the salt used to prepare the first source stock standard. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 1 year.*

6.11 Cr^{+6} Intermediate Standard, 10mg/L (**Second Source**): Dilute **second source** 500mg/L Cr^{+6} stock standard to 100mL with DI water. ***Store in a polypropylene bottle and refrigerate.*** *Shelf Life = 3 months, or when parent expires (whichever is shorter).*

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples should be collected according to an approved sampling plan.

7.2 The maximum holding time prior to analysis is 24 hours for water samples and aqueous extracts prepared as described in this SOP. Soil samples must be extracted within 28 days of collection.

7.3 To retard the chemical activity of hexavalent chromium, all samples and extracts should be stored at 4±2°C until analyzed.

8. PROCEDURE

NOTE: A batch is defined as twenty (20) field samples or less of like matrix. One of each of the laboratory quality control (QC) samples outlined below (i.e., Method Blank, Blank Spike/LCS, MS (also serves as the aqueous interference check sample)/MSD set, must be prepared for each batch of field samples to be analyzed. **Note that the aqueous Post Spike Sample is prepared as an aqueous extract for solid matrix sample batches only.**

8.1 AQUEOUS EXTRACTION OF SOLIDS/PREPARATION OF SOLID MATRIX QUALITY CONTROL (QC) SAMPLES

8.1.1 Weigh 4.0g of moist sample into a 50mL disposable polypropylene centrifuge tube.

8.1.2 Method Blank. Weigh 4.0g clean silica sand into a 50mL disposable polypropylene centrifuge tube.

8.1.3 Blank Spike (Laboratory Control Sample, LCS). Weigh 4.0g clean silica sand into a 50mL disposable polypropylene centrifuge tube. Spike with 1.2mL of 10mg/L Cr^{+6} stock standard (second source). Be sure to have another person witness the spiking.

8.1.4 Matrix Spike/Matrix Spike Duplicate (MS/MSD). For one of the samples in the batch, spike two duplicate 4.0g aliquots with 0.40mL of 10mg/L Cr^{+6} stock standard (first source). Be sure to have another person witness the spiking.

8.1.5 In order to determine the proper volume of extract to be processed and read by the spectrophotometer, a post spike/interference check sample (PS/ICS) analysis must be performed. Select a representative field sample and prepare an additional aliquot to be extracted for use as the PS/ICS. ***This sample is analyzed after the calibration standards and blanks, but before any field samples are analyzed, and is evaluated to determine what dilutions (if any) are required for the subsequent sample analyses.*** Where sample or extract dilution is required, DI water is used as the diluent.

8.1.6 To all of the above, add 40.0mL 0.01M $CaCl_2$ using a graduated cylinder. (**NOTE:** Remove an amount equivalent to the amount of spike added to LCS, MS and MSD from the graduated cylinder before adding $CaCl_2$ to these prepared aliquots).

8.1.7 Cap the tubes and shake the samples for 1 hour on the TCLP tumbler.

8.1.8 Centrifuge the tumbled tubes for about 15 minutes @ 3500rpm in order to settle the solids.

8.1.9 Transfer a 20.0mL aliquot of each extract (or an aliquot portion diluted to 20mL) into an acid-washed 1-inch (diameter) cuvette.

8.2 PREPARATION OF AQUEOUS FIELD AND QUALITY CONTROL (QC) SAMPLES

8.2.1 For each aqueous sample to be analyzed, pipet 20.0mL of sample (or aliquot diluted to 20mL) into an acid-washed 1-inch (diameter) cuvette.

Turbid samples should be filtered using a syringe and a 0.45µm or 0.7µm filter disk to remove or reduce suspended particles as much as possible before aliquotting. If turbidity and/or color are not filtered out, it can be accounted for by taking initial absorbance readings after the addition of the 10% H_2SO_4 and subtracting it out from the final absorbance reading after the addition of diphenylcarbazide.

8.2.2 Method Blank. Pipet 20.0mL of DI water into a 1-inch cuvette.

8.2.3 Blank Spike (Laboratory Control Sample, LCS). Pipet 20.0mL of DI water into a 1 inch cuvette. Spike with 0.20mL of 10mg/L Cr^{+6} intermediate standard (second source). Be sure to have another person witness the spiking.

8.2.4 Matrix Spike/Matrix Spike Duplicate (MS/MSD). Select a representative water sample (i.e., similar color, odor, etc.) from the batch and transfer two duplicate 20.0mL aliquots (or aliquots diluted to 20.0mL) into two 1-inch diameter spectrophotometer cuvettes. Spike each aliquot with 0.20mL of 10mg/L stock standard (first source). **Be sure to have another person witness the spiking.**

NOTE: Since water sample aliquots are prepared and analyzed directly (i.e., no "extraction" step is involved), the aqueous MS/MSD samples also serve as the Post Spike/Interference Check Sample (PS/ICS) for the aqueous matrix.

The PS/ICS is analyzed after the calibration standards and blank, but before any field samples are analyzed, and is evaluated to determine what dilutions (if any) are required for the subsequent sample analyses.

8.3 COLORIMETRIC ANALYSIS OF STANDARDS, WATER SAMPLES AND AQUEOUS EXTRACTS

8.3.1 STANDARD CURVE PREPARATION

Prepared fresh on each day of analysis. Use DI water to achieve the final volume. Prepare working standards in matching 1-inch, acid-washed spectrophotometer cuvettes as described below:

Standard Concentration	Volume of 10 mg/L	Final Volume

(mg/L)	Intermediate Std (mL)	(mL)
0	0	20.0
0.01	0.02	20.0
0.05	0.10	20.0
0.10	0.20	20.0
0.30 (CCV)**	0.60	20.0
0.50	1.00	20.0
0.10 (ICV)*	0.20 *	20.0

* Independent Calibration Verification (ICV). The ICV must be prepared from a second source that is independent of that which is used to prepare the calibration standards. ***Use the Second Source 10mg/L Intermediate Standard.*** An Initial Calibration Blank (ICB), consisting of a 20.0mL aliquot of DI water, must be analyzed immediately following the ICV.

** This standard is analyzed repeatedly as the Continuing Calibration Verification (CCV). A Continuing Calibration Blank (CCB), consisting of a 20.0mL aliquot of DI water, must be analyzed immediately following each CCV.

8.3.2 SPECTROPHOTOMETER SETUP

The spectrophotometer must be properly adjusted before use. Insert the proper stray light filter into position. Adjust the wavelength to 540nm. Insert the DI water blank cuvette into the cuvette holder. While in TRANS MODE, press and hold the ZERO SET button while adjusting the ZERO knob until the display indicates 0.00. Set the MODE switch to ABS and adjust 100%T/A knobs to exactly 0.000. If further information is required, see Barnstead/Thermolyne Corp. Operator's Reference Manual, Model 340 Digital Spectrophotometer.

8.3.3 COLOR DEVELOPMENT

- To each cuvette, add 0.5mL of 10% H_2SO_4 and vortex (Take and record in LIMS the initial absorbance readings at this time if necessary).

  NOTE: ***If an extract is colored, or if a sample is colored or remains turbid after filtering, after the addition of the 10% H_2SO_4, place the cuvette into the spectrophotometer and measure the absorbance at 540nm. This initial absorbance reading will later be subtracted from the final absorbance reading measured after adding DPC color reagent, to yield a corrected absorbance reading.***

- Add 0.20mL DPC solution to the cuvettes and vortex.

- Allow the samples to stand until the color is fully developed (5-10 minutes).

8.3.4 ANALYTICAL SEQUENCE

The standard solutions are analyzed first, followed immediately by the ICV/ICB. Then the PS/ICS samples are analyzed so that the proper dilution needed to process the remaining field samples can be determined. Color and turbidity can interfere with absorbance readings. Dilution and other means are used to compensate for this interference.

- Absorbance measurements must begin with the calibration standards, immediately followed by the ICV/ICB. Record all measurements obtained.

- Analyze the Post Spikes/ICSs that were previously prepared in Steps 8.1.5 and 8.2.4. The quality control limits for all PS/ICS recoveries is 85-115 %. ***If the PS/ICS spike recovery falls outside of this range, the spike must be repeated on a diluted aliquot of the same sample/extract until satisfactory PS/ICS recovery is achieved. Once the necessary level of dilution (if any) is determined, the other samples in the batch must also be diluted at the same level prior to analysis. The analyte reporting limit for the diluted sample analyses is elevated accordingly.***

- After the ICV and ICB have been analyzed, **up to ten** samples (i.e., Method Blank, BS/LCS, PS/ICSs, field samples, etc.) can be analyzed. Prepare samples/extracts (or dilutions thereof), develop and analyze as previously discussed.

- ***The continuing calibration verification (CCV) standard, and the Continuing Calibration Blank (CCB), must be analyzed between each set of ten field or laboratory QC samples run, and at the close of the analytical sequence.***

- Continue to analyze samples in sets of ten or less followed by the analysis of the CCV/CCB pair until all samples have been analyzed.

8.4 EVALUATION OF THE CALIBRATION CURVE

8.4.1 Prepare a standard curve by plotting the observed absorbance versus concentration for each calibration standard. Enter the information into the LIMS system.

8.4.2 Enter the absorbance data obtained for each solution analyzed (calibration standards, QC samples and field samples). Also, enter additional data as necessary (e.g., sample volumes or weights, dilutions, percent solids, etc.). This information is also entered into the LIMS system.

8.4.3 Using LIMS, evaluate the linear regression analysis between absorbance and Cr^{+6} concentrations for the calibration standards. The correlation coefficient (r^2) for the regression must be $\geq$0.995.

8.4.4 Evaluate the ICV sample. The ICV result must agree within ±10 % of the expected value.

8.4.5 Evaluate the ICB sample result (result must be less than analyte reporting limit).

8.4.6 Evaluate the CCV results. The CCV result must agree within ±10% of the expected value.

8.4.7 Evaluate the CCB results (results must be less than analyte reporting limit).

NOTE: *Acceptance criteria and corrective actions are detailed in the attached QC Summary Table.*

8.5 CALCULATION OF SAMPLE CONCENTRATION

8.5.1 The Cr^{+6} concentration in water samples is calculated as follows:

$$Cr^{+6}\ \text{Concentration (mg/L)} = A * D$$

where:

A = abs * slope + intercept (the *slope* and *intercept* are obtained from the regression analysis)

D = Dilution factor if a dilution was necessary to produce a response within the calibration range

8.5.2 The Cr^{+6} concentration in solid samples is calculated as follows:

$$Cr^{+6}\ \text{Concentration (mg/Kg)} = \frac{A * D * V}{W}$$

where:

A = abs * slope + intercept (the *slope* and *intercept* are obtained from the regression analysis)

D = Dilution factor if a dilution was necessary to produce a response within the calibration range

V = Extract volume (V = 40mL if this SOP is followed without deviation)

W = Dry weight of sample extracted (W = 4.0g * percent solids if this SOP is followed without deviation)

9. QUALITY CONTROL (QC)

NOTE: *Acceptance criteria and corrective actions are detailed in the attached QC Summary Table.*

9.1 DEFINITION OF ANALYSIS BATCH

For this method, an analysis batch is defined as a group of twenty (20) or fewer field samples that is associated with one unique set of batch QC samples and processed as a unit. Batch QC samples are defined as the method blank (MB), laboratory control sample (LCS), matrix spike and duplicate (MS/MSD) and Post Spike/Interference Check Sample. All quality control samples must be carried through all stages of the sample preparation and measurement steps

9.2 BLANKS

Method blanks (MBs) are run to demonstrate that interferences from the analytical system, glassware, and reagents are under control. For this procedure, the MB consists of DI water, or clean silica sand that has been extracted as described previously in this SOP. The blank must not yield positive results greater than the reporting limit (usually 0.010mg/L, 0.10mg/Kg Cr^{+6}).

9.3 SPIKED SAMPLES

9.3.1 Blank/Laboratory Control Spike (LCS) samples consist of clean matrices that are spiked with a known amount of target compound. For this SOP, DI water is used as the clean matrix for aqueous sample batches; silica sand is used as the clean matrix for solid sample batches. LCS analyses are performed to evaluate the accuracy of the analytical system.

9.3.2 Matrix Spike (MS) and Matrix Spike Duplicate (MSD) samples consist of additional sample aliquots which are spiked with a known amount of target compound. MS/MSD analyses are performed to determine the effect of sample matrix interferences.

9.3.3 For this SOP, a Post Spike/Interference Check Sample, consisting of an aliquot of aqueous sample or extract is prepared for each solid/aqueous matrix batch. The PS/ICS analysis is run to verify and correct for reducing conditions, and chemical, color or turbidity interferences. If the result of this spikes falls outside of the 85-115% acceptable range, the sample is diluted and reanalyzed until a dilution that produces an acceptable result is determined. All associated prepared samples are then diluted at the same level for analysis.

9.3.4 EVALUATION OF SPIKED SAMPLE RESULTS

Spiked samples are evaluated based on percent recovery (%R), which

is a calculation of the amount of target yielded vs. the amount of target anticipated. The following equation is used to calculate spike recovery:

$$\%R = \frac{Concentration_{Found} - Concentration_{Aliquot}}{Concentration_{Anticipated}} \times 100$$

where:

$Conc_{Found}$	=	amount of target yielded by the spiked analysis
$Conc_{Aliquot}$	=	amount of target found in the unspiked aliquot ("zero" for clean LCS matrix aliquots; sample results for sample matrix aliquots)
$Conc_{Anticipated}$	=	amount of target expected to be yielded based on amount spiked

The control limits established for the LCS analysis are 90-110 % (aqueous matrix) and 80-120 % (solid matrix).

Advisory limits for the MS/MSD analysis are set at 85-115 % of the anticipated value (aqueous matrix) and 75-125 % (solid matrix).

The control limits established for all Post Spike/Interference Check Sample analyses are 85-115 %. If the result of the spike falls out of the acceptable range, the sample is be diluted and reanalyzed. When acceptable recovery is achieved, all samples associated with the ICS are diluted at the same level.

9.3.5 DUPLICATE PRECISION

The matrix spike samples (both matrices) are prepared and analyzed in duplicate to measure analytical precision. Precision is evaluated in terms of Relative Percent Difference (RPD), and is calculated as follows:

$$RPD\ (\%) = \frac{|Result_x - Result_{Dup}|}{\frac{(Result_x + Result_{Dup})}{2}} \times 100$$

An RPD of $\leq$20 is set as the advisory quality control limit.

9.4 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study shall consist of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the analyte reporting limit (RL). The MDL study should be performed as needed and at a minimum, annually.

10. DEVIATIONS FROM METHOD

10.1 Section 3a of Method SM3500-Cr B and Section 5.2 of Method SW7196A describes the creation of the chromium stock solution as dissolving 0.1414g

$K_2Cr_2O_7$ in DI water and bringing the solution to a 1L final volume. Paragon creates a 10-times stronger chromium stock standard by dissolving 0.1414g $K_2Cr_2O_7$ in DI water and bringing the solution to a 100mL final volume. Furthermore, Section 3b of Method SM3500-Cr B and Section 5.3 of Method SW7196A describes the creation of the standard chromium solution by diluting 10.0mL of chromium stock solution to a 100mL final volume. Paragon creates the standard chromium solution by diluting 2.0mL of the chromium stock solution to a 100mL final volume. Therefore, at 10mg/L Cr^{+6}, Paragon's standard chromium solution is 2-times stronger than that provided for in the Method.

10.2 Section 7.1 of Method SW7196A and Section 4e of Method SM3500-Cr B prescribe that the colorimetric analysis of calibration standards and samples be done in 100mL volumetric flasks (standards and samples are brought to 100mL using DI water). Paragon uses a 20.0mL final sample volume and conducts the color development directly in the 1-inch diameter spectrophotometer cuvettes.

10.3 Section 7.2.1 of SW Method 7196A indicates that the method is suitable for the analysis of hexavalent chromium ranging in concentration from 0.5 to 5mg/L Cr^{+6}. Based on use of more concentrated chromium standards and a 20.0mL final sample volume (rather than 100mL as cited in the Method), Paragon has established a typical calibration range of 0.010 to 0.50mg/L Cr^{+6} using these Methods.

10.4 Section 4e of Method SM3500-Cr B indicates the use of a 0.2N sulfuric acid solution to accomplish pH adjustment. It further cites pH adjustment to 1.0±0.3 pH units and advises use of a pH meter to check the pH. Paragon utilizes a 10% sulfuric acid solution as provided for in Section 5.4 of Method SW7196A. Method SW7196A cites pH adjustment to 2±0.5 pH units and does not specify the use of a pH meter to check the pH. Paragon follows Method SW7196A.

10.5 Based on sample volumes and reagent strengths cited in the Methods, Section 4e of Method SM3500-Cr B and Section 7.1 of Method SW7196A prescribe the addition of 2.0mL diphenylcarbazide to the 100mL final sample volume for color development. In accordance with reagent strengths, the 20.0mL final sample volume employed, and color development carried-out directly in the spectrophotometer cuvettes (all discussed above), Paragon uses 0.20mL of diphenylcarbazide to achieve color development.

10.6 Section 7.3 of Method SW7196A indicates that the spike added concentration for the post spike/interference check sample should not be less than 30mg/L Cr^{+6}. This SOP prescribes a spike added concentration of 0.20mg/L Cr^{+6}, which is in accordance with the analytical range established by Paragon's procedure as described in this SOP.

This Method reference further states that if the recovery for the PS/ICS is not within 85-115 %, the sample must be diluted and the spike repeated; and goes on

to suggest that "if the interference persists after sample dilution, an alternative method (Method SW7195, Coprecipitation, or Method SW7197, Chelation/Extraction) should be used". The Method further suggests that the presence of residual reducing agent be tested for by processing an alkaline extract. Paragon does not perform any of these additional procedures. This SOP prescribes that if the recovery of the diluted PS/ICS is outside of the 85-115 % acceptance limits, the PS/ICS analysis will be repeated at increasing dilutions until acceptable recoveries are achieved.

10.7 Section 2.3 of Method E218.4 (Atomic Absorption, Chelation-extraction) states that the diphenylcarbazide colorimetric procedure as found in "Standard Methods for the Examination of Water and Wastewater" may also be used.

10.8 Paragon does not pretreat hexavalent chromium samples to remove the cupferrates of molybdenum, vanadium, iron and copper by extraction into chloroform (followed by acid fuming digestion) as provided for in Section 1b of Method SM3500-Cr B. Nor does Paragon perform azide reduction to remove permanganate interferences.

10.9 Section 8.5 of Method SW7196A calls for the analysis of one matrix spike replicate OR one replicate sample for every ten samples. Paragon accomplishes this by preparing and analyzing one matrix spike/matrix spike duplicate per batch of 20 samples.

10.10 Section 4a of Method SM3500-Cr B and Section 7.1 of Method SW7196A discuss correcting standard and sample (respective citations) absorbances by subtracting out the absorbance of the reagent water blank. Paragon does not correct absorbance readings using the reagent water blank because a 0.0 standard (consisting of reagent water) is incorporated as part of the calibration curve.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All laboratory personnel must be trained in the use and location of these items.

11.1.2 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

11.1.3 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

11.1.4 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents

and acids).

11.1.5 All flammable compounds must be kept away from ignition sources.

11.1.6 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.1.7 Food and drink are prohibited in all lab areas.

11.2 WASTE DISPOSAL

11.2.1 All aqueous solutions may be disposed of in the Aqueous Laboratory Waste satellite collection vessel.

11.2.2 Solid residues may be disposed of in the Contaminated Soils and Solids Waste satellite collection vessel.

11.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

11.2.4 Certain clients may require that the samples and residues from the analysis of their samples are segregated and returned to the client's location. The Waste Compliance Officer will provide specific procedures and materials for these samples.

DOCUMENT REVISION HISTORY

7/26/05: Added Program Specification directive in "Responsibilities", updated format.

6/26/06: Provided for use of acid-washed glassware; added DOCUMENT REVISION HISTORY.

7/18/08: Clerical corrections. Added hold time for soils (7.2).

Analytical Method: SW7196A & SM3500-Cr B	**Parameter:** Hexavalent Chromium (Colorimetric)		**Summary of Quality Control Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
Initial Calibration; minimum 5-point (plus blank)	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria)	Correlation coefficient (r^2) for linear regression must be $\geq$0.995	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve.
Independent Calibration Verification (ICV); at or below midpoint	Once after each initial calibration	Response must agree within $\pm$10% of initial calibration	Prepare another ICV and analyze. If ICV still fails, system must be recalibrated.
Continuing Calibration Verification (CCV); at or below midpoint	Run after every ten samples and to end any run sequence (must be followed by a CCB analysis)	Response must agree within $\pm$10% of initial calibration	Check that calculations and preparation are correct, evaluate/correct instrument malfunction; reanalyze. If CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCV must be reanalyzed.
Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB)	ICB is run following the ICV; CCB is run after each CCV and to close a run sequence	Cr^{+6} content of the blank must be <RL; RL usually 0.010mg/L, 0.10mg/Kg Cr^{+6}	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable blank must also be reanalyzed.
Method Blank (MB)	Matrix-specific; one prepared for each sample batch of $\leq$20 field samples	Cr^{+6} content of the blank must not exceed reporting limit (RL); RL usually 0.010mg/L, 0.10mg/Kg Cr^{+6}	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples must also be reprepared and analyzed.
Blank (laboratory control) Spike (BS, LCS)	Matrix-specific; one prepared for each sample batch of $\leq$20 field samples	Recoveries must be within $\pm$10 % of expected values (aqueous matrix); $\pm$20 % of expected values (solid matrix)	Check for documentable errors (e.g., calculations and spike preparation). If no computation errors are found, prepare a fresh spike and analyze. If quality criteria still not met, all field and quality control samples must be reprepared and analyzed.
Matrix Spike (MS)	Matrix-specific; one prepared for each sample batch of $\leq$20 field samples	Recoveries must be within $\pm$15% of expected values (aqueous matrix); $\pm$25 % of expected values (solid matrix)	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative.
Matrix Spike (laboratory) Duplicate	Matrix-specific; one prepared for each sample batch of $\leq$20 field samples	(See MS recovery criteria above) RPD should be $\leq$20	(See MS recovery criteria above). For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department and QA Managers.
Method Detection Limit (MDL) Study; run at an analyte concentration near to but lower than the reporting limit (RL)	As needed; at a minimum annually	Positive result < the analyte reporting limit (RL)	Determine the reason for failure and fix problem with the system. Repeat the MDL study. If criteria still not met, discuss with QA Manager (RL may be adjusted if required).

PARAGON ANALYTICS
STANDARD OPERATING PROCEDURE 1125 REVISION 4

TITLE: DETERMINATION OF PERCHLORATE IN WATER USING ION CHROMATOGRAPHY -- METHODS EPA 314.0 AND SW9058

FORMS: 1116 (use current iteration)

APPROVED BY:

TECHNICAL MANAGER Steve Workman DATE 4/13/06
QUALITY ASSURANCE MANAGER Rob Schell DATE 4/12/06
LABORATORY MANAGER [illegible] DATE 4-12-06

HISTORY: Rev0, 7/18/01; Rev1, 8/23/02; Rev2, 2/13/04; Rev3, 2/7/05; Rev4, 4/10/06. re-released w/o revision 7/18/08 DAS

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) and the methods it references -- US EPA 314.0 and SW9058 -- describe procedures for the analysis of perchlorate in aqueous samples and aqueous extracts of environmental solid sample matrices using ion chromatography.

2. SUMMARY

Perchlorate is separated and measured using an analytical system consisting of an autosampler, pump, ion chromatograph (IC) and personal computer (PC). The IC contains ion exchange columns, a suppressor device, and a conductivity detector.

Small volumes of sample (typically 5mL) are injected via the autosampler onto the IC to flush and fill the 1.00mL sample loop. The contents of the filled sample loop are then injected into a sodium hydroxide (NaOH) eluent stream, which is pumped through a series of two ion exchange columns (guard and analytical). The perchlorate is separated by the two exchange columns, and then carried by the eluent stream through a third (suppressor) column. The suppressor column reduces the perchlorate to its acid form ($HClO_4$) and also reduces the background conductivity of the eluent. The modified eluent stream then passes through a conductivity detector, whose signals are captured and maintained by a PC. Perchlorate is identified based on retention time and is quantitated using an external standard calibration method.

Aqueous samples and solid extracts must be screened for conductivity and must be diluted or pretreated as necessary prior to analysis.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving

this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the ability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful analysis of a proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the workorder file indicate that this review for precision, accuracy, and completeness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Contaminants in the reagents, glassware, and/or other sample processing apparatus can produce method interferences that cause discrete artifacts or elevated baselines. These interferences can lead to false positive results or elevated detection limits as a consequence of elevated baseline noise.

4.2 Interferences can be divided into three different categories:

- ***direct chromatographic co-elution*** - where an analyte response is observed at very nearly the same retention time as the target anion;
- ***concentration dependent co-elution*** - observed when the response of higher than typical concentrations of the neighboring peak overlap into the retention window of the target anion; and
- ***ionic character displacement*** - where retention times may significantly shift due to the influence of high ionic strength matrices (e.g., high mineral content or hardness), overloading the exchange sites in the column and significantly shortening the target analyte's retention time.

Direct Chromatographic Co-elution may be solved by changing columns, eluent strength, modifying the eluent with organic solvents (if compatible with IC columns), changing the detection system, or by selective removal of the interference with pretreatment. Sample dilution will have little to no effect. The analyst MUST verify that these changes do not induce any negative affects on method performance by repeating and passing all associated quality control (see

Sections 8 and 17).

Some ***Concentration Dependent Co-elution or Ionic Character Displacement*** difficulties may resolve with sample dilution, however, sample dilution will proportionately elevate the analyte reporting limit. Therefore, careful consideration of project objectives should be given prior to performing dilutions. An alternative to sample dilution, may be dilution of the eluent (see Section 13).

4.3 Pretreatment cartridges (see Section 12) can be effective as a means of eliminating certain matrix interferences. With any proposed pretreatment, the analyst MUST verify that the target analyte is not affected by monitoring recovery after pretreatment via analysis of a Laboratory Fortified Matrix (LFM) (i.e., matrix spike) sample. It must also be ensured that no background contaminants are introduced by the pretreatment. This is accomplished by successful analysis of a Laboratory Reagent Blank (LRB) (i.e., method blank). With advances in analytical separator column technology that employ higher capacity anion exchange resins, the need for pretreatment cartridges has been greatly reduced.

4.4 Sample matrices with high concentrations of common anions such as chloride, sulfate and carbonate, can make the analysis problematic by destabilizing the baseline in the retention time window for perchlorate. This is evidenced by observing a protracted tailing following the initial elution of the more weakly retained anions (i.e., chloride, carbonate, and sulfate) that extends into the perchlorate retention time window. The concentrations of these common anions can be indirectly assessed by monitoring the conductivity of the matrix prior to analysis, and diluting or pretreating as necessary.

4.5 The analyst must use his/her professional experience to evaluate the potential for carry over peaks that may affect the detection of perchlorate in subsequent analyses. Chromatographic baselines, peak characteristics, etc. should be closely reviewed. Analyses yielding suspect results must be repeated. Rinse blanks may be added to the analytical sequence as necessary to control/correct carryover.

4.6 Field samples must be filtered through no larger than a 0.45µm nominal pore size membrane or frit to remove particulates and prevent damage to the analytical system. Syringe mounted, cartridge type, filters work well. Filters specifically designed for IC applications should be used.

5. APPARATUS AND MATERIALS

5.1 Dionex DX-120 ion chromatograph or equivalent, equipped with an autosampler, eluent pump and conductivity detector.

5.2 Dionex anion exchange guard (AG16) and analytical separator (AS16) columns, 4mm, or equivalent. Columns used must be rated as having low to very low

hydrophobicity. This requirement for low hydrophobicity allows the efficient, reproducible, and symmetrical band elution of polarizable anions, such as perchlorate. If the perchlorate analysis is attempted on a hydrophobic column -- such as those typically used for the analysis of common anions -- poor performance will result due to very asymmetric, tailing peaks. If the guard column is omitted from the system, the retention times will be shorter.

5.3 Anion MicroMembrane suppressor (AMMS III) column, 4mm, or equivalent. Must be capable of producing a stable baseline with no more than 5 nanosiemen (nS) noise/drift per minute of monitored response over the background conductivity.

NOTE: Proper suppressor performance is essential to analytical data reproducibility and sensitivity of the conductivity detector. If pretreated samples or sample matrices that contain appreciable concentrations of metals (e.g., Fe or Al) are frequently analyzed, cationic components may bind to the suppressor membrane and over time, affect suppressor performance. If the instrument begins to have problems with reduced peak response or asymmetrical perchlorate peaks, the suppressor membranes should be cleaned per manufacturer's instructions.

5.4 personal computer (PC) capable of running the Dionex *PeakNet* software, or equivalent

5.5 Dionex autosampler vials ("PolyVials"), or equivalent, 5mL, with filter caps

5.6 filter disks, 0.45µm, designed for IC use

5.7 insertion tool for the PolyVial filter caps

5.8 Eppendorf™ adjustable pipettor, or equivalent with tips

5.9 pasteur pipets, disposable

5.10 sample beakers, plastic, disposable, 50mL

5.11 centrifuge tubes, plastic, disposable, 50mL

5.12 volumetric flasks, various sizes, Class A

5.13 syringes, plastic, disposable, 10mL

5.14 conductivity meter, capable of measuring matrix conductance over a range of 1-10,000 µS/cm

5.15 analytical balance, capable of weighing to 0.0001g

5.16 centrifuge, table top model

5.17 magnetic stir plate, large

5.18 stir bar, Teflon-coated

5.19 water bath, capable of maintaining 25±2°C temperature

5.20 TCLP-type rotary tumbler

5.21 matrix pretreatment cartridges:

- Barium form - Dionex OnGuard-Ba cartridges, or equivalent. These cartridges are used to reduce matrix levels of sulfate.
- Silver form - Dionex OnGuard-Ag cartridges, or equivalent. These cartridges are used to reduce matrix levels of chloride.
- Hydrogen form - Dionex OnGuard-H cartridges, or equivalent. These cartridges used to reduce cations in the sample matrix. This protects the analytical column by removing silver that has leached from the Ag cartridge and may indirectly minimize the effect of carbonate by removing the cationic counter ion.

6. REAGENTS AND STANDARDS

6.1 Reagent Water: Deionized (DI) Water, 17.8MΩ or better, perchlorate-free and with particulates <0.20 microns.

6.2 Potassium Chloride (KCl) Standard Solution, 0.01N: Used to verify the performance of the conductivity meter. Made by dissolving 0.745g KCl in reagent water and diluting to a final volume of 1.00L in a Class A volumetric flask. On a properly functioning and calibrated conductivity meter, the reference conductance for this solution is 1410µS/cm at 25°C. Readings are acceptable within the range of 1380-1440µS/cm at 25°C). *Shelf Life = until deteriorates (i.e., until incapable of generating an acceptable reference reading).*

6.3 Helium (He) Compressed Gas, high purity grade or better; used to pressurize the eluent reservoir. Eluent is susceptible to carbonate contamination resulting from absorption of carbon dioxide (CO_2) from the atmosphere. Note that an ascarite trap can be placed in-line between the He tank and the eluent reservoir to further minimize possible CO_2 contamination.

6.4 Sodium Hydroxide (NaOH) Stock Solution, 50% NaOH (w/w): Used to create

the Sodium Hydroxide Eluent Solution. Purchase from a vendor. This reagent must be as free of carbonate as possible. *Shelf Life = until deteriorates (deterioration evidenced by increased perchlorate retention time and poor peak shape).*

Sodium Hydroxide (NaOH) Eluent Solution, 0.10M NaOH: Made in-house by the treatment and dilution of the commercially purchased 50% Sodium Hydroxide Stock Solution. A 4L polypropylene carboy (manufactured by Dionex) is used as a reservoir for the eluent. Prior to preparing fresh eluent, the reservoir must be emptied of all previous fluid and thoroughly rinsed with reagent water. After rinsing, a clean Teflon-coated magnetic stir bar is placed inside the carboy. The reservoir is then filled with 4L of reagent water and purged with Helium for 30-40 minutes to remove carbon dioxide (CO_2). After purging, about 15mL of 50% Sodium Hydroxide Stock Solution (allow NaOH to warm to room temperature) is quickly added to the vessel using a syringe. The reservoir is immediately capped tightly and placed on a magnetic stir plate. The eluent solution is agitated on the stir plate for 10-15 minutes to ensure complete mixing. *Shelf Life = until deteriorates (deterioration evidenced by increased perchlorate retention time and poor peak shape).* Note that this eluent is specific to the columns specified; alternative columns will likely have other eluent requirements.

NOTE: The retention time for perchlorate can change significantly when small amounts of CO_2 are absorbed by the Sodium Hydroxide Eluent Solution. Since CO_2 from the ambient atmosphere dissolves readily in solutions of NaOH, it is *critical* that every precaution be employed to minimize exposure of the solution to air.

It is recommended that two people work together as a team to prepare the eluent solution. When the container of 50% NaOH Stock Solution is uncapped, one person can direct a stream of Helium gas into the open container to minimize entry of CO_2, while the other person draws the solution up into the syringe. Then, one person can first remove and later replace the cap from the eluent reservoir, while the other person dispenses the 50% NaOH Stock Solution from the syringe into the purged reagent water in the reservoir.

According to Dionex, the 50% NaOH Stock Solution is more likely to be contaminated with carbonate at the surface of the solution and along the inside walls of the bottle. Therefore, it is helpful if the syringe used to draw and dispense the 50% NaOH Stock Solution is fitted with a long tip (i.e., like a hypodermic needle) so that the solution can be drawn out of the center of the bottle. Also, the long tip allows the 50% NaOH Stock Solution to be dispensed well below the surface of the purged water in the reservoir, thus avoiding contact with ambient air and minimizing potential CO_2 contamination.

Alternatively, use of a Dionex EG40, or equivalent, apparatus that automatically generates the hydroxide eluent is acceptable.

6.5 Sulfuric Acid (H_2SO_4) Solution, 50%: Made in-house by adding 500mL of concentrated sulfuric acid to reagent water and bringing to a final volume of 1L. *Shelf Life = no restrictions; make as needed (i.e., when solution volume is depleted).*

6.6 Sulfuric Acid (H_2SO_4) Solution, 5N: Made in-house by adding 278mL of 50% sulfuric acid solution to reagent water and bringing to a final volume of 1L. *Shelf Life = no restrictions; make as needed (i.e., when solution volume is depleted).*

6.7 Sulfuric Acid (H_2SO_4) Solution, 0.07N: Used to regenerate the AMMS III suppressor column. Made in-house by adding 29g 5N sulfuric acid solution to reagent water and bringing to a final volume of 3,600mL. *Shelf Life = no restrictions; make as needed (i.e., when solution volume is depleted).*

6.8 Perchlorate Stock Standard Solutions, 1000 mg (ClO_4^-)/L: Two stock solutions are required (i.e., "first source" and "second source"). At minimum, the lot numbers must vary. The stock solutions may be purchased as certified solutions or prepared by adding 0.1231g of ACS reagent grade perchlorate sodium salt ($NaClO_4$) to a 100mL volumetric flask and diluting to volume with reagent water. ***Note that Sodium perchlorate represents a molar weight fraction of 81.2% perchlorate anion.*** *Shelf Life = 1 year.*

NOTE: Per SOPs 300, all standards and spiking solutions must be properly documented, labeled and used within their expiration dates.

6.9 Perchlorate Intermediate Standard Solutions, 0.500mg (ClO_4^-)/L: Made each day of use by diluting 0.05mL of first source Perchlorate Stock Standard Solution to a final volume of 100mL using reagent water.

6.10 Mixed Common Anion Stock Solution, 20mg/mL each Cl^-, $SO_4^=$, $CO_3^=$: Made in-house by dissolving 4.0g sodium chloride (NaCl), 3.72g sodium sulfate ($NaSO_4$) and 4.4g sodium carbonate (Na_2CO_3) in a final volume of 100.0mL reagent water. *Shelf Life = 1 year.*

6.11 Instrument Performance Check (IPC) Solution: The IPC check solution is analyzed with each analytical batch to confirm instrument performance and the MCT. The IPC check solution is prepared to contain 25µg/L ClO_4^- and a concentration of common salts (sodium chloride, sodium sulfate and sodium carbonate) that results in a solution conductance near to (i.e., within ±10%) that specified as the MCT (see Section 8). The solution is prepared each day of use by diluting 0.25mL of the 0.500mg (ClO_4^-)/L first source Perchlorate Intermediate Standard Solution, and an appropriate aliquot (usually 0.1mL) of Mixed Common

Anion Stock Solution, to a final volume of 5.00mL using reagent water.

6.12 Intermediate Spiking Solution, 2.5mg (ClO_4^-)/L, first and second source: Pipet 0.25mL Perchlorate Stock Solution into a 100mL volumetric flask and bring to volume with reagent water. Made each day of use.

6.13 Perchlorate Calibration Standard Solutions, suite of 5 solutions, 0.004-0.100mg (ClO_4^-)/L: Made each day of use by diluting aliquots of the first source Perchlorate Intermediate Standard Solution with reagent water to create a range of standards spanning the IC's calibrated linear range (used for initial calibration). See Table below:

Perchlorate Calibration Standards

Calibration Standard Name	Amount of 1st Source 500µg/L Perchlorate Intermediate Standard Solution Used	Final Volume of Calibration Standard Prepared
100µg/L (level 6; 5X)	1.00mL	5.00mL
75µg/L (level 5; 6.66X)	0.75mL	5.00mL
50µg/L (level 4; 10X)	0.50mL	5.00mL
25µg/L (level 3; 20X)	0.25mL	5.00mL
10µg/L (level 2; 50X)	0.10mL	5.00mL
4µg/L (level 1; 100X)	0.04mL	5.00mL

6.14 Quality Control Sample (QCS), also referred to as the Initial Calibration Verification (ICV) Standard: Made from the ***second*** source 2.5mg (ClO_4^-)/L perchlorate Intermediate Spiking Solution, at a concentration near to the midpoint of the calibration curve. A 0.10mL aliquot of second source perchlorate intermediate standard solution is brought to a 5.00mL final volume using reagent water. *Shelf Life = made daily.*

6.15 Continuing Calibration Check Standard (CCCS): Made daily by bringing a 0.25mL aliquot of the first source 0.500mg (ClO_4^-)/L Perchlorate Intermediate Standard Solution to a 5.00mL final volume using reagent water.

6.16 Initial Calibration Check Standard (ICCS): Made daily, at a concentration matching the lowest point of the calibration curve. Bring a 0.04mL aliquot of the first source 0.500mg (ClO_4^-)/L Perchlorate Intermediate Standard Solution to a 5.00mL final volume using reagent water.

6.17 Laboratory Fortified Blank (LFB) or Laboratory Control Sample (LCS): Made daily by bringing a 0.05mL aliquot of the ***second*** source 2.5mg (ClO_4^-)/L perchlorate Intermediate Spiking Solution to a 5.00mL final volume using reagent water.

6.18 Laboratory Fortified Matrix (LFM) or Matrix Spike (MS) Sample: Made daily by

replacing 0.05mL of selected sample with 0.05mL of first source 2.5mg (ClO_4^-)/L Intermediate Spiking Solution (final volume 5.00mL). For solids extracts, multiply spike volumes by 8 for a 40mL final volume.

NOTE: One duplicate (i.e., field, laboratory, or spiked) must also be prepared per each batch of similarly prepared samples. It is Paragon's general policy to prepare the MS in duplicate (duplicate sample referred to as the MSD).

7. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

7.1 All samples should be collected according to an approved sampling plan. Samples may be collected in plastic or glass bottles. All bottles must be purchased pre-cleaned or thoroughly cleaned and rinsed with reagent water. The volume of sample collected should be sufficient to ensure a representative sample, allow for replicate and laboratory fortified matrix analyses, and to minimize waste disposal.

7.2 No chemical preservation is required.

7.3 Samples do not need to be shipped iced or stored cold in a refrigerator but every effort should be taken to protect the samples from temperature extremes. A thermally insulated sampling kit, designed to fit sampling bottles securely during shipment, may be used to protect the samples from these temperature extremes.

7.4 The maximum allowable holding time until analysis for perchlorate is 28 days from collection. Perchlorate has been shown to be stable for more than 28 days but extended holding time studies (beyond 35 days) were not conducted by EPA. Typically, when analytes are believed to be stable, a 28 day holding time is established as a sufficient time period to permit a laboratory to conduct the analysis.

8. PRELIMINARY CONSIDERATIONS

8.1 DETERMINATION OF THE MATRIX CONDUCTIVITY THRESHOLD (MCT) The conductivity of an aqueous/solid extract matrix is related to the amount of common salts present in the matrix. Salts contribute to and are measured as Total Dissolved Solids (TDS).

The anions contained in common salts can interfere with the chromatographic separation of ClO_4^- when their concentration in a sample is too high. Since conductivity is an index of salt content, samples can be screened prior to analysis for ClO_4^- by measuring the sample conductance. The Matrix Conductivity Threshold (MCT) is the maximum allowable conductance of a sample that is measurable by the ion chromatograph without requiring dilution or pretreatment. The MCT is used to evaluate the results of sample conductivity screening, it is the

value above which samples must be diluted or pretreated prior to analysis. The MCT can be established at the conductance level of the highest Mixed Common Anion Stock Solution (see Section 6) which can be successfully analyzed and quantitated, or can be determined by calculation and regression analysis based upon the data generated by analyzing a series of sequentially increasing common anion-fortified reagent water samples, each of which also contains a constant concentration of perchlorate. Because the MCT is dependent on the conditions, hardware, and state of the analytical system employed, it is not method defined and must therefore be determined by the individual analytical laboratory during the Initial Demonstration of Capability (IDC). The MCT is confirmed with each analysis batch by analyzing an Instrument Performance Check (IPC) Solution (see Section 6). Paragon's IPC check solution performance consistently confirms the MCT in the range of 3,500-4,000µmhos/cm.

8.2 METHOD DETECTION LIMIT (MDL) STUDY

The MDL is the minimum concentration of an analyte that can be identified, measured and reported with 99% confidence that the analyte concentration is greater than zero. Details for conducting an MDL study are provided in the cited EPA Methods. An MDL study MUST be performed as a component of the Initial Demonstration of Capability (IDC) and whenever there is a significant change in the background, or instrument response. It is Paragon's policy to, at minimum, verify MDLs annually.

8.3 MINIMUM REPORTING LEVEL (MRL), ALSO REFERRED TO AS THE ANALYTE REPORTING LIMIT

The MRL/analyte reporting limit is the threshold concentration of an analyte that a laboratory can expect to accurately quantitate in an unknown sample. The MRL should be established at an analyte concentration either greater than three times the MDL or at a concentration which would yield a response greater than a signal to noise ratio of five. Setting the MRL too low may cause repeated quality control (QC) failure upon analysis of the ICCS. **Although the lowest calibration standard may be below the MRL, the MRL must never be established at a concentration lower than the lowest calibration standard and can only be used if quality control criteria for this standard are met.**

8.4 The Initial Demonstration of Capability (IDC) is performed after an acceptable initial calibration of the IC has been achieved. The IDC is used to characterize instrument and laboratory performance prior to performing field sample analyses by this method. Additionally, each analyst must also perform a one-time IDC prior to the analysis of client samples to assure/demonstrate method proficiency. The IDC study includes the following components:

- an initial demonstration of low system background; accomplished by the successful analysis of Laboratory Reagent Blanks (LRBs); no

contamination can be noted above ½ the MRL/analyte reporting limit.

- an initial demonstration of accuracy (IDA); accomplished by the successful analysis of a replicate series of Laboratory Fortified Blanks (LFBs; also referred to as laboratory control samples, LCSs); percent recovery must be ±15% of the true value.
- an initial demonstration of Precision (IDP); calculated %RSD of the above replicate analyses must be <10%.

Details regarding the conduct of an IDC study are provided in the cited EPA Methods.

9. SYSTEM START-UP AND SHUT-DOWN

9.1 In order to keep the NaOH eluent pressurized, the He gas tank should always be left on with the regulator set to deliver between 3-5psi.

9.2 Power on the IC by depressing the white button on the front of the instrument.

9.3 From the "**MAIN MENU**" window in *PeakNet*, click on the "**PEAKNET RUN**" icon. In the PeakNet Run window, select the "Direct Control" icon. In the Direct Control window, click to start the pump and eluent pressure. The eluent flow rate should be set at 1.00mL/min. Turn off from the Direct Control window. Alternately the pump and eluent pressure can be turned on or off by pressing Local/Remote on front panel to highlight Local and manually pressing pump, eluent pressure.

9.4 Allow the pressure to stabilize for about 30 minutes before starting an analytical sequence.

9.5 Turn off the power (white button on main instrument panel). **Do NOT turn off the He gas tank valve.**

10. SEQUENCE SET-UP

10.1 Analytical sequences are set-up using the *PeakNet* software. A new "**SCHEDULE**" is created for each day. Typically this schedule is renamed from the previous day's schedule and then edited to create the new schedule.

10.2 Each day's data are stored in a new subdirectory named for the day, using a yymmdd format (e.g., 050214, denoting February 14, 2005).

10.3 A *PeakNet* "method" is created each time a calibration is performed. The method is a subprogram that controls the events that take place throughout the analytical sequence (e.g., trigger autosampler, operate injection valve, start and end data acquisition, etc.) The method also contains the integration parameters that are used in processing the raw data, including a Table with the calibration curves and

retention time windows for each analyte. The retention time Table can be updated daily, if necessary, based on the first CCV analyzed or each time a new calibration is established.

11. INITIAL CALIBRATION

11.1 Prepare the calibration standards as prescribed in Section 6.

11.2 To setup the autosampler, prepare aliquots of standards, pre-filtered sample or extracts in 5mL Dionex vials; dilute as necessary. Place filter caps half way down on vials and vortex. Use insertion tool to push cap down fully on vials. Load vials into cassettes for the autosampler.

11.3 Analyze 1.00mL of each calibration standard. Note that the entire 5mL aliquot is drawn into the instrument, however, a 1.00mL sample loop is used for analysis.

NOTE: With the equipment designated in this SOP at the settings indicated, perchlorate should elute between 12-15 minutes.

11.4 Generate the calibration curve by tabulating peak area responses against the perchlorate concentration. Note that peak areas must be used as a measure of response since they have been found to be more consistent, in terms of quantitation, than peak heights. Peak height can tend to be suppressed as a result of high levels of common anions in a given matrix that can compete for exchange sites leading to peak broadening. Using peak areas, it is the analyst's responsibility to review all chromatograms to insure accurate baseline integration of target analyte peaks, since poorly drawn baselines will significantly influence peak areas.

Paragon uses a second order quadratic fit to create the perchlorate calibration curve. Paragon typically employs six data points to establish the curve. The coefficient of determination (r^2) for the calibration curve equation must be ≥ 0.990.

11.5 Analyze a Quality Control Sample (QCS)/Initial Calibration Verification (ICV) Standard. To be acceptable, the QCS/ICV must yield results within ±10% of the true value. If this criterion is not met, identify and correct the problem, recalibrate the system and analyze an acceptable QCS/ICV.

11.6 Establish the perchlorate retention time window (RTW). The width of the retention time window used to make identifications should be based upon measurements of actual retention time variations of standards measured over the course of a day. Three times the standard deviation of retention time may be used as a suggested window size, but the retention time window should not extend beyond ±5% of the retention time for perchlorate. The experience of the analyst should weigh heavily in the interpretation of these chromatograms.

12. SAMPLE PREPARATION

12.1 EXTRACTION OF SOLID SAMPLES

12.1.1 Weigh 4.0g of sample into a 50mL polypropylene centrifuge tube. Add 40mL DI water.

12.1.2 Mix the suspension thoroughly and tumble using a rotary tumbler (TCLP-type) for about 60 minutes.

12.1.3 Centrifuge the resulting slurry for about 15 minutes.

12.1.4 Filter the supernatant as necessary using a 0.45µm filter disk.

12.1.5 The terminology for the supernatant will be treated the same as a water sample matrix throughout this SOP. Follow the same screening and preparation procedures described in the Sections above.

12.1.6 Analyze as described in Section 13 below.

12.2 CONDUCTIVITY SCREENING

The electrical conductivity of the aqueous/solid extract solutions are directly related to the concentration of dissolved salts in the sample.

12.2.1 CONDUCTIVITY METER CALIBRATION VERIFICATION

Periodically verify the performance of the conductivity meter as follows:

- Thoroughly rinse the conductivity electrode with reagent water. Place the electrode in the reagent water, turn on the meter and confirm the conductance of this reagent water blank at <1 µS/cm.
- Pour approximately 15mL Standard KCl Solution (see Section 6) into a small plastic disposable beaker and place the electrode into the solution.

The reference conductance for this solution is 1410µS/cm at 25°C. The conductivity meter must yield a conductance between 1380µS/cm and 1440µS/cm to be in calibration. Record reading in logbook (Form 1116).

If the conductivity meter fails calibration, recalibrate the unit per manufacturer's instruction and repeat the Steps above.

12.2.2 SAMPLE SCREENING

Prior to conducting any field sample analysis, the conductivity of that matrix must be determined. When the conductance of a field sample is

above the MCT (defined in Section 8), sample dilution or pretreatment must be performed in order to protect the instrument and to provide for sample analysis within the instrument's calibrated analytical range. Visual appearance of the sample, historical data or additional information provided by the client may provide information for determining the extent of dilution or if sample pretreatment is needed.

NOTE: Samples do not need to be refrigerated, but if samples are held chilled as standard practice for sample control, ensure that the samples have come to room temperature before performing sample preparation or analysis.

- Pipet approximately 15mL of sample into a small disposable plastic beaker. Reseal the sample bottle to protect the sample integrity.

NOTE: **Do not shake or mix the sample before acquiring the sample aliquot.**

- Place the electrode into the sample and measure the conductivity. Record in logbook (Form 1116).

- Discard the used sample aliquot. Rinse the electrode thoroughly with reagent water between each matrix conductivity measurement. Refer to the following Sections if sample dilution or pretreatment is required based on the conductivity screening results.

- Test the conductivity of an aliquot of IPC solution. Record in the dedicated conductivity laboratory logbook (Form 1116).

12.3 PREPARATION OF SAMPLES WITH MATRIX CONDUCTIVITY ABOVE THE MCT

12.3.1 MATRIX DILUTION

Reagent water can be used to dilute an aliquot of sample to bring the sample's conductivity within the MCT (defined in Section 8). Because the dilution factor will proportionately elevate the sample's analyte reporting limit, it is necessary to evaluate whether or not the elevated analyte reporting limit meets client data quality objectives (DQOs) should perchlorate not be detected upon dilution. Sample pretreatment (described in a subsequent Section below) can be used as an alternative to sample dilution. The sample pretreatment technique does not introduce any factor that requires the analyte reporting limit to be elevated proportionately.

- If the conductivity of the matrix (measured in the sample screening

step above) exceeds the MCT, estimate the dilution required by dividing the measured matrix conductance by the MCT; round up as necessary. Example: For a sample with a matrix conductivity of 12,000 and with an MCT of 3,500, the necessary dilution would be 4X.

- Dilute two sample aliquots accordingly to create a 15mL sample analysis volume. Record the dilution factor required in the dedicated conductivity laboratory logbook (Form 1116).

NOTE: The recorded dilution information is hand-entered into the *PeakNet* sample analysis sequence set-up so that the sample's dilution factor can be incorporated in the automated calculation of perchlorate following analysis.

- Measure the conductance of one of the diluted sample aliquots to confirm that the matrix conductance is now below the MCT. Discard this aliquot and filter and analyze the other prepared aliquot.

Remember that if perchlorate is not detected above the elevated analyte reporting limit and the elevated analyte reporting limit does not meet the client's DQOs, sample pretreatment techniques should be employed.

12.3.2 PRETREATMENT

Pretreatment is accomplished using a series of three types of cartridges arranged in a specific order. The barium cartridge is used to reduce matrix levels of sulfate. The silver cartridge is used to reduce matrix levels of chloride. The hydrogen cartridge is used to remove silver that may have leached from the silver cartridge, and may also have an indirect effect by removing carbonate. ***Note that these pretreatments will not effectively reduce matrix concentrations of other anions such as nitrate or phosphate.***

NOTE: Extreme caution should be exercised in using pretreatment cartridges. Artifacts that can foul the guard and analytical columns are known to leach from certain cartridges, causing loss of column capacity (indicated by shortened retention times and irreproducible results).

Sample matrix pretreatment may be used as standard practice to assist in the quantitation of low levels of perchlorate or to prolong IC column life.

The procedure for use of the pretreatment cartridges is described below:

- Individually and thoroughly rinse each pretreatment cartridge with reagent water in order to ensure that all residual background contaminants are removed from the cartridge. Perform this rinse per manufacturer's instructions.

  Where pretreatment cartridges are used, the LRB/laboratory method blank, LFB/laboratory control sample, and LFM/matrix spike sample and duplicate must also be passed through the pretreatment cartridges. The LRB/laboratory method blank should be prepared and analyzed ***before*** processing any client samples to determine if any artifacts are introduced by the cartridges. If artifacts are noted at a concentration greater than ½ the MRL/analyte reporting limit, triple or quadruple the volume of reagent water rinse suggested by the manufacturer and repeat until an acceptable blank is generated. ***If additional rinsing is required, it must be consistently applied to all the cartridges prior to conducting any matrix pretreatment.***

- Attach the three prepared cartridges in the following order: Barium (Ba), Silver (Ag) and Hydrogen (H). *It is recommended that all three cartridges be employed unless the analyst has specific knowledge that a matrix primarily has high levels of a specific common anion.*

- Filter 3mL of field or QC sample through the series of rinsed, stacked cartridges to condition/rinse the cartridges. Use a plastic syringe to push the fluid through at a flow rate of 1.0mL/min or less (approximately one drop every 3 to 4 seconds). ***This flow rate is critical to the pretreatment and must be carefully followed.***

- Discard the conditioning/rinse fraction and begin collecting the aliquot of field or QC sample.

- When sufficient sample volume has been collected (e.g., 15mL), measure the conductance of the pretreated aliquot being certain that the conductivity meter's probe has been thoroughly rinsed with reagent water and excess water has been shaken from the tip.

If the matrix conductivity is below the MCT, discard the measured

aliquot and collect more pretreated field or QC sample for analysis.

If the matrix conductivity is still above the MCT, the flow rate through the pretreatment cartridge is likely too fast and the pretreatment should be repeated with new cartridges.

In some instances, double pretreatment cartridges (Ba, Ba, Ag, Ag, H, H) may need to be applied.

- Note total volume of reagent water rinse employed (Step 1) and the number and types of pretreatment cartridges used on the laboratory benchsheet.
- Appropriately filter and place an aliquot of pretreated field or QC sample (matrix conductivity below MCT) into an autosampler vial.
- Analyze as described in Section 13.

12.4 PREPARATION FOR MATRICES WHICH DO NOT EXCEED THE MCT

12.4.1 Pour an aliquot of field sample into a small plastic beaker. Reseal the sample bottle to protect the sample's integrity.

12.4.2 Using a Luer-lock, plastic 10mL syringe, withdraw approximately 10mL of sample from the beaker and attach a clean 0.45µm particulate filter directly to the syringe.

12.4.3 Filter the sample into an autosampler vial.

NOTE: If the autosampler vials or vial caps are designed to automatically filter the sample matrix as the sample is loaded on the IC system, this filtration procedure can be omitted and the sample can be directly transferred to the autosampler vial.

12.4.4 Prepare and load the necessary QC samples into the autosampler.

12.4.5 Analyze as described in Section 13 below.

13. SAMPLE ANALYSIS

A sample analysis sequence may be initiated once a successful calibration and verification (see Section 11) has been achieved.

13.1 Analyze an ICCS (see Section 6). The ICCS is a standard analyzed at a concentration equal to the lowest standard of the calibration suite. To be acceptable, percent recovery (%R) for this standard must be ±25%. If this

criterion is not met, re-prepare and analyze the ICCS. If the ICCS still fails, the system must be recalibrated.

13.2 The IPC Solution sample must be analyzed first in the sequence. ***All quality control criteria for this analysis (see Section 17) must be met before sample analyses can proceed.***

13.3 Analyze the laboratory fortified blank (LFB), also referred to as the laboratory control sample (LCS). The %R acceptance limits are ±15% (aqueous) and current laboratory-derived limits (soils).

13.4 Analyze the laboratory reagent water blank (LRB), also referred to as the laboratory method blank (MB). The concentration of target analyte in the blank must be < the analyte RL. Note that if reporting data for regulatory purposes, the target analyte cannot be present at levels greater than ½ the RL (Method 314.0) or must be free of contamination <MDL (Method SW9058). If a blank is not acceptable, the source of the contamination must be determined and resolved prior to conducting any sample analysis.

13.5 Up to 10 field samples plus the laboratory fortified matrix (LFM)/matrix spike sample and duplicate (see Section 17) can be analyzed. Note that the QC samples are not included as part of the 10 sample analysis allotment.

NOTE: One Laboratory Fortified Blank (LFB)/Laboratory Control Sample (LCS), one duplicate, one Laboratory Fortified Matrix (LFM)/Matrix Spike (MS) Sample and one Laboratory Reagent Blank (LRB)/Laboratory Method Blank (MB) are prepared with each batch of similarly prepared samples. These QC samples may or may not be pretreated contingent upon whether or not the associated samples were pretreated. Because of LIMS (Paragon's in-house Laboratory Information Management System) restrictions, in instances where an analysis batch contains *both* not pretreated and pretreated samples, the pretreated QC samples are analyzed as representing the most rigorously treated samples and therefore representative of the entire mixed sample batch.

13.6 Analyze a CCCS (also referred to as a continuing calibration verification, CCV, standard). To be acceptable, the CCCS must yield results within +15% (i.e., between 85-115%) of the known value. If the CCCS fails the acceptance criteria, the source of the problem must be identified and resolved before continuing analyses. All samples analyzed since the last acceptable CCCS must be reanalyzed.

Up to 10 field samples and QC samples can be analyzed between CCCS analyses.

13.7 Compile the peak response information for the analyzed samples. If the response of a sample analyte exceeds the calibration range, the sample must be diluted with an appropriate amount of reagent water and reanalyzed. If this is not possible, then three new calibration concentrations must be employed to create a separate high concentration calibration curve, one standard near the estimated sample concentration and the other two bracketing an interval equivalent to approximately ±25% around the estimated sample concentration. ***Important! The response generated by these three new high concentration calibration standards must not exceed the upper linear range for the conductivity detector.***

13.8 Should more complete resolution be needed between perchlorate and a co-eluting shoulder peak, the eluent may be diluted. This will spread out the peaks, causing later elution of perchlorate. Analysts are advised to carefully evaluate use of eluent dilution since other coelutions may be encountered which were not initially evident when these eluent changes are incorporated. ***Additionally, the analyst must verify that this dilution does not negatively affect performance by repeating and passing all the QC criteria in Sections 8 and 17, and by re-establishing a valid initial calibration curve (Section 11). Additionally, note that eluent dilution adversely effects the MDLs for each analyte.***

14. DATA ACQUISITION AND PROCESSING

14.1 Data acquisition begins by clicking on the "**START**" icon in the "**PEAKNET RUN**" window. Usually a new injection is made every 20 minutes or less. Each chromatogram is stored in a separate file. Filenames are automatically given to each chromatogram based on information that is entered when the sequence is created (i.e., a filename prefix, and a value for the counter). The filename prefix is the date of acquisition, and the counter is set to increment by one for each injection (e.g., 02140005 designates the 5th injection made on February 14th).

14.2 Data processing (peak identification, integration, quantitation) is performed after the chromatograms have been acquired. Identify perchlorate in the sample chromatogram by comparing the retention time of the suspect peak to the established RTW. If the perchlorate retention time has slightly shifted (generally towards shorter times) since the initial calibration, but is still within acceptance criteria and are reproducible during the analysis batch, the analyst should use the retention time in the daily calibration check standards to confirm the presence or absence of perchlorate anion.

14.3 ***It is important to review the integration to ensure that baselines are drawn correctly.*** In cases where it is necessary to modify a baseline, the raw data must include printouts of the chromatogram before and after the baseline correction (refer to SOP 939 for further directives).

14.4 Compute sample concentration using the initial calibration curve generated in

Section 11. Only values that fall between the lowest and highest calibration standards are reported. Samples yielding results that exceed the highest standard should be diluted and reanalyzed. When this is not possible, the alternate calibration procedure described in Section 13 must be followed.

14.5 Report results in µg/L units.

15. RUN LOG

A record of each day's analyses is entered into the instrument run logbook. This can be accomplished by taping a printout from the *PeakNet* program into a hardbound laboratory notebook. The following information is recorded:

- Date of analysis
- Analyst's initials
- Solution ID (including any dilutions)
- Filename
- Schedule ID

16. MAINTENANCE AND TROUBLESHOOTING

A maintenance logbook is used to record all information concerning instrument maintenance. The logbook documents all repairs and symptoms of problems.

16.1 The fritted disks (sometimes called "bed supports") at the ends of the guard and analytical columns and inside the in-line filter case should be changed periodically. The system backpressure will gradually increase over time as the fritted disks become clogged with small particles.

16.2 Small peaks may be observed in the blanks in the perchlorate RTW after analyzing samples high in dissolved salts. This carryover can be addressed by either:

- Setting up the autosampler to pass an aliquot of reagent water through the sample loop between injections.

  To accomplish this, place a vial of reagent water between each vial containing sample or standard in the autosampler. The autosampler recognizes the added vial as a "rinse vial" because the filter cap is pushed down to the first position using the special insertion tool.

- Cleaning the sample loop and the tubing that carries the sample solution from the autosampler to the IC with 0.1N HCl using a syringe with a Luer-lock connector. ***All traces of HCl must be removed from the system by rinsing the line thoroughly with reagent water before analyzing samples.***

17. QUALITY CONTROL (QC)

17.1 ANALYSIS BATCH

An analysis batch is defined as a sequence of no more than 20 field samples or extracts thereof and the following required QC samples:

- Instrument Performance Check Standard (IPC)
- Laboratory Reagent Blank (LRB), also known as the laboratory method blank (MB). If pretreatment cartridges were used to process samples in the batch, a pretreatment LRB/MB must also be analyzed.
- Initial Calibration Check Standard (ICCS)
- Laboratory Fortified Blank (LFB), also known as the laboratory control sample (LCS). If pretreatment cartridges were used to process samples in the batch, a pretreatment LFB/LCS must also be analyzed.
- Continuing Calibration Check Standard (CCCS), when the batch contains more than 10 field samples, also known as the continuing calibration verification (CCV) standard. The CCCS run at the end of an analytical sequence after all samples have been analyzed is known as the End Calibration Check Standard (ECCS).
- Laboratory Fortified Matrix (LFM), also known as the matrix spike (MS) sample. If pretreatment cartridges were used to process samples in the batch, a pretreatment LFM/MS sample must also be analyzed.
- Either a Field Duplicate, a Laboratory Duplicate or a duplicate of the LFM. Usually a duplicate of the LFM is analyzed and is referred to as the matrix spike duplicate (MSD) sample.

Additional batches may be added sequentially on to the end of the sample analysis sequence as long as all QC samples that define an individual batch (i.e., IPC, LRB, ICCS, LFB, LFM and duplicate) are individually reanalyzed with each successive serial batch and the QC criteria for these analyses are continually met.

NOTE: One LFB/LCS, one LFM/MS and duplicate, and one LRB/MB are prepared with each batch of similarly prepared samples. These QC samples may or may not be pretreated contingent upon whether or not the associated samples were pretreated. Because of LIMS restrictions (LIMS only permits unique sample references), in instances where an analysis batch contains *both* not pretreated and pretreated samples, the pretreated QC samples are analyzed as representing the most rigorously treated samples and therefore representative of the entire mixed sample batch.

17.2 INSTRUMENT PERFORMANCE CHECK (IPC) SOLUTION

The IPC solution (see Section 6) contains a specific concentration of perchlorate and other test substances (namely chloride, sulfate and carbonate) used to evaluate the performance of the analytical system with respect to a defined set of criteria. An IPC is analyzed with each sample analysis batch to verify the MCT (MCT defined in Section 8).

To be acceptable, the IPC solution must meet ***all*** of the following criteria:

- the conductance must be within ±10% of the initial value.
- the resultant peak area/height ratio must not exceed 25%D when compared to the area/height ration of the LCS.
- the recovered perchlorate must be ±20% of the true value.
- the perchlorate retention time cannot shift more than 5%.

If any of the above conditions are not met, reanalyze the IPC. If quality criteria are still not met, the MCT (see Section 8) must be repeated and revised to a more appropriate lower matrix conductivity threshold or the source of the problem must be determined and corrected and the IPC reanalyzed. A new IDC must also be performed.

17.3 BLANKS

Blanks are run to demonstrate that interferences from the laboratory environment, analytical system, reagents and glassware are under control. A Laboratory Reagent Blank (LRB), also referred to as a laboratory method blank (MB), is an aliquot of reagent water that is treated exactly as a sample including exposure to all glassware, reagents and equipment. The concentration of target analyte in the blank must be < the analyte RL. Note that if reporting data for regulatory purposes, the target analyte cannot be present at levels greater than ½ the RL (Method 314.0) or must be free of contamination <MDL (Method SW9058). If a blank is not acceptable, the source of the contamination must be determined and resolved prior to conducting any sample analysis. Any samples analyzed prior to the noncompliant blank must be reanalyzed.

17.4 INITIAL CALIBRATION CHECK SAMPLE (ICCS)

The ICCS is a standard analyzed at a concentration equal to the lowest standard of the calibration suite. It is analyzed prior to any field samples to verify the previously established calibration curve and to verify the ability to quantitate perchlorate at the MRL. To be acceptable, percent recovery (%R) for this standard must be ±25%. If this criterion is not met, re-prepare and analyze the ICCS. If the ICCS still fails, the system must be recalibrated.

17.5 LABORATORY FORTIFIED BLANK (LFB)/LABORATORY CONTROL SAMPLE (LCS)

The LFB/LCS is an aliquot of reagent water to which a known quantity of perchlorate is added. The LFB/LCS is analyzed exactly like a sample, and its purpose is to determine whether the methodology is in control and whether the laboratory is capable of making accurate and precise measurements.

The LFB/LCS is analyzed immediately following the ICCS. By analyzing the LFB/LCS initially, a control check is performed on the concentrated solution used to prepare the LFM/MS. If any deviations in the perchlorate concentration are present, it will be reflected in the LFB/LCS and not exclusively attributed to a matrix upon analysis of the LFM/MS.

Percent Recovery (%R) for the LFB/LCS is calculated as shown below:

$$\%R = \frac{Concentration_{Found}}{Concentration_{Expected}} \times 100$$

where:

$Conc_{Found}$ = actual analyte concentration found in the LFB/LCS
$Conc_{Expected}$ = anticipated/known concentration of the LFB/LCS (based on the amount spiked)

The recovery for perchlorate must fall in the range of 85-115% (aqueous), within laboratory-derived limits (soils). An acceptable LFB/LCS must be achieved before field samples can be analyzed. If the LFB/LCS recovery does not meet the recovery criterion, the source of the problem must be identified and resolved before analyses can proceed.

17.6 CONTINUING CALIBRATION CHECK SAMPLE (CCCS)/CONTINUING CALIBRATION VERIFICATION (CCV) STANDARD

The CCCS/CCV is a first source mid-level calibration standard analyzed bracketing each set of 10 field sample analyses to verify the continuing validity of the previous calibration. To be acceptable, the CCCS/CCV must yield results within $\pm$15% of the known value. If the CCCS/CCV fails the acceptance criteria, the source of the problem must be identified and resolved before continuing analyses. All samples analyzed since the last acceptable CCCS/CCV must be reanalyzed.

17.7 LABORATORY FORTIFIED SAMPLE MATRIX (LFM)/MATRIX SPIKE (MS)

The LFM/MS is an aliquot of an environmental field sample to which a known quantity of perchlorate is added. The LFM/MS is analyzed exactly like a sample,

and its purpose (when compared to the LFB/LCS results) is to determine whether the sample matrix contributes bias to the analytical result. LFM/MS samples that exceed the calibration range must be diluted for analysis.

The background concentration of perchlorate present in the native sample matrix must be initially determined by analysis of a separate sample aliquot, and the measured value of the spiked LFM/MS is corrected for this background concentration as follows:

$$\%R = \frac{Concentration_{Spike} - Concentration_{Native}}{Concentration_{Expected}} \times 100$$

where:

$Conc_{Spike}$ = analyte concentration found in the LFM/MS
$Conc_{Native}$ = analyte concentration found in the unspiked native sample
$Conc_{Expected}$ = anticipated/known concentration of the LFM/MS (based on the amount spiked)

If the perchlorate percent recovery falls outside the acceptance range of ±20%, check freshness of the spiking standard, spike preparation, and calculations. Narrate if sample matrix interference is suspected.

To be valid, the concentration of the spike added must be equal to or greater than the concentration present in the native sample. In the event that the fortified level is less than the observed level of the native matrix, the recovery should not be calculated.

17.8 DUPLICATES

Field Duplicates (FDs) are two separate samples collected at the same time and placed under identical circumstances and treated exactly the same throughout field and laboratory procedures. Field duplicate samples may or may not be provided by the client. Analyses of field duplicates indicate the precision associated with sample collection, preservation and storage, as well as with laboratory procedures.

Laboratory Duplicates (LDs) are two sample aliquots (LD_1 and LD_2), taken in the laboratory from a single sample bottle, and analyzed separately with identical procedures. Analyses of LD_1 and LD_2 indicate precision associated specifically with the laboratory procedures by removing variation contributed from sample collection, preservation and storage procedures.

In short, duplicates are analyzed as a measure of the precision of the analytical results generated. The laboratory must analyze some type of duplicate for a minimum of 5% of the collected field samples, or at least one with every analysis

batch, whichever is greater. The sample matrix selected for this duplicate analysis must contain measurable concentrations of the target anions in order to establish the precision of the analysis set and ensure the quality of the data. Without prior knowledge or strong suspicion that an unknown sample has measurable perchlorate concentration, the best alternative is to analyze a duplicate LFM/MS. It is Paragon's policy to analyze the LFM/MS in duplicate; this sample is referred to as the Matrix Spike Duplicate (MSD).

The precision between the duplicate analyses is expressed as Relative Percent Difference (RPD), calculated as follows:

$$RPD\ (\%) = \frac{|Result_1 - Result_2|}{\frac{1}{2}(Result_1 - Result_2)} \times 100$$

where:

$Result_1$ = analyte concentration found in the initial analysis
$Result_2$ = analyte concentration found in the duplicate analysis

For this procedure, the RPD between duplicates should not exceed 15%. If the RPD criteria are not met, check freshness of the spiking standard, spike preparation, and calculations. Narrate if sample matrix interference is suspected.

17.9 METHOD DETECTION LIMIT STUDY

A method detection limit (MDL) study consists of the analysis of a blank and a minimum of seven replicate analyses at a concentration level near to the capabilities of the method and below the Minimum Reporting Limit (MRL) for the analyte. The MDL study is performed in conjunction with the IDC (see Section 8) and should be performed as needed and at a minimum, annually.

18. DEVIATIONS FROM METHOD

18.1 Section 9.4.1.2 of Method EPA 314.0 suggests that concentrations of the LFM/MS "should be varied to reflect the range of concentrations expected in field samples". Paragon prepares a spiking solution of unvaried concentration, as expected concentrations of client field samples are not known.

18.2 Section 10.3.2 of Method EPA 314.0 states, "If more than 10 field samples are included in an analysis batch, the analyst must alternate between the middle and high continuing calibration check standard levels." Paragon consistently analyzes a CCCS/CCV that falls between the mid and high calibration standard levels.

18.3 Method EPA 314.0 makes one mention of a "well mixed sample" (Section 11.1.5). Based on the belief that the dissolved anions exist in equilibrium in a sample solution, Paragon does not mix or shake the field sample prior to preparation and

analysis. Particulate interferences are allowed to settle before a sample aliquot is obtained. Furthermore, the sample aliquot is centrifuged or filtered to further minimize the effects of particulates.

18.4 The note following Section 7.5 and Section 8.2 of Method SW9058 recommends that both samples and standards be stored at 4±2 °C. Method EPA 314.0 specifically states that refrigeration is not required. Paragon refrigerates field samples as standard practice. Text in this SOP discusses the need for samples and standards to be at room temperature prior to use.

18.5 One Laboratory Fortified Blank (LFB)/Laboratory Control Sample (LCS), one Laboratory Fortified Matrix (LFM)/Matrix Spike (MS) Sample and duplicate, and one Laboratory Reagent Blank (LRB)/Laboratory Method Blank (MB) are prepared with each batch of similarly prepared samples. These QC samples may or may not be pretreated contingent upon whether or not the associated samples were pretreated. Because of LIMS restrictions (LIMS only permits unique sample references), in instances where an analysis batch contains both not pretreated and pretreated samples, the pretreated QC samples are analyzed as representing the most rigorously treated samples and therefore representative of the entire mixed sample batch.

19. SAFETY, HAZARDS AND WASTE DISPOSAL

19.1 SAFETY AND HAZARDS

19.1.1 The building is equipped with a safety shower, eyewash station, fire extinguisher, fire blanket, as well as a first aid kit. All lab personnel must be trained in the use and location of these items.

19.1.2 The toxicity or carcinogenicity of each reagent used in this method have not been fully established. Each chemical should be regarded as a potential health hazard and exposure should be as low as reasonably achievable.

19.1.3 Read the MSDSs before preparing standards or using any solvents or reagents for the first time.

19.1.4 Sodium Hydroxide (NaOH), used in the preparation of the eluent is considered caustic.

19.1.5 Any chemicals with a Threshold Limit Value (TLV) of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

19.1.6 All flammable compounds must be kept away from ignition sources.

19.1.7 Wear gloves, safety glasses, and a lab coat when working with any

chemical materials (e.g., standards, solvents, reagents, or samples), handling materials or equipment potentially contaminated with chemicals or within a laboratory area.

19.1.8 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

19.1.9 Food and drink are prohibited in all lab areas.

19.2 WASTE DISPOSAL

19.2.1 Quantity of chemicals purchased should be based on expected usage during its shelf-life and the disposal cost of unused material. Actual reagent preparation volumes should reflect anticipated usage and reagent stability.

19.2.2 The eluent waste shall be disposed of in the Aqueous Laboratory Waste satellite collection vessel, otherwise known as the CLE Waste Stream.

19.2.3 All empty solvent bottles are disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced or the bottle labeled as empty prior to disposal.

19.2.4 Certain clients may require that the samples and residues from their analyses be returned. The Waste Compliance Officer will address these samples.

DOCUMENT REVISION HISTORY

4/10/06: Added reference Program Specification directive in "Responsibilities". Added clarification and detail regarding equipment operation. Added DOCUMENT REVISION HISTORY.

Analytical Method: EPA 314.0; SW9058	**Parameter:** Determination of Perchlorate by Ion Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
MCT Determination; verified in each analysis batch via the analysis of the IPC solution. The MCT is used to determine if sample dilution or pretreatment is needed.	One-time study done in conjunction with method development and as needed (based on significant analytical system changes) to determine the maximum ionic strength of a solution capable of being analyzed by the IC system.	The MCT cannot exceed the instrument's linear calibration range and should be about 20% under the maximum capability of the IC system.	If MCT must be modified as evidenced by unacceptable IPC solution results, lower the MCT by 10% (or some other value deemed appropriate) and recalibrate the system accordingly. New MDLs and a revised MRL must also be generated. The data generated by the performance of these procedures can serve as the analyst's IDC for the new operating conditions. Sample analyses cannot proceed until a suitable MCT is established.
Initial Demonstration of Capability (IDC)	A one-time study during method development, and also performed by each analyst prior to processing client samples, to demonstrate acceptable proficiency.	All quality criteria defined by the cited EPA Methods (as presented in SOP Sections 8 and 17) must be met.	Sample analyses cannot proceed until an acceptable IDC is performed.
Initial Calibration; minimum 5-point	As needed (i.e., at on-set of analyses or when continuing calibration does not meet criteria). Because the initial calibration spans the linear range of the instrument, analysis of the initial calibration satisfies the linear calibration range verification requirements discussed in Section 9.2.2 of Method SW9058.	Second order quadratic fit calibration curve generated electronically by instrument software. Coefficient of Determination (r^2) of the calibration curve equation must be ≥ 0.990.	Check that the calibration standards were prepared properly. Evaluate/ correct instrument malfunction and reanalyze initial calibration to obtain acceptable curve. Sample analyses cannot proceed until an acceptable initial calibration is achieved.
Quality Control Sample (QCS)/ Independent Calibration Verification (ICV) Standard	Run once after each initial calibration at a concentration at or above the midpoint of the calibration curve.	Response must agree within ±10% of known value.	Prepare another QCS/ICV and analyze. If QCS/ICV still fails, system must be recalibrated (see quality requirements above).
Retention Time Window (RTW)	Derived from data obtained over the course of a day.	May be 3X standard deviation of RTs observed, not to exceed ±5% of the retention time value.	If perchlorate retention time is not reproducible, problem must be identified and corrected and a new IDC and initial calibration must be performed.
IPC Solution	Run once with each analysis batch at the beginning of the analytical sequence.	Conductivity of the solution must be within ±10% of the initial value. Resultant peak area/height ratio must agree within 25% when compared to analysis batch LCS. Perchlorate %R must be within ±20% of true value.	If any of the QC criteria are not met, reanalyze the IPC solution. If IPC criteria still not met, the MCT must be revised and confirmed via the analysis of a new IPC solution. A new IDC and initial calibration must also be performed.

Analytical Method: EPA 314.0; SW9058	**Parameter:** Determination of Perchlorate by Ion Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
		Retention time for perchlorate must not shift by more than 5%.	
Laboratory Reagent Blank (LRB)/ Method Blank (MB)	Run early in the sample analysis batch sequence. Reagent water blank that is processed in the same manner as the associated samples.	Must not contain perchlorate at a concentration greater than the RL. If reporting data for regulatory purposes the target analyte cannot be present at levels greater than ½ the RL (Method 314.0) or must be free of contamination <MDL (Method SW9058)	Check all calculations. If no computation errors are found, prepare a fresh blank and analyze. All samples run since the last acceptable LRB/MB must also be reanalyzed.
Initial Calibration Check Sample (ICCS)	A standard at a concentration equal to the lowest standard of the calibration suite, analyzed once per analysis batch near the beginning of the analytical sequence.	%R must be ±25% of the known value.	If quality criterion not met, re-prepare and analyze the ICCS. If the ICCS still fails, the system must be recalibrated.
Laboratory Fortified Blank (LFB)/ Laboratory Control Sample (LCS)	Run early in the sample analysis batch sequence. Aliquot of reagent water blank is spiked with a known amount of analyte and QC sample is processed in the same manner as the associated field samples.	%R must be ±15% (aqueous), within laboratory-derived limits (soils)	If quality criterion not met, re-prepare and analyze the LFB/LCS. If the LFB/LCS still fails, the problem must be identified and corrected before sample analyses can proceed.
Continuing Calibration Check Sample (CCCS)/ Continuing Calibration Verification (CCV) Standard	Near to mid-level standard run to bracket the analysis of 10 field samples.	Response must agree within ±15% of known concentration.	Check that calculations and preparation are correct, evaluate/correct instrument malfunction; reanalyze. If CCCS/CCV still fails, recalibrate system. All samples analyzed after the last acceptable CCCS/CCV must be reanalyzed.
Laboratory Fortified Matrix (LFM)/ Matrix Spike (MS) and LFM/MS (laboratory) Duplicate	One MS/MSD set per batch of ≤20 field samples (this provides an average frequency of one per ten samples per Method SW9058 requirements).	%R ±20% of the expected values Method 314.0 (Method SW9058 allows for ±25%). RPD should be ≤15.	Check for documentable errors (e.g., calculations and spike preparation). If no errors are found, then sample matrix effects are the most likely cause. Note in narrative. For RPDs outside of QC limits, check all calculations for errors. If no errors are found, discuss with Department/ Project/QA Managers.
Method Detection Limit (MDL) Study	Run initially as part of the IDC then as needed, at a minimum annually.	Positive result < the MRL.	Determine the reason for failure and fix problem with the system. Repeat the MDL study.

Analytical Method: EPA 314.0; SW9058	**Parameter:** Determination of Perchlorate by Ion Chromatography		**Summary of Internal Quality Control (QC) Procedures and Corrective Actions**
QC Check	Frequency	Acceptance Criteria	Corrective Action
	Run at the reporting limit (MRL).		If criteria still not met, discuss with QA Manager (MRL may be adjusted if required).

FORMS: **NONE**

APPROVED BY:

TECHNICAL MANAGER _____ DATE 4/30/07

QUALITY ASSURANCE MANAGER _____ DATE 4/28/07

LABORATORY MANAGER _____ DATE 5-7-07

HISTORY: **SOP 620:** Rev0, 2/11/92; Rev1, 7/23/92; Rev2, 3/4/93; Rev3, 1/28/94; Rev4, 1/25/95; Rev5, 7/19/95; Rev6, 3/15/96; Rev7, 1/30/97; Rev8, 5/23/97; Rev9, 3/2/99; Rev10, 4/4/01. **SOP 1126:** Rev11, 1/23/02; Rev12, 12/16/02; Rev13, 2/10/03; Rev14, 4/16/04; Rev15, 11/2/05; Rev16, 4/27/07.

1. SCOPE AND APPLICATION

This standard operating procedure (SOP) and the methods it references -- EPA Method 150.1, SW9040B (aqueous), SW9045C (soils, sludges and wastes), and SM4500-H^+ B -- describes the electrometric measurement of pH in environmental matrices. Some water content is required to conduct the pH measurement. Method SW9040B is used to measure the pH of single or multiphase matrices whose aqueous phase constitutes at least 20% of the total volume of the sample matrix. Method SW9045C is used to measure the pH of solid, sludge, or non-aqueous liquid matrices, whose water content, if present at all, constitutes less than 20% of the total volume of the sample matrix. The corrosivity of concentrated acids and bases, or concentrated acids and bases mixed with inert substance, cannot be measured using this SOP.

2. SUMMARY

The basic principle of electrometric pH measurement is to determine of the activity of the hydrogen ion [H+] by potentiometric measurement using standard buffers and a reference electrode. Paragon uses a pH meter equipped with a combination pH electrode to measure pH. The pH is measured directly in water samples (while stirring). The pH of soils and wastes is measured by mixing with deionized water (1:1 ratio) and measuring the pH of the aqueous suspension. The pH-unit measuring device is calibrated with a series of standard buffer solutions of known pH at a temperature of 25±2°C.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and complete all documentation required for review.

3.2 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.3 Analysts must demonstrate the capability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of an unknown proficiency test sample.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicates that this review for precision accuracy, completeness, and reasonableness is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving this method to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 In general, the glass electrode is not subject to solution interferences from color, turbidity, colloidal matter, oxidants, reductants, or moderate salinity (<0.1 molar salinity).

4.2 The sodium ion is the most likely interference for the pH electrode. The electrode used in this SOP is constructed from a special low sodium error glass. Error due to sodium is negligible when measuring pH values less than 12.

4.3 pH measurements are affected by temperature in two ways (1) mechanical effects that are caused by changes in the properties of the electrode, and (2) chemical effects caused by equilibrium changes. Temperature difference between calibration buffers and samples could cause errors. If the sample temperature differs by more than ±2°C from the buffers, it is necessary to make corrections for temperature. In order to overcome these temperature differences, all standards (buffers) and samples are placed in a water bath maintained at 25±2°C until equilibrated (approximately 1 hour).

4.4 Errors will occur if the electrode becomes coated. If the electrode becomes coated with an oily material, rinse the electrode with mild detergent or methanol. If inorganic deposits are coating the electrode, soak the electrode in 0.1M HCl for one-half hour, followed by soaking in the electrode storage solution for at least one hour. Refer to the electrode's instruction manual for additional information on cleaning the electrode.

4.5 The electrode junction should be flushed by holding the probe and pressing down on the top after use in especially dirty or viscous samples or when the electrode

response becomes sluggish. After flushing the junction, the probe should be filled with internal filling solution.

5. APPARATUS AND MATERIALS

5.1 pH meter, Fisher Accumet 50 or equivalent capable of reading two decimal places

5.2 Combination pH electrode, Orion ROSS-SURE FLOW or equivalent with internal filling solution

5.3 Centrifuge tubes, 50mL, plastic, disposable

5.4 Magnetic stir plate and Teflon^{TM}-coated stir bars

5.5 Laboratory balance, capable of weighing ±0.01g

5.6 Water bath maintained at 25±2°C

6. REAGENTS

NOTE: Only reagent grade chemicals and deionized (DI) water shall be used in all pH tests.

6.1 Standard buffer solutions: Certified; purchased from vendors. These commercially available solutions must be validated by comparison with NIST standards. These buffer solutions may be purchased at various pH units (e.g., 4, 5, 7, 9, and 10). For the procedures described in this SOP, solutions at 2.00, 4.01, 7.00, 10.01, 12.45 pH units are used. A second source (at a pH of 7.00) buffer is also required. *Shelf Life* = per manufacturer's expiration date as long as condition is good.

6.2 Electrode internal filling solution: Use only Orion ROSS Reference Electrode Filling Solution 3M KCl Cat. No. 810007 with the ROSS SURE-FLOW pH electrode. *Shelf Life* = one year after date of opening.

6.3 Electrode storage solution: Add 0.25g of potassium chloride (KCl) to 50mL of pH 7 buffer solution. *Shelf Life* = replenish as needed to maintain sufficient volume.

6.4 Hydrochloric Acid (HCl), 0.1M: Dilute 0.83mL concentrated HCl to 100mL using deionized water. *Shelf Life* = one year.

7. SAMPLE COLLECTION, PRESERVATION AND HANDLING

7.1 All samples should be collected according to an approved sampling plan.

7.2 The measurement of pH is intended to be a field parameter, as the buffering capacity of a sample may change the pH of the sample. EPA Methods 150.1 and SW-846 9040B and 9045C state that "samples should be analyzed as soon as possible." Paragon strives to analyze all pH samples as soon as possible after

receipt; prior notification and/or special arrangements for Saturday sample receipt and analysis are encouraged between the client and the laboratory. However, the intention of this 4 day window is to accommodate the scenario of Friday sample collection, followed by login and release of the sample to the laboratory for analysis the following Monday, with the laboratory performing the analysis within 1 day of internal receipt.

7.3 High-purity waters and waters not at equilibrium with the atmosphere are subject to changes when exposed to the atmosphere. Therefore, the sample containers should be filled completely and kept sealed prior to analysis.

7.4 Samples must be refrigerated at 4±2°C until analysis.

8. PROCEDURE

8.1 pH METER STANDARDIZATION, GENERAL OPERATION AND ELECTRODE CARE

Over time, a pH electrode's slope and its zero potential will change. ***Therefore, the pH electrode must be standardized each day before use.*** Standardization requires the use of at least three certified buffer solutions. Paragon uses 4.01, 7.00 and 10.01 buffer solutions to standardize the pH meter. For corrosivity characterization, and if the sample pH is <4 or >10 pH units, the calibration of the pH meter should include a buffer of pH 2.00 for acidic wastes and pH 12.45 for caustic wastes. The procedure for standardizing the pH meter follows.

8.1.1 If not already prepared, turn on the water bath and set to maintain a temperature of 25±2°C.

8.1.2 To clear the existing values from the pH meter's previous standardization, press "channel" on the main screen until the display indicates the current pH channel (channel B). Then press "pH" to select pH mode. Next press "standardize". A menu of standardization options will appear. Press "2" to clear the existing standards. The pH meter will return to the main screen (all pH standardization points have been cleared from the memory).

8.1.3 Check the pH electrode's internal filling solution level. The level of the filling solution must cover the coil and be at least one inch above the sample level. Uncover the filling hole and add more internal filling solution if needed. The filling hole must remain uncovered during analysis.

8.1.4 Place fresh aliquots (approximately 20mL) of the pH 4.01, 7.00 and 10.01 buffers in 50mL centrifuge tubes and cap the tubes. Record the IDs of the buffers on the bench sheet. Place all buffers into the water bath and allow to equilibrate for at least 1 hour.

NOTE: If corrosivity is the requested method or the sample pH is <4 or >10 pH units, the meter must be re-calibrated using the 2.00, 7.00 and 12.45 pH buffer solutions.

NOTE: The pH buffer aliquots dispensed into the centrifuge tubes are useable only for that day's calibration. These buffer aliquots must be disposed of daily.

8.1.5 pH meter standardization can begin once the pH buffers have come to temperature in the water bath. Press "channel" on the pH meter's screen until the display indicates the current pH channel (channel B). Then press "pH" to select pH measurement. Make sure the filling hole of the pH electrode is uncovered.

8.1.6 Remove the centrifuge tube containing the first source pH 7.00 buffer from the water bath and record the temperature of the water bath on the bench sheet. Uncap the centrifuge tube, add a stir bar, and stir gently on the stir plate.

NOTE: All aqueous samples and buffer standards must be stirred while taking pH measurements. Place an insulation pad on top of the stir plate to prevent error from the transfer of heat to the solution being measured.

8.1.7 Place the pH electrode in the pH 7.00 buffer solution. Allow the pH meter's display to stabilize (i.e., no change in pH reading for at least ten seconds).

8.1.8 Press "standardize" (a menu of standardization options is displayed). Press "1" to select "Update or Add a Standard". Enter the value of the pH buffer being used for standardization, then press "enter". The screen will display on-screen instructions, press "enter". The pH meter will return to the main screen with the added buffer point shown. Record the buffer point on the bench sheet. If the buffer tube is to be re-read later in the run as a continuing calibration verification (CCV), it must be placed back into the water bath immediately to maintain the proper temperature.

NOTE: The pH electrode must be rinsed thoroughly between measured solutions using deionized water.

8.1.9 With the pH meter in measurement mode, repeat Steps 8.1.6 through 8.1.8 for the pH 4.01 and pH 10.01 buffers to complete the three-point standardization. **If corrosivity is the requested method or the**

sample pH is <4 or >10 pH units, the meter must be re-calibrated using the 2.00, 7.00 and 12.45 pH buffer solutions.

8.1.10 Additional pH electrode considerations:

- Rinse the pH electrode with DI water between each measured solution. Avoid rubbing or vigorous wiping of the glass electrode to reduce the chance of error due to polarization.
- After analyzing dirty or viscous samples, or when electrode response becomes sluggish, it may be necessary to empty the electrode completely and hold the junction open under running deionized water. Empty any water from the electrode and refill with fresh ROSS filling solution. Flush the electrode by pushing down on the top briefly, check the internal filling solution level again and add more if necessary.
- Alternately, the general cleaning procedure can be performed. Soak the electrode in 0.1M HCl for thirty minutes, followed by soaking in the pH storage solution for at least one hour.
- Store the pH electrode by immersing in the storage solution. The filling hole is covered during storage and the meter is placed in standby mode.

8.2 FIELD AND QC SAMPLE PREPARATION AND ANALYSIS

NOTE: All samples and buffer solutions, including the Initial Calibration Verification (ICV) and Continuing Calibration Verification (CCV), must be placed in the water bath for at least 1 hour prior to pH measurement.

8.2.1 Prepare the ICV by transferring an aliquot (approximately 20mL) of second-source pH 7.00 buffer to a 50mL centrifuge tube. Place the centrifuge tube in the water bath and allow to equilibrate for at least one hour.

8.2.2 The previously prepared first-source pH 7.00 buffer aliquot can be used as the CCV. Keep the centrifuge tube in the water bath to maintain the proper temperature.

8.2.3 Label a series of 50mL centrifuge tubes with the identities of the samples to be analyzed (or mark otherwise).

8.2.4 For each aqueous sample, transfer a 20mL aliquot into a designated centrifuge tube, cap and place the tubes in the water bath. Prepare one out of every ten field samples in duplicate.

8.2.5 For each solid matrix sample to be analyzed, place a 20g aliquot of sample into a 50mL centrifuge tube and add 20mL of DI water. Record the sample weight and DI water volume on the bench sheet. Cap the tubes and shake the mixtures manually for five minutes. Additional DI water may be added if the sample readily absorbs water and no free aqueous phase is present. Place the prepared tubes in the water bath. Prepare one out of every ten field samples in duplicate.

NOTE: Analysis can proceed once the prepared solutions have been allowed to equilibrate in the water bath for at least one hour. This time period also allows the solids to settle for the solid matrix samples being analyzed.

8.2.6 When analysis is ready to proceed, press the "pH" and "meas/monitor" keys to place the pH meter in continuous pH mode. **Make sure the filling hole of the pH electrode is uncovered.**

8.2.7 **The ICV must be analyzed following standardization of the pH meter before any samples can be analyzed.** Remove the ICV from the water bath and record the temperature of the water bath on the bench sheet. Uncap the tube and add a stir bar. Stir gently on the stir plate. Use an insulation pad to prevent the transfer of heat to the measured solution. Immerse the pH electrode into the ICV.

8.2.8 Wait until a stable reading is achieved (i.e., no change in reading for at least ten seconds). Record the ICV's pH value on the bench sheet.

The ICV is run to verify the pH meter's initial standardization. The ICV result must agree within ±0.05 pH units of the known value (i.e., pH 7.00) before sample analyses can proceed. If the ICV fails, check the integrity of the second source buffer. Replace the ICV and reanalyze. If the ICV still fails, the pH meter must be restandardized.

8.2.9 Following an acceptable ICV analysis, up to 10 samples (including a Duplicate) can be analyzed, followed by a CCV. The CCV must be analyzed to bracket the first ten sample analyses between the ICV and CCV. Following the CCV, up to 10 more samples can be analyzed, followed by the CCV again. The sequence of up to 10 sample analyses followed by the CCV can be continued until all of the samples have been analyzed. Put the CCV back into the water bath after each reading to maintain it at the proper temperature.

If any of the CCV results fails to agree within ±0.1 pH units from the expected value, the pH meter must be restandardized and all samples run after the last acceptable CCV analysis must be reanalyzed.

8.2.10 For aqueous samples, uncap the tube and add a stir bar. Stir gently on the stir plate. Use an insulation pad to prevent the transfer of heat to the measured solution. Immerse the pH electrode into the sample solution. Wait until a stable reading is achieved then record the sample's pH on the bench sheet. Report the results as "pH in water at 25°C."

8.2.11 Do not add a stir bar to the centrifuge tubes containing the prepared solid matrix samples. For solid sample analysis, immerse the pH electrode just deep enough into the aqueous phase to make electrical contact; do not push the electrode into the settled solids. Wait until a stable reading is achieved, then record the sample's pH on the bench sheet. Report solid results as "solid pH in water at 25°C."

8.2.12 A laboratory duplicate is run for every ten environmental samples analyzed. The pH results for aqueous sample duplicates should agree within ±0.2 pH units of each other. The pH results for solid sample duplicates should agree within ±0.5 pH units of each other. If these criteria are exceeded, consideration will be given to the CCV standard performance. If no problems occurred with the CCV analyses, the laboratory will remark in the case narrative that the duplicate precision criteria have been exceeded, and will report the analysis results as is.

9. QUALITY CONTROL

Calibration checks and duplicate analyses are discussed in PROCEDURE above.

10. DEVIATIONS FROM METHOD

10.1 Paragon does not employ a temperature sensor to provide temperature compensation control at the pH meter. Instead, temperature compensation is facilitated by the use of a water bath maintained at 25±2°C. This approach allows for a consistent temperature between calibration buffers and samples without the need for additional calculations due to temperature differences.

10.2 Method SW9040B, Section 7.4 and Method EPA 150.1, Section 8.4 states that successive aliquots be measured (usually 3) until the difference is less than 0.1 pH units. Paragon does not employ this practice, but runs a duplicate sample per 10 environmental samples.

10.3 Method SW9040B, Section 7.1.2 states that for corrosivity characterization, the sample must be measured at 25±1°C if the pH is above 12.0. Paragon maintains the water bath at 25±2°C.

10.4 Method SW9040B, Section 7.1.2 states that for corrosivity characterization, the calibration of the pH meter should include a buffer of pH 2 for acidic wastes and

a pH 12 buffer for caustic wastes. Paragon uses a pH 12.45 buffer for caustic wastes.

11. SAFETY, HAZARDS AND WASTE DISPOSAL

11.1 SAFETY AND HAZARDS

11.1.1 Read the MSDSs before preparing standards or using any solvents or reagents.

11.1.2 Wear gloves, safety glasses, and a lab coat when working with any chemical materials (e.g., standards, solvents, reagents, or samples) or handling materials or equipment potentially contaminated with chemicals.

11.1.3 Any chemicals with a Threshold Limit Value of less than 50ppm shall be worked with in a laboratory fume hood (e.g., solvents and acids).

11.1.4 Any non-original containers used to hold reagents (e.g., wash bottles or automatic dispenser bottles) shall be labeled at a minimum with compound name, NFPA Health, Flammability, and Reactivity ratings, and date.

11.2 WASTE DISPOSAL

11.2.1 Used buffer solutions may be disposed of in the sanitary sewer system.

11.2.2 Corrosive only wastes such as glacial acetic acid and sulfuric acid waste are disposed of by discharging into the waste water tanks (down the lab sink drains). Materials which are corrosive only (i.e., no hazardous components or characteristics other than corrosivity) may be neutralized using on-site water treatment procedures.

11.2.3 The aqueous samples or supernatant of solid samples shall be disposed of in the Aqueous Laboratory Waste.

11.2.4 The soil/solid samples and sediments of solid samples shall be disposed of in the Contaminated Soils and Solids.

11.2.5 All empty solvent bottles must be disposed of according to the appropriate SOPs. Please note that all labels and markings must be defaced prior to disposal.

STANDARD OPERATING PROCEDURE 1127 REVISION 7

TITLE: DETERMINATION OF NITROGEN AS NITRATE PLUS NITRITE (NO_3^--N + NO_2^--N), NITRITE (NO_2^--N), AND NITRATE (NO_3^--N) IN ENVIRONMENTAL WATER AND SOIL SAMPLES USING A COLORIMETRIC, AUTOMATED, CADMIUM REDUCTION PROCEDURE -- METHODS EPA 353.2, SM 4500-NO_3^- I, AND QUIKCHEM 10-107-04-1-C

FORMS: NONE

APPROVED BY:

TECHNICAL MANAGER Steve Wahlman DATE 7/21/08

QUALITY ASSURANCE MANAGER Deb Schaefer DATE 7/20/08

LABORATORY MANAGER K. Hurd DATE 7/21/08

HISTORY: Rev0, 3/2/02; Rev1, 8/23/02; Rev2, 12/13/02; Rev3, 3/6/03; Rev4, 12/15/04; Rev5, 7/26/05; Rev6, 4/10/06; Rev7, 7/20/08.

1. SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) references EPA Method 353.2, Standard Method (SM) 4500-NO3- I, and Quikchem Method 10-107-04-1-C for the determination of nitrate + nitrite (NO_3^--N + NO_2^--N) and nitrite only (NO_2^--N) in environmental water and soil samples. Nitrate (NO_3^--N) is determined by calculating the difference of [(NO_3^--N + NO_2^--N) - NO_2^--N] results. A Lachat Auto Flow Injection Analyzer, using a copperized cadmium reduction column procedure, is used to analyze the prepared samples. Values are reported as nitrogen, in the forms of nitrate + nitrite (NO_3^--N + NO_2^--N), nitrite (NO2--N), and nitrate (NO_3^-).

2. SUMMARY

Solid samples are first extracted with deionized water (at approximately a 1:10 ratio) by shaking using a rotary tumbler. The total nitrate + nitrite (NO_3^--N + NO_2^--N) content of the aqueous leachates or samples is determined quantitatively by first reducing nitrate (NO_3^--N) to nitrite (NO_2^--N) by passing the sample through a copperized cadmium column. The resultant nitrite (NO_2^--N), which consists of the original nitrite plus the reduced nitrate, is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl)ethylendiamine dihydrochloride to form a highly colored azo dye. This azo dye is then measured colorimetrically at 520nm. Aqueous samples are quantitated using a calibration curve created from standards made in deionized water. Native nitrite (NO_2^--N) *only* content is determined by conducting the analysis in a manner that bypasses the cadmium reduction column. The NO_2^--N is diazotized and coupled to yield an azo dye that is measured colorimetrically and quantitated using calibration curves. Finally, native nitrate (NO_3^--N) content is determined by subtracting the native nitrite ***only*** results from the combined nitrate + nitrite results.

3. RESPONSIBILITIES

3.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for review.

3.2 Analysts must demonstrate the ability to generate and interpret acceptable results utilizing these methods. This demonstration may come in the form of Supervisory/training review, results of precision and accuracy tests performed, or the successful completion of a proficiency evaluation test.

3.3 It is the responsibility of all personnel who work with samples or data involving this method to consult the applicable LIMS Program Specification for client-specific requirements prior to initiating handling of samples or data.

3.4 The Department Supervisor or designee performs final review and sign-off of the data. Initialing and dating the file indicate that this review for precision, accuracy, and completeness and is complete and satisfactory. Any errors that are found require corrective action, which includes notification to the technician/analyst who performed the work and documentation of measures taken to remediate the data.

3.5 It is the responsibility of all personnel who work with samples involving these methods to note any anomalies or out-of-control events associated with the analysis of the samples. Any discrepancies must be noted and corrective action taken and documented.

4. INTERFERENCES

4.1 Nitrate is very common in the laboratory environment because nitric acid is used extensively throughout the laboratory. Nitrate contamination of samples and blanks can be very troublesome. It is extremely important to use clean laboratory technique at all times. Use clean, disposable containers whenever possible and minimize the use of glassware.

4.2 This colorimetric procedure requires an optically clear sample. Further, turbid samples or samples with suspended solids can cause a build up of suspended matter in the reduction column and restrict flow. Because nitrate and nitrite are found in a soluble form, if necessary, the sample should be pre-filtered through a 0.45µm pore diameter membrane filter. Sample color may also be corrected for by dilution to overcome the color interference, or by running the samples through the manifold with the cadmium column in the off-line position and without the addition of color reagent (the absorbance reading can then be calculated by subtracting the final from the initial absorbance reading, to obtain a corrected absorbance reading).

4.3 Concentrations of iron (Fe), copper (Cu) or other metals above several µg/mL lower reduction efficiency. EDTA is added to the buffer solution to eliminate this interference.

4.4 Residual chlorine can interfere by oxidizing the cadmium (Cd) column, thereby reducing efficiency. Removal of residual chlorine can be achieved by adding sodium thiosulfate ($Na_2S_2O_3$) solution.

4.5 Samples that contain large concentrations of oil and grease will coat the Cd granules surface. This interference can be removed by pre-extracting the sample with an organic solvent.

4.6 Sample color that absorbs at about 520nm interferes with the colorimetric determination. This may be corrected by diluting the sample or by running the sample through the manifold with the cadmium column in the off-line position and without the addition of color reagent for color formation, and calculating the corrected absorbance reading.

4.7 Samples that are over acidified with sulfuric acid preservative will cause a negative response within the peak area during analysis. Standard procedures recommend acidifying samples for nitrate + nitrite (NO_3^--N + NO_2^-- N) to a pH of less than 2 for preservation. All samples will have the pH adjusted to between 2 - 9 prior to analysis.

4.8 If the absorbance reading is too high on the laboratory blank, try flushing the column with DI water. If the buffer appears to be contaminated, prepare a fresh batch of solution using clean laboratory techniques. If high blanks continue to be a problem, remove the Cu-Cd granules from the column, treat with 6N HCl and 2% $CuSO_4$ and repack the column (see Section 12 of this SOP).

4.9 If the nitrite (NO_2^-- N) check sample's percent recovery becomes too high (>120%), treat reduction column granules as described in Section 12 of this SOP or repack the column in order to improve the column's efficiency.

5. APPARATUS AND MATERIALS

5.1 Flow injection analysis equipment designed to deliver and mix/react sample and reagents in the required order and ratios. Lachat QuikChem 8000, or equivalent, equipped with the following:

5.1.1 Autosampler, with sample tubes (12x75)

5.1.2 Peristaltic multichannel pump

5.1.3 Reaction unit or analytical manifold with Cadmium

5.1.4 Absorbance detector with 520nm filter

5.1.5 Data system (Windows 3.1 and Omnion software Version 1.4, or equivalents)

5.2 Volumetric dispensers, Eppendorf™ or equivalent, capable of dispensing 0.01-5.0mL

5.3 TCLP-type mechanical tumbler, capable of 1 hour soil extraction by agitation

5.4 Corning pH meter, Model 320 or equivalent, and appropriate buffer solutions for calibration. Capable of a two-point calibration.

5.5 Centrifuge, capable of sustaining approximately 3500rpm

5.6 Centrifuge tubes with caps, disposable, 50mL

5.7 Volumetric flasks, various sizes, Class A

5.8 Magnetic stir bars, Teflon coated

5.9 Magnetic stir plate, capable of variable speed control

5.10 Analytical balance, capable of weighing ± 0.0001g, verified per SOP 305

5.11 Syringe, with 0.45µm filter disk

6. REAGENTS

NOTES: Only ACS grade or better chemicals and reagents may be used. Reagents and solutions may be stored in either plastic or glass containers.

To prevent bubble formation, degas all solutions, except the standards or otherwise noted reagents, with helium. Use He at 140KPa (20lb/in^2) through a helium degassing tube. Bubble the He through the solution for one minute.

6.1 Ammonium Chloride/EDTA Buffer: Make in-house by dissolving 85g of ammonium chloride (NH_4Cl) and 1.0g Disodium Ethylenediamine Tetraacetate EDTA ($C_{10}H_{14}N_2O_8 \bullet 2H_2O$) salt in 800mL degassed DI water. Adjust to pH 8.5 with 10N Sodium Hydroxide (NaOH). Dilute to 1000mL with degassed DI water. *Shelf life = 1 year.*

6.2 Sodium Hydroxide Solution, 10N: Dissolve 160.0g Sodium Hydroxide (NaOH) to a final volume of 400mL using DI water. Not degassed. *Shelf life = 1 year.*

6.3 Color reagent: To 250mL degassed DI water, add 50mL concentrated Phosphoric Acid (H_3PO_4) and 20.0g Sulfanilamide. After dissolving the sulfanilamide completely, add 1.0g N-(1-naphthyl)-ethylenediamine dihydrochloride. Mix to dissolve, then dilute to 500mL with degassed deionized water. *Store refrigerated in an amber container. Shelf life = 6 months.*

6.4 Copper Sulfate ($CuSO_4$) Solution, 2%: Dissolve 4g Copper Sulfate ($CuSO_4 \bullet 5H_2O$) in 100mL DI water. Use a magnetic stirring bar and stir plate to speed dissolution. Not degassed. *Shelf life = Make fresh daily.*

6.5 Copper Sulfate ($CuSO_4$) Solution, 0.2%: Dilute 2% copper sulfate solution (above) ten-fold. *Shelf life = Make fresh daily.*

6.6 Hydrochloric Acid (HCl), 6N: Cautiously add 1 part concentrated HCl to 1 part DI water. Not degassed. *Shelf life = 1 year.*

6.7 Cu-Cd granules: Wash 10-20g new or used 0.3-1.5mm diameter (40 - 60-mesh) Cadmium (Cd) granules with 6N HCl and rinse with DI water. Swirl the Cd granules in portions of 100mL of 2% $CuSO_4$ until a dark colloidal precipitate begins to develop. Gently flush with DI water to remove all precipitated Cu. *Self life = Indefinite, good as long as darkened color persists; regenerate as needed as described in Section 12 of this SOP.*

6.8 Ottawa sand, EMD, SX0075-3 or equivalent. *Keep container sealed tightly. No special storage or shelf life considerations.*

6.9 Ammonium Hydroxide (NH4OH), conc., 15N: Purchased from vendor. Not degassed. *Shelf life = 1 year.*

7. NITRATE CALIBRATION STANDARDS (USED IN NITRATE + NITRITE TEST)

7.1 Nitrate (NO_3^--N) Stock Solution, 10000mg/L: Purchased from a commercial vendor or created from KNO_3 reagent grade salt. Dissolve 36.085g of KNO_3 salt in 500mL deionized water. *Store in refrigerator. Shelf life = 1 year from purchase or creation.*

7.2 Nitrate (NO_3^--N) Stock Solution, 1000mg/L, second-source: Purchased from a commercial vendor or created from KNO_3 reagent grade salt. Dissolve 3.6085g of KNO_3 salt in 500mL deionized water. KNO_3 salt must be from a different vendor or lot number than that used for the first source standard. *Store in refrigerator. Shelf life = 1 year from purchase or creation.*

7.3 Nitrate (NO_3^--N) Intermediate Standards, 100mg/L (first and second source): First-source solution is made by diluting 5.0mL of the 10000mg/L "First Source" NO_3^--N Stock Solution with deionized water, to a final volume of 500mL. This "First Source" Intermediate Standard is used to prepare the daily calibration standards and the continuing calibration verification (CCV) standards. *Store in refrigerator. Shelf Life = 1 year from purchase or creation (note: cannot exceed expiration of parent standard).*

Second-source solution is made by diluting 25.0mL of the "Second Source" 1000mg/L NO_3^--N Stock Solution with deionized water, to a final volume of 250mL. The "Second Source" Intermediate Standard is used to prepare the

Laboratory Control sample (LCS) and initial calibration verification (ICV) standard. *Store in refrigerator. Shelf Life = 1 year from purchase or creation.*

7.4 NO_3^--N Calibration Standards (per Table below): Made in-house on *each day of calibration* by dilution of the Intermediate Standard (100mg/L, first source).

Note that DI water is used as the diluent to prepare calibration standards for aqueous sample analyses. The final volume of all calibration standards is 5.0mL.

CONCENTRATION OF INITIAL SOLUTION (mg/L)	VOLUME OF INITIAL STANDARD USED (mL)	CONCENTRATION OF FINAL SOLUTION (mg/L)
100	0.10	2.0
100	0.05	1.0
100	0.025	0.50
2.0	0.50	0.20
1.0	0.50	0.10
0.5	0.50	0.05
0.1	0.50	0.01
0	0.00	0.0

7.5 Initial Calibration Verification Standard, (ICV), 0.50mg/L: Dilute 0.025mL of the 100mg/L"second source" NO_3^--N Intermediate Standard into 5.0mL, using deionized water.

7.6 Continuing Calibration Verification Standard, (CCV), 1.0mg/L: The "first source" intermediate standard is used to prepare the continuing calibration verification (CCV) standard. Dilute 0.050mL of the 100mg/L "first source" NO_3^--N intermediate standard into 5.0mL deionized water.

7.7 NO_2^--N Cadmium Column Check Standard, 1.0mg/L: Dilute 0.1mL of the 50mg/L NO_2^--N Intermediate Standard (from section 8.0) into 5.0mL deionized water.

NOTE: The Calibration Standards with concentrations of 10mg/L or less are made daily upon use.

8. NITRITE CALIBRATION STANDARDS (USED IN NATIVE NITRITE *ONLY* TEST)

8.1 Nitrite (NO_2^--N) Stock Solutions, 1000mg/L: Created from $NaNO_2$ reagent grade salts, first and second sources. Used to create the first and second source NO_2^--N 200mg/L Intermediate Standards. Dissolve 0.4925g of $NaNO_2$ salt into 100mL deionized water. *Store in refrigerator. Shelf life = 1 month.*

8.2 Nitrite (NO_2^--N) Intermediate Standards, 200mg/L (first source): First-source solution is made by diluting 20.0mL of the 1000mg/L NO_2^--N Stock Solution with deionized water, to a final volume of 100mL. This "First Source"

Intermediate Standard is used to prepare the daily calibration standards and the continuing calibration verification (CCV) standards. *Shelf Life = 1 month (note: cannot exceed expiration of parent standard).*

Note that the Laboratory Control sample (LCS) and Initial Calibration Verification (ICV) standard are made from the "second source" 1000mg/L stock solution or 200mg/L solution, described below.

8.3 Nitrite (NO_2^--N) Intermediate Standards, 200mg/L (second source): Second source solution is made by diluting 20.0mL of the 1000mg/L NO_2^--N Stock Solution with deionized water, to a final volume of 100mL. This "second Source" Intermediate Standard is used to prepare the initial calibration verification (ICV) standard and the Laboratory Control Sample (LCS) standard, which are identical. *Shelf Life = 1 month (note: cannot exceed expiration of parent standard).*

Note that the Laboratory Control sample (LCS) and Initial Calibration Verification (ICV) standard are made from the "second source" 1000mg/L stock solution or 200mg/L solution.

8.4 NO_2^--N Calibration Standards (per Table below): Made in-house *each day of calibration* by dilution of the first source 100mg/L NO_2^--N Intermediate Standard.

Note that DI water is used as the diluent to prepare calibration standards.

CONCENTRATION OF INITIAL SOLUTION (mg/L)	VOLUME OF INITIAL STANDARD USED (mL)	CONCENTRATION OF FINAL SOLUTION (mg/L)	FINAL VOLUME OF SOLUTION (mL)
200	0.050	0.50	20
200	0.020	0.20	20
200	0.010	0.10	20
0.50	0.50	0.05	5
0.20	0.50	0.02	5
0.10	0.50	0.01	5
0	0.0	0.0	5

8.5 Initial Calibration Verification Standard, (ICV), 0.1mg/L: Dilute 0.01mL of the 1000mg/L"second source" NO_2^--N Stock Standard into 100mL, using deionized water or 0.01mL of 200mg/L second source standard into 20mL of DI water.

8.6 Continuing Calibration Verification Standard, (CCV), 0.2mg/L: The "first source" intermediate standard is used to prepare the continuing calibration verification (CCV) standard. Dilute 0.02mL of the 200mg/L "first source" NO_2^--N intermediate standard into 20.0mL deionized water.

NOTE: The Calibration Standards with concentrations of 10mg/L or less are made daily upon use.

9. SAMPLE COLLECTION, PRESERVATION, HANDLING AND HOLDING TIMES

9.1 All samples must be collected according to an approved sampling plan.

9.2 Sampling and storage of samples in glass bottles or in plastic bottles are permissible. Samples should be kept cool at 4±2°C.

9.3 For analysis of NO_2^--N only, aqueous samples must be analyzed within 48 hours after collection. There is no promulgated preservation or holding time for soils.

9.4 For NO_2^--N + NO_3^--N analysis using the Cd Column, aqueous samples must be acidified to a pH≤2 with Sulfuric Acid (H_2SO_4), with analysis occurring within 28 days after collection.

10. AQUEOUS EXTRACTION OF SOLID SAMPLES AND ASSOCIATED QUALITY CONTROL (QC) SAMPLE PREPARATION

10.1 Weigh a representative 4.0g aliquot of moist sample into a labeled 50mL disposable polypropylene centrifuge tube.

10.2 Method Blank: Weigh 4.0g clean Ottawa sand into a 50mL disposable polypropylene centrifuge tube.

10.3 As applicable, prepare both NO_2^--N + NO_3^--N and NO_2^--N Blank Spike, Laboratory Control Samples (LCSs) as follows:

10.3.1 Weigh 4.0g clean silica sand into a 50mL disposable polypropylene centrifuge tube. Spike with 0.40mL of 100mg/L "second source" NO_3^--N Intermediate Standard (expected concentration = 1.0mg/L NO_3^--N).

10.3.2 Weigh 4.0g clean silica sand into a 50mL disposable polypropylene centrifuge tube. Spike with 0.010mL of 1000mg/L second source NO_2^--N intermediate standard or .050mL of 200mg/L second source standard (expected concentration = 0.25mg/L NO_2^--N).

10.4 As applicable, prepare both NO_2^--N + NO_3^--N and NO_2^--N Matrix Spike (MS), Matrix Spike Duplicate (MSD) samples as follows:

10.4.1 Select a representative sample of the batch. Spike two duplicate 4.0g representative aliquots with 0.16mL of 100mg/L "first source" NO_3^--N Intermediate Standard (expected concentration = 0.4mg/L NO_3^--N).

10.4.2 Select a representative sample of the batch. Spike two duplicate 4.0g representative aliquots with 0.02mL of 200mg/L "first source" NO_2^--N intermediate standard (expected concentration = 0.10mg/L NO_2^--N).

10.5 To all of the above add 40.0mL of deionized (DI) water.

10.6 Shake samples for 1 hour on the TCLP tumbler.

10.7 Centrifuge for approximately 15min @ 3500rpm.

11. AQUEOUS FIELD SAMPLE, AQUEOUS EXTRACT AND ASSOCIATED QUALITY CONTROL (QC) SAMPLE PREPARATION

11.1 pH ADJUSTMENT OF AQUEOUS SAMPLES
If the samples were preserved with sulfuric acid, as is the case with nitrate + nitrite samples, adjust the pH to greater than 2 but no more than 9 as follows (see comment Section 4.7):

11.1.1 Place approximately 20mL of aqueous sample into a disposable centrifuge tube containing a stir bar.

11.1.2 Place a previously calibrated pH probe into the sample aliquot and adjust the pH using 10N NaOH until the pH is between 2 - 9. If the pH exceeds 9, add the original preserved sample drop wise to bring the pH back down into range.

NOTE: If samples are drinking water samples analyzed for compliance monitoring, then use concentrated ammonium hydroxide (NH_4OH) as the pH-adjusting reagent.

NOTE: After the pH of the sample is adjusted above pH 2, a 48-hour hold time begins. Samples are normally analyzed immediately after pH adjustment. Note also that for nitrite (only) analysis, samples are unpreserved.

11.2 Aliquot 5mL of each aqueous sample or previously prepared solid sample extract (including associated QC samples) into a designated auto sampler tube. If the aqueous sample or extract contains suspended solids, filter through a 0.45µm pore-diameter membrane filter.

11.3 Prepare the aqueous Method Blank (MB) by aliquotting 5mL of DI water into an auto sampler tube.

11.4 As applicable, prepare both the NO_2^--N + NO_3^--N and NO_2^--N aqueous Blank Spike, Laboratory Control Samples (LCS) as follows:

11.4.1 Aliquot 0.025mL of 100mg/L "second source" NO_3^--N Intermediate Standard into 5mL DI water (expected concentration = 0.5mg/L NO_3^--N).

11.4.2 Aliquot 0.010mL of 1000mg/L second source NO_2^--N into 100mL DI water or 0.010mL of 200mg/L second source solution into 20mL of DI water and mix. Transfer 5mL into a designated auto sampler tube (expected concentration = 0.10mg/L NO_2^--N).

11.5 As applicable, prepare both the NO_2^--N + NO_3^--N and NO_2^--N aqueous Matrix Spike (MS), Matrix Spike Duplicate (MSD) as follows:

11.5.1 Select a representative sample for the batch. Spike two duplicate 5mL aliquots with 0.020mL of 100mg/L "first source" NO_3^--N Intermediate Standard (expected concentration = 0.40mg/L NO_3^--N).

11.5.2 Select a representative sample for the batch. Spike two duplicate 5mL aliquots with 0.01mL of 200mg/L NO_2^--N. Mix well. Transfer 5mL into a designated auto sampler tube (expected concentration = 0.10mg/L NO_2^--N).

12. PREPARATION, USE AND MAINTENANCE OF CADMIUM REDUCTION COLUMN

12.1 CADMIUM PREPARATION

Place 10-20g of coarse cadmium granules (0.3 - 1.5mm diameter) in a 150mL beaker. Wash with two 25mL portions of 6N hydrochloric acid. Rinse several times with DI water.

CAUTION: Collect and store all waste cadmium. Cadmium is toxic and carcinogenic. Wear gloves and follow the precautions described on the Material Safety Data Sheet (MSDS).

12.2 COPPERIZATION

Repeatedly mix the Cd granules in portions of 100mL 2% Copper Sulfate Solution ($CuSO_4$). Swirl for about 5 minutes, then decant the liquid (discard in appropriate waste stream) and repeat with a fresh portion of 2% copper sulfate solution. Continue this process until the blue aqueous copper color persists. Decant and wash the copperized Cd granules at least five times with DI water to remove colloidal copper. The cadmium should be black or dark gray. The copperized cadmium granules may be stored in a stoppered bottle in ammonium chloride buffer.

12.3 PACKING THE CADMIUM COLUMN

The empty cadmium column is available as Lachat Part #50230. Wear gloves and do all cadmium transfers over a special tray or beaker dedicated to this purpose. Clamp the empty column upright so that your hands are free. Unscrew one of the colored fittings from an end of the column, and pull out and save the foam plug (if necessary, glass wool fiber and be used in lieu of the foam plug). When replacing the cap, it may be necessary to apply Teflon thread tape in order to prevent leakage. The column and threads are glass, so be careful not to break or chip them.

Scoop up prepared copperized cadmium granules with a spatula and pour them into the top of the column so that they sink down to the bottom of the column. Continue pouring the copperized cadmium in while gently tapping the column with a screwdriver handle or similar device to dislodge any air bubbles and also to prevent gaps in the cadmium filling. When the cadmium granules reach about 5 mm from

the open end of the column, push in the foam plug and screw on the top fitting. Rinse the outside of the column with DI water.

If air remains in the column or is introduced accidentally, a leur-lock syringe can be used to flush the column with ammonium chloride solution and push the air out.

Carefully cap both column ends for storage.

12.4 CADMIUM COLUMN INSERTION PROCEDURE

12.4.1 Before inserting the column, pump all reagents into the manifold making sure that there are no leaks.

12.4.2 Turn the pump to the lowest setting.

12.4.3 On the column, connect one of the union connectors to the outlet tubing of the buffer mixing coil.

12.4.4 Connect the open tubing on the column to the tee fitting where the color reagent is added. **BE CAREFUL TO NOT LET AIR ENTER THE COLUMN!!**

12.4.5 Turn column valve to open position. Return the pump to normal speed.

NOTE: The direction of reagent flow through the column is not relevant.

12.5 MONITORING COLUMN EFFICIENCY

12.5.1 Visually inspect the column. Check for air bubbles in the column or lines, gaps in the column packing, or any change in the cadmium surface characteristics (cadmium granules should be dark gray). If column treatment is necessary, see Note below.

12.5.2 Condition the column by running a 5mg/L NO_3^--N standard through it three times followed by reagent washing for approximately 1min.

12.5.3 Check the flow efficiency by disconnecting the cadmium column from the manifold and reconnecting to a green pump tube. Pump buffer through the packed column and collect the effluent in a graduated cylinder. The flow rate with the column thusly connected should be greater than 4.0mL/min.

NOTE: The presence of air in the column will decrease efficiency. Usually the problem can be corrected and the granules re-activated by using a leur-lock syringe to flush the column with solution (50mL ammonium chloride solution to push out the air, or 50mL of 0.2% copper sulfate solution followed by 50mL of ammonium chloride solution to re-activate the cadmium

granules). However, if the problem cannot be corrected, the column should be repacked per Section 12.3 of this SOP.

12.5.4 If the nitrite (NO_2^-N) check sample's percent recovery becomes too high (i.e., >120%), empty the column and retreat the cadmium granules as described in the Note above. Repacking and reinstalling the column should improve the column's efficiency.

13. GENERAL LACHAT OPERATION AND MAINTENANCE PROCEDURES

13.1 LACHAT INSTRUMENT SET UP

13.1.1 Turn power switches on for auto sampler, pump and the sample-processing module. Turn on the computer.

NOTE: The auto sampler will automatically perform an operation check by lifting the probe out of the rinse reservoir and advancing the sample cartridges by one position. The sample-processing module will open and shut each of the two valves, the LED of the heater control will display the current temperature of the block, and the lamp will come on.

13.1.2 Install the proper manifold for the analysis to be conducted (e.g., nitrate + nitrite analysis).

13.1.3 Place the appropriate interference filter into the upper slot of the detector.

13.1.4 Connect the "sample loop" to ports one and four of the injection valve.

13.1.5 Connect the "carrier" line to port two of the injection valve.

13.1.6 Place the manifold on to the sample processing module and connect the "to manifold" line to port three of the injection valve.

13.1.7 Connect the heating unit tubing to the manifold (if necessary).

NOTE: No heat is necessary for NO_2^--N + NO_3^-N and NO_2^--N analysis.

13.1.8 Insert each pump tube into a pump tube cartridge and place on the pump. Adjust the tension levers to maximum tension. ***Be sure that the pump tubes are seated correctly in the cartridges. This will prevent pinching of the tubes, which may restrict flow.***

NOTE: When preparing for any analysis that requires a column, make sure the column is in the ***off-line*** position at this time.
